# 1 ABSTRACTS ON EFFICACY OF HYPNOSIS IN DISCRETE AREAS

---

The research studies cited above are some of the thousands of clinical trials that have utilized solid experimental technique and report reliable, valid, general findings on effectiveness. The following abstracts and comments highlight some significant results therein. (References are in the Bibliography).

## 1.1.1 “Efficacy of Hypnosis in the Treatment of Human Papillomavirus (HPV) in Women: Rural and Urban Samples”

Barabasz, A., Higley L., Christensen C., Barabasz, M. *Int. Jnl. Clin. Hypn.* 2010, Jan; 58(1), pp: 102-121.

### **Abstract**

This article investigates the effect of hypnosis on immunity and whether this is the key mechanism in the hypnotic treatment of the genital infection caused by human papillomavirus (HPV). HPV is the most common sexually transmitted disease and can lead to cervical and other cancers. Current medical treatments are aimed at tissue assault (acids, freezing, and surgery). Medical wart clearance rates are only 30% to 70% and recurrence is common. Our research contrasted hypnosis-only with medical-only therapies, using both urban hospital and rural community samples. Both hypnosis and medical therapy resulted in a statistically significant ( $p < .04$ ) reduction in areas and numbers of lesions. **Yet, at the 12-week follow-up, complete clearance rates were 5 to 1 in favour of hypnosis.**

## 1.1.2 “Hypnosis and irritable bowel syndrome: a review of efficacy and mechanism of action.”

Tan G, Hammond DC, Joseph G. **Source:** Michael E. DeBakey VA Medical Center, Baylor College of Medicine, Houston, TX 77030, USA. tan.gabriel@med.va.gov

### **Abstract**

Irritable bowel syndrome (IBS) is a functional gastrointestinal disorder characterized by abdominal pain, distension, and an altered bowel habit for which no cause can be found. Despite its prevalence, there remains a significant lack of efficacious medical treatments for IBS to date. In this paper we reviewed a total of 14 published studies (N=644) on the efficacy of hypnosis in treating IBS (8 with no control group and 6 with a control group). **We concluded that Hypnosis consistently produces significant results and improves the cardinal symptoms of IBS in the majority of patients, as well as positively affecting non-colonic symptoms.** When evaluated according to the efficacy guidelines of the Clinical Psychology Division of American Psychological Association, the use of hypnosis with IBS qualifies for the highest level of acceptance as being both efficacious and specific. In

reviewing the research on the mechanism of action as to how hypnosis works to reduce symptoms of IBS, some evidence was found to support both physiological and psychological mechanisms of action.

### 1.1.3 “The Effectiveness of Adjunctive Hypnosis with Surgical Patients: A Meta-Analysis”

1. Guy H. Montgomery, PhD\*,
2. Daniel David, PhD\*,
3. Gary Winkel, PhD\*,
4. Jeffrey H. Silverstein, MD† and

#### **Abstract**

Hypnosis is a non-pharmacologic means for managing adverse surgical side effects. Typically, reviews of the hypnosis literature have been narrative in nature, focused on specific outcome domains (e.g., patients’ self-reported pain), and rarely address the impact of different modes of the hypnosis administration. Therefore, it is important to take a quantitative approach to assessing the beneficial impact of adjunctive hypnosis for surgical patients, as well as to examine whether the beneficial impact of hypnosis goes beyond patients’ pain and method of the administration. We conducted meta-analyses of published controlled studies ( $n= 20$ ) that used hypnosis with surgical patients to determine: 1) overall, whether hypnosis has a significant beneficial impact, 2) whether there are outcomes for which hypnosis is relatively more effective, and 3) whether the method of hypnotic induction (live versus audiotape) affects hypnosis efficacy. Our results revealed a significant effect size ( $D= 1.20$ ), indicating that surgical patients in hypnosis treatment groups had better outcomes than 89% of patients in control groups. No significant differences were found between clinical outcome categories or between methods of the induction of hypnosis. **These results support the position that Hypnosis is an effective adjunctive procedure for a wide variety of surgical patients.**

The research literature on Hypnosis is extensive. The endorsements of Hypnosis for its healing effectiveness continue to mount. In a recent report, it was revealed that a panel of the National Institutes of Health has endorsed the wider use of Hypnosis for use in conjunction with conventional medical care. Numerous clinical studies have been conducted substantiating the effectiveness of the Hypnotic state in changing individuals' lives. Some of these experimental studies have utilized poor controls for supporting generalization of results beyond the specific experimental trial reported.

### 1.1.4 PAIN, MISCELLANEOUS:

1. Ernest Hilgard (1977) and coworkers: in extensive investigations, using experimental

paradigms to induce pain (typically either a tourniquet cutting off the circulation to a limb or plunging the limb into cold water), they have demonstrated that various types of pain can be reduced by hypnotically induced analgesia. In these studies, 66% of the high susceptibility group, but only 13% of the lower and 17% of the medium susceptibility groups, were able to reduce their pain by 1/3 or more. Twenty-six percent of the high, 57% of the medium, and 31% of the low susceptibility groups were able to reduce their pain by 10-32% when compared to controls.

2. Experimentally induced pain, while undeniably noxious, is different from the experience of patients in the clinical setting. Whereas experimental pain is brief, undergone voluntarily, and can be terminated at any time by the subject, in the clinical setting, pain is often long-term, comes against the wishes of the individual and is usually experienced as being outside of personal control. Moreover, it is a part of a disease process that directly alters both physical and mental functioning.

3. In a neurochemical study of Hypnotic control of pain conducted by Domangue (1985), patients suffering arthritic pain showed a correlation among levels of pain, anxiety and depression. Anxiety and depression were inversely related to plasma norepinephrine levels. Depression was correlated with dopamine levels and negatively correlated with levels of serotonin and beta endorphin. Following Hypnotherapy, there were clinically and statistically significant decreases in depression, anxiety and pain, and increases in beta endorphin-like substances.

4. The relationship between pain and endorphins is a complicated one. In his study, Guerra (1982) found that only particular forms of the beta endorphins found in peripheral blood during painful experience are associated with the Hypnotic response.

5. Hilgard (1982) studied children with cancer. He found Hypnosis to be effective in reducing the pain and discomfort associated with repeated unpleasant medical interventions.

6. Stam (1986) reports that patients with chronic facial pain show a greater responsiveness to suggestion as measured by the Carleton University Responsiveness to Suggestion Scale (CURSS) than do normal controls. These patients had higher Hypnotic susceptibility scores than did controls, showing a high susceptibility score to be a good predictor of response to Hypnotic treatment among such patients.

7. Domangue (1985) conducted a study of 19 patients with a variety of musculoskeletal disorders. He reported significant reductions of pain and dysphoria following Hypnosis. The reductions were associated with significant increases in plasma beta endorphin.

8. Barabasz and Barabasz (1989) studied sample of 20 patients with a variety of chronic pain syndromes. They utilized an Hypnotic technique known as Restricted Environmental Stimulation Therapy (REST). All of the patients were initially rated as having low Hypnotic susceptibility on the Stanford Hypnotic Susceptibility Scale (SHSS). Following exposure to the training technique, the subjects demonstrated significant increases in both SHSS scores and in pain reduction when compared to controls.

### **1.1.5 HEADACHE PAIN:**

9. Evidence accumulated to date suggests that a number of Hypnotherapeutic approaches are highly effective in the treatment of patients with chronic migraine headaches. Although no one Hypnotherapeutic technique has been demonstrated to be most effective, all the methods appear to be superior to a standard treatment relying on pharmacological approaches alone.

10. In a study conducted by Anderson (1975), migraine patients treated with Hypnosis had a significant reduction in the number of attacks and in their severity compared to a control group who were treated with traditional medications. The difference did not become statistically significant until the second six-month follow-up period. In addition, at the end of one year, the number of patients in the Hypnosis group who had experienced no headaches for over three months was significantly higher.

11.12 In a research conducted by Schlutter (1980), Hypnosis was also found to be effective in dealing with the relief of tension headache.

13. Alladin (1988) reviewed the literature on Hypnosis, identifying fully a dozen different Hypnotic techniques that have been used in the treatment of chronic migraine headaches. Of these, Hypnotic training emphasizing relaxation, hand warming (which, according to Anderson, 1975) seems the simplest method of establishing increased voluntary control of the sensitive vasomotor system) and direct Hypnotic suggestions of symptom removal have all been shown to be effective in reducing the duration, intensity and frequency of migraine attacks during a ten-week treatment course and at thirteen-month follow-up when compared to controls.

14. A study (Gutfeld, G. and Rao, L., 1992) was conducted on 42 patients suffering from chronic headaches. These patients, all of whom had responded poorly to conventional treatments, were split into two groups. One received Hypnotherapy to relieve their daily headaches; the rest acted as a comparison group. The Hypnotherapy group experienced reduced frequency and duration of headaches, cutting the intensity by about 30%. "These results are impressive in such a difficult, hard-to-treat group of patients," commented Egilius Spierings, M.D., Ph.D. director of the headache section, division of neurology at Brigham and Women's Hospital.

### **1.1.6 CANCER:**

15. Spiegel and Bloom (1983b) reported that a study of women with metastatic breast cancer showed that patients who received group therapy with training in Hypnosis over a one-year period were able to reduce their pain experience by 50% when compared to a control group.

16. In addition, at a 10-year follow-up of these same women, the Hypnosis treatment group had a mean survival rate of 36.6 months compared to 18.9 months for the controls. This suggests that the intervention may be both important quantitative and important qualitative effects (Spiegel 1989a).

17-18. Both adolescent and adult cancer patients undergoing chemotherapy were reported

by Cotanch (1985) and by Zeltzer (1984), in separate research, to have fewer symptoms of anticipatory nausea and vomiting following Hypnotic interventions.

#### **1.1.7 CARDIOVASCULAR CONDITIONS, GENERAL:**

19. In research by Bernardi (1982), hypertensive patients showed themselves to be significantly more effective at controlling cardiovascular responses to stressors in Hypnosis than they were in the normal waking state. This was particularly true for subjects with more marked Hypnotic ability.

20. In a study by Sletvold (1986), normotensive subjects were shown able to either increase or decrease their blood pressure significantly with Hypnosis.

21. In a 1979 research study by Jackson, subjects with Hypnotic ability were shown to improve their aerobic performance significantly in response to posthypnotic suggestion. In addition, subjects with high Hypnotic susceptibility significantly improved their performance in physical exercise using posthypnotic suggestion.

#### **1.1.8 HYPERTENSION & STRESS:**

22. Kuttner (1988) found that a Hypnotic approach emphasizing storytelling and imagery was significantly more effective than behavioural techniques or standard medical practice in alleviating distress during bone marrow aspirations in young children with leukemia.

23. Hypertensive subjects were found to have characteristic patterns of increased cerebral blood flow that were most marked in the left hemisphere. During Hypnosis, they could reduce cerebral blood flow more dramatically than could normotensive controls. The changes noted in this research by Galeazzi (1982) were associated with decreases in vascular resistance and diastolic blood pressure in the rest of the body.

**24-25.** Friedman and Taub (1977, 1978) reported the results of a trial comparing Hypnosis with biofeedback or a combination of both in essential hypertension. At the end of four weeks of treatment, all groups showed a significant reduction in blood pressure. But at six-month follow-up only the patients receiving Hypnosis had maintained the reduction.

**26-27.** Generally speaking, literature review supports the value of Hypnosis in analgesia and stress reduction in a number of disorders, whether following the dissociative formulation (Miller, 1986) or a social psychology approach (Noland, 1987).

#### **1.1.9 RESPIRATORY CONDITIONS:**

**28-29.** In studies by Maher-Loughnan (1962, 1970), Hypnosis was shown to alleviate the subjective distress of patients with asthma. This change was measured either by the number of attacks or the amount of medication that was needed when compared to supportive therapy.

30. In further study by Maher-Loughnan (1970) asthmatic subjects were randomly assigned to either Hypnosis or relaxation therapy. The results showed both treatment modalities of benefit to the patients, but the improvement in the Hypnotherapy group was significantly greater. There was a peak of improvement between the seventh and twelfth weeks of

treatment. In addition, only the Hypnotic subjects showed improvement in physiologic measures of respiration (forced expiratory volume).

31. Ewer and Stewart (1986) reported a randomized control trial of Hypnosis in patients with moderate asthma. Patients with a high Hypnotic susceptibility showed a 74.9% improvement in bronchial hyper-responsiveness (to methacholine challenge), a 5.5% increase in peak expiratory flow rate, a 26.2% decrease in the use of bronchodilator and a 41% improvement in daily ratings outside of the clinic. Twelve patients with a high Hypnotic susceptibility score showed a 75% improvement. However, a control group of 17 patients and a second group of 10 patients with a low level of Hypnotic susceptibility showed no change in either objective or subjective measures.

32. A study by Olness (1985) showed that children trained in self-Hypnosis could significantly alter their tissue levels of oxygen as measured by transcutaneous PO<sub>2</sub> measures.

#### **1.1.10 STRENGTHENING THE IMMUNE SYSTEM:**

33. Hypnosis strengthens the disease-fighting capacity of two types of immune cells, reports Patricia Ruzyla-Smith and her co-workers at Washington State University in Pullman. Thirty-three college students who achieved a Hypnotic trance easily and 32 students who had great difficulty doing so were recruited for the study. Students who underwent Hypnosis displayed larger jumps in two important classes of white blood cells than participants who received relaxation or no method. The greatest immune enhancement occurred among highly hypnotizable students in the Hypnosis group.

#### **1.1.11 INTESTINAL CONDITIONS:**

**34-35.** Whorwell (1984) reported successful treatment of Irritable Bowel Syndrome using Hypnosis in a controlled study of a group of patients who had a severe chronic form of the disorder and had not responded to conventional therapies. Patients were randomly allocated to either psychotherapy or Hypnotherapy groups. The psychotherapy patients showed a significant improvement in measures of pain, distension and in general well-being despite a lack of change in bowel habit. In contrast, the Hypnotherapy patients showed a dramatic improvement in all measures which persisted at a two-year follow-up. (Whorwell, 1987). Hypnotherapy, including suggestions for improved gastrointestinal function and pain reduction, was significantly better than Hypnosis for simple deep muscle relaxation.

36. Harvey (1989) reported a similar improvement following Hypnotherapy in 20 of the 33 patients with refractory Irritable Bowel Syndrome at three-month follow-up.

37. Colgan (1988) reported a randomized trial of 30 patients with frequently relapsing duodenal ulcer disease. The subjects were treated for ten weeks with either Hypnotherapy or ranitidine or the drug alone. At a twelve-month follow-up, all of the drug-only patients, but only half of the drug-plus-Hypnotherapy patients, had relapsed.

#### **1.1.12 HEMOPHELIA:**

38. Swirsky-Saccetti (1986) reported on research with hemophiliacs. Over an eighteen-week

follow-up, a group of hemophiliac patients who were taught self-Hypnosis significantly reduced both their level of self-reported distress and the amount of the factor concentrate they required to control bleeding when compared with a control group of patients who did not undergo Hypnosis.

39. A 30-month follow-up by LaBaw (1975) with hemophiliac patients demonstrated the effectiveness of group procedures for self-Hypnosis in reducing distress and the amount of blood products required when compared to control groups in patients ranging from five to forty-eight years of age.

#### **1.1.13 SURGERY:**

40. Patients undergoing head and neck surgery who were trained with preoperative Hypnosis had significantly shorter postoperative hospitalizations than did matched controls (Rapkin, 1988).

41. Swedish researchers studied 50 women prior to surgery. Twenty-five of the women were assigned to the experimental group who were briefly Hypnotized each day for several days before their scheduled operations. Twenty-five were assigned to a control group who were not Hypnotized. While in a Hypnotic state, the women in the experimental group heard suggestions to relax and feel hungry. After surgery only 10 had nausea (15 experienced no nausea), compared to 17 in the no-Hypnosis control group (8 experienced no nausea).

#### **1.1.14 CHILDBIRTH:**

42. In 1963, Schwartz reported on a study in which Hypnotherapy was used successfully to prolong pregnancy and prevent premature delivery.

43-45. Omer (1986a, 1986b, 1987a) found that frequency of physical complaints and the general level of anxiety were correlated with premature labour and premature contractions. A brief technique emphasizing the use of self-Hypnosis was employed as an adjunct to pharmacological treatment. The prolongation of pregnancy was significantly higher for this group than for the medication-along control group, and infant weight was also significantly greater.

#### **1.1.15 MISCELLANEOUS CONDITIONS:**

46. In a careful single-case controlled study of a patient with Raynaud's disease, Conn (1984) showed a rapid and dramatic vasodilatation in response to Hypnotic suggestion.

47. In research reported by Spanos (1988), a pair of randomized, carefully designed studies were conducted with a group of people who had warts. Subjects who were given Hypnotic or nonhypnotic suggestions were significantly more likely to achieve wart regression than placebo or no-treatment groups.

48-49. In a report by David Spiegel in the Harvard Mental Health Letter, the following research was cited: a) Several controlled experiments have shown that Hypnosis can be effectively used to eliminate warts; and b) Studies have been done on persons suffering from pseudoseizures, in which they lose consciousness or motor control and make jerking movements typical of epilepsy (but without the associated brain damage). Such patients

have been taught to limit or eliminate these symptoms by using Hypnosis.

## **PSYCHOLOGICAL APPLICATIONS**

### **1.1.16 ANXIETY:**

50. In a report by David Spiegel in the Harvard Mental Health Letter, the research was cited that Hypnosis methods have been used successfully for anxiety associated with medical procedures.

51. Two hundred forty-one patients who were undergoing percutaneous vascular and renal procedures were randomly tested on three testing regimens, one of which was Hypnosis. Patients rated their pain and anxiety on 1-10 scales before, every 15 minutes during, and after the procedures. Pain remained flat over the duration of procedure time in the Hypnosis group; pain increased linearly with procedure time in both other groups. Anxiety decreased over time in all three groups; the sharpest decrease was in the group that was hypnotized. Procedure times were significantly shorter in the Hypnosis group. In addition, Hypnosis showed itself to be superior in improving hemodynamic stability.

### **1.1.17 PHOBIC REACTIONS:**

52. In a report by David Spiegel in the Harvard Mental Health Letter, the following research was cited: One seven-year study showed that 50% of patients afraid of flying were improved or cured after Hypnosis treatment for a fear of flying.

### **1.1.18 DEPRESSION:**

53. In a neurochemical study of Hypnotic control of pain conducted by Domangue (1985), patients suffering arthritic pain showed a correlation among levels of pain, anxiety and depression. Anxiety and depression were inversely related to plasma norepinephrine levels. Depression was correlated with dopamine levels and negatively correlated with levels of serotonin and beta endorphin. Following Hypnotherapy, there were clinically and statistically significant decreases in depression, anxiety and pain, and increases in beta endorphin-like substances.

## A RESEARCH

### ABUSE

1995

Barber, Joseph (1995, November). When hypnosis causes trouble. [Paper] Presented at the annual meeting of the Society for Clinical and Experimental Hypnosis, San Antonio, TX.

NOTES: Sexual acting out occurs, even with highly trained and responsible clinicians. But other problems occur, and it is the same qualities of hypnosis that make it useful that also make for problems. I found 20 publications that exhibited problems in therapy, and they all discussed only the mental illness of the patients.

Bryant, Richard A. (1995). Fantasy proneness, reported childhood abuse, and the relevance of reported abuse onset. International Journal of Clinical and Experimental Hypnosis, 43 (2), 184-193.

This study investigated the relationship between fantasy proneness and the age at which reported childhood sexual abuse occurs. Seventeen adult females who reported having been sexually abused before the age of 7 years, 20 females who reported having been abused after the age of 7 years, and 20 females who reported having never been abused were administered two measures of imaginative involvement (Tellegen Absorption Scale [TAS] and Inventory of Childhood Memories and Imaginings [ICMI]). Participants who were reportedly abused early in childhood obtained higher scores on the TAS and ICMI than participants who were reportedly abused later in childhood, who in turn obtained higher scores than the control participants. Findings are discussed in terms of factors that mediate fantasy proneness and reports of childhood abuse

Eisen, Mitchell L.; Henn-Haase, Clare (1995, November). Memory and suggestibility for events occurring in and out of hypnosis. [Paper] Presented at the annual meeting of the Society for Clinical and Experimental Hypnosis, San Antonio, TX.

NOTES: Resistance to misinformation uses two paradigms: 1. Elizabeth Loftus - expose Subject to slides or videotape, give misinformation with leading or misleading questions 2. Martin Orne - pseudomemory, i.e. age regress people in hypnosis and suggest events occurred.

Each approach yields mixed results. Misinformation is accepted more readily in context of hypnosis; but there is no relationship to hypnotizability. Spanos found that highs were more responsive to social pressure. In general, in the absence of social pressure, when presented subtly and outside the context of hypnosis, the relationship diminishes. Other factors play a more prominent role: source of information, type of information, salience of information, etc.

They examined whether events occurring in context of hypnosis were more prone to distortion when assessed in biased fashion with use of misleading information, than outside hypnosis. Also, form of questions (dichotomous or with 'I don't remember' option).

They gave the Harvard and asked afterwards 3 misleading items (e.g. did you clench your fist, when they didn't do it). Also asked them to circle items if they had no memory of it. Tellegen Absorption Scale and Dissociation scale (DES) were administered a week later. Also a week later asked about events that occurred, including confederate items. Half of Ss had 2 choices, half had also 'I don't remember' as a third option.

In a previous study, resistance to misleading information was related to the strength of the initial memory and not to hypnotizability (article published in AJCH).

**RESULTS.** When given 3 choices, the number of misleading items endorsed dropped from .7 to 0.4 which is the most robust finding in the study and affects the rest of the study. Many Ss who endorsed the items reported minutes later that they had no memory for the event (on the check list). While many Ss given only two choices wrote in the margin that the event had never occurred.

Offering an 'I don't know' third option decreased endorsement of the Harvard items also, from 6.4 to 5.2 which is significant. The relationship between hypnotizability and endorsement of misleading items became much weaker when accounting for this.

Scoring high on DES is significantly related to accepting misinformation. Tellegen Absorption Scale also related to accepting misleading information. Harvard Hypnotizability Scale was not related to accepting misinformation.

Total memory on the Harvard (before cue plus after cue) did not correlate with resistance to misleading information. History of abuse was related to hypnotizability. Have to evaluate whether it was traumatizing, multiple abuse, etc.

Ganaway, George K. (1995). Hypnosis, childhood trauma, and dissociative identity disorder: Toward an integrative theory. International Journal of Clinical and Experimental Hypnosis, 43 (2), 127-144.

It is contended that prevailing exogenous trauma theory provides in most cases neither a sufficient nor a necessary explanation for the current large number of diagnosed cases of dissociative identity disorder (multiple personality disorder) and related dissociative syndromes purported to have arisen as a response to severe early childhood physical and sexual abuse. Relevant aspects of instinctual drive theory, ego psychology, object relations theory, self psychology, social psychological theory, sociocultural influences, and experimental hypnosis findings are drawn on to demonstrate the importance of adopting a more integrative theoretical perspective in the diagnosis and treatment of severe dissociative syndromes. Further cooperative experimental and clinical research on the etiology, prevalence, and clinical manifestations of the group of dissociative disorders is strongly encouraged.

Guyer, Charles G. II; Van Patten, Isaac T. (1995). The treatment of incest offenders -- a hypnotic approach: A brief communication. International Journal of Clinical and Experimental Hypnosis, 43 (3), 266-273.

Incest has become more prominent in public awareness over the past 15 years. The major focus of this interest has been on the incest survivor. The incest offender has received less attention. A hypnotic approach to treating incest offenders is outlined that involves a seven-stage approach. A case example is presented and future research directions suggested.

Holroyd, Jean (1995). Handbook of clinical hypnosis, by Judith W. Rhue, Steven Jay Lynn, & Irving Kirsch (Eds.) [Review]. International Journal of Clinical and Experimental Hypnosis, 43 (4), 401-403.

#### NOTES

"This is a book for the thinking clinician" (p. 401). "The editors are to be congratulated for making this volume much more coherent than most edited books" (p. 402). "My impression is that the book is best suited for an intermediate or advanced course on hypnotherapy, or for people who are already using hypnosis in treatment. Although there is some material on the basics of hypnotic inductions and a few introductory sample scripts for inductions, a beginners" course should probably use a different book, or this book could be accompanied by an inductions manual. ... I recommend it very highly" (p. 403).

Levitt, Eugene E.; Pinnell, Cornelia Mare (1995). Some additional light on the childhood sexual abuse-psychopathology axis. International Journal of Clinical and Experimental Hypnosis, 43 (2), 145-162.

This exposition is an attempt to unravel the complexities of the relationship between childhood sexual abuse and adult psychopathology. Four facets of the relationship are examined in some detail: (a) the extent of childhood sexual abuse; (b) the probability that sexual abuse in childhood will result in psychopathology in the adult; (c) the reliability of early life memories in later life; and (d) the role of recovered memory of trauma in the healing process. The conclusions of this logico-empirical analysis are that first, government statistics tend to underestimate the extent of childhood sexual abuse, whereas independent surveys tend to overestimate it. Estimating prevalence is further complicated by variations in the definitions of key terms. Possibly the only safe conclusion is that true prevalence cannot be reliably determined. Second, empirical investigations of childhood sexual abuse conclude that not all victims are emotionally injured. A substantial number of these investigations find that a majority of victims suffer no extensive harm. Other variables such as family dynamics are involved; there may be only a few cases in which emotional harm results from sexual abuse as a single factor. Third, memory research suggests that memory in general is a dynamic, reconstructive process and that recall of childhood events is particularly vulnerable to distortion. Memory cannot dependably produce historical truth. Last, there is some clinical evidence that abreaction of a traumatic event in adulthood may have a remediative effect. Similar evidence for childhood trauma is lacking. The belief in the healing effect of recalling and reliving a childhood trauma depends on the therapist's orientation.

**Nagy, Thomas F. (1995). Incest memories recalled in hypnosis -- a case study: A brief communication. International Journal of Clinical and Experimental Hypnosis, 43 (2), 118-126.**

Accuracy of repressed memories recovered in hypnosis cannot be reliably determined with any greater certainty than non-hypnotically recalled events. Therefore, the practice of therapists' accepting hypnotically enhanced memories as veridical, absent corroborating evidence, is not advocated. A 52-year-old woman with a 27-year history of panic attacks and sleep disorder inadvertently recovered incest memories in hypnosis. Photographs and remembered events by other family members were thought by the patient to provide general support although they did not constitute actual proof of abuse. Implications are discussed.

**1994**

**Bloom, Peter B. (1994). Clinical guidelines in using hypnosis in uncovering memories of sexual abuse: A master class commentary. International Journal of Clinical and Experimental Hypnosis, 42 (3), 173-178.**

"Joan," a clinical psychologist, requested a psychiatric consultation to determine whether hypnosis could recover accurate memories of suspected child abuse by her still living father. Are there clinical guidelines in using hypnosis in uncovering such possible memories of sexual abuse? We asked Dr. Peter B. Bloom to share his views with us.

**NOTES: Gives case example and clinical guidelines for using hypnosis in uncovering memories of sexual abuse. 1. In medical practice, "Primum non nocere," i.e. "First do no harm." 2. "No therapist should ever, either directly or indirectly, suggest abuse outside of a specific therapeutic context--certainly not to a client who is on the phone making a first appointment!" 3. "A therapist must not jump quickly to the conclusion that abuse occurred simply because it is plausible." 4. "A therapist should never simply assume that a client who cannot remember much from childhood is repressing traumatic memories or is in denial." 5. "Remember 'a client is most vulnerable to suggestion and the untoward influence of leading questions when therapy begins to delve into painful life situations from the past, particularly from childhood.'" 6. "Therapists ... should be cautious about suggesting that clients cut off communication with their families." 7. "Therapists should reconsider the 'no pain, no gain' philosophy of treatment." 8. "The context of therapy is as important as the content." 9. "Tolerate ambiguity." (Sincerity and conviction on the part of the patient reporting abuse are not in and of themselves reason to believe the material.) 10. "Respect the current science of memory." 11. "Maintain responsibility for making the diagnosis and choosing the treatment." 12. "Pursue alternative diagnoses to account for the symptoms." 13. "Historical and narrative truth: Understand the difference."**

**COMMENT:** The tenet that insight is necessary for change and growth is not true. Change can occur without insight, although insight may be helpful in maintaining change once it has occurred.

**SUMMARY:** These guidelines are presented to enhance safe practice, however, clinicians should use their own judgement to determine the best path to follow with each patient.

**NOTE:** Guidelines 1, 8, 9, 10, 11, 12, and 13 are those of Peter B. Bloom. Those labeled as Guidelines 2, 3, 4, 5, 6, and 7 were taken with permission from Yapko, M. (1993 September/October). "The seductions of memory. The false memory debate." *Family Therapy Networker*, 17, pp. 30-37. All discussions, however, are those of Peter B. Bloom.

**Bowers, Kenneth S. (1994, October). Bringing balance to controversy. [Paper] Presented at the annual meeting of the Society for Clinical and Experimental Hypnosis, San Francisco.**

**NOTES:** Skeptics argue that concept of "repression" has no scientific merit, though even if a valid concept, it wouldn't validate all memories recovered. Skeptics regard laboratory evidence as essential, while clinicians are impressed by case reports. See Polonyi, Personal Knowledge.

It is not reasonable to say there is no evidence for fugue states, when seeing one, if it has not been demonstrated in the laboratory. But you can investigate some of the phenomena in the laboratory.

Most of the time it is an affectively loaded idea that is repressed; in contrast, trauma usually lead to intrusions into consciousness. So repression of a traumatic event may be a rare way to deal with the event.

Claims for repression and ESP differ in that there are probably observable mechanisms in the former (e.g. thought avoidance). If a person ejects thoughts about a topic frequently enough, the ejections become automatic. Freud's original description of repression used the word "intentional" and it was a footnote that took out that idea. (See Erdelyi's publications).

Recent research we conducted on intuition and on problem solving is relevant to this problem.

[The remainder of Bowers' presentation is not summarized here.]

**Frankel, Fred H. (1994, October). On patients remembering abuse when it in fact may not have occurred. [Paper] Presented at the annual meeting of the Society for Clinical and Experimental Hypnosis, San Francisco.**

**NOTES:** The concept of hidden memories has supported the profession of psychotherapy for a century. This process can only occur if there is a mechanism to support it. Bowers says, if memory is not reliably accurate, it is not reliably inaccurate either.

"Ideas passing as descriptions lead us to equate the tentative with [the factual.]" - Gould.

Three studies purporting to establish repression: 1. Briere & Comte sampled 450 adults who reported abuse. They asked, "Was there ever a time when you couldn't remember the forced experience?" How does respondent understand the question?

Clients were all in therapy. 2. Herman and Schatzow (1989) "verification of abuse" study. 53 Ss in a survivor's group. Reports percentages who had no or little recall. Authors don't acknowledge that the group discussion and the attitude of therapist may have shaped the response. It is also not clear how many Ss who claimed to have "verified" their accounts were among those who had severe amnesia for the event. They could be Ss who had never lost the memory in the first place. 3. Williams interviewed women who earlier were in Emergency Rooms because of abuse being suspected. 38% did not report childhood abuse when questioned, and author concluded it was due to repression. Significant numbers of adults cannot remember things even past the age of 5.

Problem with wording of questions. Some of the women interviewed might have preferred not to report the event. This was not investigated in the study.

Freyd, Jennifer J. (1994). Betrayal-trauma: Traumatic amnesia as an adaptive response to childhood abuse. Ethics and Behavior, 4.

Betrayal-trauma theory suggests that psychogenic amnesia is an adaptive response to childhood abuse. When a parent or other powerful figure violates a fundamental ethic of human relationships, victims may need to remain unaware of the trauma not to reduce suffering but rather to promote survival. Amnesia enables the child to maintain an attachment with a figure vital to survival, development, and thriving. Analysis of evolutionary pressures, mental modules, social cognitions, and developmental needs suggests that the degree to which the most fundamental human ethics are violated can influence the nature, form, processes, and responses to trauma.

NOTES: "A logical extension of this research direction, based on a strategy that has been very effective in cognitive neuroscience, would be to look for neuroanatomical underpinnings of the cognitive mechanisms implicated in dissociation. ... For instance, the ability to dissociate current experience may depend partly on representational structures that support spontaneous perceptual transformations of incoming events. One possible perceptual transformation that is amenable to scientific investigation, would be the creation of spatial representations in which the mental 'observer' is spatially distinct from the real body of that observer. Such a representation would fit patient descriptions of 'leaving their body' during a traumatic episode and viewing the scene as if from afar. Additionally one could investigate the role of mental recoding and restructuring during memory 'recovery' and psychotherapy" (pp. 19-20).

Loftus, Elizabeth; Polonsky, Sara; Fullilove, Mindy Thompson (1994). Memories of childhood sexual abuse: Remembering and repressing. Psychology of Women Quarterly, 18, 67-84.

