## Section 1

## Introduction

The 2000 Census has a wealth of information on Washington's population. Linking this with similar data from the 1990 Census provides valuable insights on how the state and its counties have changed over time.

One factor is an area's age distribution and how this has changed. So much of what we do and what we need is related to our age. If an area has a growing number of children under 18, it will need to expand its primary and secondary schools. If the number of young adults is increasing, providing affordable housing for families is important. On the other hand, a rapidly growing number of older adults increases the priority placed on smaller housing units. Health care, transportation and other social services are influenced by the age structure and how it changes, as are the products and services provided by businesses.

The graphs in this publication give a visual portrayal of how the age structure in Washington and each of its 39 counties changed between 1990 and 2000. These show the number of persons in each five-year age group. The horizontal bars represent 2000 age groups and the line graph, 1990 age groups.

Because Washington counties vary so much in overall population, the scale at the bottom of each pyramid varies by the size of the county population. The table under each pyramid gives the numbers on which the pyramids are based and shows how each age group grew (or decreased) during the decade. At the bottom of that table you will find a county's median age in 1990 and 2000. This is the measure that divides the age structure in half-half of the population is younger and half is older than the median age. It is a quick summary measure to see if and how much a county has aged in 10 years.

Changes in the number of people in an age group may occur for several different reasons. As younger groups age, they replace those that are older. The aging of the baby boom is the best example of this pattern and is evident in many Washington counties. The baby boom started in 1946 and ended in the mid 1960's. It followed a period of time, the great depression, when fertility was extremely low. Fertility increased slightly during World War II, and surged after the war. Thus, growth in the 35 - to 55 -year-old age groups in many counties is due at least in part to the babyboom cohort growing older.

In addition, migration will also influence changes in the age structure by adding persons through in-migration or subtracting them through out-migration. ${ }^{1}$ Persons between the ages of 20 and 35 are the ones most likely to move, and the migration patterns of these young adults are especially important because these have both direct and indirect impacts. This adds or subtracts young adults, but these young adults often
have children who migrate with them, or give birth to children once they have migrated. Thus growth or decline of the population under 20 is closely tied to growth or decline of the population between 20 and 50 .

Just as births add children at the youngest ages, mortality at older ages subtracts adults from a county's population. As a result, the number of persons in each older age group after 60 is smaller than the preceding one.

Many of these patterns are evident in the state's age structure. The large number of persons between 35 and 54 and the increase at those ages represents the aging of the baby boom. In addition, somewhat more people are in these groups than would be expected due to aging alone. There are also more persons than would be expected due to aging alone for all age groups under 35 (even though the number of persons in the 25 - to 34 -year-old groups declined slightly during the decade). Thus in-migration contributed to growth at these ages, and the childbearing of in-migrants resulted in increases under age 20.

The toll taken by rising death rates at older ages is clearly evident after age 60. The fact that the number of persons in the two age groups between 50 and 59 decreases dramatically from the preceding younger age group is due to the history of very low fertility during the Great Depression and the onset of the baby-boom-not to a rapid onset of mortality at those ages. Overall, the state's median age increased by 2.2 years.

Different counties often have very similar age structures and patterns of change. For this reason, counties are grouped into categories (see map at front for county classifications). In some instances, these counties are geographically contiguous. In other cases, they are located in different parts of the state.

[^0]Number in Age Group

## Section 2

## Large, Rapid Growth Counties

Several counties, most on the I-5 corridor, grew well above the state average of 21 percent. Benton, Skagit, Snohomish and Thurston counties all grew by around 28 percent, while Clark County grew by 45 percent. These counties were also large, with populations of between 102,000 to 345,000 in 2000, gaining between 23,000 and 107,000 persons during the decade. As a result, all show growth in nearly every age category, but this growth is particularly notable in the number of middle-aged adults as well as in the number of youth under 19. The number of persons in the three age groups between 45 and 59 grew by between 47 and 110 percent in just a decade.

This rapid growth was a combination of the aging of the baby boom coupled by the in-migration of other baby-boomers to these counties and is the direct cause of the rapid growth in the school-aged population.

It is interesting to note that all show some out-migration of high school youth similar to many rural counties in the state (see the section on young adult out-migration counties below). While the indentation on the age pyramid in the 20 - to 29 -year-old age groups for the counties in this category is not as dramatic as for the rural counties, it is still notable, especially in Benton and Skagit counties. This indicates that once young adults graduate from high school many leave the area for educational and job opportunities elsewhere. However, in the age groups above 30, growth through in-migration indicates that these counties are attractive for persons who are likely to have families.