Women involved in out-patient treatment for substance abuse were interviewed to examine their recollections of childhood sexual abuse. Overall, 54% of the 105 women reported a history of childhood sexual abuse. Of these, the majority (81%)

remembered all or part of the abuse their whole lives; 19% reported they forgot the abuse for a period of time, and later the memory returned. Women who remembered the abuse their whole lives reported a clearer memory, with a more detailed picture. They also reported greater intensity of feelings at the time the abuse happened. Women who remembered the abuse their whole lives did not differ from others in terms of the violence of the abuse or whether the violence was incestuous. These data bear on current discussions concerning the extent to which repression is a common way of coping with childhood sexual abuse trauma, and also bear on some widely held beliefs about the correlates of repression.

**NOTES:** In previous research, it was reported that violent or incestuous abuse is particularly susceptible to repression. This study differs from previous investigations in the definition of violence. In the present study, 'violence' is defined as any act involving vaginal, oral, or anal sex. Earlier research defined 'violence' as involving sexual assault with physical injury or fear of death.

Depending on the definition of repression, a sizeable minority (31% or almost 1/5) of this sample forgot their earlier abuse for a period of time. The authors state that this suggests there is little 'robust repression' in this sample. They cannot rule out the possibility that some women who were abused still, to this day, do not recall the experience; or that some who continue to have memory loss based on organic causes, including blackouts.

The authors suggest that future research in this area use more specific questions, including assessing whether Subjects respond to statements like: "There was a time when I would not have been able to remember the abuse, even if I had been directly asked about it," or "There was a time when I would not have been able to report the abuse because I had no idea that it had even happened to me." Also, when Subjects report that a memory had emerged after a period in which they had no recall, the Experimenter should enquire about how and when the recovered memory occurred. The authors conclude that remembering abuse is more common than forgetting it.

**Lynn, Steven Jay; Myers, B.; Sivec, H. (1994). Psychotherapists' beliefs, repressed memories of abuse, and hypnosis: What have we really learned?. [Comment/Discussion] .**

The authors are responding to an article by Michael D. Yapko in the same issue of AJCH, "Suggestibility and repressed memories of abuse: A survey of psychotherapists' beliefs." They are of the opinion that "Yapko's research and data analysis do not justify the conclusion that many, if not virtually all, therapists are naive, credulous, and out of touch with the scientific literature, although it is evident that certain therapists can be so described" (p. 184). They state that "Yapko's research is important insofar as it suggests that unfounded stereotypes of hypnosis persist even among Ph.D.- and M.D.-level clinicians" (p. 184).

**Malinoski, Peter; Aronoff, Jodi; Lynn, Steven J.; Moretsky, Michael (1994, August). Hypnosis and early memories. [Paper] Presented at the annual meeting of the American Psychological Association, Los Angeles.**

## NOTES

We studied autobiographical memory in the college population, as manifested in the therapy situation, as a way of investigating an individual difference variable. Most people do not have recall before age 3 or 4 (and probably infantile amnesia begins before age 2).

Administered Autobiographical Memory Scale (AMS), and later in context of a hypnosis scale. 247 students were in phase 1, conducted as two separate experiments so that Ss wouldn't link the AMS to measures used in the second study.

First study was presented as a study of personal memories. Asked Ss to distinguish first five birthdays, circumstances around loss of first tooth, first day of high school. Also, they were asked about their earliest memory events, rated according to 3 scales (detail, vividness, accuracy of recall). Authors summed Ss' responses on these 3 ratings for the 8 item scale.

Part II. Administered various scales: Life Experiences, Fantasy Proneness, Wilson & Barber's scale, Imagery Control Scale, Global Psychopathology, 25 item scale of physical and sexual abuse, Brier's list of symptoms of abuse, and DES (Dissociative Experiences Scale). Imbedded were 12 items to test carelessness in responding (e.g. "I have never said Hello to anyone who wore eyeglasses.")

RESULTS. Phase 1. Two people indicated they had memories dating to before their first birthday; an additional 5% of Ss gave memories between 12-24 months. This would probably be impossible. Another 14.4% described events between 24-36 months; 37.4% said their earliest memory was at age 3. Mean age for earliest memory was 3.4 years (which agrees with other surveys.) Only 1 subject stated his earliest memory was as late as the tenth year of life.

High intercorrelation was obtained, ranging .79 to .89, between ratings on any of the memory event ratings (as detailed, vivid, or accurate). There was a negative correlation of these ratings with age of recall. Ss who report more detail, vividness, and competence, were also likely to report earlier first memories.

Authors divided Ss into three groups based on age of first memory: 12 with first memory earlier than first year; those whose first memory was between 1-7 years; and those with a later first memory. The earlier memory group were more fantasy prone; and rated their memories as more reliable, vivid. This suggests there are persons who report memories that are covered by infantile amnesia, report them with greater detail, and are more fantasy prone than those who report memory events beginning later in life. This is consistent with Wilson & Barber's finding that fantasy prone people have vivid recall of early childhood events.

None of the memory reports correlated with psychopathology or dissociation. Dissociation (DES) was correlated with abuse indicators, however. Compared top and lowest 10% and middle range on DES on their memory scores and found no relationship. There was no support for the idea that report of early life events in dissociative people is compromised. Failure to recall early memories shouldn't suggest that people are dissociative (which some therapists tend to do).

All three memory measures were associated with Harvard Scale scores. The AMS was administered at the same time as the Harvard. Objective responding on the Harvard correlated with detail, vividness, and accuracy of recall. Also,

involuntariness of response correlated with all 3 measures of the AMS. Finally, subjective involvement correlated with all three measures of AMS. At least when hypnosis is measured first, and explicit connection is suggested, there is a connection. Further research is needed to see if the relationship holds when measured in independent contexts. This may explain why High Hypnotizables are more prone to pseudo memories and leading questions. They may come to confuse them with historical reality.

The results suggest caution for early memory reports. They may be vulnerable to confusing fantasy and reality, as well as to biasing effects.

Mulhern, Sherrill (1994). Satanism, ritual abuse, and multiple personality disorder: A sociohistorical perspective. International Journal of Clinical and Experimental Hypnosis, 42 (4), 265-288.

During the past decade in North America, a growing number of mental health professionals have reported that between 25% and 50% of their patients in treatment for multiple personality disorder (MPD) have recovered early childhood traumatic memories of ritual torture, incestuous rape, sexual debauchery, sacrificial murder, infanticide, and cannibalism perpetrated by members of clandestine satanic cults. Although hundreds of local and federal police investigations have failed to corroborate patients' therapeutically constructed accounts, because the satanic etiology of MPD is logically coherent with the neodissociative, traumatic theory of psychopathology, conspiracy theory has emerged as the nucleus of a consistent pattern of contemporary clinical interpretation. Resolutely logical and thoroughly operational, ultrascientific psychodemonology remains paradoxically oblivious to its own irrational premises. When the hermetic logic of conspiracy theory is stripped away by historical and socio/psychological analysis, however, the hypothetical perpetrators of satanic ritual abuse simply disappear, leaving in their wake the very real human suffering of all those who have been caught up in the social delusion.

Nash, Michael R. (1994). Memory distortion and sexual trauma: The problem of false negatives and false positives. International Journal of Clinical and Experimental Hypnosis, 42 (4), 346-362.

Logically, two broad types of mnemonic errors are possible when adult psychotherapy or hypnosis patients reflect on whether they were sexually abused or not as a child. They may believe that they were not abused when in fact they were (false negative error), or they may believe they were abused when in fact they were not (false positive error). The author briefly reviews the empirical evidence for the occurrence of each of these types of errors, and illustrates each with a clinical case. Further, in considering the incidence, importance, and clinical implications of these errors, the author contends that clinical efficacy in no way assures that a false negative or a false positive has been avoided. A plea is made for theorists and

researchers to acknowledge that both categories of errors can occur and to conduct future clinical and laboratory research accordingly.

Nash, Michael R. (1994, October). Reports of early sexual trauma: The problem of false negatives and false positives. [Paper] Presented at the annual meeting of the Society for Clinical and Experimental Hypnosis, San Francisco.

NOTES The problem of false positives and problem of false negatives are distinct and should be treated differently. The question involves pseudomemories vs repression.

Evidence for false positives: 1. Memory research 2. Developmental psychopathology 3. Contemporary psychoanalytic theory 4. Clinical field studies

No laboratory researcher has produced false memories that are as vivid, or as emotionally loaded as early abuse.

Evidence for repression: 1. "Repressor Personality" research (Weinberger & Schwartz, who view it as a trait rather than a state). 2. Implicit memory research 3. Hypnosis research on memory (see Nash chapter in Fromm & Nash book on research in hypnosis) 4. Clinical field studies

Spanos, Nicholas P.; Burgess, Cheryl A.; Burgess, Melissa Faith (1994). Past-life identities, UFO abductions, and satanic ritual abuse: The social construction of memories. International Journal of Clinical and Experimental Hypnosis, 42 (4), 433-446.

People sometimes fantasize entire complex scenarios and later define these experiences as memories of actual events rather than as imaginings. This article examines research associated with three such phenomena: past-life experiences, UFO alien contact and abduction, and memory reports of childhood ritual satanic abuse. In each case, elicitation of the fantasy events is frequently associated with hypnotic procedures and structured interviews which provide strong and repeated demands for the requisite experiences, and which then legitimate the experiences as "real memories." Research associated with these phenomena supports the hypothesis that recall is reconstructive and organized in terms of current expectations and beliefs.

Spence, Donald P. (1994). Narrative truth and putative child abuse. International Journal of Clinical and Experimental Hypnosis, 42 (4), 289-303.

Memories of early child abuse can be read in at least two distinct ways -- as true accounts of an unspeakable event or as metaphors for a wide range of boundary violations which belong to both past and present. An actual memory of an early experience tends to fade unless repeatedly rehearsed; because abuse memories are inherently shameful, it seems reasonable to be skeptical of this kind of repetition and to be suspicious of their sudden emergence. An actual memory of an early experience would be told from the child's point of view and would probably contain many false starts, internal contradictions, and all the other earmarks of a confused

memory that refer to an early happening; by contrast, a seamless account with a tight narrative structure and an almost total absence of doubt or irrelevant detail is almost certainly false. An actual memory would tend to have its own flavor and style; by contrast, a memory of child abuse that sounds too much like other memories is more likely a metaphor for something else. Therapists, lawyers, and other professionals need to be trained to listen metaphorically to these accounts, to be on guard against hearing them as concrete references to a particular time and place, and to beware of reinforcing them prematurely.

Spiegel, David (1994, October). On patients not remembering abuse when it in fact may have occurred. [Paper] Presented at the annual meeting of the Society for Clinical and Experimental Hypnosis, San Francisco.

#### NOTES:

False memories and false non-memories may be two sides of the same coin. What is the evidence for repression?

If people are abducted by extraterrestrials, why don't they just keep them? [Joke!] It seems counter-intuitive that people would forget important, arousing things that happen.

The three main components of hypnosis (suggestibility, absorption, and dissociation) are also aspects of memory: 1. Absorption relates to encoding (narrowing attention); also happens during traumatic events (Loftus' "gun memory" which is so clear, while they don't encode what gunman's face looks like). 2. Dissociation relates to memory storage (compartmentalization of information). Traumatized people have symptoms of dissociation, depersonalization. If you are in an unusual mental state, you may watch the event; the memory is stored without the usual network of associations. 3. Suggestibility relates to retrieval. The way questions are asked influences one's response. But hypnosis is not an infinite influencer; the main damage to memory contributed by hypnosis is "confident errors" (McConkey).

We did research one week after the Loma Prieta earthquake, and found significant cognitive alterations, memory alterations, etc. In our sample, 1/4 of the people felt detached from their body or from the ground right after the earthquake.

Memory alterations were compared with data from other studies after other traumas. Difficulties with memory occurred in 29% of our sample.

The disorganization of memory can follow even just witnessing trauma (e.g. the recent slaying of 8 people in the law office in San Francisco) And people who witnessed the execution of Harris. They were in no danger themselves, yet the level of dissociative symptoms were as high in the former.

The Briere & Cone and Herman & Shatzow studies are based on self report of earlier trauma, and that is a problem in research. But Williams' study does have the age of people when they were abused as children; see her article in Journal of Consulting and Clinical Psychology.

#### COMMENTS FROM THE AUDIENCE:

Dabney Ewin: Sex abuse trauma differs from earthquakes because the abuser says, "If you tell anybody I'll kill you." This is like a post hypnotic suggestion, which is carried out compulsively when given to the victim during fear.

**Dale:** How do we account for the vigor in the attempts of each side to convince the other. The people who have been real victims of sexual abuse need to be able to talk with the people who are victims of False Memory Syndrome. The impact on a family is just as traumatic as the sexual abuse itself.

**Response by D. Spiegel:** I wouldn't recommend that combination, but the point you make about damage to the falsely accused is relevant. Their lives are shattered but remember the damage done throughout life by sexual abuse.

**Stewart, James (1994).** Hypnotherapy with dental patients. [Lecture] UCLA Hypnosis Seminar.

**NOTES:** [Dr. James Stewart is both a dentist and a clinical psychologist.] Among dental patients, 15% of patients are anxious; 75% of those patients could associate that fear to early childhood experiences, and showed signs of post traumatic stress disorder (PTSD) but only when they have to go for dental treatment. Those 75% respond well to hypnosis (respond quickly, short-term; it is even great to do the therapy in the dental chair, e.g., relieving trauma in trance).

It is important to diagnose PTSD because treatment will be different if the patient has an anxiety disorder. The disorders are not "simple phobias" because the trauma does not meet the criterion of "silly and unreasonable."

In hypnosis I routinely use the suggestion, "find a safe place," and may tell them they can go through a videotape or a filing cabinet to find a safe place. If the patient cannot remember a safe place, it is diagnostic of serious problems, more than dental anxiety. The exploration, verbalization of a safe place enhances rapport. A dentist should not accept a referral for hypnosis when the dental work has to be done next week; better to use sedation, and schedule hypnosis Rx later.

For anxiety or pain, do not try to relax it away; better to go where it is, define it (size, density, etc.) How does it feel? Can you put your finger on it? Like vapor? Soft, like steel?

**PTSD.** During World War I they called it malingering and gave shock (not ECT). During World War II the psychoanalytic view was that PTSD was pre-Oedipal. Viet Nam used phenothiazines for "delayed stress reactions." Almost all the variance in the number and severity of symptoms can be explained by the length of time the patients were in battle. During World War II, they did a lot of age regressions under sodium pentathol (a "catharsis") which was often very successful, but there was no theoretical understanding. After that the patient got psychoanalysis.

These days in doing desensitization for phobias I do not bother with developing a hierarchy [of feared situations] and I let the patient go through the anxiety more often. Also, one can have the patient walk away from the scene until they subjectively feel far enough away not to feel anxiety.

**Yapko, Michael D. (1994).** Suggestions of abuse: True and false memories of childhood sexual trauma. New York, NY: Simon & Schuster.

**NOTES:** From the section titled "A Note to Therapists:"

"I would encourage you not to (1) preclude open communication at all times among family members; (2) act as your client's 'hired gun'; (3) act as if

corroboration of allegations of abuse were unnecessary; (4) jump quickly to the conclusion abuse occurred simply because it is plausible; (5) suggest a history of abuse to someone who is not your client; (6) refer a client out for hypnotic confirmation or disconfirmation on the false premise that hypnosis is some kind of lie detector; (7) ask leading or suggestive questions; (8) assume repression is in force when someone does not have much memory from childhood; (9) rely on your memory of the interaction. Tape your investigative sessions and review them later for any evidence of possible unintentional contamination of your client's recollections" (p. 217).

### 1993

Eisen, Mitchell (1993). Assessing the hypnotizability of college students from addictive families. Contemporary Hypnosis, 10, 11-17.

**ABSTRACT:** The present study examined the relation between hypnotizability and the report of growing up in an addictive family where one or both parents were addicted to drugs and/or alcohol. A sample of 113 college students (47 male, 66 female) were studied for measure of childhood abuse, addiction history, dissociation and hypnotizability. As predicted, subjects from an addictive family were more hypnotizable than subject from a nonaddictive family. However, no relation between family addiction and dissociation was secured. Whereas abuse was found to be related to dissociation, it was not related to hypnotizability. The findings are discussed in terms of the effects of child abuse and neglect on dissociation and hypnotizability as it relates to the addictive family.

### NOTES

Author reviews the literature in area of abuse and hypnotizability as well as dissociation. Subjects were unaware of purposes of the experiment when they volunteered. Of 113 Ss, 18% were reared in an addictive family; 13 Ss reported being abused, of whom 6 reported sexual abuse and seven physical abuse. Five of the 21 Ss who reported being reared in addictive families also reported being abused (3 physical, two sexual). Only one S reported both physical and sexual abuse.

Used HGSHS:A, Children of Alcoholics Screening Test, and Dissociative Experiences Scale of Carlson and Putnam (1986). Those with addiction in the family had Harvard scale mean score of 8.05, compared to those who didn't have it with mean of 6.95. No significant effect was found for ABUSE or the interaction of ABUSE and family addiction. The abuse question was, "Before the age of 12 parent punishment of you resulted in your physical injury (bruises, scarring, broken bones, etc.). Second question was, "Before the age of 12, did you participate in sexual behaviors (either with or without coercion) with a much older person?"

The Discussion thoroughly explores the possible reasons why their results differ from those of others.

Hawkins, Russell (1993). An analysis of hypnotherapist-client sexual intimacy. International Journal of Clinical and Experimental Hypnosis, 41, 272-286

While sexual interaction between psychologists, physicians, and other health therapists of all kinds and their clients is typically condemned by professional bodies as unethical, the controversy regarding the potential for hypnosis to produce compliant behavior in unwilling or nonconsenting subjects suggests that hypnotherapist-client sex may warrant special attention. Because the experiments required to clarify the potential for hypnosis to potentiate nontrivial compliance are themselves unethical and/or inconclusive, experimental methods cannot be adequately used to clarify this issue. Instead, the matter can be addressed by reference to other forms of evidence, such as the responses of therapists and clients to anonymous surveys and the analysis of cases, that have reached the courts. Consideration of this qualitatively deficient evidence suggests that even if the use of hypnotic suggestion can lead to compliance to sexual demands, overt coercion is seldom used in practice. Social psychological and situational factors are particularly salient in understanding therapist-client sex. The question of whether there are special properties of the dynamics of the hypnotic experience, other than specific coercive suggestion and beyond those typically found in other forms of therapy, is considered. Comparisons are drawn with other examples of socially condemned sex, such as teacher-student sex, sexual harassment in the workplace, incest, and extramarital sex.

Litwin, R. G.; Cardena, E. (1993, August). Dissociation and reported trauma in organic and psychogenic seizure patients. [Paper] Presented at the annual meeting of the American Psychological Association, Toronto, Canada.

Early detection and differential diagnosis of non-epileptic seizures (NES) versus epileptic seizures (ES) is a major clinical issue in comprehensive epilepsy centers. Recent research suggests that differences in dissociative experiences between NES and ES patients may prove useful for diagnostic purposes. Non-epileptic seizures are frequently conceptualized as a dissociative response to past emotional trauma or abuse; dissociation in ES occurs as a result of electrophysiological abnormalities, most often associated with the temporal lobes. The purpose of this study was to evaluate the effectiveness for the differential diagnosis of NES from ES of several measures of dissociation and of a self-report measure for physical and sexual abuse. Four quantitative measures of dissociation were utilized in this study: the dissociative disorders interview schedule (DDIS), dissociative experience scale (DES), Tellegen absorption scale (TAS) and the Stanford Hypnotic Clinical Scale (SHCS). The incidence of sexual and physical abuse was obtained from structured questions in the DDIS. Forty-one patients being evaluated for intractable seizures participated in this study; 13 ES patients with non-temporal lobe involvement (ES/NTL), 18 ES patients with temporal lobe focus (ES/TLE) and 10 patients with NES spells of psychiatric origin. The main researcher was blind to these diagnoses until the study was completed. Results show a trend toward greater incidence of dissociative experiences in the NES versus ES group on the DDIS, TAS and DES, although these differences tended to be modest and not statistically significant, perhaps given the small N of the study. There were no significant trends or differences in dissociative experiences reported by ES/NTL patients versus ES/TLE patients. Contrary to the study's hypothesis, ES patients were slightly more

susceptible to being hypnotized than NES patients. As hypothesized, a significant difference was that NES patients reported physical and sexual abuse of higher incidence and longer duration than did ES patients. Logistic regression analysis for prediction of NES using the DES, TAS and SHCS instruments correctly predicted only 10% of NES patients. However, exploratory logistic regression analysis using the demographic variables of gender, months of sexual abuse and years of recurrent seizures suggest that these characteristics may be specific and sensitive in the prediction of NES. Being a female, having a higher incidence and longer duration of abuse and fewer years of recurrent seizures all predicted significantly the existence of non-epileptic seizure events, allowing for a 95% accuracy in diagnostic prediction. Our findings reinforce prior research indicating that dissociation is an important symptom component of both ES and NES events. The trend toward more prevalent dissociative experiences in the NES group suggests that in depth examination of these differences and of key demographic variables may help differentiate between these two groups.

From Bulletin of Division 30, Psychological Hypnosis, Fall 1993, Vol. 2, No. 3.)  
London, Ray William (1993, October). Refreshed adult memories: Abuse survivor or therapeutic victim?. [Paper] Presented at the annual meeting of the Society for Clinical and Experimental Hypnosis, Arlington Heights, IL.

NOTES: The author addresses four areas: 1. public policy 2. psychological issues 3. legal issues (evidence) 4. how to properly deal with it

A definition of sexual abuse is being applied to behaviors that for years were not considered out of bounds (e.g. entering a bathroom where someone else is). Furthermore, using the word "survivor" for abused people equates patients with survivors of concentration camps, who do not present with repressed memories typically. National incidence of child abuse remains unclear estimates are 6 to 60% of females. In Florida, only 13% of cases reported are confirmed.

Some therapists who specialize in this area in surveys indicate that they have false beliefs regarding memory and effects of trauma.

[These represent only partial notes on a lengthy and substantial paper.]

Rhue, Judith W.; Lynn, Steven Jay (1993, October). Dissociation, childhood sexual abuse, and fantasy. [Paper] Presented at the annual meeting of the Society for Clinical and Experimental Hypnosis, Arlington Heights, IL.

NOTES: We are reporting on part of an ongoing study, with results still being analyzed. We are looking at imagination, fantasy, and dissociation in abused and non-abused children. This focuses on the relationship between dissociation and fantasy and imagination.

For Janet, dissociation was the primary defense against trauma. [Quotes D. Spiegel also.] There is a body of research on trauma associated with the development of dissociation. 1. NIH found 97% of multiple personality patients reported trauma in childhood; 83% were sexually abused; 75% were repeatedly physically abused; 68% had both types of abuse. 2. Bliss - studied 70 MPDs and found same results. 3.

Ross, Norton, and Noosney [?name] - found same results 4. Coombs & Milstein - same

The incidence of retrospective reports of abuse is much lower in other types of patients.

So, what is going on during child abuse? We wanted to look at children experiencing or who recently experienced abuse. Also looked at a children's scale of dissociation symptoms and validated other studies.

We studied 39 children referred to Ohio University College of Osteopathic Medicine; 12 had primary problem as sexual abuse (8 of whom were female). Non-abused Ss were either behavioral or adjustment disorders. 8 reported severe physical abuse. Parents concurred in presence of abuse. Physical abuse consisted of broken bones, burns, etc. Average age 9-10.

Ss were given the Beck Depression Scale, Children's Fantasy Inventory, Meyers' Children's Creative Imagination Scale, Children's Perception Alteration Scale, Figure Drawings, WISC-R, and 2-3 other measures. Research assistants administering the scales didn't know the children's diagnoses.

We found no support for the hypothesis that sexual abuse in childhood is associated with imagination, fantasy, or dissociative tendencies--not surprising considering that only 4 Ss were abused by their father or stepfather, 2/3 of Ss had fondling as the most severe abuse they had experienced; only 2 had intercourse; 2/3 were abused only 1-3 times. Sexual abuse that is not violent, severe, prolonged, or perpetrated by a parent may not lead to the same problems.

In a sample of women whose assaults were rape, only 25% reported it as rape.

On other hand, physical punishment was more reliably associated with dissociation (.47), imagination and fantasy in absorption scale (.41-.51 with question about using imagination to block awareness of punishment). Physical punishment was associated with increased dissociation.

Sample size is small and the trend is in the predicted direction, so later results may be significant.

Conclusion: measures of fantasy, dissociation, and imagination were correlated. Children's Perception Alteration Scale and the measures of fantasy and imagination were validated. Diverse measures of fantasy were highly correlated with one another.

We need a non-abused sample to add to this research.

The clinical sample had a higher dissociation score than Evers, Sanders, and Shostick's cutting score. We use 60 as a cutting score (for an abused sample) while they used 55.

#### COMMENTS FROM THE AUDIENCE:

Jack Watkins: the sexual abuse for the most part was not painful. Answer by Rhue: The group of sexual abuse cases includes very wide varieties of experiences; we need to examine that in our research. Also, trauma and the perception of trauma is an individual matter.

Etzel Cardena: We presented a paper at APA in which sexual abuse was a predictor of psychogenic seizures, and most important, the duration of the abuse.

Phyllis Alden: In a recent study in Germany, it was length of time for the abuse that predicted [dissociative symptoms?].

Sivec, Harry; Lynn, Steven Jay (1993, October). Hypnosis and early memories. [Paper] Presented at the annual meeting of the Society for Clinical and Experimental Hypnosis, Arlington Heights, IL.

**NOTES:**

The investigators hypnotized people and asked that they recall their earliest memories. Gorham & Hafner tested highs and lows in 2 sessions, one with a hypnotic induction. Ss in hypnosis reported more themes, whether high hypnotizables or not. Ss might have held back in non hypnosis condition however.

Hypothesized that early memories would have affect-laden materials.

20 Ss in hypnosis group, 20 Ss in relaxation condition, all highs (scored minimum of 9 of 12 on the Harvard Scale). Ss were told they were randomly selected from a pool and that it was a study of personality. Ss were administered a number of questionnaires and tests.

The two groups received either a Stanford Form C Scale induction or a relaxation procedure.

We used the procedure of Bloom [spelling?] for recall of two memories, and to probe the earliest memory. Also to recall two recent memories. Counterbalanced for order of presentation.

Positive affect, negative affect, affect intensity, and primary process were rated; 12 themes were rated. ANOVA was used.

Earliest memory at 3.8 yrs. Next earliest is 7.5 for hypnosis and 5.2 for relaxation groups. 4.3 is earliest for hypnosis group; there may be a basement effect. Negative affect varied by condition and by order of administration and recency of memory assessed. When early memories were elicited first, no differences were found in groups; when elicited second, negative affect was greater for [missed words]. Affect was more abundant and intense in the hypnosis group, but only when recent memories were elicited before early memories and only in the [missed words].

Early recollections were slightly more primary process (bizarre) than later, which should alert clinicians.

Themes didn't differ between groups. Early memories involved more trauma than later memories. Negative affect correlated with psychopathology measures for earliest memory but not later memory.

Used posthypnotic experiences scales. There is a decrease in unpleasant experiences, suggesting the benefit of catharsis when recalling early memories.

Watkins, Helen H. (1993). Ego-State therapy: An overview. American Journal of Clinical Hypnosis, 35, 232-240.

Ego-state therapy is a psychodynamic approach in which techniques of group and family therapy are employed to resolve conflicts between the various "ego states" that constitute a "family of self" within a single individual. Although covert ego states do not normally become overt except in true multiple personality, they are hypnotically activated and made accessible for contact and communication with the therapist. Any of the behavioral, cognitive, analytic, or humanistic techniques may then be employed in a kind of internal diplomacy. Some 20 years experience with

this approach has demonstrated that complex psychodynamic problems can often be resolved in a relatively short time compared to more traditional analytic therapies.

1992

Claridge, Karen (1992). Reconstructing memories of abuse: A theory-based approach. Psychotherapy, 29, 243-252.

The recovery of traumatic memories is an important part of therapy with survivors of abuse. This article describes a conceptual framework for memory reconstruction based on Horowitz' (1986) theory of stress response syndromes. The client's history of intrusive symptoms provides a way to anticipate the nature of the trauma, even when no memory of it exists. Ongoing intrusive symptoms are used to retrieve memory fragments, and their emotional impact is used to build the client's emotional tolerance. Emphasis is placed on preparing for memories by identifying what the client will need when the memories return, building coping skills, and beginning to restructure cognitions at the "what if" stage of remembering. Case material is used to illustrate.

Darken, Rachel (1992). Hypnosis in the treatment of survivors of sexual abuse. Australian Journal of Clinical and Experimental Hypnosis, 20, 105-110.

This paper outlines the problems of child sexual abuse and its long-term sequelae, often reaching down generations. In psychotherapy with survivors of childhood sexual abuse, hypnosis offers a flexible treatment modality and the paper focuses particularly on the use of hypnosis and self-hypnosis for the "reparenting" element of psychotherapy.

Faller, Kathleen Couborn (1992, Summer). Can therapy induce false allegations of sexual abuse?. The Advisor (Published by American Professional Society on the Abuse of Children), 5 (3), 3-6.

NOTES: "Concern about the impact of therapy on children's accounts of sexual abuse should be understood in the context of two phenomena: (1) the adult need to deny that children are sexually abused, and (2) adult identification with the alleged abuser. These phenomena operate at both individual and societal levels" (p. 3).

"Research related to impact of stressful situations on children's ability to recall provides mixed results, some studies finding children are less accurate if the event is traumatic (Peters, 1991) and others finding they are not (Goodman, Reed, & Hepps, 1985).

"Research reveals that it is rare for children to falsely allege that they have been touched in their private parts. In one study, a substantial proportion of children who experienced genital and anal touch during a physical examination by a doctor did not volunteer this information when asked general questions about the examination. The majority of children in the study revealed genital and anal touch only when they were asked specific questions like, "Did the doctor touch you there?" (Saywitz, Goodman, Nicholas, & Moan, 1991)" (pp. 3-4).

"Clarke-Stewart and her colleagues (1989) have demonstrated that children's interpretation of ambiguous events can be manipulated and altered by an authority figure who insists upon a particular interpretation (see also Lindberg, 1991)" (p.4).

"In sum, the research suggests that older children are likely to provide more complete unassisted disclosure than younger children. Younger children may need more memory cues in the form of specific questions than older children. Therapists are much more likely to find false negatives than false positives. Finally, therapists should be aware of the possibility the child may identify the wrong person. ... Generally, however, the research indicates that concern about the contaminating effects of therapy on children's recollections of sexual abuse is exaggerated" (pp. 4-5).

"Research indicates that the proportion of fabricated reports may be higher in the divorce scenario than in other contexts (Faller, 1990; Jones & Seig, 1988). Studies suggest most false reports are made by adults, not children (Jones & McGraw, 1987; Jones & Seig, 1988)" (p. 5).

"Clinical research (Sorenson & Snow, 1991) and experience (Faller, 1988) indicate that for most children, revealing sexual abuse is a process which occurs over time. A typical pattern is one in which children begin with the least overwhelming experience and gradually disclose more and more as their accounts are accepted and believed" (p. 5).

"[In conclusion]... therapists should be aware of the findings from research on children's memory and suggestibility. This research indicates that there are vulnerabilities which should be taken into account during therapy" (p. 6).

Herbert, James D.; Mueser, Kim T. (1992). Eye movement desensitization: A critique of the evidence. Journal of Behavior Therapy and Experimental Psychiatry.

The scientific evidence supporting the efficacy of eye movement desensitization (EMD), a novel intervention for traumatic memories and related conditions, is reviewed. The sparse research conducted in this area has serious methodological flaws, precluding definite conclusions regarding the effectiveness of the procedure. Clinicians are cautioned against uncritically accepting the clinical efficacy of EMD. Lohr, Jeffrey M.; Kleinknecht, Ronald A.; Conley, Althea T.; Dal Cerro, Steven; Schmidt, Joel; Sonntag, Michael E. (1992). A methodological critique of the current status of eye movement desensitization (EMD). Journal of Behavior Therapy and Experimental Psychiatry.

Eye Movement Desensitization (EMD) has been recently advocated as a rapid treatment for the elimination of traumatic memories responsible for the maintenance of a number of anxiety disorders and their clinical correlates. Despite a limited conceptual framework, EMD has attracted considerable interest among clinicians and researchers. The popularity and interest generated by EMD will likely result in wide usage. We present a methodological critique of it with reference to assessment, treatment outcome, and treatment process. We also provide guidelines for judging the methodological adequacy of research on EMD and suggest intensive research to assess effectiveness, treatment components, and comparisons with other procedures.

Lynn, Steven Jay; Rhue, Judith W. (1992, October). Memory. [Paper] Presented at the annual meeting of the Society for Clinical and Experimental Hypnosis, Arlington, VA.

**NOTES:** [Author presented a dramatic case report of patient who recalled specific events that subsequently he and the patient investigated and disproved. What the patient thought they saw could not possibly have been seen.]

The experimental literature on memory gives us some things to think about. Therapy relies highly on memory, and the therapist shapes the contours of the memory by validating the memories, which are rarely doubted. Tacit acceptance of memories as historical facts is part of the contract of therapy.

Memory studies challenge the idea of accurate storage. Some people are unduly confident of their memory. Bartlett's research demonstrated distortion according to schema, interpretations, embellishments, etc. Jacobi et al indicate people's theories about what happened shape memory.

One theory is that trauma leads to amnesia, repression, dissociation. But research does not show inability to recall early life events indicates presence of a traumatic history. Repression is not prima facie evidence of abuse. The *Courage to Heal* book states that merely thinking you were abused is evidence that you probably were.

How do vague ideas crystallize? Loftus finds if inability to remember isn't attributed to ordinary forgetting, the person may look for memories, thereby creating them.

Studies of persons who confess to crimes, unsure whether they did or didn't do them, indicate that these people are easily coerced. Doubt in a memory's accuracy can be reframed by a therapist.

**Hypothesis:** Therapists who confidently state a view risk implanting pseudomemories. Therapists must be cautious.

Clients can confuse sources of information that they receive. Different sources of information can be integrated into a single memory (e.g. what occurred to them and what occurred to siblings can be integrated into a pseudomemory). Some limited evidence that early life experience memories could be implanted has been presented by Loftus.

Certain client characteristics contribute to false memories: 1. Present mood state (mood congruent memory). This effect is reliable when people are clinically depressed. Though clinicians may say it indicates early childhood abuse, the memory might be selective or biased. 2. History of fantasy-proneness. In childhood this type of person might have had problems distinguishing fantasy from reality. LaBelle et al found absorption made it difficult to distinguish sounds in hypnosis from what really occurred, creating pseudo- memories. With this population it is essential to avoid suggesting abuse.

Lynn was successful in implanting an idea of abuse in an alter called Person. He used the Orne technique (from the BBC film "Hypnosis on Trial") to ask a patient what she had told him about her dog during the hypnosis; he did this to convince her of the importance of exploring her amnesic episodes.

Does hypnosis foster a literal re-experiencing of childhood events? NO. Nash, in an exhaustive review, failed to find correspondence between information from hypnotic

age regression and childhood events. He notes that literal reliving is not possible. It is possibly an expression of primary process thinking. Hypnosis doesn't ameliorate memory problems; and it may exacerbate memory problems.

Lynn views primary process thinking observed in hypnosis as due to the demand of hypnosis to fantasize and relinquish critical thinking or objectivity. This plus Therapist and Patient expectancies may foster tenacious beliefs that events occurred.

Many hypnotic suggestions may interfere with memory. The AMA 1985 report suggests that hypnosis can influence confidence in a 'memory' with no actual improvement in accuracy.

The effects aren't limited to hypnosis however. Simulators and controls also generate pseudomemories. Repeated questioning of Ss who are led to believe that questioning helps distinguish memories from fantasies, actually diminishes the accuracy of memories.

Hypnotizability is correlated with pseudomemory occurrence. We should evaluate a client's hypnotizability when evaluating for pseudomemories.

Perceived verifiability rate is important, as pseudomemories are higher where you can't verify the reported memory, it is thought. Therefore, approach with caution. Make every effort to corroborate memories.

Subjective reports may tell narrative truths even though inconsistent with the historical record, and could be useful independent of historical accuracy. I agree that those 'memories' could be important, just as age progression or past life regression material could be useful in therapy. But should we base our interpretations or conclusions on events that are not confirmed? A patient's belief in abuse by their parent has enormous implications for a family.

Therapists should understand the dynamics of a request for using hypnosis to recall forgotten memories before using uncovering techniques. Ask yourself, "Why is this being requested?" Also ask other questions: 1. Is the person fantasy prone, dissociative, suggestible, a high hypnotizable? 2. Is the person stabilized enough to focus on an abreaction? 3. Is there conscious or unconscious motivation to avoid responsibility for one's own behavior? 4. Is there a wish to arrive at a facile solution, a magic cure, the royal road to the unconscious; or is there an attempt to control the treatment hour, to avoid issues, to test the therapist? 5. Is therapy stalled, not moving forward? 6. Am I angry with the client because they expect to uncover more?

Instead of using hypnosis to retrieve memories, I may focus on the issues to which I answer 'Yes' in the forgoing list.

I do not believe current research is sufficiently persuasive to throw out hypnosis for retrieving memories. The dangers of pseudomemory are endemic to therapy. Incorporating hypnosis into a broader frame of therapy depends on the skill of the clinician. However, we must use hypnosis with great caution

**COMMENTS FROM AUDIENCE.** Joseph Dane: In 75% of cases that could be verified, they found corroborating evidence: what should you look for as an index that the memory recalled in hypnosis is more likely to be accurate?

Lynn: Many instances of abuse are corroborated. No one questions the veracity of all memories. To my knowledge there are no ways of corroborating genuine from

false memories. We know subjective conviction is not sufficient, and clients' affective experience can be very misleading. Since my experience [in the case study reported at the beginning of this presentation] I have talked with many therapists who have had similar experiences.

David Spiegel - the problem is not the hypnosis: patients go in and out of hypnosis all the time, momentarily. The problem is, how do I explore the material in psychotherapy? There is no substitute for corroboration if you can get it. But you have to be sensitive to the vulnerability of those people.

Howard Hall: What is a genuine memory? No memory is undistorted. More importantly, can we verify significant events that might have had long term consequences, like abuse? We should try to verify memories when we base treatment programs on them. The only memories in the literature that have a reputation of being accurate are highly traumatic events that stand out, and these reports are anecdotal in nature.

Murrey, Gregory J.; Cross, Herb J.; Whipple, Jim (1992). Hypnotically created pseudomemories: Further investigation into the 'memory distortion or response bias' question. Journal of Abnormal Psychology, 101 (1), 75-77.

In order to study whether pseudomemories represent actual memory distortions or are a result of response bias, 60 highly hypnotizable subjects and subjects from the general population were divided into 4 experimental groups and were tested for pseudomemory manifestation after receiving a false suggestion. Of the 4 groups of subjects, 3 were offered a monetary reward as a motivation to distinguish false suggestion from the actual occurrence. Pseudomemory manifestation was found to be significantly higher among subjects not offered a reward than among subjects who were offered such a reward. The implications of these findings are discussed.

#### NOTES:

The article contains a review of the literature through 1989. The study tested the hypothesis that when it is important to distinguish fantasy from reality in a hypnosis experiment, subjects can do so--a position presented by Spanos and McLean (1986). They used a verifiable event to test for pseudomemory production, as in research published by McCann and Sheehan (1988). Subjects were 30 high hypnotizable and 30 unselected students.

Subjects were shown a videotape of a mock robbery scene. The next week, Groups A, B, and C heard audiotapes "to enhance memory," but in addition to motivating statements about "trying to remember" certain details, the tapes included misleading information (e.g. "Remember the color of the hat the robber was wearing" when in fact there was no hat on the robber). Subjects in these groups were 'influenced.'

"Both highly hypnotizable subject groups (Groups A and B) listened to the audiotape after being administered a 10-min hypnotic induction procedure (modified from that of Barber, 1969). Subject Group C listened to the audiotape without hypnosis. The control group, Group D, did not listen to the audiotape and was, therefore, classified as 'uninfluenced.'"

A week later subjects responded to multiple-choice and yes-no or true-false questions about the robbery scene. The yes-no question about whether the robber was wearing a hat served as the dependent variable, a measure of pseudomemory. "To motivate subjects to report the truth rather than to follow any perceived expectations of the experimental of social context, we offered subjects in Groups B, C, and D a monetary reward if they achieved the most correct answers on the quiz (according to the videotape). The reward was offered just before administration of the quiz to ensure that no collusion between the subjects could occur. Group A was not offered any such reward" (p. 76).

"The number of subjects in Group A (hypnotized, influenced, no reward) who reported the false information at posttest (12) was significantly greater than that of Group B (hypnotized, influenced, offered reward.... However, the difference in incidence of pseudomemory between Group B and the control group, Group D (not hypnotized, uninfluenced, offered reward), was nonsignificant" (p. 76).

Table 1 Incidence of Pseudomemory Per Group -----

	False suggestion	Group A	Group B	Group C
Group D				
result (n=15)	(n=15)	(n=15)	(n=15)	
Accepted	12	6	7	3
Rejected	3	9	8	12

----- Note. Group A = hypnotized, influenced, not offered reward.

Group B = hypnotized, influenced, offered reward.

Group C = not hypnotized, influenced, offered reward.

Group D = not hypnotized, not influenced, offered reward.

In the Discussion, the authors wrote, "Because the only variable among these groups was the reward, a reasonable conclusion from the findings is that pseudomemories manifested by the subjects were (for the most part) not actual memory distortions. Presumably, the reward provided the subjects in Group B an incentive to 'report the truth' and a disincentive to give biased reports on the basis of the perceived expectations of the social or experimental context. Thus these data suggest that pseudomemory effects or the occurrence of the pseudomemory phenomenon among highly hypnotizable subjects can be minimized by providing a motivation to subjects to give unbiased reports.

"A major implication of these findings is that researchers should control for response bias resulting from perceived social demands or from leading test designs when they conduct pseudomemory research. Of further concern is the fact that a number of researchers contend that hypnotic interrogation of eye-witnesses can greatly facilitate the creation of pseudomemories (Levitt, 1990; Loftus, 1979; Orne, 1979; Putnam, 1979), and therefore hypnosis either should not be allowed in the courtroom or should be strictly controlled. Yet in light of our findings, response bias may be a confound in pseudomemory research, and thus researchers need to be cautious when making inferences to specific situations from data obtained in an experimental setting.

"Despite the existence of a confound of (unmeasured) differences in hypnotizability between the two groups, there was no significant difference between Group B and

the control group (Group D). This suggests that if response bias is controlled for, there may not be significant differences in manifestation of pseudomemories between highly hypnotizable subjects and subjects representative of the general population. However, further research is needed in order to address this question" (pp. 76-77).

Ofshe, Richard J. (1992). Inadvertent hypnosis during interrogation: False confession due to dissociative state; mis-identified multiple personality and the satanic cult hypothesis. International Journal of Clinical and Experimental Hypnosis, 40, 125-156.

Induction of a dissociative state followed by suggestion during interrogation caused a suspect to develop pseudo-memories of raping his daughters and of participation in a baby-murdering Satanic cult. The pseudo-memories coupled with influence from authority figures convinced him of his guilt for 6 months. During this time, the suspect, the witnesses, and all the evidence in the case were studied. No evidence supported an inference of guilt and substantial evidence supported the conclusion that no crime had been committed. An experiment demonstrated the suspect's extreme suggestibility. The conclusion reached was that the cult did not exist and the suspect's confessions were coerced- internalized confessions. During the investigation, 2 psychologists diagnosed the suspect as suffering from a dissociative disorder similar to multiple personality. Both psychologists were predisposed to find Satanic cult activity. Each concluded that the disorder was due to "programming" by the non-existent Satanic cult.

Perry, Nancy W. (1992, Summer). How children remember and why they forget. The Advisor (Published by American Professional Society on the Abuse of Children), 5 (3), 1-2; 13-16.

NOTES: "'My memory is the thing I forget with.' (a child's definition, cited in Grossberg, 1985, p. 60)" (p. 1).

"Unlike the simpler forms of memory retrieval, free recall is strongly age-related... the recall skills of preschool children develop gradually" (p. 2). "...in some cases, younger children can provide more accurate information than adults (Lindberg, 1991). For example, if an event is particularly salient (as sometimes happens in cases of trauma), recall may be exceptionally good (Brainerd & Ornstein, 1991; Lindberg, 1991)" (p. 13).

"Children have limited ability to use memory strategies. For this reason, children often know more than they can freely recall" (p. 13).

"The use of rehearsal as a memory strategy is almost automatic for adults. ... Ten-year-olds also commonly use rehearsal to aid memory. Young children, however, have not mastered rehearsal (Harris & Liebert, 1991).

"Another memory strategy is imagery, which involves (1) mentally picturing a person, place, or object, or (2) visually associating two or more things that are to be remembered. Children develop imagery much later than other memory strategies. Indeed, some people never learn this memory strategy (Flavell, 1977)" (p. 13).

"... stress alone may not impair memory processes. Indeed, stress can lead to arousal, heightened attention, and improved encoding (Deffenbacher, 1983). However, stress that results from intimidation may lead to either impairment in encoding or problems in recalling or reporting memories" (p. 14).

"Because the effect of suggestion on material that has been well encoded tends not to be significantly different across age groups (Cohen & Harnick, 1980), it may be that younger children's inferior performance on suggestive tasks results from inferior encoding" (p. 15).

Putnam, Frank W. (1992). Using hypnosis for therapeutic abreactions. Psychiatric Medicine, 10, 51-65.

The dramatic reliving of traumatic events under hypnosis, is a powerful therapeutic intervention useful in the treatment of victims of trauma. First systematically applied in World War I, abreaction coupled with psychotherapeutic processing of the recovered material is increasingly being used with victims of child abuse and chronic PTSD. Abreactions are helpful in recovering dissociated or repressed traumatic material, reconnecting missing affect with recalled material and for transforming traumatic memories. Although abreactions can be induced with medications, hypnosis is the method of choice except in acute situations where it is not possible to establish rapport. A variety of hypnotic techniques for the induction and management of abreaction are discussed, together with the indications and contraindications for their use.

Summit, Roland C. (1992, Summer). Opinion: Misplaced attention to delayed memory. The Advisor (Published by American Professional Society on the Abuse of Children), 5 (3), 21-25.

NOTES

1:

NOTES: "I believe this is the time to cap a century of progress with a monumental achievement in awareness. We must cherish and develop the concept that what we don't know can hurt us. We can establish, for the first time, that our lives and even the nature of our society can be shaped by experiences so terrible that they are, in the words of Josef Breuer a century ago, 'forbidden to consciousness' (1895, p. 225). We may learn that huge chunks of oppositional thought, cruelty, perversity, helplessness, self-destruction and mental illness are derived from this hidden reservoir of suffering, and we could inspire unprecedented achievements in healing, prevention and enlightened peacemaking" (p. 21).

"We have been slow to consider the implications of dissociation for protective awareness of child sexual abuse" (p. 22).

"And we should respect the painful threat that enlightenment poses for our comforting faith in a just and fair society. We would have to consider that we may be capable as a people of hiding our most grotesque activities under the cover of dissociation, so that we don't know we're doing it, our victims can't say it's happening, and as an outer society we will insist that no such thing could possibly exist" (p. 22).

"While it is urgently important to know that dissociation is real, it is doubly important not to endorse as accurate, in fact, details or encounters that may be part of a still unknown process of distortion" (p. 22).

"The most distinguished clinicians, the people who occupy the platform of authority as scientists and educators, are joining with those who, until now, have been recognized mainly for their adversarial positions. Now those two poles are coming together in aroused opposition to the phenomenon of delayed memory, especially when acquired in therapy with young women in their 30's, especially when those therapists lack an M.D. or a Ph.D. diploma. We face, once again, an ageist, sexist, elitist professional standoff around an issue that deserves to be explored in harmony" (p. 24).

"In California and several other states the statute of limitations has been suspended for individuals who can demonstrate delayed discovery of childhood trauma" (p. 24).

"The rush to judgment is not confined to civil litigation. There is no statute of limitations on murder" (p. 24).

"How many kids have hidden the memory of unspeakable assaults which can be unearthed years later to plunge them into courtroom testimony? How many free citizens could be sued or imprisoned by such remote discoveries? What should we do as scientists in support of or in opposition to those delayed memories?" (P. 24).

"We know that skepticism can quash the emergence of dissociated memories. Can we prove that therapeutic zeal cannot enhance such memories? Survivors who gain a clear picture of sexual assault in the climactic period of discovery tend to fade out the sharp edges as they achieve resolution and healing. The most seasoned survivors may discount the intermediate memories which once provided the impetus for their recovery" (p. 25).

Yapko, Michael D. (1992). Editor's Viewpoint. Milton H. Erickson Foundation Newsletter, 12 (3), 2.

#### NOTES:

"A controversial issue is heating up, and therapists are beginning to feel the heat. The issue involves the common practice of helping clients recover apparently repressed memories of early childhood sexual trauma.

"In the second edition of my hypnosis textbook, Trancework (1990, Brunner/Mazel), I included a special section on the possibility of hypnotically implanting false memories---vivid memories of things that never actually happened that the client comes to believe as true recollections. I pointed out the risks of suggestive procedures and urged caution in suggesting memories of any sort, whether a formal hypnotic induction took place or not.

"Early this year a non-profit foundation was formed in Philadelphia called the False Memory Syndrome Foundation which serves as a clearing house for relevant information, and even publishes a newsletter. It also provides support to families broken apart by these problems. If you are interested in the complex issues regarding suggestion and memory, you can contact the FMS Foundation at 3508 Market Street, Suite 128, Philadelphia, PA 19104, telephone (215) 387-1865. David Calof's group also publishes Treating Abuse Today. They, too, are cognizant of the relevant issues. Their address is 2722 Eastlake Avenue East, Seattle, WA 98012, telephone (206) 329- 9101" (p. 2).

1991

Chu, James A.; Dill, Diana L. (1991). Dissociation, borderline personality disorder, and childhood trauma. American Journal of Psychiatry, 148 (6), 812.

Comments on the article by S. N. Ogata et al (see PA, vol 78:4681) on the high prevalence of childhood physical and sexual abuse in inpatients with borderline personality disorder. It is suggested that dissociative symptoms in borderline patients may simply be a less severe form of intrapsychic fragmentation than multiple personalities.

Cornell, William F.; Olio, Karen A. (1991). Integrating affect in treatment with adult survivors of physical and sexual abuse. American Journal of Orthopsychiatry, 61 (1), 59-69.

Presents a theoretical and technical model for affectively centered treatment of adults abused as children, focusing on the function of denial and dissociation as central defense mechanisms. The concept is introduced of working at an "affective edge." At this experiential point, a client can maintain both cognitive understanding and emotional and bodily awareness without triggering denial and dissociation. This approach fosters careful monitoring of the client's functioning both during and between therapeutic sessions. The proposed therapeutic approach uses noninvasive touch and body-centered techniques. Focus is on integrating affect and on the importance of the therapeutic relationship.

Friedrich, William N. (1991). Hypnotherapy with traumatized children. International Journal of Clinical and Experimental Hypnosis, 39 (2), 67-81.

The psychological impact of trauma can include cognitive, affective, and behavioral components. The degree to which a child is either overwhelmed by or unable to access the traumatic event can make the working through of the event in therapy difficult. Hypnotherapy is a useful modality not only for alleviating symptoms but also for uncovering the traumatic event(s) with associated affects, integrating and making sense of the experience. 4 case studies are reported to illustrate the utility of hypnotherapy with young, traumatized children.

Rhue, Judith W.; Lynn, Steven Jay (1991). Storytelling, hypnosis and the treatment of sexually abused children. International Journal of Clinical and Experimental Hypnosis, 39 (4), 198-214.

The present article describes an assessment and therapy program for sexually abused children using hypnotherapeutic techniques which center on storytelling. Storytelling presents the therapist with an opportunity to use comforting suggestions, symbolism, and metaphor to provide the emotional distance necessary to deal with the trauma of abuse. Hypnotherapy proceeds in a stepwise fashion from the building of a sense of safety and security; to imaginative sharing; to the introduction of reality events; to the final step of addressing complex emotional issues of loss, trust, love, and guilt brought about by the abuse.

Sanders, Barbara; Giolas, Marina H. (1991). Dissociation and childhood trauma in psychologically disturbed adolescents. American Journal of Psychiatry, 148, 50-54.

Tested the hypothesis that dissociation in adolescence is positively correlated with stress or abuse experienced earlier by assessing the relationship between degree of dissociation and degree of reported childhood stress, abuse, or trauma in 47 13- 17 year old disturbed adolescents. Subjects had been institutionalized for periods of 1-13 weeks. Subjects completed a Dissociative Experiences Scale (DES) and a child abuse and trauma questionnaire. Scores on the DES correlated significantly with self-reported physical abuse or punishment, sexual abuse, psychological abuse, neglect, and negative home atmosphere but not with abuse ratings made from hospital records. Findings support the view that dissociation represents a reaction to early negative experience and places multiple personality disorder at the extreme end of a continuum of dissociative sequelae of childhood trauma.

Smith, William H. (1991). Antecedents of posttraumatic stress disorder: Wasn't being raped enough? A brief communication. International Journal of Clinical and Experimental Hypnosis, 39, 129-133.

Many rape victims, like those traumatized by war, accidents, and natural disasters, are able to recover from their ordeal with supportive, crisis-oriented treatment. For others, however, symptoms may persist and require more intensive treatment. Hypnosis allows a modulated re-experiencing and abreaction of the traumatic event that can help to provide the victim with a relieving sense of mastery, and it fosters a receptive context for reassurance and interpretation regarding the irrational or exaggerated thoughts and feelings involved. 2 case examples are presented in which earlier conflicts appeared to play a role in perpetuating the patients' symptoms. Detecting and addressing these antecedents resulted in complete alleviation of long-standing problems through relatively brief treatment using hypnosis.

Terr, Lenore C. (1991). Childhood traumas: An outline and overview. American Journal of Psychiatry, 148, 10-20.

Suggests 4 characteristics common to most cases of childhood trauma: visualized or otherwise repeatedly perceived memories of the traumatic event; repetitive behaviors; trauma-specific fears; and changed attitudes about people, life, and the future. Childhood trauma is divided into 2 basic types. Type I trauma includes full, detailed memories, "omens," and misperceptions while Type II trauma includes denial and numbing, self-hypnosis and dissociation, and rage. Characteristics of both types of childhood trauma can exist side by side. Such crossover Type I - Type II traumatic conditions of childhood are characterized by perceptual mourning and depression and childhood disfigurement, disability, and pain. Case examples are provided.

NOTES: This is a newspaper article about Eileen Franklin-Lipsker of Palo Alto, who testified that her father, George T. Franklin, killed an 8-yr-old girl in 1979 and that she repressed the memory for nearly two decades.

1990

**Hoencamp, Erik (1990). Sexual abuse and the abuse of hypnosis in the therapeutic relationship. International Journal of Clinical and Experimental Hypnosis, 38, 283-297.**

**In the Netherlands, individuals charged with rape may be prosecuted only in instances in which the suspect could have known that the victim was unconscious or in a state of powerlessness. Hypnosis might be looked upon as a method by which an unscrupulous person could sustain such a state of powerlessness in a victim. As an expert witness, the present author participated in a court case against a lay hypnotist who was accused of abusing 9 women. The methods and strategy used by the lay hypnotist are presented as well as are the diverse reactions of the women involved in the case. Feelings of nonvolition appear to have been a relevant factor in the coercion, especially in women who demonstrated hypnotic phenomena such as arm levitation, catalepsy, etc. The basis for sexual coercion was established only after the interpersonal relationship had been redefined as a therapeutic relationship. Introduction within the pseudotherapeutic relationship of a sexual rationale for the presented complaints helped to provide a framework for actual sexual acts to occur. With certain individual patients, the introduction of hypnosis enhanced the subjective experience of nonvolition and with it the vulnerability for abuse. It may be hypothesized that patients with a tendency for external attribution and high hypnotizability are specifically at risk for this kind of abuse when hypnosis is used in the context of a therapeutic relationship.**

**Perry, Campbell (1990). Coercion by hypnosis? Invited discussion of Levitt, Baker, and Fish: Some conditions of compliance and resistance among hypnotic subjects. American Journal of Clinical Hypnosis, 32 (4), 242-243.**

**NOTES: "A postexperimental inquiry (following Orne, 1959) might have informed the reader of the degree to which operationalization of the coercion in terms of disobedience was successful. Without this additional step, it is difficult to determine whether what was found in the laboratory by these investigators applies to what has been reported in clinical and field settings for almost 200 years" (p. 242).**

**"In particular, elsewhere, the authors equate coercion with involuntariness and appear to view involition as a euphemism for coercion. While I agree that perceiving involition of one's own behavior may contribute to the commission of unconsenting acts in hypnosis, the two are easily distinguished at the conceptual level. Laboratory subjects ordinarily report much behavior in hypnosis that is experienced involuntarily, without the issue of it being coerced ever being broached" (p. 242).**

**Author describes cases in which patients claimed they participated in sex with hypnotist against their wills because they were hypnotized. "What may be happening in both of these reports is that the hypnotized subjects found themselves responding involuntarily; from this, they appear to have adduced that they could not resist the hypnotist's suggestion. That is, they were coerced not by hypnosis but by their belief, which was a direct function of the experience of involuntariness, that they could not resist" (p. 243). "In short, if a hypnotized person equates involuntary behavior with powerlessness, "coercion" may occur in this limited sense. Conceptually, this appears**

### **1990-1991**

Rhue, Judith W.; Lynn, Steven Jay; Henry, Stephanie; Buhk, Kerry; Boyd, Patti (1990-91). Child abuse, imagination and hypnotizability. Imagination, Cognition and Personality, 10, 53-63. to be a far cry from equating involition with coercion" (p. 243).

Research was designed to provide a rigorous test of J. R. Hilgard's hypothesis that hypnotizability is related to a history of physical punishment and to imaginative involvements. College students who reported a history of physical abuse (N = 21) and sexual abuse (N = 23) were compared with control subjects who either lost a parent by way of death or divorce (N = 20) or who were from intact homes (N = 35), under test conditions that minimized the possibility that context effects would prejudice the findings. No support was found for the hypothesis that increased hypnotizability was associated with a history of physical or sexual abuse: All of the groups are indistinguishable on measures of objective and subjective response to hypnosis. However, consistent with Hilgard's hypothesis, physically and sexually abused subjects were found to be more fantasy-prone than subjects in both nonabused control conditions.

Ross, Colin A.; Miller, Scott D.; Reagor, Pamela; Bjornson, Lynda; et al. (1990). Structured interview data on 102 cases of multiple personality disorder from four centers. American Journal of Psychiatry, 147, 596-601.

Data from 102 patients with multiple personality disorder at 4 different centers were collected using the Dissociative Disorders Interview Schedule (C. A. Ross et al, 1989; C. A. Ross, 1989) and the Structured Clinical Interview for Diagnostic and Statistical Manual of Mental Disorders - III --- Revised (DSM-III--R) Dissociative Disorders (M. Steinberg et al; ) The presenting characteristics of Subjects at all 4 centers were very similar. The clinical profile that emerged included a history of childhood physical and/or sexual abuse in 97 (95.1%) of the cases. Subjects reported an average of 15.2 somatic symptoms, 6.4 Schneiderian symptoms, 10.2 secondary features of the disorder, 5.2 borderline personality disorder criteria, and 5.6 extrasensory experiences; their average score on a dissociative experiences scale was also meaningful. Multiple personality disorder appears to have a stable, consistent set of features.

### **1989**

Ganaway, George K. (1989). Historical versus narrative truth: Clarifying the role of exogenous trauma in the etiology of MPD and its variants. Dissociation, 2, 205-220.

The author notes a current trend toward viewing multiple personality disorder (MPD) and its variants as a form of chronic post-traumatic stress disorder based solely on exogenous childhood trauma, and cautions against prematurely reductionistic hypotheses. He focuses on Kluft's Third Etiological Factor, which includes the various developmental, biological, interpersonal, sociocultural, and psychodynamic shaping influences and substrates that determine the form taken by the dissociative defense. He hypothesizes a credibility continuum of childhood and contemporary memories arising primarily from exogenous trauma at one end, and

endogenous trauma (stemming from intrapsychic adaptational needs) at the other. The author offers alternative multidetermined explanations for certain unverified trauma memories that currently are being accepted and validated as factual experiences by many therapists. He describes some potentially deleterious effects of validating unverified trauma memories during psychotherapy, and recommends that the MPD patients' need for unconditional credibility be responded to in the same manner as other transference-generated productions.

#### NOTES

1:

NOTES: Authors discuss a dual memory theory. The first memory system is prominent in early childhood, and is a system in which are organized and evoked by persons, locations, and emotions. Such memories are not easily "transportable" outside the original experience. These memories are accessed through images of face and place, actions, or feelings. The second memory system begins to develop in early childhood, is verbally mediated, and stores experiences in narrative form. Such memories are accessible through verbal interaction, and can be reviewed and shared with others verbally. For a small child, to access all of a memory one would need to tap into both memory systems. The authors suggest that the first memory system continues to be available throughout one's life, especially when strong emotion was associated so that verbal cues are not attached. [This has implications for retrieval of "lost" memories using imagery-based approaches like hypnosis.]

Sanders, B.; McRoberts, G.; Tollefson, C. (1989). Childhood stress and dissociation in a college population. Dissociation, 2, 17-23.

ABSTRACT: Two studies are reported demonstrating that individual differences in dissociation in college students are positively related to differences in self-reported stressful or traumatic experiences in youth. In Study 1, differences in the degree of stress or unpredictable physical violence experienced in childhood or early adolescence were shown to be related to scores on the Dissociative Experiences Scale (DES). Study 2 replicated these relationships and extended them to another dissociation measure, the Bliss scale. Study 2 also demonstrated that both dissociation measures correlate positively with reported physical and psychological abuse. These findings for a nonclinical population are discussed in relation to the etiology of dissociation in clinical groups.

1988

Chu, James A. (1988). Ten traps for therapists in the treatment of trauma survivors. Dissociation, 1, 24-32.

Patients who have survived trauma, particularly those who have experienced early childhood abuse, stand out in the clinical experience of many therapists as being among the most difficult patients to treat. These patients have particular patterns of relatedness, along with intense neediness and dependency which make them superb testers of the abilities of their therapists. They often push therapists to examine the rationales and limits of their therapeutic abilities, and frequently force therapists to examine their own personal issues and ethical beliefs. A conceptual framework for

understanding treatment traps is presented, along with 10 traps which these patients present, consciously and unconsciously, in the course of treatment. Included are traps around trust, distance, boundaries, limits, responsibility, control, denial, projection, idealization, and motivation.

Lynn, Steven Jay; Rhue, Judith W. (1988). Fantasy proneness: Hypnosis, developmental antecedents, and psychopathology. American Psychologist, 43 (1), 35-44.

This article presents a summary of the findings of our ongoing research program on the fantasy-prone person. In seven studies, nearly 6,000 college students were screened in order to obtain five samples of 156 fantasy-prone subjects. Fantasy-prone subjects (fantasizers) were selected from the upper 2%-4% of the college population on a measure of imaginative involvement and contrasted with nonfantasizers (lower 2%-4%), and medium fantasy-prone subjects (middle range). General support was secured for Wilson and Barber's construct of fantasy proneness: Fantasizers were found to differ from nonfantasizers, and in many cases also from medium-range subjects, on measures of hypnotizability, imagination, waking suggestibility, hallucinatory ability, creativity, psychopathology, and childhood experiences. Differences in hypnotizability were most reliable when subjects participated in a multisession study and were screened not only with the screening inventory, but also with an interview that substantiated their fantasy-prone status. However, our findings indicated that less correspondence between fantasy proneness and hypnotizability exists than Wilson and Barber suggested. Hypnotic responsiveness is possible even in the absence of well-developed imaginative abilities, and not all fantasizers were highly hypnotizable. Fantasizers recollected being physically abused and punished to a greater degree than other subjects did and reported experiencing greater loneliness and isolation as children. Many fantasizers appeared to be relatively well-adjusted; however, a subset of fantasizers were clearly maladjusted based on self-report, Minnesota Multiphasic Personality Inventory (MMPI), and Rorschach test data. Because of the diversity inherent in the fantasy-prone population, it is misleading to think of individuals at the extreme end of the fantasy-proneness continuum as conforming to a unitary personality type.

Terr, Lenore C. (1988). What happens to early memories of trauma? A study of twenty children under age five at the time of documented traumatic events. Journal of the American Academy of Child and Adolescent Psychiatry, 27, 96-104.

The verbal and behavioral remembrances of 20 children who suffered psychic trauma before age 5 were compared with documentations of the same events. Ages 28 to 36 months, at the time of the trauma, serves as an approximate cutoff point separating those children who can fully verbalize their past experiences from those who can do so in part or not at all. Girls appear better able than boys to verbalize parts of traumas from before ages 28 to 36 months. Short, single traumas are more likely to be remembered in words. At any age, however, behavioral memories of trauma remain quite accurate and true to the events that stimulated them.

Miller, Arnold (1986). Hypnotherapy in a case of dissociated incest. International Journal of Clinical and Experimental Hypnosis, 34 (1), 13-28.

This case study describes hypnotherapy with a young woman who, in the course of treatment, began to remember her incestuous relationship with her alcoholic father. Her presenting symptoms included self-assaultive masturbation, suicidal fantasies, depression, impaired sexual functioning, and inability to resume her education. Different phases of treatment entailed uncovering work, mastering the incest experience with the help of emotionally corrective experiences, the use of part-selves to assist coping, and the integration of several part-selves into a more effective personality. After 4 years of treatment she has successfully resumed her education, has normal sexual functioning, and is no longer incapacitated by depression.