With the exception of Benton County, all are on the I-5 corridor. This rapid growth, coupled with commuting patterns, is a primary factor behind the increasing congestion along the I-5 corridor.

Number in Age Group
Benton County: 1990 and 2000

| Age | Number |  | Change |  |

## Section 3

## Large, Moderate Growth Counties

Counties in this category include King, Kitsap, Pierce and Spokane, having growth rates between $15 \%$ and $22 \%$ in the last decade. While growth rates were somewhat slower, the four counties in this category include the largest counties in the state. Thus, the number of people added was substantial. The number added ranged from a low of 42,000 in Kitsap County to a high of 230,000 in King County.

Kitsap, Pierce and Spokane counties all had notable increases in the number of persons under 19 and between the ages of 45 and 59. This is similar to the age group increases for counties in the rapid growth category. These moderate growth counties differ primarily in the somewhat slower growth rates overall in these age groups. Pierce and Spokane counties also differ in that there is little indentation in the age pyramid for the number of persons in the 20- to 24 -year-old age group. Both counties are home to smaller educational institutions, thus, area high school graduates can stay in the area for a post-secondary education. If they leave, young adults coming to area colleges replace them.

King County's age structure differs from that of other counties in this category. It has a high concentration of persons in the 25 - to 54 -year-age groups and a relatively small number of youth under 19. There was a notable increase in the number of those 44 to 59 years old during the last decade, but much of the growth was due to aging alone. On the other hand, little or no increase occurred in the number of persons between 20 and 34 in the last decade. However, the number of persons in these age groups is much larger than would be expected due to aging alone; thus, King County experienced a substantial amount of in-migration of young adults.

Number in Age Group
Kitsap County: 1990 and 2000

| Age | Number |  | Change |  |
| :---: | :---: | :---: | :---: | :---: |

## Section 4

## Young Adult Out-Migration Counties

In a large number of nonmetro counties young adults leave shortly after high school graduation. These counties show a dramatic indentation in the age pyramid for the 20 - to 24 -year-old age group and often for the 25 - to 29 -year-old age group. County age structures begin to show recovery from this loss in the 30 - to 34 -year-old age group, and especially after age 35 . Many of the counties that exhibit this pattern do have community colleges, but do not have 4 -year colleges or universities, nor are they within easy commuting distance of counties that do. They may also lack the types of jobs that are attractive to high school graduates.

Sometimes parents, school administrators and other county officials, view this phenomenon with concern and wonder what can be done to stem the loss of high school youth. However, we live in an era when training beyond high school is essential for all but the lowest paid, least desirable jobs. Many jobs, especially those with health and pension benefits, require at least a college education. Thus this is a pattern that is difficult to counteract. In addition, all but the slowest growing counties in this category show more growth in the age groups after age 35 and definitely between 45 and 60 than would be expected by aging alone. So middle-aged adults, especially those who are likely to have children, do find these areas attractive.

Because so many Washington counties can be classified in this category, I have divided them by their rate of growth during the last decade, and by the notable increase in older adults in Jefferson and San Juan counties.

## Section 4.1

Young Adult Out-Migration, Slow Growth

Four Washington counties, Columbia, Garfield, Grays Harbor, and Wahkiakum, were the slowest growing counties in the state between 1990 and 2000, increasing by less than 7 percent. While each of these shows some recovery from the loss of high school graduates, much of this is due to aging of younger cohorts.

## Section 4.2

## Young Adult Out-Migration, Moderate Growth

Asotin, Clallam, Cowlitz, Ferry, Island, Klickitat, Lewis, Lincoln, Okanogan, Pacific, and Skamania counties all grew between 13 and 19 percent in the last decade, just below the state average of 21 percent. These counties differ from the slow growth counties in that all experienced consistent growth in the number of persons between the ages of 40 and 64 . In nearly all counties, growth in these age groups was greater than would be expected due to aging alone, indicating in-migration. In many cases the growth in these age groups was quite dramatic. For example, in most counties the 45 - to 49 - and 50 - to 54 -year-old age groups were the fastest growing with the numbers increasing by between 62 and 100 percent. In-migration coupled with the aging of the baby boom was responsible for this rapid increase.

The loss of 20- to 24-year-olds is somewhat muted in Asotin, Cowlitz, Lewis, and, especially, Island counties. Of the first three, Asotin is adjacent to Whitman County and Washington State University and the latter two are on the fringe of rapidly growing metro counties.

Island County is somewhat unique in that the pattern of high school out-migration is much more muted than in other counties in this group. But what is particularly interesting is that this pattern was not at all evident in 1990, and has evolved during the decade. It will be interesting to see if this pattern becomes more accentuated during this decade or once again disappears from the county's age structure.