1984

Nash, Michael R.; Lynn, Steven Jay; Givens, Deborah L. (1984). Adult hypnotic susceptibility, childhood punishment, and child abuse: A brief communication. International Journal of Clinical and Experimental Hypnosis, 32, 6-11.

Earlier empirical and theoretical work has suggested that there is a relationship between higher hypnotic susceptibility and severity of childhood punishment. Experiment 1 surveyed the parents of 14 extremely high and 11 extremely low susceptible Ss concerning punishment. Low susceptible Ss were found to be more frequently punished than highs; no significant differences were found on the severity measure. Experiment 2 assessed the hypnotizability of 16 adult Ss who reported being physically abused before the age of 10 and compared these scores to those of 300 adult Ss who had not reported being abused. The mean hypnotizability of abused Ss was greater than that of controls, and the distribution of their scores appeared bimodal. Limitations of both experiments are discussed and suggestions are made for future investigations.

Stava, L. (1984). The use of hypnotic uncovering techniques in the treatment of pedophilia: A brief communication. International Journal of Clinical and Experimental Hypnosis, 32 (4), 350-355.

This case study describes the use of the hypnotic uncovering techniques of induced dreams (Sacerdote, 1967) and the affect bridge (Watkins, 1971) in reducing inappropriate sexual arousal in a male pedophile. Treatment effects were examined through the use of both psychophysiological measures of penile tumescence and psychological tests. The hypnotherapeutic treatment regime consisted of 25 sessions over approximately 9 months. At the end of treatment, psychophysiological measures revealed a definite reduction of sexual excitation to slides of prepubescent children. Psychological testing indicated reduced defensiveness as well as reduced sexual anxiety to adult women. Various hypnotherapeutic experiences which may have contributed to the treatment effects are discussed.

Active Alert Hypnosis

2001

Fredericks, Lillian E. (2001). The use of hypnosis in surgery and anesthesiology. Springfield IL USA: Charles C Thomas.

#### NOTES

The authors suggest that any induction procedure legitimizes acceptance of primary-type suggestions that are at variance with everyday experience. Such primary (i.e. "waking") suggestions are actually accepted at a higher rate than most people think (Barber & Calverley, 1962), and passing those suggestions convinces the subject he must be "hypnotized." However, inductions with the word "sleep" tend to retard subject's response to suggestions. An induction that is more oriented to alert states would be very useful for many people and situations. "Hyperempiria" in Greek means hyper-experience or enhanced quality of experience. The hyperempiric induction contains suggestions of increased alertness, mind expansion, enhanced awareness, and enhanced sensitivity.

Gibbons, Don E. (2001). Experience as an art form: Hypnosis, hyperempiria, and the Best Me technique. San Jose CA: Authors Choice Press. (([available online:] <http://www.iuniverse.com/bookstore/marketplace>))

#### NOTES

1:

The Best Me Technique is a procedure for constructing suggestions which incorporates many different dimensions of experience -- beliefs, emotions, sensations, thoughts, motives, and expectations -- for maximum involvement and effectiveness. Best Me suggestions may be used with either hyperempiria, an alert induction based on suggestions of mind expansion and increased alertness and sensitivity, or with more traditional forms of hypnotic induction.

2000

Barabasz, Arreed (2000, August). EEG markers of hypnosis: The induction makes a difference. [Paper] Presented at the annual meeting of the American Psychological Association, Washington, D. C..

Rather than attempt to uncover some simplistic unidimensional EEG "signature" of the hypnotic state, this study obtained EEG Event Related Potentials (ERPs) in response to two conditions: suggestion only and an alert hypnotic induction plus the identical suggestion. The suggestion asked the ten participants to hallucinate having earplugs in their ears to attenuate a series of computer generated tone pips. Hypnotizability testing was completely separated in both time (6-9 months prior) and context from this research. Alert hypnosis (Barabasz, 1985; Barabasz & Barabasz, 1996) was used to preclude effects that might be wrought by relaxation. Only the hypnotizable participants showed statistically significant attenuation of their EEG ERPs in response to the hypnotic induction plus suggestion condition in contrast to the identical suggestion alone. An independent post-experimental inquiry revealed that the one highly hypnotizable participant who responded in an equivalent manner to both conditions spontaneously entered hypnosis in an effort to respond to the essence of the instructions. Consistent with previous research (Barabasz, Barabasz, Jensen, Calvin, Trevisan, & Warner, 1999; Barabasz & Lonsdale, 1983; Spiegel, Cutcomb, Ren, & Pribram, 1985), the data reveal that when responses are time locked to events, robust physiological markers of the hypnotic state emerge that reflect alterations in consciousness corresponding to participants' subjective experiences of perceptual alteration. These effects were not produced by suggestion alone but only by hypnosis in hypnotizable participants. It would appear that hypnotic state induced responses go beyond those wrought by suggestion alone when efforts are made to establish sufficient hypnotic depth. However, it remains important to understand that less demanding effects can also be produced by social influence, context and personal abilities (Kirsch, Council, & Mobayed, 1987; Lynn, Rhue, & Weekes, 1990). Given the leptokertic distribution of hypnotizability in the general population, social influence may account for a number of the more easily produced responses seen particularly in non-clinical university participant research situations where samples are comprised primarily of those with moderate hypnotizability. [Abstract in *Psychological Hypnosis: A Bulletin of Division 30*, Vol. 10, No. 1, Winter-Spring 2001.]

Eimer, Bruce. N. (2000). Clinical applications of hypnosis for brief and efficient pain management psychotherapy. *American Journal of Clinical Hypnosis*, 43 (1), 17-40. (July)

This paper describes four specific clinical applications of hypnosis that can make psychotherapy for pain management briefer, more goal-oriented, and more efficient: (1) the assessment of hypnotizability; (2) the induction of hypnotic analgesia and development of individualized pain coping strategies; (3) direct suggestion, cognitive reframing, hypnotic metaphors, and pain relief imagery; and (4) brief psychodynamic reprocessing during the trance state of emotional factors in the patient's experience of chronic pain. Important theoretical and clinical issues regarding the relationship between hypnotizability to the

induction of hypnotic analgesia are presented, and attempts to individualize pain treatment strategies on the basis of assessed differences in hypnotizability and patients' preferred coping strategies are described. Some ways are also presented of integrating direct hypnotic suggestion, COGNITIVE-EVALUATIVE reframing, hypnotic metaphors, and imagery for alleviating the SENSORY and AFFECTIVE-MOTIVATIONAL components of pain, with an exploratory, insight-oriented, and brief psychodynamic reprocessing approach during trance for resolving unconscious sources of resistance to treatment, and reducing the emotional overlay associated with chronic pain. Some basic assumptions underlying the use of this approach are discussed, and a brief step-by-step protocol is outlined.

**Elter-Nodvin, Edeltraud (2000). Computerized content analysis: A comparison of the verbal productions of high hypnotizable, low hypnotizable and simulating subjects (Dissertation). (<http://www.televid.com/elternodvin/dissertation/>)**

: This research was designed to investigate the domain of hypnosis and to explore how the ""state"" of hypnosis, along with the susceptibility to hypnosis relate to lexical choice in verbal productions as well as to primary/secondary process mentation. ... College students were screened for level of hypnotic susceptibility ... [yielding] 32 high hypnotizable subjects and 57 low hypnotizable subjects [randomly assigned to two groups] ... 29 low hypnotizable subjects and 28 low hypnotizable simulating subjects.

Responses to six Thematic Apperception Test (TAT) cards and responses to five free speech story-openings were collected and tape-recorded during [counterbalanced waking and hypnosis conditions]... verbal productions were transcribed and [computer] analyzed by ... the Dartmouth Adaptation of The General Inquirer ... and COUNT with the Regressive Imagery Dictionary ... .

To summarize, findings suggest that the changes in SECONDARY PROCESS and THOUGHT, as well as the DAGI-III-variable EMOTION and the COUNT-RID-variable EMOTION, may be a result [sic] other than hypnotic ability or the hypnotic experience. The possibility has been raised, that subjects who had been instructed to simulate hypnosis were successful in discerning the experimental, implicit demands to respond with decreased SECONDARY PROCESS and THOUGHT as measured by the DAGI-III and COUNT-RID respectively and to present the appearance of a genuinely hypnotized subject. The same was true for the increase in EMOTION as measured by the DAGI-III as well as by the COUNT-RID. The interaction between the condition (baseline vs. hypnosis) and the group (level of hypnotic susceptibility) would have provided the strongest support for the assertion that hypnosis changes a dimension (e.g. enhances primary process responding or decreases secondary process mentation) in highly hypnotizable subjects.

The likelihood that the hypnotic main-effect can be attributed at least to some extent to demand characteristics has been supported by the current results. The hypnotic state , even though it can be measured through behavioral measures such as the HGSHS and the CAH, cannot be measured by content measures of verbal productions.

Findings are discussed in regard to previous literature suggesting a link between primary process and hypnosis and suggestions for future research are made. In addition, theoretical and practical implications are discussed. - From dissertation at web site <http://www.televid.com/elternodvin/dissertation/>

Gibbons, Don (2000). Applied hypnosis and hyperempiria. New York NY: Plenum Press. ([available online:] <http://www.iuniverse.com/bookstore>)

## NOTES

The book features both traditional hypnotic procedures and hyperempiric inductions based on suggestions of increased awareness, mind expansion, and increased alertness and sensitivity. It contains sections on the use of suggestion as an instrument of personal growth in areas such as improving study skills, taking examinations, achievement motivation, artistic expression, emotional enrichment, aesthetic appreciation and enjoyment, interpersonal effectiveness, musical performance, problem solving, public speaking, salesmanship, sports performance, theatrical performance, and writing ability.

1999

Alarcsn, A.; Capafons, A.; Bayot, A.; Cardeqa, E. (1999). Preference between two methods of active-alert hypnosis: Not all techniques are created equal.. American Journal of Clinical Hypnosis, 41 (3), 269-276

In a cross-over design (N=80), we compared the differential liking and preference for two hypnotic techniques involving physical activity: active-alert and waking-alert (or alert-hand) procedures. Participants expressed significantly higher liking and preference for the waking-alert as compared to the active-alert procedure. The latter technique, which also had significantly lower suggestibility scores (Cardeqa et al., 1998) was also associated with a significantly higher attrition rate (23%). These significant differences may be explained by the greater physical effort and difficulty associated with the active-alert technique. It seems that the waking-alert method extends the advantages of active hypnosis (e.g., alertness, enhanced self-mastery) to individuals who may dislike or are unable to cope with the greater demands required by the active-alert procedure.

Anderson, Kathryn (1999, November). A test of Barabasz' alert hypnosis on EEG Beta and Theta production for children with ADHD. [Paper] Presented at Annual Meeting of the Society for Clinical and Experimental Hypnosis, New Orleans, LA.

This study tested the effects of Barabasz's Instant Alert Hypnosis (IAH), also known as Instantaneous Neuronal Activation Procedure (INAP, Barabasz and Barabasz, 1995) used as an adjunct to neurotherapy. The sixteen children who participated in this study met DSM - IV criteria for attention deficit hyperactivity disorder (AD/HD). Trials of neurotherapy alone were compared to neurotherapy combined with alert hypnosis on beta-theta ratios at five electrode sites (Fp1, Fp2, Fz, Cz and Pz). The results showed that EEG beta-theta ratio means were significantly higher (more than twice as large) in the trials of neurotherapy

combined with alert hypnosis in contrast to neurotherapy alone. Beta was significantly enhanced while theta was inhibited. The clinical implications of these findings with regard to improved treatment efficacy and reduced time in treatment are discussed. [Abstract taken from SCEH "FOCUS", Winter 2001..]

1998

Cardeqa, E.; Alarcsn, A.; Capafons, A.; Bayot, A. (1998). Effects on suggestibility of a new method of active-alert hypnosis: Alert hand.. International Journal of Clinical and Experimental Hypnosis, 46 (3), 280-294.

Research has shown that the active-alert method described by Banyai and Hilgard (1976) produces a similar increase on suggestibility as relaxation-based techniques, but it has some limitations, including the need for a stationary bicycle and a certain level of physical fitness. The authors compared that method with the new "alert hand" method, which emphasizes activity and alertness, but is simpler and less strenuous. In a repeated measures, counterbalanced design (N=80), the authors found that (a) the alert hand method produced significantly higher objective and subjective suggestibility scores than the active-alert technique, and (b) a high percentage (23%) of volunteers discontinued participation during the active-alert method but not during the the alert hand method. The alert hand method extends the benefits of active hypnosis for people who may have difficulties with the physical demands required by the active-alert method, and it seems to enhance suggestibility.

Gibbons, Don (1998). Suggestion as an art form: Alternative paradigm for hypnosis?. [Paper] Presented at annual meeting of American Psychological Association, San Francisco. ([available online:] <ftp://members.aol.com/gibbonsdon/artform.txt>)

This paper proposes a change in the manner in which we think about suggestion-induced phenomena, moving from primary reliance upon a medical/counseling model to a concurrent view of suggestion as an art form and hypnosis as an artistic medium. the rationale for such an alternative paradigm is discussed, and a procedure for scripting suggestions within the new paradigm -- the Best Me technique -- is presented, along with a specific illustration of its application, possible implications for current clinical practice, and suggestions for transition to the new paradigm.

1997

Bayot, A.; Capafons, A.; Cardeqa, E. (1997). Emotional self-regulation therapy: A new and efficacious treatment for smoking.. American Journal of Clinical Hypnosis, 40 (2), 146-156.

We described emotional self-regulation therapy, a recently-developed suggestion technique for the treatment of smoking, and present data attesting to its efficacy. Of the 38 individuals who completed treatment, 82% (47% of the initial sample) stopped smoking altogether and 13% (8% of the initial sample) reduced

their smoking. A follow-up at 6 months showed that 66% (38% of the initial sample) of those who had completed the treatment remained abstinent and reported minimal withdrawal symptoms or weight gain. In a no-treatment comparison group, only 8% reduced their smoking or became abstinent.

1996

DeBenedittis, Giuseppe De (1996). Hypnosis and spasmodic torticollis -- report of four cases: A brief communication. International Journal of Clinical and Experimental Hypnosis, 44 (4), 292-306.

Dystonia and particularly spasmodic torticollis are neuromuscular disorders that are extremely resistant to most therapies (physical, medical, or surgical). Torticollis is a unilateral spasm of the neck muscles, particularly of the sternocleidomastoid, that produces violent, tonic turning of the head to one side. The etiology remains uncertain, although the role of psychogenic factors has been emphasized. This article reviews the literature and reports four cases of spasmodic torticollis treated successfully with hypnosis. In all four cases, psychogenic causes were involved. Postural hypnosis (i.e., hypnosis in the standing position) was employed to counteract and minimize muscle spasms due to postural reflexes. A hypnobehavioral approach was adopted along with hypnotic strategies that included hierarchical desensitization, sensory-imaging conditioning, ego-boosting suggestions, and hypnosis-facilitated differential muscle retraining. In two cases, a combined hypnosis and electromyographic-biofeedback approach was used to equilibrate and retrain affected neck muscles. Although the hypnotherapeutic process took several months to induce and stabilize significant changes, outcome results were good to excellent in all cases, with marked reduction of the torticollis and the hypertrophy of the neck muscles as well as a reduced interference of symptoms in daily living. -- Journal Abstract

Wark, David (1996). Teaching college students better learning skills using self-hypnosis. American Journal of Clinical Hypnosis, 38 (4), 277-287.

Reports the effects of self-hypnosis used by 51 college students enrolled in a 10-wk course on efficient learning skills. All Ss were administered the Creative Imagination Scale (CIS). Subsequently, they learned to enter and deepen alert self-hypnosis. They gave themselves personal suggestions and then studied in hypnosis. They reported their depth of hypnosis and satisfaction with each session. Grades were collected the quarter before, during and after the course. Satisfaction and depth data indicated the Ss were involved throughout the course. Statistical testing showed that Ss who scored highest on the CIS had the lowest initial GPA, improved most during the course, and significantly increased their GPA in the quarter after

1995

Capafons, A.; Amigs, S. (1995). Emotional self-regulation therapy for smoking reduction: Description and initial empirical data.. International Journal of Clinical and Experimental Hypnosis, 43 (1), 7-19.

Self-regulation therapy (Amigs, 1992) is a set of procedures derived from cognitive skill training programs for increasing hypnotizability. First, experiences are generated by actual stimuli. Clients are then asked to associate those experiences with various cues. They are then requested to generate the experiences in response to the cues, but without the actual stimuli. When they are able to do so quickly and easily, therapeutic suggestions are given. Studies of self-regulation therapy indicate that it can be used successfully to treat smoking.

Holroyd, Jean (1995). Handbook of clinical hypnosis, by Judith W. Rhue, Steven Jay Lynn, & Irving Kirsch (Eds.) [Review]. International Journal of Clinical and Experimental Hypnosis, 43 (4), 401-403.

#### NOTES

"This is a book for the thinking clinician" (p. 401). "The editors are to be congratulated for making this volume much more coherent than most edited books" (p. 402). "My impression is that the book is best suited for an intermediate or advanced course on hypnotherapy, or for people who are already using hypnosis in treatment. Although there is some material on the basics of hypnotic inductions and a few introductory sample scripts for inductions, a beginners" course should probably use a different book, or this book could be accompanied by an inductions manual. ... I recommend it very highly" (p. 403).

Barabasz, Arreed F.; Barabasz, Marianne (1994, October). EEG responses to a reading comprehension task during active alert hypnosis and waking states. [Paper] Presented at the annual meeting of the Society for Clinical and Experimental Hypnosis, San Francisco.

NOTES: Evoked potentials differ between High & Low hypnotizables during hypnosis but not during waking (Barabasz & Lonsdale, 1983; Spiegel et al, 1985; Spiegel & Barabasz, 1988). Showed critical importance of instructions. We may not be aware of the suggestions that subjects are giving themselves. Or experimental cues may lead to de facto instructions.

Freeman, M. Barabasz & I found differences in high theta during cold pressor pain (reported elsewhere in this conference).

Active alert hypnosis improves attentional processing in military pilots (Barabasz, 1985, Journal of Aviation, Space & Environmental Medicine). INAP = Instantaneous Neuronal Activation Procedure. To enhance responsiveness to cockpit cues. Didn't have way of doing in flight measures of hypnosis. INAP was used clinically with airline pilots (Rhue, Lynn, & Kurtz Handbook on Clinical Hypnosis)

Active alert focused attention hypnosis increases frontal EEG topographic energy and frequency shifts (increased beta) in highly hypnotizable normal and attention deficit disordered children (Barabasz, Crawford & Barabasz, 1993; in press). No

significant changes are found with low hypnotizables (Barabasz & Barabasz, 1993). But sample was small.

Can alert focused attention hypnosis alter EEG topography and attentional processing in subjects of average hypnotizability?

MRI type mapping shows that attention deficit kids don't have normal patterns.

Subjects: all 11 Ss (female) who volunteered for a vitamin B-6 depletion study, with EEG evaluation, also volunteered for hypnosis testing for a \$5.00 payment (SHCS score range 2-3).

Used active alert procedure during reading comprehension task, disguised as normal reading procedure. Counterbalanced waking, attentional instructions and alert focused attention hypnosis conditions were imbedded in standard EEG situation.

Nelson Denny H.S. Reading Comprehension Test. "Focus your attention to read faster than normal, paying attention to what you read."

Used an eye roll induction, and looked for signs of entering hypnosis before they roll their eyes down; were able to cut no. of sessions in neurofeedback training by 50% by using these instructions. To come out next year in Rhue and Lynn.

Reading rate and comprehension increased in alert hypnosis (and words per minute also in attentional instructions). Neurobehavioral feedback for ADD is to decrease theta and increase beta and it ordinarily takes 60 sessions; 40-80 sessions without hypnosis, 15-25 with hypnosis. Eyeball induction cuts that. (See Barabasz & Barabasz, 1996. Chapter in Lynn, Kirsch, & Rhue, "Casebook of Clinical Hypnosis." Washington, DC.: APA Press.)

### 1991

Miller, Mary Frances; Barabasz, Arreed F.; Barabasz, Marianne (1991). Effects of active alert and relaxation hypnotic inductions on cold pressor pain. Journal of Abnormal Psychology, 100 (2), 223-226.

Contrasted relaxation and active alert hypnotic inductions with or without a specific suggestion for cold pressor pain analgesia. Groups of high (n = 38) and low (n = 27) hypnotizability subjects were tested; hypnotizability had been determined from results of the Stanford Hypnotic Susceptibility Scale, Form C. Cold pressor pain data were obtained after counterbalanced exposure to relaxation and active alert inductions. Highly hypnotizable subjects demonstrated lower pain scores than did low hypnotizability ones. Pain reports did not differ between induction conditions. Highly hypnotizable subjects given an analgesic suggestion showed lower pain scores than did those exposed only to hypnosis. The findings, conceptualized within E. R. Hilgard's (1977a) neodissociation theory, show that relaxation is not necessary for hypnotic analgesia.

NOTES: The relaxation induction was the SHSS, Form B. The active alert induction used the same instructions except suggestions for alertness, invigoration, and freshness were substituted for drowsiness and relaxation. During the active alert induction, the subjects rode a bicycle ergometer at a constant load of 1-3 kg and a constant rate of 1-2 rotations per s (Banyai & Hilgard, 1976).

**1990**

**Cikurel, Katia; Gruzelier, John (1990). The effect of an active-alert hypnotic induction on lateral asymmetry in haptic processing. British Journal of Experimental and Clinical Hypnosis, 7, 17-25.**

**In order to elucidate further left hemispherical inhibitory dynamics in response to instructions of hypnosis, bilateral haptic processing times were compared before and during a traditional hypnotic relaxation procedure and an active-alert procedure in which subjects pedaled a bicycle ergometer and instructions on mental alertness were incorporated with hypnosis. Previous evidence suggesting a slowing of left hemispherical processing and a facilitation of right hemispherical processing in susceptible subjects was replicated, and was shown to characterize high rather than medium susceptibles, the latter showing a bilateral slowing of processing. These effects occurred with both induction procedures whose influence on susceptibility was highly correlated. In fact the lateral shift in processing in the direction of left hemispherical inhibition and right hemispherical facilitation was favoured by the active-alert procedure, indicating that neuropsychological changes which occur with hypnosis cannot be discounted as a by-product of relaxation.**

**Malott, James M. (1984). Active-alert hypnosis: Replication and extension of previous research. Journal of Abnormal Psychology, 93 (2), 246-249.**

**NOTES: Compared levels of hypnotic responsiveness resulting from 4 induction procedures: (a) verbal active-alert induction alone, (b) bicycle pedaling alone, (c) verbal active-alert induction plus bicycle pedaling and (d) traditional relaxation induction. Ss were 48 undergraduates. Stanford Hypnotic Susceptibility Scale scores indicated that the verbal induction plus pedaling procedure was significantly more effective than either the verbal- or pedaling-alone procedures. There were no significant differences in scores produced by the verbal plus pedaling and traditional relaxation inductions. Findings are consistent with A. M. Ludwig's (1966) proposal that there exists a range of stimulation necessary for the maintenance of normal waking consciousness and that levels of stimulation above or below that range are conducive to the production of altered states of consciousness. This study adds experimental controls to the research design used by Banyai for active alert induction.**

**Raikov, V. L. (1978). Specific features of suggested anesthesia in some forms of hypnosis in which the subject is active. International Journal of Clinical and Experimental Hypnosis, 26 (3), 158-166.**

**Experiments are reported in which highly hypnotizable Ss while imagining themselves, during hypnosis, to be cosmonauts with "jammed legs" in a space**

capsule did not feel an unannounced needle prick that pierced the skin. Control experiments with nonhypnotizable, professional actors showed that imagination alone was unsuccessful in producing this result. Additional experiments using autogenic training showed that the autogenic training alone, without analgesia training, did not alleviate the pain but may have reduced the anxiety connected with the pain; further training involving analgesia reduced the felt-pain as well. Theoretical discussion stresses the importance of attention, imagination, and orientation for experiencing analgesia as well as the added and decisive role played by the modifications of consciousness brought about in deep hypnosis.

**Raikov, V. L. (1976). The possibility of creativity in the active stage of hypnosis. International Journal of Clinical and Experimental Hypnosis, 24, 258-268.**

Creative capacity was studied by means of suggestions given to Ss under the condition of active hypnosis. In deep hypnosis it was suggested to S that he was a famous person with a specific talent. In a series of experiments Ss performed under active hypnosis such tasks as drawing, playing musical instruments, and playing chess. The results illustrated that creative processes can be facilitated in Ss capable of deep hypnosis and there is a carry-over of the creative achievements from hypnosis to the waking state. Low hypnotic Ss and control groups did not show improvements in the tasks. A particular significant increase in creativity was observed when Ss capable of deep hypnosis performed several successive creative tasks while hypnotized. The theoretical and experimental definitions of several new approaches to active hypnosis are also discussed.

**Kratochvil, Stanislav (1970). Sleep hypnosis and waking hypnosis. International Journal of Clinical and Experimental Hypnosis, 18, 25-40.**

Subjected 6 highly susceptible female students to a short-term training procedure to induce 2 different types of hypnosis: (a) a sleep hypnosis, and (b) an active waking hypnosis. Ss behavior in both types, during the carrying out of 11 standard suggestions, was rated by 2 independent Os. The behavior in both artificially induced types of hypnosis differed significantly at the 1% level in the expected direction. The failure to obtain more dramatic results is attributed to the shortness of training, to the implicit demands concerning activity, or to Ss' personality traits, which may lower the intrapersonal variability. The relevance of the results for the Pavlovian theory of hypnosis is discussed: They do not support the hypothesis that behavioral characteristics which resemble sleep are intrinsic phenomena of the hypnotic state. ## ACUPUNCTURE

1991

Moret, V.; Forster, A.; Laverriere, M. C.; Lambert, H.; Gaillard, R. C.; Bourgeois, P.; Haynal, A.; Gemperle, M.; Buchser, E. (1991). Mechanism of analgesia induced by hypnosis and acupuncture: Is there a difference?. *Pain*, 45, 135-140.

Hypnosis and acupuncture can alleviate experimentally induced pain but the mechanism of analgesia remains unclear for both techniques. Experimental pain was induced by cold pressor test (CPT) in 8 male volunteers. Analgesic effect of hypnosis (HA) and acupuncture (AA) was assessed before and after double-blind administration of placebo or naloxone, in a prospective, cross-over study. We found that pain intensity was significantly lower with HA as compared with AA, both with naloxone ( $P < 0.001$ ) and placebo ( $P < 0.001$ ). Within HA or AA groups, pain scores did not differ significantly when naloxone or placebo was administered. During AA, however, pain scores were similar to control values when naloxone was given ( $P = 0.05$ ) but decreased significantly with placebo ( $P < 0.002$ ). Analog scales for pain intensity and pain relief showed a good correlation ( $r = 0.94$ ). Plasma levels of B-endorphins did not change significantly in any combination. Heart rate, peripheral arterial blood pressure and skin conductance were very insensitive indices to assess pain intensity or relief, as well as intensity of acupuncture stimulation or depth of hypnotic trance. We conclude: (1) HA and AA can significantly reduce pain from CPT, and HA is more effective than AA; (2) HA and AA are not primarily mediated by the opiate endorphin system; and (3) plasmatic levels of B-endorphins are not significantly affected by HA or AA nor by naloxone or placebo administration.

## NOTES

The authors measured blood pressure, heart rate, skin conductance, mood (Clyde Mood Scale), beta endorphin levels, and hypnotizability.

Before the experimental sessions they obtained Ss' opinions about the analgesia effectiveness of hypnosis and acupuncture. For each Subject they established a value for 'intolerable' pain (the longest duration of arm immersion in cold water). Efficacy of treatment was defined as none (0% on the efficacy scale) for this Control session..

During the experimental sessions they gave hypnosis or acupuncture analgesia for 20 minutes, then an injection of either naloxone or placebo. Double-blind controls were used. Five minutes after the injection they began CPT and the Subject was told to maintain their hand in the water for the same amount of time as in the control session. Pain intensity and treatment efficacy were scored, then the S completed a mood scale. Five blood samples were collected over the course of the procedure: (a) first rest period, (b) treatment period, (c) after injection, (d) after CPT, (e) second rest period.

Results (see Abstract). "When naloxone was administered, HA was no more effective than AA in alleviating pain ( $P = 0.109$ ). However HA was significantly more effective than AA when placebo was administered ( $P < 0.05$ ). Whichever technique was used there was no significant alteration in pain relief by either naloxone or placebo ( $P = 0.426$  within the HA group and  $P = 0.519$  within the AA group)" (p. 137).

"Compared to the control session, the pain relief was significantly better with HA, both when placebo (62.53%,  $P < 0.001$ ) and when naloxone (49.3%,  $P < 0.001$ ) was administered. This was not true with AA and placebo (15.21%,  $P = 0.1$ ) nor with AA and naloxone (13.38%,  $P = 0.5$ )" (p. 137).

"When naloxone or placebo was administered, the mean pain relief scores did not differ significantly with HA ( $P = 0.56$ ) or with AA ( $P = 0.852$ ). There was a good correlation ( $r = .94$ ) between ratings of pain and treatment efficacy" (pp. 137-138).

Outcome was not related to Subjects pre-experimental beliefs about efficacy of hypnosis or of acupuncture. During the experimental sessions, all Ss reported that hypnosis was more effective than acupuncture.

Neither hypnosis nor acupuncture affected beta endorphin plasma levels; neither naloxone nor placebo affected beta endorphin plasma levels.

Mood was somewhat affected by treatments. "When compared with the baseline value (i.e., before each session), mean scores for happiness were significantly lower after AA with placebo than after AA with naloxone ( $P = 0.05$ ). The other evaluated categories of mood (friendliness, aggressiveness, clear thought, sleepiness and dizziness) were not affected by either session" (p. 139).

In the Discussion, authors indicated that "variables such as heart rate, arterial blood pressure and skin conductance were very insensitive indices for assessing pain or pain relief as well as intensity of acupuncture stimulation or depth of hypnotic trance" (p. 139).

Why was hypnoanalgesia better than acupuncture analgesia? "Firstly, a preconceived opinion could favor hypnosis; this was not the case amongst these subjects. Secondly, the influence of what was felt to be a more pleasant experience (HA) might help to lower pain ratings. Subjective preference for hypnosis was frequently expressed informally; however, scores from the Clyde Mood Scale did not suggest mood enhancement after HA. Thirdly, the intensity of analgesia might

have been more uniform with HA than with AA. ... Interestingly, we found no difference in pain ratings between good and poor hypnotic subjects, even if theoretically poor hypnotic subjects could be expected to experience less pain relief with HA" (p. 139).

Effect of naloxone. "Although the failure to achieve statistical significance may be due to the small number of subjects, our results suggest that, if opiate receptors play a role in HA or AA, it is not of primary importance" (p. 139). The authors go on to state that the data on plasma beta-endorphin and CSF beta-endorphin are confusing, and elaborate the discussion of that variable on p. 139.

**Lewith, G. T.; Kenyon, J. N. (1984). Physiological and psychological explanations for the mechanism of acupuncture as a treatment for chronic pain. *Social Science & Medicine*, 1367-1378.**

Many suggestions have been made about the possible mechanism of acupuncture as an analgesic therapy. This review provides a comprehensive account of the neurological, neurohumoral and psychologically-based hypotheses put forward. Although the exact mechanism of this treatment remains unclear, it is apparent that reproducible neurological and chemical changes occur in response to acupuncture, and that these changes almost certainly modify the response to, and perception of, pain. The mechanism of chronic pain is incompletely understood, but within this framework we understand acupuncture as completely as most other types of analgesic treatment.

**1981**

**Knox, V. Jane; Gekoski, W. L.; Shum, Kit; McLaughlin, Deborah M. (1981). Analgesia for experimentally induced pain: Multiple sessions of acupuncture compared to hypnosis in high- and low-susceptible subjects. *Journal of Abnormal Psychology*, 90 (1), 28-34.**

Repeated trials with cold-pressor pain were used to (a) determine whether the modest relation between hypnotic susceptibility and response to acupuncture analgesia obtained in previous experiments is enhanced over a series of treatments; (b) compare acupuncture and hypnotic analgesias; and (c) assess whether acupuncture analgesia increases with repeated treatments. Twenty high and 20 low hypnotically susceptible subjects participated on 5 different days. For half of each susceptibility group, Sessions 1- 3 consisted of a baseline trial followed by an acupuncture analgesia trial. The remaining subjects had two no-treatment trials on each of these sessions. For all subjects Session 4 was a baseline followed by a hypnotic analgesia trial, and Session 5 was a repetition of the procedures followed in Sessions 1-3. Repeated exposures to acupuncture did not alter its analgesic effect in either susceptibility group; there were no instances of significant postacupuncture pain reduction. High susceptibles, but not low susceptibles, reported marked pain reduction after hypnotic analgesia. From these and previous findings it is concluded

that the effect of acupuncture on experimentally induced pain is at best small and fragile.

NOTES

1:

NOTES: 8 of 10 highly hypnotizable subjects but only 3 of 10 low hypnotizable subjects thought hypnosis was more effective than acupuncture

1978

Mendelson, G. (1978). Acupuncture analgesia. 2. Review of current theories. Australian and New Zealand Journal of Medicine, 8, 100-105.

An experiment was designed to evaluate the protective effects of different agents - acupuncture, hypnosis, Morphine, aspirin, Diazepam and placebo - upon experimentally-induced pain in humans. Twenty normal, healthy volunteers were subjected to cold water and tourniquet- induced pain and the protective effects of 35 minutes of hypnotic suggestion, electro- stimulation of both acupuncture points and non-acupuncture points, 10 mg/kg of Morphine, 5 grains of aspirin, 10 mg of Diazepam and a mild sugar placebo were evaluated. Data was collected on subjective evaluation of pain, EKG, EEG, respiration, skin temperature, peripheral vascular activity and EMG. A special study was also done to evaluate the effects of all the above agents on the somatosensory evoked potentials and EEG. The data were further analyzed on the basis of hypnotic susceptibility of the volunteers. The results indicated: 1) Hypnosis, acupuncture at specific sites with electrical stimulation and Morphine Sulphate had about the same reduction in experimental pain. 2) Hypnosis produced different effects from those resulting from acupuncture stimulation on EEG. 3) Acupuncture stimulation in specific loci resulted in a latency increase in the early secondary response on somatosensory evoked potential. 4) Cold water pain was remarkably reduced after true acupuncture point stimulation. 5) Tourniquet (ischemic) pain was reduced by both hypnosis and true acupuncture site stimulation. 6) Skin temperature was significantly reduced on the side of acupuncture points (true) stimulation.

Ulett, George A.; Parwatikar, Sakashiv D.; Stern, John A.; Brown, Marjorie (1978). Acupuncture, hypnosis and experimental pain: II. Study with patients. Acupuncture and Electro-Therapeutic Research: International Journal, 3, 191-201.

The experiment was designed to explore the correlation between the protective effects of hypnosis and acupuncture on externally induced short lived pain and to evaluate various data retrospectively in relation to acupuncture treatment responders and non-responders. Twenty patients with a history of chronic pain were subjected to cold water induced pain and the data on the effect of 35 min of hypnotic suggestion and 20 min of acupuncture stimulation on the pain and other physiological variables was gathered in a controlled setting. These patients had previously had acupuncture treatment. Eleven had benefitted from it in excess of 50% and nine had reported less than 50% improvement in their condition. Findings indicate: (1) acupuncture responsive patients experience less acute pain when such pain is induced externally. (2) hypnotic susceptibility and response to acupuncture

are independent of each other and the former cannot be used as a predictor of acupuncture treatment success. (3) Hypnosis appears to have more definite and predictable protective effect than acupuncture. (4) Younger patients appear to have a better response to acupuncture treatment than do older patients. It is suggested that the research in acupuncture be furthered in view of the fact that acupuncture seems to have positive effect in certain patients.

**This study investigated a number of psychosocial variables that have been suggested as possible mediating factors in acupuncture therapy. Forty-two volunteers with bursitis and/or tendonitis of the shoulder served as subjects. All were randomly assigned to one of four treatment groups: acupuncture - positive milieu, acupuncture - negative milieu, placebo acupuncture - positive milieu, and placebo acupuncture - negative milieu. Pretreatment and posttreatment subjective pain reports and shoulder motion studies, as well as pretreatment assessments of hypnotic susceptibility and suggestibility, were determined for each subject. Results indicated that (a) acupuncture and placebo acupuncture were equally effective in producing highly significant ( $p < .001$ ) reductions in subjective pain reports; (b) neither treatment effectively improved objective shoulder motion; (c) subjects treated in the positive milieu reported more improvement than those in the negative milieu ( $p < .053$ ); and (d) hypnotic susceptibility, suggestibility, belief in the treatment, and the satisfaction of expectations showed no relationship to treatment outcome. It is concluded that acupuncture therapy provides a powerful placebo. Treatment milieu variables warrant future study in the attempt to understand the acupuncture phenomena.**

Stern, John A.; Brown, M.; Ulett, George A.; Sletten, Ivan (1977). A comparison of hypnosis, acupuncture, morphine, Valium, aspirin, and placebo in the management of experimentally induced pain. *Annals of the New York Academy of Sciences*, 296, 175-193.

What general conclusions can we come to on the basis of these investigations? We conclude that hypnosis and suggestions of analgesia, morphine, and acupuncture stimulation (of LI 4, 14, and 15 on the arm exposed to painful stimulation) are effective in reducing experimentally induced pain. This is true for both a cold pressor pain-induction procedure and an ischemic pain-induction procedure. Hypnotic suggestibility does not account for the effectiveness of acupuncture stimulation, though good hypnotic Ss show better protection against pain with hypnotic suggestion and morphine.

"Good hypnotic Ss experience more pain than is true for Poor hypnotic Ss when exposed to the same pain-induction procedure. The effect is more marked for the cold-pressor than the ischemic pain procedure. Good hypnotic Ss are more responsive -- i.e., show greater reduction in pain perception -- to drugs and intervention procedures that produce significant subjective sensations (morphine and diazepam) than is true of Poor hypnotic Ss. This is not true for aspirin and placebo. Last, but not least, Ss low in hypnotic susceptibility tend to perceive painful stimuli as more painful when under the influence of diazepam as compared to the nondrug condition" (p. 192).

1976

Chaves, John F.; Barber, Theodore Xenophon (1976). Hypnotic procedures and surgery: A critical analysis with applications to 'acupuncture analgesia'. *American Journal of Clinical Hypnosis*, 18 (4), 217-236.

Although hypnotic procedures are useful for reducing the anxiety of surgery and helping patients tolerate surgery, they do not consistently eliminate pain. Six factors that are part of or associated with hypnotic procedures help patients tolerate surgery. These factors pertain to patient selection, the patient-physician relationship, the preoperative 'education' of the patient, the adjunctive use of drugs, and the use of suggestions of analgesia and distraction. It appears that the same factors account for the apparent successes of 'acupuncture analgesia' as well. A frequently-overlooked fact, that most internal tissues and organs of the body do not hurt when they are cut by the surgeon's scalpel, is also important in understanding how surgery can be performed with either 'hypnoanesthesia' or 'acupuncture analgesia.'

**Moore, Mary E.; Berk, Stephen N. (1976). Acupuncture for chronic shoulder pain: An experimental study with attention to the role of placebo and hypnotic susceptibility. *Annals of Internal Medicine*, 84 (4), 381-384.**

**One half of 42 Ss treated for painful shoulders received classic acupuncture, and one half received a placebo in which the needles did not penetrate the skin. Half of each of these groups was treated in a positive setting to encourage the subject, and half in a negative setting designed to keep encouragement at a minimum. All patients were independently rated for susceptibility to hypnosis. Although range of motion did not improve, the majority of patients reported significant improvement in shoulder discomfort to a blind evaluator after treatment; placebo and acupuncture groups did not differ in this respect, however. The positive and negative settings did not affect treatment outcome. In all groups, those who were not rated as highly susceptible to hypnosis tended to fail to achieve the highest levels of relief, but such differences were not statistically significant.**

**NOTES: There were 42 subjects, and they were tested with the Spiegel Hypnotic Induction Profile. "Both acupuncture and placebo proved to be effective in relieving shoulder discomfort. 69% of the total group made lower assessments of discomfort on the post-treatment rating than on the pretreatment rating" (p. 382).**

**"Acupuncture was not more effective than placebo in relieving discomfort, however. The average percentage of improvement among those who had acupuncture was not, statistically, significantly different from those who had placebo. Indeed, what little difference there was actually was in the opposite direction, the placebo group improving on the average somewhat more than the acupuncture group" (pp. 382-383).**

**"In the negative setting, however, where the subject was required to suffer in silence, acupuncture seemed to be less effective than the placebo in relieving discomfort" (p. 383).**

**"Although the subjects perceived that the treatment relieved their shoulder discomfort, there was no objective evidence of improvement in the shoulder as measured by change in the range of motion scores before and after treatment" (p. 383).**

**(The placebo was needle pricked against the skin at true site, then rapidly and lightly tapped against the surface of the skin without penetration.)**

**"Those who were not susceptible to hypnosis failed to experience as much relief from discomfort as those who were" (p. 383).**

**"The fact that acupuncture was not more successful in relieving shoulder discomfort than a sham procedure suggests that its much publicized success may be merely a powerful placebo effect" (p. 383).**

**Katz, Kao, Spiegel et al (1974) also found that low hypnotizables did not benefit much in terms of pain relief with acupuncture.**

**1975**

**Ahlberg, D.; Lansdell, H.; Gravitz, M. A.; Chen, T. C.; Ting, C. Y.; Bak, A. F.; Blessing, D. (1975). Acupuncture and hypnosis: Effects on induced pain. *Experimental Neurology*, 49, 272-280**

The reactions of 14 volunteers to electrical stimulation near the supra-orbital nerve were studied under acupuncture, placebo-acupuncture, and hypnosis. As the intensity of stimulation increased, a minimum sensation, a minimum pain, and then a maximum or intolerable pain sensation were produced. Under hypnosis the average intensity of the stimulus for producing these sensations was higher than before the trance induction. Under acupuncture and placebo-acupuncture no clear increase in current intensity was observed. Acupuncture, as well as hypnosis, did not consistently change the blood, blood pressure, pulse rate, EKG, respiratory rate, or EEG.

Saletu, B.; Saletu, M.; Brown, M.; Stern, J.; Sletten, I.; Ulett, G. (1975). Hypno-analgesia and acupuncture analgesia: A neurophysiological reality?. *Neuropsychobiology*, 1, 218-242.

The effects of hypnosis, acupuncture and analgesic drugs on the subjective experience of pain and on objective neurophysiological parameters were investigated. Pain was produced by brief electric stimuli on the wrist. Pain challengers were: hypnosis (induced by two different video tapes), acupuncture (at specific and unspecific loci, with and without electrical stimulation of the needles), morphine and ketamine. Evaluation of clinical parameters included the subjective experience of pain intensity, blood pressure, pulse, temperature, psychosomatic symptoms and side effects. Neurophysiological parameters consisted of the quantitatively analyzed EEG and somatosensory evoked potential (SEP). Pain was significantly reduced by hypnosis, morphine and ketamine, but not during the control session. Of the four acupuncture techniques, only electro-acupuncture at specific loci significantly decreased pain. The EEG changes during hypnosis were dependent on the wording of the suggestion and were characterized by an increase of slow and a decrease of fast waves. Acupuncture induced just the opposite changes, which were most significant when needles were inserted at traditional specific sites and stimulated electrically. The evoked potential findings suggested that ketamine attenuates pain in the thalamo-cortical pathways, while hypnosis, acupuncture and morphine induce analgesia at the later CNS stage of stimulus processing. Finally some clinical-neurophysiological correlations were explored.

1974

Chaves, John F.; Barber, Theodore Xenophon (1974). Acupuncture analgesia: A six-factor theory. *Psychoenergetic Systems*, 1, 11-21.

The dramatic successes claimed for acupuncture suggest that Western medicine has failed to identify important factors that pertain to the nature of pain and its control. This may not be the case, as there are at least six factors which are often overlooked by writers describing the absence of pain (i.e., analgesia) during acupuncture: (a) the patients accepted for surgery under acupuncture usually believe that it will work, (b) drugs are frequently used in combination with acupuncture, (c) the pain associated with surgical procedures is less than is generally assumed, (d) the patients are prepared in special ways for surgery under acupuncture, (e) the acupuncture needles distract the patient from the pain of surgery and, (f) suggestions for pain relief are present in acupuncture treatment. It is concluded that more research is

needed to determine whether additional factors are needed to help explain the phenomenon of acupuncture analgesia.

## **ADDICTIONS**

**1993**

**Eisen, Mitchell (1993). Assessing the hypnotizability of college students from addictive families. Contemporary Hypnosis, 10, 11-17.**

**ABSTRACT: The present study examined the relation between hypnotizability and the report of growing up in an addictive family where one or both parents were addicted to drugs and/or alcohol. A sample of 113 college students (47 male, 66 female) were studied for measure of childhood abuse, addiction history, dissociation and hypnotizability. As predicted, subjects from an addictive family were more hypnotizable than subject from a nonaddictive family. However, no relation between family addiction and dissociation was secured. Whereas abuse was found to be related to dissociation, it was not related to hypnotizability. The findings are discussed in terms of the effects of child abuse and neglect on dissociation and hypnotizability as it relates to the addictive family.**

**Page, Roger A.; Handley, George W. (1993). The use of hypnosis in cocaine addiction. American Journal of Clinical Hypnosis, 36, 120-123.**

**An unusual case is presented in which hypnosis was successfully used to overcome a \$50-0 (five grams) per day cocaine addiction. The subject was a female in her twenties. Six months into her addiction, she acquired a commercial weight-control tape that she used successfully to stop smoking cigarettes (mentally substituting the word "smoking"), as well as to bring her down from her cocaine high and allow her to fall asleep. After approximately 8 months of addiction, she decided to use the tape in an attempt to overcome the addiction itself. Over the next 4 months, she listened to the tape three times a day, mentally substituting the word "coke." At the end of this period, her addiction was broken, and she has been drug free for the past 9 years. Her withdrawal and recovery were extraordinary because hypnosis was the only intervention, and no support network of any kind was available.**

**1990**

**Suedfeld, Peter (1990). Restricted environmental stimulation and smoking cessation: A 15-year progress report. International Journal of the Addictions, 25, 861-888.**

**The first successful use of restricted environmental stimulation therapy (REST) as a method of smoking cessation was reported in this journal in 1972. Since then, close to 20 papers and articles have further investigated this application. The results have been consistently positive and have further shown that--unlike most techniques--REST combines synergistically with other effective treatment modalities. The effect of REST seems to target primarily the major problem with other known treatments in this area: It substantially reduces the relapse rate among clients who quit smoking at the end of treatment. Furthermore, REST is safe, has no known adverse**

side effects, and is easily tolerated by most participants. Nevertheless, the method has not found wide acceptance among practitioners. This paper explores and answers some of the concerns that may be involved in its relative lack of popularity.

**NOTES:** Provides a thorough review of REST (restricted environmental stimulation technique) and smoking cessation, with analysis of why the technique has not been widely adopted, how to set up a lab (including costs and equipment), and the political considerations surrounding REST research (many of which would apply to hypnosis). The author describes how sensory restriction got a bad reputation in Hebb's lab. But both "brainwashing" and intensive interrogation rely primarily on overstimulation and intense stimulus bombardment; these are occasionally interrupted for brief periods to arouse fear and uncertainty about their resumption. The optimal approach in treatment of smokers seems to be to combine an approach that maximizes immediate cessation rates, with REST which maximizes continuing maintenance rates. Tikalsky (1984) reported that combining REST with self-management training and the establishment of a social support group, there was a 6-month abstinence rate of 88%. (This was a clinical treatment study rather than a controlled experiment.)

"The estimated maintenance rates after REST converge at about 50%, about twice as high as those commonly accepted as characterizing the literature (see, e.g., Hunt and Bepalec, 1974; Shumaker & Grunberg, 1986). The unusually high maintenance rates (percentage of subjects who were abstinent at every follow-up throughout 12 months, using as the baseline those who had quit at end of treatment) are in most--although not all--cases combined with only average quit rates (using total number of followed-up subjects as the baseline), indicating that the initial impact of REST is less impressive than its effect on long-term maintenance" (p. 872).

Why is REST underutilized? Some say it is a placebo. But there is evidence that "expectancy has but little effect on objectively quantifiable (as opposed to subjective) measures in REST (Barabasz & Barabasz, 1990; Suedfeld, 1969b; Suedfeld, Landon, Epstein, & Pargament, 1971)" (p. 873). See also Suedfeld & Baker-Brown (1986).

How does REST work? "In REST, the normal flow of exogenous stimuli is suddenly and very drastically reduced. As a result, attention can be (in fact, must be, if the processing of information is a basic human need) refocused to the ongoing internal generation of physiological, cognitive, affective, memorial, imaginal, and other stimulation. This enables REST participants to concentrate on working out personal problems, including (if so desired) those related to the continuation or termination of their smoking habit" (p. 874).

Second, the removal of specific smoking-related cues interrupts automatic, overlearned response sequences so most clients report that they no longer smoke mechanically, and conditioned cravings for a cigarette are extinguished in many Ss. It appears from the literature that low-arousal treatments such as hypnosis and meditation are reinforced by REST. REST should improve conditioning or cognitive change therapies because it improves learning and memory, and research supports this assumption. REST also should facilitate the acceptance of information

('messages') because it decreases defenses against novel or dissonant information, but that has not proven true in research to date.

**1988**

Neufeld, V.; Lynn, Steven Jay (1988). A single-session group self-hypnosis smoking cessation treatment: A brief communication. International Journal of Clinical and Experimental Hypnosis, 36 (2), 75-79.

This study was designed to assess the efficacy of a manual-based, single-session group of self-hypnosis intervention. At 3 months follow-up, 25.92% of the total number of participants (14 male, 13 females) reported continuous abstinence, and at 6 months, 18.52% of the participants reported continuous abstinence. Reported social support and motivation to quit were both associated with successful outcome. Comparison of the current data with other findings reported by the American Lung Association (Davis, Faust, & Ordentlich, 1984) suggests that treatment effects may not be solely attributable to the use of a maintenance manual, education, and attention. Limitations of the research associated with issues of experimental control, generalizability of the findings, and outcome measures are discussed.

**1987**

Gmur, M.; Tschopp, A. (1987). Factors determining the success of nicotine withdrawal: 12-year follow-up of 532 smokers after suggestion therapy (by a faith healer). International Journal of Addictions, 22, 1189-1200.

In 1973, 532 heavy smokers were questioned prior to treatment by the faith healer Hermano and requestioned 4 months, 1 year, 5 years, and 12 years after the therapeutic ritual. From the moment of treatment, 40% of the subjects remained nonsmokers (with no relapse) after 4 months, 32.5% after one year, 20% after 5 years, and 15.9% after 12 years. At the time of the follow-up, 37.5% of the Ss were nonsmokers, the majority of them having stopped smoking again after suffering a relapse. To investigate factors determining success, Ss who for 12 years had uninterrupted abstinence were compared with those who for 12 years had continued to smoke almost without interruption. Personality factors, sociodemographic features, and characteristics of smoking behavior showed no demonstrable connection with the tendency to relapse. On the other hand, it did prove possible to explain 16% of the variance in the responses to treatment: in particular, high alcohol consumption, markedly addictive smoking, rare attendance at church, and the attitude that 'you have to believe in the treatment' were found to be conducive to relapse and addiction.

**1984**

Manganiello, Aaron J. (1984). A comparative study of hypnotherapy and psychotherapy in the treatment of methadone addicts. American Journal of Clinical Hypnosis, 26, 273-279.

This study sought to examine the effects of hypnotherapy on the ability of

methadone-maintained patients to reduce and/or eliminate their drug-taking behavior. Seventy adult volunteers at a methadone maintenance program were randomly assigned to experimental and control groups. The experimental group received hypnotherapy for 6 months in addition to the psychotherapy offered as standard clinic treatment. The control group received only psychotherapy. After treatment a 6-month follow-up was conducted by interviews. Groups were compared to determine significant differences in the number of successful withdrawals, the mean change in methadone dose level, incidence of illicit drug use, and degree of discomfort. Significant differences were found on all measures. The experimental group had significantly less discomfort and illicit drug use, and a significantly greater number of withdrawals. At six-month follow-up, 94% of the Ss in the experimental group who had achieved withdrawal remained narcotic-free

**1981**

Throll, D. A. (1981). Transcendental meditation and progressive relaxation: Their psychological effects. Journal of Clinical Psychology, 37 (4), 776-781.

Administered the Eysenck Personality Inventory, the State-Trait-Anxiety Inventory, and two questionnaires on health and drug usage to 39 Ss before they learned Transcendental Meditation (TM) or Progressive Relaxation (PR). All Ss were tested immediately after they had learned either technique and then retested 5, 10, and 15 weeks later. There were no significant differences between groups for any of the psychological variables at pretest. However, at posttest the TM group displayed more significant and comprehensive results (decreases in Neuroticism/Stability, Extroversion/Introversion, and drug use) than did the PR group. Both groups demonstrated significant decreases in State and Trait Anxiety. The more pronounced results for meditators were explained primarily in terms of the greater amount of time that they spent on their technique, plus the differences between the two techniques themselves.

**1980**

Holroyd, Jean (1980). Hypnosis treatment for smoking: An evaluative review. International Journal of Clinical and Experimental Hypnosis, 28 (4), 341-357.

17 studies of hypnosis for treatment of smoking published since 1970 were reviewed. Abstinence after 6 months posttreatment ranged from 4% to 88%. Effectiveness of treatment outcome was examined in terms of: S population, individual versus group treatment, standardized versus individualized suggestions, use of self-hypnosis, number of treatment sessions and time span covered by the treatment, and use of adjunctive treatment. At 6 months follow-up, more than 50% of smokers remained abstinent in programs in which there were several hours of treatment, intense interpersonal interaction (e.g., individual sessions, marathon hypnosis, mutual group hypnosis), suggestions capitalizing on specific motivations of individual patients, and adjunctive or follow-up contact. The 17 studies are presented in

sufficient detail to permit clinicians to follow the published procedures, and recommendations are made for future research.

**1979**

**Crasilneck, Harold B. (1979). Hypnosis in the control of chronic low back pain. American Journal of Clinical Hypnosis, 22, 71-78.**

Twenty-nine patients were referred because of low back pain. Five were excluded on psychological grounds because they were highly masochistic, extremely depressed, or manifested a low frustration tolerance. Of the 24 in the treatment group, 18 of the patients had surgery two or more times, and six one time. In each case low back pain returned within three to six months after surgery. Twenty of the patients were addicted to or excessively dependent on medications including acetaminophen, secobarbital, codeine phosphate, oxycodone hydrochloride, and morphine sulphate. Common factors among the patients included (1) consistent pain which was primarily organic in origin, (2) analgesic dependence, (3) insomnia, (4) reactive depression, (5) excessive interpersonal dependence, and (6) a fear of becoming a lifelong 'backache cripple.' Twenty patients responded positively; four patients failed to respond to the repeated hypnotic induction techniques and were considered failures. Sixteen reported an average of 80% relief during the first four sessions, and all 20 patients reported an average of 70% relief (based on verbal estimates by patients) by the sixth session. Fifteen voluntarily discontinued medication by the third week of therapy, and the rest were withdrawn by their physicians during the ensuing four weeks. Most patients were seen daily the first week, three times the second week, twice the third week, and thereafter as necessary. The mean number of out-patient sessions was 31 over an average of nine months. All patients were taught self-hypnosis. None of the individuals retained their addiction, and only occasionally did they require analgesics. Patients were seen by their referring physicians as needed during the course of hypnotherapy, and frequent consultations between the therapists created a combination of treatments best suited for each patient. It is concluded that hypnosis may be utilized maximally as an important adjunct to other therapeutic methods in the treatment of low back pain.

**1978**

**Stanton, Harry E. (1978). A one-session hypnotic approach to modifying smoking behavior. International Journal of Clinical and Experimental Hypnosis, 26, 22-29.**

Recent literature reviewing attempts to modify smoking behavior through the use of hypnosis is outlined, and an approach utilizing only 1 treatment is described. This single session includes: (a) the establishment of a favorable "mental set" on the part of the patient, (b) a hypnotic induction, (c) ego-enhancing suggestions, (d) specific suggestions directed toward the cessation of smoking, (e) an adaption of the "red balloon" visualization, and (f) success visualization. Of 75 patients treated by this technique, 45 ceased smoking. 6 months after the treatment session, 34, or 45%, were still nonsmokers, attesting to the efficacy of the method.

1977

Barkley, R. A.; Hastings, J. E.; Jackson, T. L., Jr. (1977). The effects of rapid smoking and hypnosis in the treatment of smoking behavior. 25 (1), 7-17.

29 Ss were assigned to one of 3 treatment conditions and treated for their cigarette smoking over a 2-week period. These conditions were: group rapid smoking, group hypnosis, and an attention-placebo control group. All treatments produced significant reductions in average daily smoking rates during the treatment phase but all Ss returned to near baseline levels of smoking by the 6-week follow-up. The rapid smoking and hypnosis groups did not differ from the control group in smoking rates at treatment termination or at the 6-week follow-up. They also did not differ from the control group in the number of Ss abstaining from smoking by treatment termination but did differ at follow-up. Eventually, at the 9-month follow-up, only Ss from the group rapid smoking condition had significantly more abstainers than the control group. The results suggested that rapid smoking can work as effectively in group procedures as previous individualized approaches had demonstrated. Group hypnosis, while less effective than some previous individualized approaches had indicated, was nevertheless only marginally less effective than the group rapid smoking procedure. The use of abstinence rates as opposed to average rates of smoking was strongly recommended as the best measure of treatment effectiveness for future research in this area.

1970

Kline, Milton V. (1970). The use of extended group hypno-therapy sessions in controlling cigarette habituation. International Journal of Clinical and Experimental Hypnosis, 18, 270-282.

Results of the present experimental approach to the treatment of smoking habituation tend to be consistent with the view of smoking habituation as a dependence reaction, parallel to drug addiction, and with the concept that habituation must be examined as a psychosomatic entity. Therapeutic approaches must take into account the psychophysiological characteristics of deprivation behavior. Hypnosis, and particularly extended periods of hypnotherapy involving the reduction and control of deprivation behavior, seems to offer a promising approach to the therapeutic treatment of smoking habituation. (German & Spanish summaries) (17 ref.) (PsycINFO Database Record (c) 2003 APA, all rights reserved)

Spiegel, Herbert (1970). A single-treatment method to stop smoking using ancillary self-hypnosis. International Journal of Clinical and Experimental Hypnosis, 18 (4), 235-250.

Discusses the 1st 615 patient-smokers who were treated with a single 45-min session of psychotherapy reinforced by hypnosis. Technique of treatment, including rationale of approach, induction procedure, assessment of hypnotizability, and training instructions to stop smoking are presented in detail. 6-mo follow-up study results are discussed. Of 44% who returned a questionnaire, hard-core smokers

stopped for at least 6 mo. Another 20% reduced their smoking to varying degrees. Results of a 1-session treatment compare favorably with, and often are significantly better than, other longer-term methods reported in the literature. It is suggested that every habitual smoker who is motivated to stop be exposed to the impact of this procedure, or its equivalent, so that at least 1 of 5 smokers can be salvaged. (French & Spanish summaries). (PsycINFO Database Record (c) 2003 APA, all rights reserved)

Spiegel, Herbert (1970). A single-treatment method to stop smoking using ancillary self-hypnosis: Final remarks in response to the discussants. International Journal of Clinical and Experimental Hypnosis, 18 (4), 268.

Reexamines the major points of the author's papers (see PA, Vol. 45:Issue 1) on smoking modification. Data inclusion, therapy length, Ss' ability to change, and use of multiple therapists and tape recordings as reinforcement are discussed. It is concluded that the method should be used to "sharpen our techniques that we can relatively quickly learn who has the capacity to change for given goals, and then to help evoke the desired change as efficiently as possible." (PsycINFO Database Record (c) 2003 APA, all rights reserved)

1964

Ludwig, Arnold M.; Lyle, W. H. (1964). The experimental production of narcotic drug effects and withdrawal symptoms through hypnosis. International Journal of Clinical and Experimental Hypnosis, 12, 1-17.

The purpose of this study was to evaluate the role of suggestion in the production of certain narcotic drug effects and in the narcotic abstinence syndrome. In addition, we were interested in determining the extent to which actual narcotic drug effects could be reversed through post-hypnotic suggestion. The results of our study indicated that formerly addicted Ss, who had experienced at least one "cold turkey" withdrawal from narcotics, were able to attain a highly realistic suggested narcotic drug and withdrawal experience through hypnosis with appropriate physiological and behavioral changes, which they were unable to achieve in other control conditions. Moreover, when actual narcotic drugs were administered, certain Ss were able to return to normal behavior following appropriate post-hypnotic suggestions. Hypnosis was deemed to be essential in the production of all these effects. (PsycINFO Database Record (c) 2002 APA, all rights reserved)

Ludwig, Arnold M.; Lyle, William H., Jr.; Miller, Jerome S. (1964). Group hypnotherapy techniques with drug addicts. International Journal of Clinical and Experimental Hypnosis, 12 (2), 53-66.

This study was designed to investigate the appropriateness of a number of group hypnotherapeutic techniques which might be used in the treatment of addict patients. It is the belief of the investigators that the more "magical," "authoritative," and practical-oriented techniques seem more appropriate and

useful than techniques designed to elicit deep, insightful understanding of the emotional problems underlying drug addiction. Many of the specific hypnotherapeutic techniques used are described, and some of the difficulties and advantages of group hypnosis as a treatment method are discussed. (PsycINFO Database Record (c) 2002 APA, all rights reserved)

## **AGE DEVELOPMENT**

**1994**

**Freyd, Jennifer J. (1994). Betrayal-trauma: Traumatic amnesia as an adaptive response to childhood abuse. *Ethics and Behavior*, 4.**

**Betrayal-trauma theory suggests that psychogenic amnesia is an adaptive response to childhood abuse. When a parent or other powerful figure violates a fundamental ethic of human relationships, victims may need to remain unaware of the trauma not to reduce suffering but rather to promote survival. Amnesia enables the child to maintain an attachment with a figure vital to survival, development, and thriving. Analysis of evolutionary pressures, mental modules, social cognitions, and developmental needs suggests that the degree to which the most fundamental human ethics are violated can influence the nature, form, processes, and responses to trauma.**

**NOTES: "A logical extension of this research direction, based on a strategy that has been very effective in cognitive neuroscience, would be to look for neuroanatomical underpinnings of the cognitive mechanisms implicated in dissociation. ... For instance, the ability to dissociate current experience may depend partly on representational structures that support spontaneous perceptual transformations of incoming events. One possible perceptual transformation that is amenable to scientific investigation, would be the creation of spatial representations in which the mental 'observer' is spatially distinct from the real body of that observer. Such a representation would fit patient descriptions of 'leaving their body' during a traumatic episode and viewing the scene as if from afar. Additionally one could investigate the role of mental recoding and restructuring during memory 'recovery' and psychotherapy" (pp. 19-20).**

## **AGE REGRESSION**

**1993**

**De Pascalis, Vilfredo (1993). EEG spectral analysis during hypnotic induction, hypnotic dream and age regression. International Journal of Psychophysiology, 15, EEG was recorded monopolarly at frontal (F3, F4), central (C3, C4) and posterior (in the middle of O1-P3-T5 and O2-P4-T6 triangles) derivations during the hypnotic induction of the Stanford Hypnotic Clinical Scale (SHCS) and during performance following suggestions of hypnotic dream and age-regression as expressed in the before-mentioned scale. 10 low-hypnotizable and 9 highly-hypnotizable and right-**

handed female students participated in one experimental session. Evaluations were Fast-Fourier spectral analyses during the following conditions: waking-rest in eyes-open and eyes-closed condition; early, middle, and late phases of hypnotic induction; rest-hypnosis in eyes closed condition; hypnotic dream and age regression. After spectral analysis of 0 to 44 Hz, the mean spectral amplitude estimates across seven Hz bands (theta 1, 4-6 Hz, theta 2, 6-8 Hz; alpha 1, 8-10 Hz; alpha 2, 10-13 Hz; beta 1, 13-16 Hz; beta 2, 16-20 Hz; beta 3, 20-36 Hz) and the 40-Hz EEG band (36-44 Hz) for each experimental condition were extracted. In eyes-open and -closed conditions in waking and hypnosis highly-hypnotizable subjects produced a greater 40-Hz EEG amplitude than did low hypnotizable subjects at all frontal, central and posterior locations. In the early and middle hypnotic induction highly-hypnotizables displayed a greater amount of beta 3 than did low hypnotizables and this difference was even more pronounced in the left hemisphere. With posterior scalp recordings, during hypnotic dream and age regression, high hypnotizables displayed, as compared with the rest-hypnosis condition, a decrease in alpha 1 and alpha 2 amplitudes. This effect was absent for low hypnotizables. Beta 1, beta 2 and beta 3 amplitudes increased in the left hemisphere during age regression for high hypnotizable; low hypnotizables, in contrast, displayed hemispheric balance across imaginative tasks. High hypnotizables during the hypnotic dream also displayed in the right hemisphere a greater 40-Hz EEG amplitude as compared with the left hemisphere. This difference was even more evident for posterior recording sites. This hemispheric trend was not evidenced for low hypnotizable subjects. Theta power was never a predictor of hypnotic susceptibility, 40-Hz EEG amplitude displayed a very high main effect ( $p < 0.004$ ) for hypnotizability in hypnotic conditions by displaying a greater 40-Hz EEG amplitude in high hypnotizables with respect to lows.

#### NOTES

In the Discussion section, the authors indicate that they have no idea why they didn't replicate results of other theta studies, including their own, except maybe due to complex interaction among personality, subject selection, situation-specific factors, and hypnotizability.