## Section 4.3

# Young Adult Out-Migration, Above Average Growth 

Counties in this category include Chelan, Douglas, Mason, Pend Oreille, and Stevens, all of which grew between 24 and 32 percent. In nearly all counties, the number of persons in all age groups over 35 increased during the decade, with substantial increases in the number between 40 and 59. The aging of the baby boom is partially responsible for this growth. However, with the exception of Douglas County, all show much greater growth at these ages than would be expected due to aging alone indicating that in-migration has contributed substantially to county growth and amplified the impact of the baby boom.

All counties in this category also experienced growth in the number of children between 5 and 19. This is a direct result of the increasing number of adults who were already parents when they moved to the area, or who had children after their move. Chelan and Douglas counties had the greatest growth at these younger ages, and the number of children under 5 also increased. The somewhat different pattern for these counties may be due to the fact that growth of the Hispanic population accounted for about 56 percent of all growth in the first two, but for only between 11 and 16 percent in the other three. In Mason County, the loss of young adults between 20 and 24 is more muted than in the other counties in this category, which may be due to the fact that the county borders on three metropolitan areas.

## Section 4.4

## Young Adult Out-migration, Retirement Counties

Jefferson and San Juan counties are unique in the very rapid growth of persons between 40 and 64 during the last decade. In both counties, the number of persons between 50 and 60 increased by close to 200 percent. Rapid growth also occurred in the number of persons between 45 and 49. Some of this growth was due to the aging of persons who were 35 to 50 years old in 1990, but much of this growth was due to in-migration at these age groups. Growth also occurred in each age category over 65. Normally these categories should grow only slowly as mortality begins to influence population change.

In contrast, there was little or no growth in the number of persons between 20 and 39. The number of teenagers and young adults increased modestly in each county, but not enough to counteract the very rapid growth in the older age groups.

As a consequence, these counties have a notably top heavy appearance with a large concentration of the population between 45 and 59. In 2000, 26 percent of Jefferson County's population, and 29 percent of San Juan's were between these ages compared to just 16 percent of the state's population. During this decade, the number of persons between 50 and 65 will increase, even if in-migration to these counties slows, as persons already living there grow older.

The median ages in these counties reflect these patterns. These increased by 6.2 and 4.9 years respectively in just a decade compared to the state's overall increase of 2.2 years. The median age in both counties is now over 47, by far the oldest counties in the state, and about 12 years older than the state average.

## Section 5

## Young, Central Washington Counties

In central Washington, Adams, Franklin, Grant, and Yakima counties all have conspicuously young age structures. Between 35 and 38 percent of each county's population is less than 20 years of age, compared to 29 percent for the state as a whole. In addition, the number of persons under 20 grew more rapidly in these counties than in the state as a whole. In Adams and Yakima counties this growth was only slightly above the state's, an increase of 23 and 24 percent respectively compared to 21 percent for the state. But in Franklin and Grant counties it was much more rapid-33 and 41 percent respectively.

The uniqueness of these counties is reflected in their median ages. These are the youngest in the state, between 28.0 and 31.2. In addition, these are the only counties where the median age decreased during the last decade.

With the exception of Yakima County, these are all nonmetropolitan counties. As reported earlier, many of the state's nonmetro counties show a notable indentation in their age pyramids for the 20 to 30 or 35 -year-old age groups, as young adults leave the area after high school to pursue further schooling and employment. This indentation does not show up in these counties, and yet there is no large educational institution in any of these.

These differences from state and other nonmetro county patterns are attributable to the rapid growth of the Hispanic population in the area. This population grew by between 77 and 142 percent in these counties. All or nearly all of the population growth in Adams, Franklin, and Yakima counties was due to growth in the Hispanic population. In Grant, 66 percent of the county's population growth was due to growth in the number of Hispanics.

## Section 6 College Counties

Several smaller Washington counties are the home to colleges or universities and this creates unique age structures. Instead of an indentation in the pyramids for the 20- to 24 -year-old age group, there is a high concentration of the population in these years. Kittitas and, especially, Whitman counties are the best examples of this pattern. In Whitman County nearly a quarter of the population is in this one age group. This is somewhat less in Kittitas-17 percent-but still well above the state average of just 7\%. Walla Walla and Whatcom counties also show a greater concentration in this age group than other Washington counties. With the exception of Whitman County, these counties also witnessed a substantial increase in the number of 20 - to 24 year-olds.

Walla Walla and Whatcom counties also have a large number of 15 - to 19-year-olds perhaps because of the additional presence of community colleges. Both of these counties experienced growth in the number of 40 - to 54 -year-olds, but the pattern of concentration in the college-aged population became more rather than less notable during the last decade.