They observe that the alpha results conform with previous findings (p. 163). Beta bands were sensitive. Highs showed left-hemisphere prevalence in all beta bands during age regression; they also showed hemispheric balance in the hypnotic dream condition. Beta 3 amplitude was also greater among highs than lows. "among high hypnotizables, beta 3 amplitude in the early hypnotic condition was greater in the left hemisphere as compared to the right and as the hypnotic induction proceeded hemisphere balancing, with reduced beta 3 amplitude, was displayed. This result appears in agreement with the predictions of the neurophysiological model proposed by Gruzelier et al. (1984) and Gruzelier (1988) as well as with other studies in which beta rhythm was found to discriminate performances between high and low hypnotizables (e.g., Meszaros et al., 1986, 1989; Sabourin et al., 1990)" (p. 163-164). 40 Hz amplitude was higher in highs and increased in right hemisphere during the hypnotic dream, especially in posterior areas. "This pattern of hemispheric

activation may be interpreted as an expression of the greater right-hemisphere activation and of the release of posterior cortical functions during the hypnotic dream and is compatible with the predictions of the Gruzelier model of hypnosis, however, the results obtained in this study for 40-Hz EEG amplitude failed to reveal an inhibition of the left-hemisphere activity with the progress of the hypnotic induction" (p. 164).

(They note that De Pascalis & Penna, 1990, agreed with the Gruzelier 1988 model: highs in early induction had increase of 40-Hz in both hemispheres, but as induction proceeded they had inhibition of left and increase in right hemisphere activity. In this current experiment, only beta 3 showed the hemispheric trend of Gruzelier's model. They cite other details of current study, p. 164, not consonant with Gruzelier.)

"The 40-Hz EEG rhythm, which according to Sheer (1976) is the physiological representation of focused arousal, appeared to discriminate between differential patterns of high and low hypnotizables. Both during hypnotic induction and during hypnotic dream and age regression highly hypnotizables exhibit greater 40-Hz EEG amplitude with respect to the lows. These findings support the validity of the assumption that hypnosis is characterized by a state of focused attention (Hilgard, 1965) and that 40-Hz EEG activity reflects differential attentional patterns among subjects high and low in hypnotizability. On the basis of these findings it would appear that 40-Hz EEG and beta 3 spectral amplitudes may prove to be useful measures of individual hypnotizability" (p. 164).

1988

ravindakshan, K. K.; Jenner, F. A.; Souster, L. P. (1988). A study of the effects of hypnotic regression on the auditory evoked response. International Journal of Clinical and Experimental Hypnosis, 36, 89-95.

Hypnotic regression in 6 hypnotizable Ss experienced in regression was studied by means of the auditory evoked response (AER). AER latency and amplitude is affected by arousal, attention, stimulus strength, and age. Ss aged between 27 and 61 years were regressed to the age of 7-9 years, and AERs were compared among three states of consciousness: normal awareness, hypnotic relaxation, and hypnotic regression. There was no change in AER morphology in the direction of that seen in children. Thus, age regression is not seen as a reversion to an earlier stage of neurological development but perhaps as role playing which is spontaneous and uninhibited, with the benefit of innocent belief in its accuracy.

NOTES: Raikov (1982) regressed 2 experienced Ss, comparing his results with those of actors acting as children and low hypnotizable subjects; he claimed to be able to reproduce neonatal reflexes in the highly hypnotizable Ss but not in the actors and low hypnotizable subjects.

AER's were used "because latency of the major waves and amplitude of the response is affected by level of arousal and attention..., strength of the stimulus, and, more importantly for this study, by age.... Surwillo (1981) noted that peak latencies of AERs were 16-21 msec longer in children aged 9-13 than in adults..." (p. 90)

**DISCUSSION** reviews the literature. "Changes in the intensity of light stimulation can cause significant shifts in the amplitude and latency of the visual evoked response, but neither the amplitude nor the latency have been changed by suggested alterations in stimulus intensity during hypnosis (Andreassi, Balinsky, Gallichio, de Simone, & Mellers, 1976; Beck & Barolin, 1965; Beck, Dustman, & Beier, 1966; Zakrzewski & Szelenberger, 1981). Similarly, significant changes were seldom found in the AER with suggested variations of sound intensity during hypnosis (Amadeo & Yanovski, 1975) and in somatosensory responses to electrical stimuli applied to the fingers with suggested anesthesia during hypnosis (Halliday & Mason, 1964). Deehan and Robertson (1980) were able to abolish the AER completely during hypnosis, but their stimuli were very different from that used in the present study.

"In all such studies, hypnosis and suggestions were aimed at changing the intensity of the stimulus to S's awareness, while the actual intensity of the stimulus was unaltered. In the present study, the authors attempted to find whether the morphology of the AER in children could be reproduced by age regression, without altering the nature or intensity of the stimulus in its delivery.... Like previous investigators, the present authors noticed that the tracings were cleaner and easier to produce during hypnosis (see Figure 1), although the changes in neurological development observed by Raikov (1982) were not evident" (pp. 93-94).

**1988-1999**

**Brink, Nicholas E. (1988-89). Using imagery as a planning and treatment guide in therapy. Imagination, Cognition and Personality, 8, 187-200.**

Procedures and case studies of how imagery can provide a means to redefine the problem, an agenda for therapy, information for determining the appropriate interventions, a criteria for evaluating progress, and the appropriate time for termination are presented. Images are evoked using one of several imagery situations. These images may converge on the common dynamic pattern clarifying the problem, represent different aspects of the problem, or represent different problems, depending upon the hypnotic suggestion used in evoking the images. The emerging pattern(s) provide the agenda for therapy. Emotional energy in imagery work is used to determine the appropriate timing and content for the therapeutic interventions. Emotional release provides a means of evaluating progress. When each of the items on the agenda are resolved with an emotional release the time for termination is near at hand. Therapy begins by evoking a minimum of three images using one of several situations, including time regression, seeing behind doors on a hallway, or going down in an elevator. These images may represent different aspects of the problem, different problems, or, by using the affect bridge, may converge on a common dynamic pattern clarifying the nature of a single problem.

**1961**

**Barber, Theodore Xenophon (1961). Experimental evidence for a theory of hypnotic behaviour: II. Experimental controls in hypnotic age-regression. International Journal of Clinical and Experimental Hypnosis, 9, 181-193.**

5 studies are often cited in support of the contention that involuntary infantile or childhood behavior patterns are revived under hypnotic age-regression. These studies are presented and re-evaluated in terms of other experimental evidence. The author concludes that the "good" hypnotic subject may vividly imagine that he is a child and may perform childlike behavior; "however, it has not been demonstrated that during "hypnotic age-regression" earlier patterns of behavior are revived that could not be performed voluntarily by an appropriately motivated but un hypnotized adult. ## NOTES

### "Summary and Conclusions

"Six 'good' hypnotic Ss were given a ten-minute 'hypnotic induction' and a series of 'hypnotic tests.' Both basic skin conductance and momentary variations in skin conductance (GSR) were recorded during the experiment.

"The results were as follows:

1. There was no significant variation in skin conductance during the 'hypnotic induction procedure.'
2. Skin conductance generally increased throughout the remainder of the experiment, i.e., when the Ss were given suggestions of 'sensory hallucinations,' 'age-regression,' 'analgesia,' 'negative hallucinations,' and 'post'-hypnotic behavior.
3. The Ss usually showed a GSR when they were given 'hallucinatory' suggestions, i.e., when they were told that they were becoming 'itchy,' 'thirsty,' and 'very hot.'
4. The GSR to a pinprick was essentially the same before the experiment and during 'hypnotic analgesia.' Also, the GSR was essentially the same, during 'hypnotic analgesia,' (a) when three Ss were told they would receive a pinprick but did not receive the pinprick, (b) when they were told they would receive a pinprick and did receive the pinprick, and (c) when they received a pinprick without being told they would receive it.
5. Four Ss showed a GSR each time they were asked to look at a 'negatively hallucinated' object and person. Two Ss did not show a GSR when they were asked to look at the 'negatively hallucinated' object (or person). The four Ss who showed a GSR stated, during or after the experiment, that they were by no means convinced that the person or object was no longer in the room. The two Ss who did not show GSR stated, after the experiment, that they had been 'certain' that the object (or person) was not present in the room.
6. Although the Ss stated that they did not 'remember' the 'post'-hypnotic suggestion (or anything else about the experiment), they usually showed a GSR when the E made the preliminary movements to give the signal for the 'post'-hypnotic behavior. (They also showed a GSR when E gave the signal for the 'post'-hypnotic behavior.)

"Since skin conductance is an index of the S's level of 'activation,' 'arousal,' or 'excitation,' these results indicate the following:

1. Ss do not necessarily become more 'passive' or 'relaxed' during the 'hypnotic induction procedure.'
2. Ss often become more and more 'excited' and 'aroused' when they are given a series of 'active' suggestions such as 'sensory hallucinations,' 'age-regression,' etc.
3. Ss often show momentary 'excitement' when they are 'hallucinating.'
4. A pinprick can 'arouse' a S to the same extent during 'hypnotic analgesia' as it can during 'normal waking.' In addition, 'hypnotic analgesic' Ss are often just as much 'aroused' by the threat of a pinprick as they are by an actual pinprick.
5. Many Ss become momentarily 'excited' when they are asked to look directly at an object (or person) which they have been told they will not be able to see. However, some Ss do not show this momentary 'excitement.'
6. Although Ss may state that they do not 'remember' the 'post'-hypnotic suggestion, they often become momentarily 'excited' when the E makes preliminary motions to give the signal for the 'post'-hypnotic act" (pp. 90-92).

### AGE REGRESSION

Fellows BJ. Creamer M. An investigation of the role of 'hypnosis', hypnotic susceptibility and hypnotic induction in the production of age regression. *British Journal of Social & Clinical Psychology* 1978;17(2):165-71 In response to criticisms of the methodology of Barber's(1969)experiments, a 2x2 factorial design, varying hypnotic susceptibility and hypnotic treatment, was used to study the role of 'hypnosis' in the production of age regression by suggestion. Twenty subjects of high hypnotic susceptibility and 20 subjects of low hypnotic susceptibility were randomly allocated to one of two treatment conditions:hypnotic induction procedure or motivational instructions. Both treatments were followed by suggestions to regress to the age of seven years. Two measures of age regression were taken:the Draw-A-Man-Test and a subjective rating of the reality of the experience. The results showed significant effects of both variables, with high susceptibility and induction treatment producing better regression on both measures than low susceptibility and motivation treatment. Hypnotic susceptibility was the stronger of the two variables. The ranking of the four conditions corresponded with predictions of hypnotic depth from the state theory of hypnosis, but the findings were not inconsistent with the non-state theory. The drawings of all regressed groups were more mature than the norms for the age of seven and the drawings of a group of seven year old children.

O'Brien RM. Kramer CE. Chiglinsky MA. Stevens GE. Nunan LJ. Fritzo JA. Moral development examined through hypnotic and task motivated age regression. *American Journal of Clinical Hypnosis* 1977;19(4):209-13 Thirty 17-28 yr old volunteers who had scored above 8 on the Stanford Hypnotic Susceptibility Scale, Form C, were randomly assigned to 3 groups (hypnosis, task motivation, and control). The 2 treatment groups were age regressed to the 1st grade. They were then examined through 5 moral dilemma stories to ascertain their level of functioning on L. Kohlberg's (1968) stage theory of moral development. The control group experienced the same examination without age regression. Results show that both treatment groups were at a significantly lower moral stage than the control group but that there was no significant difference between the 2 groups of age-regressed Subjects. In addition, it was found that a group of 10 actual 1st graders

**gave answers that were at a much lower level than those of the age-regressed Subjects. These results demonstrate cognitive age regression on Kohlberg's stages of moral development. They also suggest that task motivation situations are as efficient as hypnosis in producing this phenomenon.**

## **AGE / DEVELOPMENT**

**1994**

**Freyd, Jennifer J. (1994). Betrayal-trauma: Traumatic amnesia as an adaptive response to childhood abuse. Ethics and Behavior, 4.**

**Betrayal-trauma theory suggests that psychogenic amnesia is an adaptive response to childhood abuse. When a parent or other powerful figure violates a fundamental ethic of human relationships, victims may need to remain unaware of the trauma not to reduce suffering but rather to promote survival. Amnesia enables the child to maintain an attachment with a figure vital to survival, development, and thriving. Analysis of evolutionary pressures, mental modules, social cognitions, and developmental needs suggests that the degree to which the most fundamental human ethics are violated can influence the nature, form, processes, and responses to trauma.**

### **NOTES**

**1:**

**NOTES: "A logical extension of this research direction, based on a strategy that has been very effective in cognitive neuroscience, would be to look for neuroanatomical underpinnings of the cognitive mechanisms implicated in dissociation. ... For instance, the ability to dissociate current experience may depend partly on representational structures that support spontaneous perceptual transformations of incoming events. One possible perceptual transformation that is amenable to scientific investigation, would be the creation of spatial representations in which the mental 'observer' is spatially distinct from the real body of that observer. Such a representation would fit patient descriptions of 'leaving their body' during a traumatic episode and viewing the scene as if from afar. Additionally one could investigate the role of mental recoding and restructuring during memory 'recovery' and psychotherapy" (pp. 19-20).**

**1970**

**Fromm, Erika (1970). Age regression with unexpected reappearance of a repressed childhood language. International Journal of Clinical and Experimental Hypnosis, 18, 79-88.**

**Describes the case of a 26-yr-old, 3rd-generation Japanese-American who thought he knew no Japanese. When hypnotically age-regressed to levels below age 4, he spontaneously and unexpectedly spoke Japanese, while only English was spoken at the adult and age-regression levels above 4 yr. The psychodynamics of the S's repression of the childhood language and questions pertaining to the nature and theory of age regression are discussed. (Spanish & German summaries) (16 ref.) ## **ALCHOLOSM**

**1993**

**Eisen, Mitchell (1993). Assessing the hypnotizability of college students from addictive families. Contemporary Hypnosis, 10, 11-17.**

**The present study examined the relation between hypnotizability and the report of growing up in an addictive family where one or both parents were addicted to drugs and/or alcohol. A sample of 113 college students (47 male, 66 female) were studied for measure of childhood abuse, addiction history, dissociation and hypnotizability. As predicted, subjects from an addictive family were more hypnotizable than subject from a nonaddictive family. However, no relation between family addiction and dissociation was secured. Whereas abuse was found to be related to dissociation, it was not related to hypnotizability. The findings are discussed in terms of the effects of child abuse and neglect on dissociation and hypnotizability as it relates to the addictive family.**

### **NOTES**

**1:**

**Author reviews the literature in area of abuse and hypnotizability as well as dissociation. Subjects were unaware of purposes of the experiment when they volunteered. Of 113 Ss, 18% were reared in an addictive family; 13 Ss reported being abused, of whom 6 reported sexual abuse and seven physical abuse. Five of the 21 Ss who reported being reared in addictive families also reported being abused (3 physical, two sexual). Only one S reported both physical and sexual abuse.**

**Used HGSHS:A, Children of Alcoholics Screening Test, and Dissociative Experiences Scale of Carlson and Putnam (1986). Those with addiction in the family had Harvard scale mean score of 8.05, compared to those who didn't have it with mean of 6.95. No significant effect was found for ABUSE or the interaction of ABUSE and family addiction. The abuse question was, "Before the age of 12 parent punishment of you resulted in your physical injury (bruises, scarring, broken bones, etc.). Second question was, "Before the age of 12, did you participate in sexual behaviors (either with or without coercion) with a much older person?"**

**The Discussion thoroughly explores the possible reasons why their results differ from those of others.**

## **ALLERGY**

**1965**

**Barber, Theodore Xenophon (1965). Physiological effects of 'hypnotic suggestions': A critical review of recent research (1960-64). Psychological Bulletin, 201-222.**

**Recent studies are reviewed which were concerned with the effectiveness of suggestions given under "hypnosis" and "waking" experimental treatments in alleviating allergies, ichthyosis, myopia, and other conditions and in eliciting deafness, blindness, hallucinations, analgesia, cardiac acceleration and deceleration,**

emotional responses, urine secretion to sham water ingestion, narcotic-like drug effects, and other phenomena. The review indicates that a wide variety of physiological functions can be influenced by suggestions administered under either hypnosis or waking experimental treatments, and direct and indirect suggestions to show the particular physiological manifestations are crucial variables in producing the effects.

1964

Black, Stephen (1964). Mind and body. London: Kimber

NOTES

1:

NOTES: Defines psychosomatic disease as one that responds to psychotherapy. Believes only 5% are highly hypnotizable, that hypnosis is learnable in 1/2 hour, that hypnosis is not a useful treatment for psychosomatic disorders because you can't use interpretation [of unconscious]. The 'unconscious' is "... a complex of informational systems derived from such primaevial mechanisms" (p. 133). "Primaevial mind is involved in these mechanisms of genetics and immunology" (p. 133). "There is thus a 'somatic mind' which is unconscious and presumably without any means of verbalization of experience--and a 'cerebral mind' which is conscious" (p. 133). The dividing line is not clear.

Rapport is discussed on pp. 160, 169 as one of the spontaneous characteristics of hypnosis, in the absence of suggestion. The same for posthypnotic suggestion (rapport and amnesia). Spontaneous physiological changes in hypnosis relate to mind-body relationships (p. 169)

Conditioned reflex is discussed on p. 161

"...the subjective evidence indicates that a perceptual change involving any sensory modality can be produced by DSUH" [direct suggestion under hypnosis] p. 178. Suggestion can selectively affect different parts of the body p. 197.

Research: "Hypnosis is not only the most important and practical way of proving the existence of the unconscious--which is still in doubt in some circles--but is in fact the only way in which unconscious mechanisms can be manipulated under repeatable experimental conditions for purposes of investigation" (p. 152).

Mind-body is "amenability to control" Catatonia, which characterizes both animal and human hypnosis, seen in hypnosis, is induced by constriction (i.e. disorientation). The Cartesian concept of mind and body tends to confuse the issue p. 157.

Rapport is discussed (p. 157).

Suggestion (p. 159) "It was this concept of 'suggestion'--which so obviously parallels 'amenability to control' in animals--that eventually established hypnosis in the French schools of psychiatry as a state of increased suggestibility. ... still the standard definition of hypnosis in most medical psychiatric textbooks and in lay dictionaries" (p. 159).

Black (1969) did some biochemical sleuthing to learn how information transmitted by words becomes information encoded somatically, as when psychosomatic allergies flare and recede or disappear. What accounts for suggestion "curing" an allergic skin reaction in one part of the body while another part not included in the

suggestion remains reactive? What accounts for the instantaneous skin allergy cure which sometimes occurs with suggestion (in 24 hours)?

Skin sensitivity tests in highly hypnotizable Ss who were also very allergic were inhibited by direct suggestion under hypnosis under highly controlled experimental conditions--and in one subject the effect (inhibition) was relatively permanent--ruling out (he suggests) a neurological mechanism. He did further experiments to examine whether the result was due to an instant neurological mechanism and a long-term endocrinal mechanism.

p. 212 He ruled out peripheral blood flow as the cause of diminished skin sensitivity (there was no change in blood flow with suggestions of heat or cold). Therefore decrease in blood flow couldn't explain in neurovascular terms the 'instant' inhibition of skin sensitivity (allergy) tests. Was it due to systemic--especially adrenal-- changes? He demonstrated increases in plasma cortisol under hypnosis with suggestions of fear. On p. 230 he summarizes the facts he established by skin sensitivity tests, plasma- cortisol studies, and histology - endocrinological.

## AMNESIA

Schnyer DM, Allen JJ. Attention-related electroencephalographic and event-related potential predictors of responsiveness to suggested posthypnotic amnesia. *International Journal of Clinical & Experimental Hypnosis* 1995;43(3):295-315 Higher frequency electroencephalographic (EEG) activity around 40 Hz has been shown to play a role in cognitive functions such as attention. Furthermore, event-related brain potential (ERP) components such as N1 and P1 are sensitive to selective attention. In the present study, 40-Hz EEG measures and early ERP components were employed to relate selective attention to hypnotic response. Participants were 20 low hypnotizable individuals, half assigned as simulators, and 21 high hypnotizable individuals. Each of these groups was subsequently divided into two groups based on recognition amnesia scores. The four groups differed in 40-Hz (36-44 Hz) EEG spectral amplitude recorded during preinduction resting conditions but not in EEG amplitude postinduction. The groups also differed in N1 amplitudes recorded during hypnosis. Regression analysis revealed that these effects only distinguish the high hypnotizable participants who experienced recognition amnesia from all other groups. The findings support the role of selective attention in hypnotic responsiveness, and the utility of subdividing high hypnotizable individuals is discussed.

Simon MJ, Salzberg HC The effect of manipulated expectancies on posthypnotic amnesia *Int J Clin Exp Hypn.* 1985;33(1):40-51 The effects of manipulated S expectancy and direct suggestions for amnesia on posthypnotic amnesia were assessed. 120 undergraduate students were randomly assigned to 6 groups: negative expectancy (for amnesia)/suggestions (for amnesia); no expectancy/suggestions; negative expectancy/no suggestions; no expectancy/no suggestions; and 2 control groups. The results indicated that the expectancy manipulation had no effect on the occurrence of posthypnotic amnesia measured by the Stanford Hypnotic Susceptibility Scale, Form A (Weitzenhoffer & Hilgard, 1959), whereas suggestions for amnesia were found to have a significant effect. Hypnotized suggestion and no

suggestion Ss remembered significantly less than Ss in the nonhypnotized control groups. The implications of the findings were discussed.

NOTES

1:

Cites J. Herman, Mason, and Miller who accused Freud of retreating from trauma theory to save his theory. Feminists view the Oedipal theory as a coverup for the denial of child sexual abuse. This moral position fuels trauma theory and practice. It is the moral dimension of this debate that gives so many problems for the investigation of traumatic memory.

The intellectual origins of repressed trauma are examined here. Freud's early trauma theory, his later conflict theory.

Etiology of Hysteria (1896) presents Freud's argument, based on 18 patients: child is passive victim of experience imposed on them; memory is repressed and hysterical symptoms are derivatives of these repressed memories; when memories return as pictures the task of therapy is easier than if returning as thoughts. Bartlett's memory research showed visual image is followed by sense of confidence that surpasses what should be there.

The fact that patients had to be compelled to remember was offered by Freud as evidence against the idea that the memories were suggested. The patients initially would deny the reality of their memories, which Freud used in saying that we should not think that patients would falsely accuse themselves. In letter to Fleiss, he presented the conflict theory, which he presented in 1905 in Three Essays on Sexuality and later in My Views...on Etiology of Neurosis.

In 1905 Freud indicated he was unable to distinguish fantasy from true reports (and did not deny the existence of the latter). Freud often reconstructed the "memories" from dreams, transference, signs, symptoms, fantasies, etc. They were not produced as conscious memories, and it was Freud who inferred the sexual abuse. From signs of distress he took evidence of proof.

Freud presented his theory to his patients and then sought confirmation.

Freud asks us to abandon historical for narrative truth. The problems with Freud's first theory became worse with his second theory. In Introductory Lectures Freud states that opponents say his treatment talks patients into confirming his theories. He relies on the patient's inner reality confirming the theoretical ideas given to him. Success depends on overcoming internal resistance, however. The danger in leading a patient astray by suggestion has been exaggerated, because the analyst would have had to not allow the patient to "have his say." Freud denied strongly ever having done this.

Incorrect interpretations would not be accepted by the patients, and if believed would be suggestion. Brunbaum, another writer, said that this doesn't mean acceptance of a faulty idea won't occur. Both Milton Erickson and especially Pierre

Janet reported cases in which suggestions were used to give benign memories to replace malignant ones.

Freud also viewed patient resistance to his interpretations as evidence that the interpretations were correct. Thus both resistance and acquiescence were thought to be validating. Popper's critiques using philosophy of science note that this makes his theory untestable.

Freud could not distinguish between the patient's reluctant acceptance of the truth and reluctant acceptance of a suggestion.

Contemporary theorists struggle less than Freud did with the problem of suggestion and suggestibility (and Freud did not have available the research on those areas!) Emotional upheaval that accompanies "insight" is readily taken to be validating. It may be true that bad memories are repressed, but that doesn't mean that all bad memories are true.

Treatment groups focus on recalling memories and sharing memories with others in the group, not on current relationships. Hermann states that the group provides powerful stimulus for remembering. The group, of course, is reinforced by others remembering. Repeatedly considering the possibility of abuse can increase the sense of familiarity.

Current views expressed by some clinicians that certain symptoms and syndromes (eating disorders, etc.) indicate early sexual trauma are similar to Freud's theory of hysteria. In these proposals, the inability to recall abuse becomes evidence that it occurred; and it tallies with the patient not having a sense of remembering.

Because some believe it is necessary to bring memory to light for cure to occur, there is a tendency to believe the reports of early childhood abuse.

Recognizing that some "memories" may have been a product of a therapist's suggestion helps prevent untoward effects. Modern therapists recapitulate Freud's "slip" when they do not acknowledge the role of suggestion.

Endorsing repression does not commit us to a belief that recovered memories must be accurate in all particulars. A memory that is repressed does not escape the usual kinds of degradation of memory.

And just because the material comes from unconscious sources, or has emotional accompaniments, it doesn't mean it is true. (Bowers gave an example of his dream that Israel and Venezuela shared a common border, which was rectified by his waking awareness of the Atlantic Ocean and the Mediterranean. He noted that nothing like the Atlantic can be called upon if the dream is that one's parent molested oneself at the age of six.)

Ian Hacking, in *Rewriting the Soul*, labels a more fundamental indeterminacy (for the historical past itself). Bathing rituals in childhood can be redescribed as abuse, which determines the historical past rather than describing it. It is thus easier to justify abuse if the event is something that can be reinterpreted. For example, the conflicts of adolescents with their parents, may be reinterpreted later if personality problems continue. If in adulthood one concludes that abuse occurred, then bathing rituals can be reinterpreted as if it were earlier abuse, as if the abuse has continued for years.

NOTES

1:

Social-cognitive position is that suggestions for amnesia lead to motivated attempts to forget, and the sense of nonvolition is due to attributional error. Neo-dissociation position is that post-hypnotic amnesia is activated by suggestions, and material is not available to consciousness. Ss may mistakenly attribute their amnesia to their own efforts, or to their imaginings. (See their analgesia studies.)

Used a recall organization paradigm. Ss learn 16 item categorized word list, then are given suggestion to forget one category. After suggestion is canceled, Ss are told to report again. In their heart rate study, highs were amnesic and recalled words not targeted for amnesia. Highs weren't trying to forget, even though they were experiencing things happening cognitively during the waiting period.

Study II. One group of highs engaged in a distraction task, which would prevent their participating in task relevant practice. Ss in the distraction condition recalled fewer words, just as in the standard hypnosis condition. However, their subjective report indicated they had even a stronger feeling that something had happened beyond their volition or control than did Ss in the standard hypnotic condition.

It appears that task relevant thoughts and imagery reported by Highs are not necessary. They are co-suggestion effects. See Hargedon, Bowers, & Woody in similar work, on analgesia. However, during the recall period Highs did not work as hard as the Lows in trying to remember according to both their self-reports and the heart rate measure.

Freyd, Jennifer J. (1994). Betrayal-trauma: Traumatic amnesia as an adaptive response to childhood abuse. Ethics and Behavior, 4.

Betrayal-trauma theory suggests that psychogenic amnesia is an adaptive response to childhood abuse. When a parent or other powerful figure violates a fundamental ethic of human relationships, victims may need to remain unaware of the trauma not to reduce suffering but rather to promote survival. Amnesia enables the child to maintain an attachment with a figure vital to survival, development, and thriving. Analysis of evolutionary pressures, mental modules, social cognitions, and developmental needs suggests that the degree to which the most fundamental human ethics are violated can influence the nature, form, processes, and responses to trauma.

Schefflin, Alan W. (1994). Forensic hypnosis: Unanswered questions. Australian Journal of Clinical and Experimental Hypnosis, 22, 25-37.

Many courts have mistakenly identified hypnosis as more suggestive than eyewitness testimony or leading questions, and therefore these courts have applied unnecessarily restrictive rulings on hypnosis. The dangers of suggestion in eyewitness and interrogation cases pose reliability problems that are equally as great. In all situations, pre-trial evidentiary hearings on admissibility of 'suggestive' testimony is essential. Expert testimony should be available to assist the judge. The forensic rules to date have failed to clarify some hard cases. In resolving these cases, courts are encouraged to adopt a case-by-case analysis rather than a total prohibition on hypnotically refreshed recollection. Courts have assumed conclusions about hypnosis that the laboratory experiments suggest are incorrect - juries are not overly persuaded by hypnosis testimony, there is no inevitable concreting effect and witnesses do not become impervious to cross-examination. Thus, the restrictive per se disqualification rules for hypnotically refreshed recollection are too severe

Woody, Erik Z. (1994, October). Cognitive-processing models of hypnotic dissociation. [Paper] Presented at the annual meeting of the Society for Clinical and Experimental Hypnosis, San Francisco.

#### NOTES

1:

Spanos contended that social psychology is an appropriate ground for hypnosis, and his work highlights the value of not taking things at face value (e.g. feelings of nonvolition).

I did this research with Ken Bowers. It addresses the question, does non-volition occupy a small role in hypnosis, or are hypnotic responses performed intentionally despite the hypnotized person's feeling of non-volition.

We did not rely on the research Subject's verbal report. When one exerts intentional effort to suppress a thought, the thought gets stronger. For example, when people try to comply with instruction not to think about white bears, they think about them repeatedly (Waitner's research).

Hypnosis suggestions are for amnesia (inability to remember), not intentional forgetting.

STUDY ONE. We used Waitner type instructions vs hypnosis in high and low hypnotizability Ss, to examine the role of intention in response. We used thinking about one's favorite automobile instead of a white bear as the task stimulus. Subjects were not to think about it for 2 minutes, but to press a button whenever a

thought about the automobile surfaced. There was another waking trial with suggestions; then hypnosis and re-testing.

Ss were undergraduates screened on Harvard Scale for hypnotizability and the Waterloo Stanford Group form. High hypnotizables scored 8 or more on both scales, lows scored 4 or less on both.

The variables recorded were total number of button presses, and average length of time per press. Analysis was by a 3 way mixed model ANOVA: high low, induction condition, and suggestion condition (blank mind vs. amnesia)

#### NOTES

1:

The classic suggestion effect implies involuntary behavior. A theory by Norman & Tim Shallice (published in a book on cognitive neuropsychology by Shallice) explains the classic suggestion effect in terms of underlying control processes.

There are 2 complementary systems: 1. contention scheduling (routine acts that don't require conscious control, activating schemas through environmental events and other schemas) for well learned habitual tasks. 2. supervisory attentional system - nonroutine actions in centralized processes, accessing unique information, operating only indirectly by modulating lower level control system, biasing their selection of schemas by system #1.

These two systems permit the sense of behavior being automatic or willed. The theory can be used to explain hypnotic nonvolition. For highs, hypnosis may partly disable System #2, dissociating lower levels of control and resulting in genuine changes in behavior because System #1 would be more enabled, triggered directly by co-active schemas and environmental stimuli. This increased dependence on a lower level of control would not rule out a wide range of behavior. It's mainly novel or very complex behaviors that would diminish, plus exercise of will.

The model also illuminates our understanding of behavioral rigidity and the tendency for thought/action to be triggered by [suggestions?]. Spontaneous voluntary behavior would be diminished. (See for example Orne's studies of the effect of apparent power outage during an experiment, in which high hypnotizable Ss did not move or leave the room but sat passively, whereas low hypnotizable simulating Ss simply got up and left.)

Also a weaker "supervisor" would lead to disinhibition of inappropriate or peculiar associations or behavior. In labs one sees few such triggers, although Hilgard observed drug flashbacks. The phenomena of hypnosis sequelae appear like a disinhibition of experiences.

Hypnotic analgesia follows this model too, an automatic and controlled processing of perceptual input.

Amnesia that follows hypnosis can be explained by this theory. Shallice has a model of how memory is affected: memory is a higher control system, enabling the handling of non-routine situations. Confronted by a nonroutine memory problem, the supervisory system formulates a model of what [the information] should look like, pulls out memories, and compares the model. If hypnosis interferes with the supervisor function it should interfere with memory (the description and verification phases) leading to [hypnotic amnesia?]. [With hypnosis one would predict]: 1. Poor access to memories requiring description (not overlearned material). Recall should demonstrate good cued memory but poor free recall. [It has been observed that] hypnotic amnesia selectively impairs free recall rather than recognition recall. 2. Hypnotized Ss should show poorer verification (the ability to discriminate irrelevant from correct associations). Many studies have shown this, with impoverished verification (e.g. the "discovery" of elaborate previous lives).

A dissociated control theory of hypnosis is thus possible, emphasizing a loss of control of supervisory system processes. It would implicate changes in frontal lobe processing. The essence of hypnosis, according to this approach, is the bypassing of executive control, and the frontal lobe is viewed as a center of executive control.

There are several ways that hypnosis suggests inhibition of frontal lobe functioning: 1. impoverishment of self initiated behavior 2. other-directedness 3. frontal amnesia (unable to distinguish true memories from irrelevant memories; prone to confabulation, especially when probed with false information) 4. poorer in temporal or sequential organization in memory.

How do we proceed to make this theoretical approach useful? We should do more neuropsychological studies, as Helen Crawford does. They emphasize the inhibition of frontal lobe functions.

Testable hypotheses arise: 1. Hypnotizable Ss should show the same kind of problem solving problems as frontal lobe patients. 2. Memory of hypnotized Ss should be like patients with frontal amnesia.

**1992**

**Barrett, Deidre (1992). Fantasizers and dissociaters: Data on two distinct subgroups of deep trance subjects. Psychological Reports, 71, 1011-1014**

The study delineated two subgroups of highly hypnotizable subjects. The first subgroup (fantasizers) entered trance rapidly, scored high on absorption (mean of 34 on the 37-item Absorption Scale), and described hypnosis as much like their rich, vivid, and very realistic waking fantasy life. None of the fantasizers experienced unsuggested amnesia, and 5/19 failed to produce suggested amnesia. Only 2/19 fantasizers described hypnosis as very different from their other experiences. The earliest memories of fantasizers were all identified as occurring before age 3, and before age 2 for 11 of 19. The second subgroup (dissociaters) took time to achieve a deep trance (unlike Wilson and Barber's fantasy-prone subjects, but they did achieve as deep a trance as fantasizers), experienced hypnosis as different from any prior experiences, and were more likely to exhibit amnesia for both hypnotic

experience and waking fantasies. None of the dissociaters described their waking imagery as entirely realistic, and the earliest memories in this group were all over the age of 3 (mean age - 5). Of the 15 dissociaters, 7 scored below the norm on the Absorption Scale (Mean - 26).

Crawford, Helen J.; Kitner-Triolo, Melissa; Clarke, Steven W.; Olesko, Brian (1992). Transient positive and negative experiences accompanying stage hypnosis. Journal of Abnormal Psychology, 101 (4), 663-667.

Frequency of positive and negative experiences accompanying stage hypnosis was assessed in follow-up interviews with 22 participants of university-sponsored performances. Most subjects described their experience positively (relaxing, interesting, exciting, satisfying, illuminating, and pleasurable), but some described it negatively (confusing, silly, annoying, and frightening). Five subjects (22.7%) reported partial or complete amnesia; all were highly responsive to the stage hypnosis suggestions. One subject was completely unable to breach amnesia and felt annoyed and frightened. Five subjects (22.7%) believed the hypnotist had control over their behavior. Participants (n=15) tested subsequently on the Stanford Hypnotic Susceptibility Scale, Form C (Weitzenhoffer & Hilgard, 1962) were mostly moderately to highly hypnotizable (M = 7.07), and the scores correlated significantly (r = .68) with the percentage of passed stage hypnosis suggestions.

#### NOTES

1:

Echterling and Emmerling (1987, American Journal of Clinical Hypnosis) conducted a follow-up of 18 people who participated in stage hypnosis at a university, within a month after the experience. Referring back to the hypnosis itself, 39% reported positive experiences, 39% reported both positive and negative experiences, and 22% (four people) reported 'strongly negative' experiences. The present study contacted subjects immediately after the stage hypnosis experience, either in person or by telephone. They completed both objective questions and open-ended questions referring to three time periods: after the hypnotic induction, during the hypnotic suggestions, and after the stage hypnosis had been terminated. Subjects were invited to come to the laboratory to be tested for hypnotizability, and 15 of the 22 did return for testing.

Of the 22 Ss, 4 had previously participated in stage hypnosis, one in laboratory hypnosis, and one had been hypnotized by her father. Of the 15 tested with the Stanford Hypnotic Susceptibility Scale, Form C: 7 were high hypnotizables (scoring 9-12), 7 were medium hypnotizables (scoring 4-8), and one was a low hypnotizable (scoring 0-3). Several people reported that they 'went along with' the hypnotist's suggestions, role playing rather than actually experiencing the suggestions.

"Most of the subjects found the experience positive: 86.4%, relaxing; 86.4%, interesting; 77.3%, exciting; 59.0%, satisfying; 54.6% illuminating; and 54.6%, pleasurable. Negative experiences were also reported: 36.4%, confusing; 36.4%, silly; 9.1%, annoying; and 9.1%, frightening. Only 1 subject reported the stage hypnosis experience as entirely negative.

**"The stage hypnotists told the participants about the suggestions at the end of the stage hypnosis performance and supposedly lifted amnesia. Despite this, some participants continued to experience partial or full amnesia for the suggestions. ...**

**"One participant reported complete amnesia even after the interview and was distraught, permitting only a telephone interview and not accepting an offer to be hypnotized at a later time to help recall what had been forgotten. ...**

**"... The interviewer told her what had been observed and attempted to breach the amnesia. The subject continued to report complete amnesia.**

**"Two other participants continued not to remember many of the suggestions but showed no major concern. Waking suggestions to breach amnesia were given, but no further information was obtained.**

**"Five participants reported feeling that the hypnotist had complete control over their behavior and that they could not resist the hypnotist's suggestions" (p. 664).**

**In their Discussion, the authors note that in general, when negative experiences occur, they tend to be mild and transient. None of the subjects in this investigation reported some of the negative sequelae reported in earlier literature (headaches, nausea, drowsiness). The few subjects who had strong cognitive distortions following hypnosis were highly hypnotizable, which also was observed in an earlier study published by the first author and her colleagues (Crawford, Hilgard, & Macdonald, 1982, *International Journal of Clinical and Experimental Hypnosis*).**

**Spontaneous post hypnotic amnesia is one example of cognitive distortion. The authors remarked on the rather high incidence of spontaneous amnesia for some specific suggestions (22.7%) , which was discovered when friends of the subjects described to them what they had done on stage. In an experimental study by Hilgard and Cooper (1965), only 7% of student subjects had spontaneous amnesia (though 35% had amnesia following suggestions for posthypnotic amnesia). Furthermore, in the Hilgard and Cooper study, hypnotizability correlated with suggested amnesia but not with spontaneous amnesia. Cooper (1972) reviewed the literature on posthypnotic amnesia and observed that spontaneous occurrence is less frequent than suggested amnesia.**

**Explanations of spontaneous amnesia include ideas that high hypnotizables who experience it are significantly different from those who do not (Chertok, 1981; Weitzenhoffer, 1989); or that it is due to expectancy (Kirsch, 1985); or that it is found in people with a tendency for dissociation in and out of hypnosis, or people who may be prone to repression or dissociative and post-traumatic stress disorders. For reviews of these issues, see Kihlstrom, 1987; Kihlstrom & Hoyt, 1990; Frankel, 1990; Nemiah, 1985; Spiegel, 1990; Spiegel & Cardena, 1991).**

**The authors note that stage hypnotists, while they may otherwise be ethical, do not provide information to subjects to correct misperceptions about hypnosis. For example, in this study 22.7% of the subjects believed, after the stage hypnosis experience, that the hypnotist had control over their behavior and they couldn't resist the suggestions. "Appropriate guidelines for stage hypnosis (see also Crawford et al., 1982) include screening out participants who are in therapy or counseling, correcting misperceptions about hypnosis among the participants before the hypnosis begins, screening subjects prior to hypnosis, avoiding embarrassing or upsetting suggestions, providing dehypnosis instructions to those who do not remain**

in hypnosis (or are asked to leave the performance), terminating fully the hypnotic experience, removing all amnesia suggestions and reviewing the events at the end of hypnotic experience, and remaining available afterward for further questions" (p. 666).

Faller, Kathleen Couborn (1992, Summer). Can therapy induce false allegations of sexual abuse?. The Advisor (Published by American Professional Society on the Abuse of Children), 5 (3), 3-6.

#### NOTES

1:

"Concern about the impact of therapy on children's accounts of sexual abuse should be understood in the context of two phenomena: (1) the adult need to deny that children are sexually abused, and (2) adult identification with the alleged abuser. These phenomena operate at both individual and societal levels" (p. 3).

"Research related to impact of stressful situations on children's ability to recall provides mixed results, some studies finding children are less accurate if the event is traumatic (Peters, 1991) and others finding they are not (Goodman, Reed, & Hepps, 1985).

"Research reveals that it is rare for children to falsely allege that they have been touched in their private parts. In one study, a substantial proportion of children who experienced genital and anal touch during a physical examination by a doctor did not volunteer this information when asked general questions about the examination. The majority of children in the study revealed genital and anal touch only when they were asked specific questions like, "Did the doctor touch you there?" (Saywitz, Goodman, Nicholas, & Moan, 1991)" (pp. 3-4).

"Clarke-Stewart and her colleagues (1989) have demonstrated that children's interpretation of ambiguous events can be manipulated and altered by an authority figure who insists upon a particular interpretation (see also Lindberg, 1991)" (p.4).

"In sum, the research suggests that older children are likely to provide more complete unassisted disclosure than younger children. Younger children may need more memory cues in the form of specific questions than older children. Therapists are much more likely to find false negatives than false positives. Finally, therapists should be aware of the possibility the child may identify the wrong person. ... Generally, however, the research indicates that concern about the contaminating effects of therapy on children's recollections of sexual abuse is exaggerated" (pp. 4-5).

"Research indicates that the proportion of fabricated reports may be higher in the divorce scenario than in other contexts (Faller, 1990; Jones & Seig, 1988). Studies suggest most false reports are made by adults, not children (Jones & McGraw, 1987; Jones & Seig, 1988)" (p. 5).

"Clinical research (Sorenson & Snow, 1991) and experience (Faller, 1988) indicate that for most children, revealing sexual abuse is a process which occurs over time. A typical pattern is one in which children begin with the least overwhelming experience and gradually disclose more and more as their accounts are accepted and believed" (p. 5).

**"[In conclusion]... therapists should be aware of the findings from research on children's memory and suggestibility. This research indicates that there are vulnerabilities which should be taken into account during therapy" (p. 6).**

**Levitan, Alexander A. (1992). The use of hypnosis with cancer patients. Psychiatric Medicine, 10, 119-131**

**Hypnosis has proven to be extremely valuable in the treatment of cancer patients. Specific applications include: establishing rapport between the patient and members of the medical health team; control of pain with self-regulation of pain perception through the use of glove anesthesia, time distortion, amnesia, transference of pain to a different body part, or dissociation of the painful part from the rest of the body; controlling symptoms, such as, nausea, anticipatory emesis, learned food aversions, etc.; psychotherapy for anxiety, depression, guilt, anger, hostility, frustration, isolation, and a diminished sense of self-esteem; visualization for health improvement; and, dealing with death anxiety and other related issues. Hypnosis has unique advantages for patients including improvement of self-esteem, involvement in self-care, return of locus of control, lack of unpleasant side effects, and continued efficacy despite continued use.**

**Murrey, Gregory J.; Cross, Herb J.; Whipple, Jim (1992). Hypnotically created pseudomemories: Further investigation into the 'memory distortion or response bias' question. Journal of Abnormal Psychology, 101 (1), 75-77.**

**In order to study whether pseudomemories represent actual memory distortions or are a result of response bias, 60 highly hypnotizable subjects and subjects from the general population were divided into 4 experimental groups and were tested for pseudomemory manifestation after receiving a false suggestion. Of the 4 groups of subjects, 3 were offered a monetary reward as a motivation to distinguish false suggestion from the actual occurrence. Pseudomemory manifestation was found to be significantly higher among subjects not offered a reward than among subjects who were offered such a reward. The implications of these findings are discussed**

**NOTES: The article contains a review of the literature through 1989. The study tested the hypothesis that when it is important to distinguish fantasy from reality in a hypnosis experiment, subjects can do so—a position presented by Spanos and McLean (1986). They used a verifiable event to test for pseudomemory production, as in research published by McCann and Sheehan (1988). Subjects were 30 high hypnotizable and 30 unselected students.**

**Subjects were shown a videotape of a mock robbery scene. The next week, Groups A, B, and C heard audiotapes "to enhance memory," but in addition to motivating statements about "trying to remember" certain details, the tapes included misleading information (e.g. "Remember the color of the hat the robber was wearing" when in fact there was no hat on the robber). Subjects in these groups were 'influenced.'**

"Both highly hypnotizable subject groups (Groups A and B) listened to the audiotape after being administered a 10-min hypnotic induction procedure (modified from that of Barber, 1969). Subject Group C listened to the audiotape without hypnosis. The control group, Group D, did not listen to the audiotape and was, therefore, classified as 'uninfluenced.'"

A week later subjects responded to multiple-choice and yes-no or true-false questions about the robbery scene. The yes-no question about whether the robber was wearing a hat served as the dependent variable, a measure of pseudomemory. "To motivate subjects to report the truth rather than to follow any perceived expectations of the experimental of social context, we offered subjects in Groups B, C, and D a monetary reward if they achieved the most correct answers on the quiz (according to the videotape). The reward was offered just before administration of the quiz to ensure that no collusion between the subjects could occur. Group A was not offered any such reward" (p. 76).

"The number of subjects in Group A (hypnotized, influenced, no reward) who reported the false information at posttest (12) was significantly greater than that of Group B (hypnotized, influenced, offered reward.... However, the difference in incidence of pseudomemory between Group B and the control group, Group D (not hypnotized, uninfluenced, offered reward), was nonsignificant" (p. 76).

Table 1 Incidence of Pseudomemory Per Group -----

	False suggestion	Group A	Group B	Group C
Group D				
result (n=15)	(n=15)	(n=15)	(n=15)	-----
Accepted	12	6	7	3
Rejected	3	9	8	12

---- Note. Group A = hypnotized, influenced, not offered reward.

Group B = hypnotized, influenced, offered reward.

Group C = not hypnotized, influenced, offered reward.

Group D = not hypnotized, not influenced, offered reward.

In the Discussion, the authors wrote, "Because the only variable among these groups was the reward, a reasonable conclusion from the findings is that pseudomemories manifested by the subjects were (for the most part) not actual memory distortions. Presumably, the reward provided the subjects in Group B an incentive to 'report the truth' and a disincentive to give biased reports on the basis of the perceived expectations of the social or experimental context. Thus these data suggest that pseudomemory effects or the occurrence of the pseudomemory phenomenon among highly hypnotizable subjects can be minimized by providing a motivation to subjects to give unbiased reports.

"A major implication of these findings is that researchers should control for response bias resulting from perceived social demands or from leading test designs when they conduct pseudomemory research. Of further concern is the fact that a number of researchers contend that hypnotic interrogation of eye-witnesses can greatly facilitate the creation of pseudomemories (Levitt, 1990; Loftus, 1979; Orne, 1979; Putnam, 1979), and therefore hypnosis either should not be allowed in the courtroom or should be strictly controlled. Yet in light of our findings, response bias

may be a confound in pseudomemory research, and thus researchers need to be cautious when making inferences to specific situations from data obtained in an experimental setting.

"Despite the existence of a confound of (unmeasured) differences in hypnotizability between the two groups, there was no significant difference between Group B and the control group (Group D). This suggests that if response bias is controlled for, there may not be significant differences in manifestation of pseudomemories between highly hypnotizable subjects and subjects representative of the general population. However, further research is needed in order to address this question" (pp. 76-77).

Perry, Nancy W. (1992, Summer). How children remember and why they forget. The Advisor (Published by American Professional Society on the Abuse of Children), 5 (3), 1-2; 13-16.

#### NOTES

: "'My memory is the thing I forget with.' (a child's definition, cited in Grossberg, 1985, p. 60)" (p. 1).

"Unlike the simpler forms of memory retrieval, free recall is strongly age-related... the recall skills of preschool children develop gradually" (p. 2). "...in some cases, younger children can provide more accurate information than adults (Lindberg, 1991). For example, if an event is particularly salient (as sometimes happens in cases of trauma), recall may be exceptionally good (Brainerd & Ornstein, 1991; Lindberg, 1991)" (p. 13).

"Children have limited ability to use memory strategies. For this reason, children often know more than they can freely recall" (p. 13).

"The use of rehearsal as a memory strategy is almost automatic for adults. ... Ten-year-olds also commonly use rehearsal to aid memory. Young children, however, have not mastered rehearsal (Harris & Liebert, 1991).

"Another memory strategy is imagery, which involves (1) mentally picturing a person, place, or object, or (2) visually associating two or more things that are to be remembered. Children develop imagery much later than other memory strategies. Indeed, some people never learn this memory strategy (Flavell, 1977)" (p. 13).

"... stress alone may not impair memory processes. Indeed, stress can lead to arousal, heightened attention, and improved encoding (Deffenbacher, 1983). However, stress that results from intimidation may lead to either impairment in encoding or problems in recalling or reporting memories" (p. 14).

"Because the effect of suggestion on material that has been well encoded tends not to be significantly different across age groups (Cohen & Harnick, 1980), it may be that younger children's inferior performance on suggestive tasks results from inferior encoding" (p. 15).

#### 1991

Bowers, Kenneth S. (1991). Dissociation in hypnosis and multiple personality disorder. International Journal of Clinical and Experimental Hypnosis, 39, 155-176.

The first part of this paper examines the concept of dissociation in the context of hypnosis. In particular, the neodissociative and social psychological models of

hypnosis are compared. It is argued that the social psychological model, in describing hypnotic enactments as purposeful, does not adequately distinguish between behavior that is enacted "on purpose" and behavior that serves or achieves a purpose. 2 recent dissertations (Hughes, 1988; Miller, 1986) from the University of Waterloo are summarized, each of which supports the neodissociative view that hypnotic behavior can be purposeful (in the sense that the suggested state of affairs is achieved) and nonvolitional (in the sense that the suggested state of affairs is not achieved by high level executive initiative and ongoing effort). The second part of the paper employs a neodissociative view of hypnosis to help understand the current epidemic of multiple personality disorder (MPD). In particular, it is argued that many symptoms of MPD are implicitly suggested effects--particularly prone to occur in persons who have a lifelong tendency to use dissociative type defenses. The present author believes that this account is easier to sustain conceptually and empirically than the current view, which states that a secondary (tertiary, etc.) personality accounts for the striking phenomenological discontinuities experienced by MPD patients.

#### NOTES

1:

As an example of the fact that behavior that serves a purpose is not always performed on purpose, the author cites not falling out of bed while sleeping, and waking up in response to signals from the bladder to go to the bathroom. Lower levels of control can be dissociated from executive initiative and/or monitoring. "Since the experience of volition is closely tied to executive initiative and effort, suggested behaviors that bypass such initiative and effort are typically experienced as nonvolitional" (p. 157). Dissociated control occurs under waking conditions also, as when one dials a very familiar phone number rather than the one that they intended to dial. In this case, the behavior that is enacted is not what one consciously intended.

Miller's dissertation, also published as Miller & Bowers, 1986, is described on p. 158 ff. Without hypnosis, cold pressor pain (cold water immersion) reduced accuracy of performance on a multiple choice vocabulary test 35%. Both hypnotic analgesia and cognitive pain management strategies were equally effective in reducing pain of cold pressor test (and both interventions were more effective for high than for low hypnotizable Ss). However, the cognitive strategy group showed an additional drop of 30% in vocabulary performance from pre- to posttreatment cold water immersion (despite successfully reducing their pain). In the hypnosis condition, lows showed only a slight additional decrease (8%) while highs showed a slight (10%) increase in their vocabulary performance from pre- to posttreatment immersion. Thus, the effect of hypnosis in pain control "does not depend on S's utilization of high-level cognitive strategies. Rather, hypnotic analgesia seems to involve the dissociated control of pain--that is, control which is relatively free of the need for high- level, executive initiative and effort. ... Because hypnotic analgesia minimizes the degree of executive initiative and ongoing effort required to reduce pain, however, it seems inappropriate to view such reductions as something achieved on purpose" (p. 161).

Hughes' dissertation is described on p. 162 and ff. Instead of performance decrement on a cognitive task like vocabulary testing, she used increased heart rate as an index of cognitive effort. If heart rate increases when Ss successfully use hypnotic imagery, that would confirm the social psychological view that "suggested effects are achieved by this kind of ongoing allocation of high-level cognitive force or work" (p. 162).

Highs and lows were hypnotized and administered three trials of neutral and three trials of fearful imagery in counterbalanced order. Each imagery trial lasted 1 minute, after which Ss rated vividness of imagery, effort required, and amount of fear experienced.

Average imagery vividness was higher in highs than lows, for both neutral and fear imagery. For lows the correlation between heart rate increases and ratings of cognitive effort were .54 (neutral imagery) and .49 (fear imagery). For highs, the correlations were -.05 (neutral) and -.52 (fear). Thus, "for low but not high hypnotizable Ss, we find the predicted positive relationship between a cardiac indicator of cognitive effort and the ratings of cognitive effort involved in producing neutral imagery" (p. 163).

"First, for low hypnotizables engaged in fear imagery, ratings of effort are correlated .66 with ratings of fear. In other words, the more low hypnotizable Ss work to produce a fearful image, the more frightening the image is. Second, for high hypnotizables engaged in fear imagery, the correlation between ratings of fear and effort is minus .68-- indicating that the less effort highs report in producing fear imagery, the more frightened they become. Finally, for high hypnotizables, the correlation between ratings of fear and heart rate increase is .59, indicating that the more fear high hypnotizable Ss experience when engaged in fear imagery, the more their heart rate increases (the comparable figure for low hypnotizables is .16)" (p. 164).

The authors discuss why the pattern of correlations is different for people high and low in measured hypnotizability, and summarize the implications of both Miller's and Hughes' research. Both investigations indicate that, at least for high hypnotizable people, less initiative and effort are required to effect a response to hypnotic suggestion than one would expect. They show how behavior can be both purposeful and nonvolitional (in the sense of not exhibiting conscious intention and strategic efforts). By noting that the sense of nonvolition that accompanies a response to suggestion is an actual alteration in executive control, they provide a model for dissociative psychopathology such as MPD. For although executive control is dissociated, these experiments do not suggest that there is a second executive system or 'personality' that is responsible for the behavior.

Patients diagnosed with MPD have very high measured hypnotizability (Bliss, 1984). In fact, they seem to engage in self hypnosis, withdrawing into a trance or a dissociated state (Bliss, 1984). The authors quote Wilson & Barber (1983) as indicating that highly hypnotized, fantasy-prone normal individuals may become so absorbed in a character being imagined that they lose awareness of their own identity.

The authors offer a neodissociative account of MPD: "People prone to MPD are very high in hypnotic ability and are, therefore, vulnerable to the suggestive impact

of ideas, imaginings, and fantasies; what is more, they are high in hypnotic ability because they have learned to use dissociative defenses as a way of dealing with inescapable threat-- such as physical and sexual abuse (Kluft, 1987). ... Fantasied alternatives to reality (including a fantasied alter ego ... ) can become increasingly complex and differentiated. Gradually, these fantasied alternatives begin to activate subsystems of control more or less directly--that is, with minimal involvement of executive level initiative and control. Such 'dissociated control' of behavior does not necessarily eliminate consciousness of it, though one's actions are apt to be experienced as increasingly ego-alien. If and when the activating fantasies and resulting behaviors become sufficiently threatening, however, they can also be repressed into an unconscious (i.e., amnesic) status, thus further separating high-level executive and monitoring functions from the dissociated, ego-alien aspects of oneself. The fully realized result of this process is an individual who is subject to profound discontinuities in his or her sense of self. ... The experience of behaving in an outwardly uncharacteristic manner requires only that subsystems of control are more or less directly activated by ideas and fantasies in a manner that effectively bypasses executive initiative and control" (pp. 168-169).

923, Bowers, 1992 NOTES: Tart allegedly taught ESP skills based on reinforcement, using a machine that projected display and gave feedback immediately, so the subjects could learn to anticipate the picture better. But the picture presented next was time-linked to the S's response (so S could learn it).

1987 Behavioral and Brain Sciences review, with 2 target articles, makes one doubt strength of findings. ESP research doesn't distinguish between description of an observation and it's proposed cause.

MPD shares with ESP a tendency to predispose toward a certain explanation. Feeling like one has a separate personality leads to finding evidence for one. But an MPD account is wrong-headed because the diagnosis misconstrues a notion of personality, which is a developmental concept (a pattern of thought, feeling, and behavior). Mischel's (1968) account of human functioning competed with trait theory, so "personality" concept became extraneous.

Defining personality in terms of one's experiences or beliefs about oneself has led to further problems, encouraged by the descriptive approach of DSM III (which depends on patient reports). Drew Weston distinguished between the self and self representation. One can't argue that a computer programmed to describe itself is the same as it's descriptions.

Personality can't be reduced to person's beliefs about themselves. A secondary personality cannot be reduced to bizarre experiences a person believes are due to a second personality. Clinicians do not accept as valid the beliefs of a paranoid schizophrenic; or of an anxious neurotic. With multiple personality disorder (MPD) the patient becomes the expert and the clinician the student.

William Smith's 1986 SCEH paper: case study of patient who was convinced her problems were due to unresolved problems from a previous life. He didn't challenge her system but still worked with her successfully, communicating respect without validating her belief.

Advocates of MPDs think the observation that it is associated with high hypnotizability indicates great dissociation; critics think the association indicates

great suggestibility. There is a historical parallel: Mesmer probably didn't suggest seizure-like episodes, but implicit suggestions for seizures were probably partially responsible. Mistaken attribution permitted Mesmer to see this as validation of his theory of animal magnetism.

Clinicians are not the only ones to "suggest" MPD syndrome. High profile cases are in the media. We should also remember Orne's 1959 research showing that students who received false information a week earlier in lecture on hypnosis showed the behavior when they were hypnotized.

Janet's disaggregation (dissociation) theory said hysterics and hypnotized people responded to ideas dissociated from the main stream of consciousness. So his contemporaries thought that spontaneous amnesia was a defining feature of hypnosis; yet it is not thought to be so in our era. The idea may have circulated in Janet's time, by popular culture.

MPDs are always highly suggestible so can respond to circulating accounts in the media, and every account that reaches the media can influence these people.

We could abandon the diagnosis of MPD in favor of Spiegel's "disorder of self integration." It is less provocative, does not imply any clinical benefit in the benefits of seeking out more personalities. This might reduce the incidence of this disorder, or likelihood that a suggestible person would develop the disorder iatrogenically.

**1991**

**Davidson, T. M.; Bowers, K. S. (1991). Selective hypnotic amnesia: Is it a successful attempt to forget or an unsuccessful attempt to remember. Journal of Abnormal Psychology, 100, 133-143**

Subjects in two experiments learned a 16-item, 4-category word list and were then administered hypnotic suggestions to be amnesic for all the words in one of the categories. Even when selective amnesia was completely successful, subjects in both experiments revealed a high level of recall for words not targeted for amnesia; moreover, these words were recalled in a highly organized, category-by-category fashion. Evidently, attention to relevant retrieval (i.e., organizational) cues does not oblige recall of words targeted for amnesia. Forgetting in the presence of such powerful mnemonic cues seems to characterize hypnotic amnesia and some notes.

**NOTES**

The authors argue that mnemonic lapses of this kind represent a failed attempt to remember rather than a successful attempt to forget. Spontaneous forms of forgetting as well.

**Spiegel, David; Cardena, Etzel (1991). Disintegrated experience: The dissociative disorders revisited. Journal of Abnormal Psychology, 100 (3), 366-378.**

Presents proposed changes to the dissociative disorders section of the 4th edition of the Diagnostic and Statistical Manual of Mental Disorders (DSM-IV) and reviews the concept of pathological and nonpathological dissociation, including empirical findings on the relations between trauma and dissociative phenomenology and between dissociation and hypnosis. The most important proposals include the

creation of 2 new diagnostic entities, brief reactive dissociative disorder and transient dissociative disturbance, and the readoption of the criterion of amnesia for a multiple personality disorder diagnosis. Further work on dissociative processes will provide an important link between clinical and experimental approaches to human cognition, emotion, and personality.

1990

Gwynn, Maxwell I.; Quigley, Celia; Perlini, Arthur; Glatt, Richard; Spanos, Nicholas P. (1990, August). Eyewitness testimony: Effects of hypnotic interrogation and witness preparation. [Paper] Presented at the annual meeting of the American Psychological Association, Boston.

NOTES

1:

There is notable absence of empirical research on the effects of witness preparation on subsequent testimony. The present study investigates the separate and combined effects of hypnotic recall procedures and witness preparation on subjects' confidence in, and maintenance during cross-examination, of mug-shot identifications.

Session 1: Subjects viewed a 65 second videotape of a mock crime involving a shooting. The offender in this video was a male approximately 40-50 years old, whose face was partially obscured by the brim of a baseball cap.

Subjects were then taken individually to another room, where a second experimenter presented them with a series of five photographic mug shots. Half of the series contained the mug shot; the other did not. Subjects indicate if any portrayed the offender and then to rate their confidence in their identification.

Subjects for Session 2 were randomly assigned to one of two conditions:

Hypnotic condition ... followed by "reliving" instructions modeled after Reiser's procedures used in training police detectives.

Nonhypnotic condition ... Each subject was then presented with the mug shot lineup and rated their confidence as in Session 1 with the same second experimenter.

Subjects who in Session 2 identified any mug shot as portraying the offender returned about one week after for a mock courtroom appearance. Subjects were randomly assigned to either a "prepared" condition, or a "nonprepared" condition, with the restriction of equal numbers of offender-present vs. offender-absent lineups and hypnotic vs. nonhypnotic subjects in each condition ... The subject-witness was questioned by the third same experimenter under direct examination and then cross-examined by a fourth experimenter in the role of defense attorney.

Subjects in the prepared condition were given pointers concerning their courtroom appearance. These pointers included counseling to answer all of the questions fully, to speak in complete sentences, and to present themselves confidently.

The videotapes of the subjects' testimonies were then shown to independent blind raters who rated the degree of confidence displayed by the subject-witness at two points, first after direct examination, and again after cross-examination.

To summarize the results: 1) As in a number of previous studies, eyewitness confidence was unrelated to mug shot identification accuracy. 2) The use of hypnotic techniques as practiced by many police investigators did not lead to an increase in

the frequency or accuracy with which subjects identified a mug shot as portraying a previously viewed offender. 3) Again consistent with previous research, the use of hypnosis did lead to an increase in eyewitness confidence, without a corresponding increase in accuracy, and this confidence increase was correlated with pretested levels of hypnotic susceptibility. 4) Contrary to the speculation of researchers such as Orne, Laurence & Perry, hypnotic procedures did not lead to the creation of unshakable witnesses who were impervious to cross-examination. And, 5) The usual practice of pre-trial preparation of witnesses did lead to a resistance of witnesses to be broken down under cross-examination.

In conclusion, the key factor found to affect eyewitness confidence and mug shot identification was not the use of hypnotic memory enhancement techniques, but rather the usual practice of pre-trial witness preparation.

Spiegel, David; Cardena, Etzel (1990, October). New uses of hypnosis in the treatment of posttraumatic stress disorder. Journal of Clinical Psychiatry (Supplement), 51, 39-43.

Vietnam veterans with PTSD and those abused as children have above average hypnotizability. Hypnosis provides controlled access to memories that may otherwise be kept out of consciousness. New uses of hypnosis with PTSD victims involve coupling access to the dissociated traumatic memories with positive restructuring of those memories. Hypnosis can be used to help patients face and bear a traumatic experience by embedding it in a new context, acknowledging helplessness during the event, and yet linking that experience with remoralizing memories, such as efforts at self-protection, shared affection with friends who were killed, or the ability to control the environment at other times. In this way, hypnosis can be used to provide controlled access to memories that are then placed into a broader perspective. Patients can be taught self-hypnosis techniques that allow them to work through and thereby reduce spontaneous, unbidden, intrusive recollections. Weekes, John R.; Lynn, Steven Jay (1990). Hypnotic suggestion type, and subjective experience - the order-effects hypothesis revisited: A brief communication. International Journal of Clinical and Experimental Hypnosis, 38, 95-100.

In a replication and extension of Field, Evans, and Orne's (1965) research, no support was found for the hypothesis that suggestion order is related to hypnotic responding. Confirming earlier findings, subjects were no more responsive to suggestions ordered from easy-to-difficult than they were to suggestions ordered from difficult-to- easy. Measures of subjective involvement in suggestions, involuntariness, and archaic involvement with the hypnotist were no more sensitive to order effects, nor were order effects more apparent with subjects who received direct versus indirect suggestions. Confirming earlier research, direct suggestions did facilitate suggestion-related involuntariness and response to the hypnotic amnesia item after cancellation, whereas indirect suggestions enhanced fears of negative appraisal by the hypnotist. Thus, authoritative suggestions enhance responding to a cognitive-delusional item relative to more permissive suggestions.

Finally, female subjects were more involved in suggestions than were males, particularly in response to more difficult tests items.

Ganaway, George K. (1989). Historical versus narrative truth: Clarifying the role of exogenous trauma in the etiology of MPD and its variants. Dissociation, 2, 205-220.

The author notes a current trend toward viewing multiple personality disorder (MPD) and its variants as a form of chronic post-traumatic stress disorder based solely on exogenous childhood trauma, and cautions against prematurely reductionistic hypotheses. He focuses on Kluft's Third Etiological Factor, which includes the various developmental, biological, interpersonal, sociocultural, and psychodynamic shaping influences and substrates that determine the form taken by the dissociative defense. He hypothesizes a credibility continuum of childhood and contemporary memories arising primarily from exogenous trauma at one end, and endogenous trauma (stemming from intrapsychic adaptational needs) at the other. The author offers alternative multidetermined explanations for certain unverified trauma memories that currently are being accepted and validated as factual experiences by many therapists. He describes some potentially deleterious effects of validating unverified trauma memories during psychotherapy, and recommends that the MPD patients' need for unconditional credibility be responded to in the same manner as other transference-generated productions.

1989-1990

Kunzendorf, Robert G. (1989-90). Posthypnotic amnesia: Dissociation of self-concept or self-consciousness?. Imagination, Cognition and Personality, 9, 321-334.

Two studies of posthypnotic amnesia tested predictions derived from the 'source' monitoring theory of self-consciousness. Experiment 1 tested the prediction that posthypnotic source amnesia is irreversible, because hypnosis attenuates self-consciousness of whether one's sensations have an imaginal source or a perceptual source. In this initial study, recall amnesia was reversed by posthypnotic cueing with a prearranged signal, but source amnesia was not reversed by such cueing. Experiment 2 examined whether the cued reversal of recall amnesia is attributable, in part, to the hypnotic attenuation of self-conscious 'source monitoring' and, in part, to the reversal of recall criteria: from a criterion rejecting 'seemingly imaginary' or 'sourceless' memories, to a criterion accepting 'sourceless but familiar' memories. In this latter study, posthypnotic recall amnesia was breached when subjects were instructed to trust their seemingly imaginary memories, but not when they were instructed to try harder to remember [emphasis removed from quoted text].

NOTES

1:

Authors discuss a dual memory theory. The first memory system is prominent in

early childhood, and is a system in which are organized and evoked by persons, locations, and emotions. Such memories are not easily "transportable" outside the original experience. These memories are accessed through images of face and place, actions, or feelings. The second memory system begins to develop in early childhood, is verbally mediated, and stores experiences in narrative form. Such memories are accessible through verbal interaction, and can be reviewed and shared with others verbally. For a small child, to access all of a memory one would need to tap into both memory systems. The authors suggest that the first memory system continues to be available throughout one's life, especially when strong emotion was associated so that verbal cues are not attached. [This has implications for retrieval of "lost" memories using imagery-based approaches like hypnosis.]

Schuyler, Bradley A.; Coe, William C. (1989). More on volitional experiences and breaching posthypnotic amnesia. International Journal of Clinical and Experimental Hypnosis, 37, 320-331.

: Highly responsive hypnotic subjects, who were classified as having control over remembering (voluntaries) or not having control over remembering (involuntaries) during posthypnotic amnesia, were compared with each other on four physiological measures (heart rate, electrodermal response, respiration rate, muscle tension) during posthypnotic recall. Two contextual conditions were employed: One was meant to create pressure to breach posthypnotic amnesia (lie detector instructions); the other, a relax condition, served as a control. The recall data confirmed earlier findings of Howard and Coe and showed that voluntary subjects under the lie detector condition recalled more than the other three samples that did not differ from each other. However, using another measure of voluntariness showed that both voluntary and involuntary subjects breached under lie detector conditions. Electrodermal response supported the subjects' reports of control in this case. Physiological measures were otherwise insignificant. The results are discussed as they relate to (a) studies attempting to breach posthypnotic amnesia, (b) the voluntary/involuntary classification of subjects, and (c) theories of hypnosis.

#### NOTES

1:

The authors suggest that subjects observe themselves not remembering (i.e. not reporting memories) and conclude that they therefore could not remember. Such subjects, they say, are deceiving themselves in so far as they could remember if they were to direct their attention to salient cues.

Spanos, Nicholas P.; Lush, Nancy I.; Gwynn, Maxwell I. (1989). Cognitive skill-training enhancement of hypnotizability: Generalization effects and trance logic responding. Journal of Personality and Social Psychology, 56 (5), 795-804.

Compared low-hypnotizable subjects who simulated hypnosis, underwent cognitive skill training, or served as no-treatment controls to subjects who scored as high hypnotizables without training (natural highs) on response to analgesia, age-regression, visual hallucination, selective amnesia, and posthypnotic suggestions.

Subjects who attained high hypnotizability following skill training (created highs) did not differ from natural highs on any response index. Natural and created highs scored lower than simulators but higher than controls on the behavioral and subjective aspects of test suggestions. Simulators, however, were significantly less likely than natural highs or skill-trained subjects to exhibit duality responding or incongruous writing during age regression or transparent hallucinating. Results suggest that the hypnotic responses of natural and created highs are mediated by the same cognitive variables and that enhancements in hypnotizability produced by skill training cannot b

Van Denberg, Eric J.; Kurtz, Richard M. (1989). Changes in body attitude as a function of posthypnotic suggestions. International Journal of Clinical and Experimental Hypnosis, 37, 15-30. e adequately explained in terms of compliance. Hypothesized that highly hypnotizable subjects who remained amnesic for posthypnotic suggestions to improve body attitude would show greater changes than subjects who were not amnesic. Subjects given simulating instructions were used as a comparison group to assess experimental demands. 48 females were screened with the Harvard and assigned to one of 4 conditions: (a) high hypnotizable with amnesia suggestions, (b) high hypnotizable without suggested amnesia, (c) low hypnotizable simulator with amnesia, and (d) low hypnotizable simulator without suggested amnesia. A fifth group was formed of those high hypnotizable subjects who remembered the suggestion despite instructions to the contrary. The Body Attitude Scale (Kurtz, 1966) was administered prior to and 3 days after the experimental suggestions. Results generally demonstrated that high hypnotizable amnesic subjects manifested the greatest attitudinal and phenomenological changes as a result of the posthypnotic suggestion, although conclusions were tempered by performance of simulating subjects. The implications for hypnosis research and clinical practice are discussed.

#### NOTES

1:

"The hypothesis that hypnotized subjects would report greater positive changes in affect, self-esteem, and social functioning than simulators was tested using a brief structured questionnaire. An analysis of Subjects responses to the questionnaire while with the 'blind' research assistant (simulators in role) revealed number significant differences between groups (N = 48) on six of the seven questions. ... An analysis of Subjects' responses to the questionnaire while being debriefed by the primary investigator (simulators out of role) revealed significant differences among groups (N = 48) on three of the seven questions. ... High hypnotizable subjects with maintained amnesia demonstrated a strong tendency to be the most responsive of all groups of subjects on the first and second assessment. In contrast, the high hypnotizable Ss for whom amnesia 'broke down' reported the fewest phenomenological changes of any of the five groups during the first assessment, and comparatively few during the second assessment. Also of note is that once out of their role, simulators in both conditions dramatically reduced their reporting of positive change" (pp. 23-24).

"Moreover, a closer examination of the data demonstrated that phenomenological and behavioral differences in the groups did appear at several points during the experiment. For example, the 10 high hypnotizable subjects told to explicitly remember the suggestion did so, while 3 of the 10 simulators in this condition claimed to have forgotten it. On debriefing, these Subjects reported they did this because they believed 'really hypnotized subjects wouldn't be able to remember anything, even if they were told they could.' Further, no simulator in the amnesia condition reported they could recall the suggestion, in contrast to the high hypnotizable subjects, 44% of whom said they did remember it. With regard to phenomenological differences, simulators stated during debriefing with the primary investigator that they intentionally faked changes on BAS, and that they experienced no true effects from the suggestion for positive body attitude change. In contrast, high hypnotizability amnesic subjects reported global, pervasive changes in their mood and self-esteem that went beyond specific alterations in attitudes toward their appearance. By comparison, high hypnotizable subjects told to remember the suggestion reported greatly increased self-absorption and acute awareness of the suggestion, 'sort of like a broken record in my head'" (pp. 25-26).

"As shown by the present study, amnesia maintenance can be quite problematic. Of 18 high hypnotizable subjects for whom amnesia was suggested, only 10 remained fully amnesic for the suggestion after 3 days. In addition, those 8 subjects for whom amnesia 'broke down' showed minimal shifts on BAS, or in reports of phenomenological changes. Such frequent amnesia failure has been reported by other researchers, although the effectiveness of the suggestion is not always so compromised" (p. 26).

Van der Kolk, Bessel A.; Van der Hart, O. (1989). Pierre Janet and the breakdown of adaptation in psychological trauma. *American Journal of Psychiatry*, 146, 1530-1540.

Reviews Janet's investigations into mental processes that transform traumatic experiences into psychopathology. He was the first to systematically study dissociation as the crucial psychological process with which the organism reacts to overwhelming experiences and show that traumatic memories may be expressed as sensory perceptions, affect states, and behavioral reenactments. Janet provided a broad framework that unifies into a larger perspective the various approaches to psychological functioning which have developed along independent lines in this century. Today his integrated approach may help clarify the interrelationships among such diverse topics as memory processes, state-dependent learning, dissociative reactions, and posttraumatic psychopathology.

1988

Nadon, Robert; D'Eon, Joyce; McConkey, Kevin M.; Laurence, Jean-Roch; Perry, Campbell (1988). Posthypnotic amnesia, the hidden observer effect, and duality during hypnotic age regression. *International Journal of Clinical and Experimental Hypnosis*, 36, 19-37

The present study ought to explore potential response differences to a suggestion for posthypnotic amnesia between those high hypnotizable Ss who do and those who do not manifest the hidden observer effect. In line with the hypothesis that Ss who

responded to the hidden observer suggestion are more highly engaged in cognitive monitoring of their experience and behavior (Nogrody, McConkey, Laurence, & Perry, 1983), it was predicted that these Ss would recall more Stanford Hypnotic Susceptibility Scale, Form C (Weitzenhoffer & Hilgard, 1962) hypnotic items, and in greater detail, following the reversal of amnesia than would their no-hidden observer counterparts. In this regard, both the quantity and the quality of posthypnotic recall was examined in 15 high, 11 high-medium, and 11 low hypnotizable Ss. Data on posthypnotic recall from low and high-medium hypnotizable Ss revealed the comparability of the present sample to samples of other studies that have investigated posthypnotic recall using standardized hypnotizability scales. Contrary to prediction, hidden observer Ss recalled significantly fewer hypnotic items and in less detail. Similar results were found when high hypnotizable Ss were dichotomized with respect to the presence or absence of duality in age regression (Perry & Walsh, 1978). Results are discussed in terms of implications for future research

## NOTES

1:

Spanos and colleagues attribute amnesia to directing attention away from the target material; others "emphasize individual differences and subjective experiences over and above Ss' interpretations of, and responses to contextual demands" (p. 20).

Evans & Kihlstrom (1973) pose a 'disrupted retrieval' hypothesis, stating that it is a result of retrieval functions rather than acquisition or storage processes (because so easily reversed), and there is considerable support for this. A number of studies show that partially amnesic Ss have disorganized temporal sequencing in their recall of hypnotic events (and the disorganization of recall appears to be related to the suggestion for posthypnotic amnesia and not to hypnosis per se, as it isn't observed in Ss who haven't received a suggestion for post hypnotic amnesia).

Two studies of videotape playback support the disrupted retrieval hypothesis and the hypothesis that what high hypnotizable Ss' recall is qualitatively different from what other Ss recall (McConkey & Sheehan, 1981; McConkey, Sheehan, & Cross, 1980). 1/3 of the amnesic Ss in both studies "acknowledged their hypnotic behavior when watching the playback, while spontaneously reporting that they were unable to comment on the corresponding subjective experiences" (p. 21). None of the simulators made this behavior/experience distinction, and McConkey & Sheehan (1981) suggested that different memory retrieval mechanisms may exist for behavior vs. experience.

Hilgard (1973, 1977, 1979) has suggested that mental functioning may be regulated by a hierarchy of cognitive control systems rather than by a single mental apparatus such as consciousness--the neo-dissociation theory. He uses the metaphor of a hidden observer to describe how Ss with hypnotic analgesia may be 'aware' of pain outside of their immediate conscious awareness. He suggests that the hypnotic analgesia process is like that of posthypnotic amnesia, since the information is 'temporarily unavailable' for retrieval in both cases.

In the present study the authors developed a scoring system to assess quality of recall in responses to post hypnotic amnesia suggestion. They scored details (bits) recalled, as well as the conventional number of test items recalled.

Ss were screened by Harvard and modified SHSS:C, to yield 15 high hypnotizable Ss (9-12), 11 high-medium Ss (8-10), 11 low Ss (1-3). Amnesia data were gathered from the SHSS:C sessions. The hidden observer effect was assessed in a subsequent session. Raters classified the 15 highs as containing 6 with hidden observer experience and 9 with duality of experience in age regression.

The hidden observer instructions were different from Hilgard; they stated that "just as there are bodily processes such as heart rate, blood pressure, and temperature control that are not fully represented in consciousness, there also may be a hidden part of the person of which the hypnotized person is unaware ... [and] that this part may be registering the pain (administered by a Take-Me-Along electrical stimulator) that is not accessible to the hypnotized part during analgesia" (p. 25). Contrary to expectations, "the hidden observer Ss gave evidence of experiencing greater residual amnesia (Kihlstrom & Evans, 1977) than their no-hidden observer counterparts" (p. 30).

The authors note in their discussion that this research provides further evidence of the heterogeneity of response pattern of highly hypnotizable people, in respect to passing very difficult test items, and they provide a review of that literature. They remark on the need to investigate cognitive style differences of Highs outside the hypnosis context, just as cognitive style differences have been studied comparing Highs to Lows. "Differences among Ss of varying hypnotic abilities have been found on measures of 'absorption' (Tellegen & Atkinson, 1974); 'imaginative involvement' (J. R. Hilgard, 1970, 1979); 'fantasy proneness' (Wilson & Barber, 1982); imagery abilities (Perry, 1973; Sutcliffe, Perry, & Sheehan, 1970); preference for an imagic cognitive style (Isaacs, 1982; Nadon, 1984, 1985); and sleep and dreaming patterns (Belicki & Bowers, 1982; Evans, 1977; Gibson, 1985; Nadon, 1985). An extension of this type of work to the study of high hypnotizable Ss should lead to heuristic findings concerning the nature of hypnosis and the different ways that high hypnotizable Ss experience the suggested subjective alterations in perception, memory, and mood (Orne, 1980) that are associated with high hypnotic responsiveness" (p. 31). For example, perhaps the no-hidden observer Ss prefer an 'absorption' style and the hidden observer Ss prefer a 'dissociative' style as different pathways into hypnosis.

The results of this study combined with a study by Laurence, Nadon, Nogrady, & Perry ("Duality, dissociation, and memory creation in highly hypnotizable subjects," published in *International Journal of Clinical and Experimental Hypnosis*, 1986, 34, 295- 310) "may point to a complex relationship among types of suggestion (e.g., hidden observer, pseudo-memory, & amnesia), and indices of specific cognitive style (e.g., duality in age regression)" (p. 32). However, measurement error cannot be ruled out.

"As with memory processes within hypnotic contexts, individual differences in hypnosis need to be explained within a broader framework. Hypnotic responses do not occur in isolation of individuals' abilities, beliefs, preferred thinking styles, and past experiences. As with the study of cognitive style differences among individuals differing in hypnotizability, the study of daily life experiences among high hypnotizable Ss who do and those who do not give evidence of dissociative type

phenomena in hypnosis may shed further light on the mechanisms implicated in hypnotic responding" (p. 33).

**Spanos, Nicholas P.; Cross, Wendi P.; Menary, Evelyn; Smith, Janet (1988). Long term effects of cognitive-skill training for the enhancement of hypnotic susceptibility. British Journal of Experimental and Clinical Hypnosis, 5 (2), 73-78.**

Twelve initially low susceptible subjects, who scored in the medium or high susceptibility range on the Carleton University Responsiveness to Suggestion Scale (CURSS) following skill training, were posttested 9 to 30 months later with a group version of the Stanford Hypnotic Susceptibility Scale, Form C. Skill trained subjects scored significantly higher on behavioral and subjective dimensions of the Stanford Hypnotic Susceptibility Scale, Form C than low susceptible untrained control subjects who were posttested after an equivalent interval. Furthermore, the posttraining CURSS scores of the skill trained subjects were matched to those of subjects who received the same CURSS scores without training. Matched subjects were posttested on the Stanford Hypnotic Susceptibility Scale, Form C after only a brief delay. Skill trained and matched subjects failed to differ significantly on Stanford Hypnotic Susceptibility Scale, Form C susceptibility dimensions, but skill trained subjects showed higher levels of suggested amnesia than matched subjects. These findings support the idea that hypnotic susceptibility is modifiable and that training induced gains in susceptibility can be enduring

**Spanos, Nicholas P.; Gwynn, Maxwell I.; Della Malva, C. Lori; Bertrand Lorne D. (1988). Social psychological factors in the genesis of posthypnotic source amnesia. Journal of Abnormal Psychology, 97 (3), 322-329.**

Three experiments assessed the role of social psychological variables in source amnesia. Experiment 1 found that low-hypnotizable subjects instructed to simulate partial amnesia were more likely to exhibit source amnesia than high-hypnotizable hypnotic or task-motivated subjects. Experiment 2 found equivalent rates of source amnesia in low-hypnotizable simulators and high-hypnotizable hypnotic subjects. In addition, the findings of Experiment 2 failed to support the idea that the instructions for partial amnesia given to simulators cued for the occurrence of source of amnesia as well as for the occurrence of partial amnesia. In Experiment 3, preliminary instructions that legitimated source amnesia as a role-appropriate response produced significantly more posthypnotic source amnesia than did neutral or no instructions. Together, the findings of the 3 experiments support the relation of source amnesia to experimental demands and subjects' expectations.

**Hilgard, Ernest R. (1987). Research advances in hypnosis: Issues and methods. International Journal of Clinical and Experimental Hypnosis, 35, 248-264.**

There are substantial areas of agreement upon the classical phenomena of hypnosis, illustrated by what we now have learned about hypnotic talent, amnesia, hallucinations, analgesia, and dissociative processes. While genuine advances in knowledge about hypnosis have been made in recent decades, differing orienting

attitudes have kept some controversy alive, particularly in the interpretation of empirical findings. Differences of interpretation of the phenomenal and behavioral facts are to be expected in the present stage of developmental, cognitive, and social psychology.

## NOTES

1:

The author writes of the "domain of hypnosis" as within the larger domain of social psychology (because it is usually interpersonal); cognitive psychology (because of alterations in perception, imagination, memory, and thought); developmental and personality psychology (because of individual differences); and physiological psychology (because of neurophysiological aspects).

In terms of what we know about hypnotic talent, he notes that high hypnotizability is not generally associated with psychopathology; that it may however be associated with a personality measure called absorption; and that there may be some inherited ability (Morgan, 1973). In the author's view, hypnosis is no longer considered simply a response to suggestion, since imagination and/or fantasy are very important.

In reviewing evidence of posthypnotic amnesia the author writes, "Subtleties in language require making careful distinctions among concepts such as compliance, suggestion, compulsivity, belief, self-deception, automaticity, the voluntary, the involuntary, and a happening. If these distinctions are glossed over, the choice of words (e.g., substituting compliance for response to suggestion) may give the impression that a finding departs more widely from conventional views than it does. We, too, have found that Ss used varied strategies or skills during amnesia, but this need not deny augmentation by suggestion.

"It takes genuinely high Ss to illustrate truly high posthypnotic amnesia... Many of the truly high hypnotizable individuals cannot break amnesia, no matter how hard they try" (p. 253).

Regarding the evidence for hypnotic hallucinations and trance logic, the author suggests that trance logic is not a clear concept because the Subject is capable of good logic while tolerating some inconsistencies. "It is ordinary logic to assume that if your hallucination is your own construction, it is you who can influence it by your own wishes. In the rare cases of transparent or diaphanous hallucinations there is still an 'out there' quality. People who report that they see wispy ghosts also see them as 'out there,' so that they qualify as hallucinations. The distinction appears to be one of perception and perception-like experiences within hypnosis rather than of logic" (p. 256).

In reviewing the evidence for hypnotic analgesia, the author acknowledges that pain relief is available with other kinds of interventions, or by using other kinds of psychological processes, but that does not diminish the contribution of hypnosis (which has a long and impressive clinical history). Following laboratory studies, it is noted that "the amount of alleviation of pain through hypnosis is positively correlated with the hypnotizability of the candidate for pain reduction. This result is not universally accepted, because some clinicians are convinced that those unsuccessful in hypnotic pain reduction are resisting hypnosis" (p. 256-257). In the present paper he acknowledges but does not review physiological literature on hypnoanalgesia.

Regarding the concept of dissociation, the author indicates that he considers it a more useful concept than the concept of trance or hypnotic state "when a person is only slightly or moderately involved in hypnosis ... . The advantage is that dissociations, as compared with altered states, can be described according to limited or more pervasive changes in the cognitive or motor systems that are being activated or distorted through suggestion in the context of hypnosis. Perhaps when all-inclusive enough, such changes can justify the use of the term trance or altered state, but I believe that these terms should be used, if at all, only for those for whom the immersion in the hypnotic experience is demonstrably pervasive" (pp. 258-259). The author goes on to describe his initial discovery of the 'hidden observer' in an experimental context, and to relate the 'hidden observer' to others' earlier observations of a secondary report of an experience previously concealed from S's consciousness (Binet, 1889-1890/1896; Estabrooks, 1957; James, 1899; Kaplan, 1960). "The issues are still being worked on, but as in the case of trance logic the heart of the problem is not whether to speak of a hidden observer, but to recognize that there may be cognitive distortions in hypnosis even while some more realistic information is being processed in parallel, so that everything is not reportable by S" (p. 260).

Radtke, H. Lorraine; Thompson, Valerie A.; Egger, Lori A. (1987). Use of retrieval cues in breaching hypnotic amnesia. Journal of Abnormal Psychology, 96 (4), 335-340.

We conducted this study to determine whether hypnotically amnesic subjects would breach amnesia when forced to attend to powerful retrieval cues. Following a standard hypnotic induction procedure, 113 subjects attempted to recall a 48- item word list. The list consisted of instances of taxonomic categories presented in blocked format and was presented only once. A forced-recall procedure required subjects to recall 48 items even if that involved guessing. Next, 85 subjects were administered an amnesia suggestion and recalled the list a second time. The remaining 28 subjects served as controls and recalled the list a second time without the intervening suggestion. On Trial 3, the breaching trial, subjects were given the 12 category names and were required to recall 4 items under each. Finally, the suggestion was canceled for subjects in the suggestion condition, and all subjects completed a final cued recall. Subjects in the suggestion condition who showed amnesia on the second trial breached completely on Trial 3. We argue that the task demands prevented them from using the cognitive strategies that, under other circumstances, maintain amnesia. Limitations of the present study and suggestions for further research are discussed.

Silva, Christopher E.; Kirsch, Irving (1987). Breaching hypnotic amnesia by manipulating expectancy. Journal of Abnormal Psychology, 96 (4), 325-329.

Prior to hypnotic induction, subjects selected for high hypnotizability and ability to experience hypnotic amnesia were read one of two expectancy manipulations designed to convince them that deepening of hypnosis either would or would not

allow them to breach amnesia. After memorizing a list of six words, subjects heard a hypnotic induction, an amnesia suggestion, a challenge to remember, a trance-deepening procedure, and a second challenge to remember. On the first challenge, subjects in both conditions demonstrated considerable and equivalent degrees of amnesia. Following the trance-deepening procedure, subjects in the amnesia-expectancy condition displayed even more amnesia, whereas 80% of the Ss in the memory-expectancy condition completely recovered their memory of the word list. The data demonstrates that for most subjects in whom hypnotic amnesia can be elicited, it can be completely breached by manipulating Ss' expectancies.

Spanos, Nicholas P.; McLean, Joanne; Bertrand, Lorne D. (1987). Serial organization during hypnotic amnesia under two conditions of item presentation. Journal of Research in Personality, 21, 361-374.

Hypnotic and nonhypnotic subjects learned a 16 item list of unrelated words using either a standard presentation order (all items presented in the same order on all trials) or an incremental order (on Trial 1 only the first item was presented, on Trial 2 the first item followed by the second, etc.). Following criterion learning, the hypnotic subjects were administered an amnesia suggestion and challenged to recall, while nonhypnotic subjects engaged in a distraction task while attempting to recall. Hypnotic and nonhypnotic subjects who exhibited reduced recall (i.e., nonrecallers) showed equivalent decrements in seriation on the amnesia/distraction trial. Incremental presentation produced initial levels of seriation higher than those of standard presentation. Among nonrecallers, the incremental presentation was associated with a substantially larger reduction in seriation than was the standard procedure. Theoretical implications are discussed.

Spanos, Nicholas P.; de Groh, Margaret; de Groot Hans (1987). Skill training for enhancing hypnotic susceptibility and word list amnesia. British Journal of Experimental and Clinical Hypnosis, 4 (1), 15-23.

Subjects who pretested as low on hypnotic susceptibility received either cognitive skills training aimed at inculcating positive attitudes and interpretations concerning hypnotic responding, or no treatment. Trained subjects scored significantly and substantially higher on subjective and behavioral dimensions of susceptibility than controls. A second posttest assessed amnesia for a previously learned word list. Trained subjects showed more word list amnesia than either no treatment controls or subjects who had been matched to the trained subjects in terms of posttest susceptibility. Theoretical implications for theories of hypnotic susceptibility are discussed

**Davidson, Thomas McCabe (1986, January). Recall organization and volitional/non-volitional experiencing in posthypnotic and intrahypnotic amnesia: Inattention versus dissociation hypotheses (Dissertation, University of Waterloo). Dissertation Abstracts International, 47 (7), 3103-B.**

**"Two studies are reported which seek to evaluate the relative merits of two differing hypotheses concerning the cognitive processes underlying suggested hypnotic amnesia. The inattention hypothesis maintains that amnesia effects are produced when subjects volitionally divert attention from relevant retrieval cues so that recall is inefficient. The dissociation position is that amnesic subjects are prevented from utilizing normally relevant retrieval cues by a dissociative barrier that blocks access to target memories -- a forgetting over which subjects experience no volitional control. The two hypotheses were evaluated by means of a selective amnesia suggestion in the recall organization paradigm. "In the first experiment, high, medium, and low hypnotic susceptible subjects were administered either hypnotic induction or task-motivating instructions. Results indicated that there was no disorganization of amnesia trial recall or forgetting of words not targeted for amnesia, contrary to predictions from the inattention hypothesis. "In the second experiment, high hypnotizable subjects received the selective amnesia suggestion in both posthypnotic and intrahypnotic conditions. Intrahypnotic subjects were also separated into one group that received a ten second interval between the administration of the amnesia suggestion and the amnesia trial, and another group that had a delay between the suggestion and the amnesia trial equivalent to the posthypnotic group. Eight subjects who had testified that they were volitionally amnesic on a pre- screening amnesia test were also included in the posthypnotic condition. Again, the results indicated no recall disorganization or reduction in recall of words not targeted for amnesia. Subjects also uniformly provided evidence that their amnesia was experienced as non-volitional. There was, however, evidence that some amnesiacs were aware during the amnesia trial of the specific category targeted for amnesia. "The most important finding of both experiments is that subjects may attend to normally relevant retrieval cues and yet continue to evidence amnesia. The evidence is therefore consistent with the dissociation hypothesis, but**

disconfirms the inattention account of hypnotic amnesia. It appears that the selective amnesia context effectively prevents the successful use of volitional forgetting strategies. (Abstract shortened with permission of author)" (p. 3103).

Meagher, Christopher Roberts (1986). Suggestion and posthypnotic amnesia: Altered context or altered state? (Dissertation, University of Oregon). Dissertation Abstracts International, 47 (n1-B), 409-410. (Order No. DA 8605846)

"Posthypnotic amnesia has been investigated in the past and subsequently alluded to as either role enacted behavior or evidence for an altered state of consciousness. In order to gain further understanding of the circumstances which facilitate amnesic behavior, an experiment was carried out which was designed to vary the usual context in which recall and recognition memory are observed during posthypnotic amnesia. The suggestion for posthypnotic amnesia was altered from its usual form in that specific suggestions for recall amnesia and recognition amnesia replaced the usual general suggestion for overall memory impairment. Some Ss received the amnesia suggestion before presentation of the stimulus material rather than after stimulus presentation. In addition to the usual verbal stimuli, nonverbal stimuli were used. "A group of 44 highly hypnotizable, undergraduate Ss was divided into four treatment conditions. Three groups were hypnotized and given instructions to repeat a list of nine words taken from the Rey Auditory Verbal Learning Test, and to copy the nine figures of the Bender Gestalt Test. A fourth group performed these tasks in a normal waking state. One hypnotic group was given prestimulus suggestions for recall and recognition amnesia. Another was given poststimulus suggestions for recall and recognition amnesia, and the third hypnotic group received no amnesia suggestions. The dependent measures consisted of the scores on tests of recall and recognition of the stimulus words and figures. "A repeated measures multivariate analysis of variance revealed significant effects for hypnosis /suggestion condition, type of stimulus, and type of test. Further analysis determined that the two hypnotic groups given amnesia suggestions did not differ from each other but did show significantly greater amnesia than did either the no suggestion hypnotic control group or the waking control group. Recognition performance was significantly better than was recall performance for all groups in both stimulus situations. Nonverbal recall was significantly better than verbal recall for the two control groups given no amnesia suggestion. There was no stimulus effect for any other group and testing condition. The results of this experiment are discussed in terms of theories of hypnosis and memory, contextual variables of the hypnotic situation, and previous germane research" (pp. 409-410).

Radtke, H. Lorraine; Spanos, Nicholas P.; Malva, C. Lori Della; Stam, Henderikus J. (1986). Temporal organization and hypnotic amnesia using a modification of the Harvard Group Scale of Hypnotic Susceptibility. International Journal of Clinical and Experimental Hypnosis, 34, 41-54.

The Harvard Group Scale of Hypnotic Susceptibility, Form A (Shor & E. Orne, 1962) was modified to permit better assessment of amnesia and changes in temporal

organization during amnesia. First, a baseline measure of recall was obtained before administration of the amnesia suggestion. Second, on the recall trial following cancellation of the suggestion, Ss recalled everything they could remember. Amnesia was assessed by comparing recall during the suggestion with recall before it and after it was canceled. Temporal organization was assessed by correlating the order of item administration with Ss' recall orders. Hypnotic susceptibility and amnesia were independently related to temporal organization. Overall, high hypnotizable Ss organized less than medium or low hypnotizables, and amnesics showed less temporal organization than nonamnesics, but neither of these variables interacted with recall trial. The results are discussed in terms of recent theories of hypnotic amnesia.

#### NOTES

1:

Subjects in general tended to use less temporal organization during the suggestion compared to the baseline and postsuggestion trials. Although they did not obtain a disorganization effect comparable to that found in the clustering studies (e.g., Spanos & Bodorik, 1977), the results "replicated past studies that found differences in the recall organization of high and low hypnotizables during an amnesia suggestion" (p. 50), while suggesting that "the previous findings were not due to hypnotic amnesia" (p. 50).

"The baseline differences replicated Schwartz (1980) who found similar differences between high and low hypnotizable Ss following a hypnotic induction procedure but in the absence of an amnesia suggestion. Since we also found differences posthypnotically, it is questionable whether the hypnotic induction procedure was a causal factor in the Schwartz study. Furthermore, the presence of such differences on the postsuggestion trial represents a failure to replicate Evans's (1980) finding of no differences between high and low hypnotizable Ss under comparable nonhypnotic conditions. The present results are also contrary to those of two other studies that found no differences between high and low hypnotizables on rho scores on the amnesia trial (Radtke & Spanos, 1981; St. Jean & Coe, 1981) and a recent study using word stimuli which found a significant correlation between hypnotizability and temporal organization only during the amnesia suggestion (Kihlstrom & Wilson, 1984). Taken together these studies suggest that temporal organization (at least when hypnotic experiences are recalled) varies as a function of hypnotizability and therefore may be attributed to an individual difference factor" (p. 50).

The authors go on to say they have replicated other studies (p. 50), noting that the Harvard may not be the best method for investigating this issue, and individual testing of memory may be better (p. 51).

Schacter, Daniel L. (1986). Amnesia and crime: How much do we really know?. American Psychologist, 41, 286-295.

Claims of amnesia occur frequently after the commission of violent crimes and can have a significant bearing on the outcome of criminal trials. This article considers the relation between amnesia and crime within the broader context of research on memory and amnesia and provides a critical evaluation of current knowledge

concerning the issue. Particular attention is paid to the problem of distinguishing between genuine and simulated claims of amnesia. It is suggested that reliable data concerning the nature of amnesic episodes that occur after the commission of a crime are sparse, and that there is as yet little evidence that genuine and simulated amnesia can be distinguished in criminal cases. The results of several laboratory studies are summarized that indicate that feeling-of-knowing ratings distinguished between genuine and simulated amnesia under conditions in which psychologists and psychiatrists did not.

Sheehan, Peter W.; Tilden, Jan (1986). The consistency of occurrences of memory distortion following hypnotic induction. International Journal of Clinical and Experimental Hypnosis, 34, 122-137.

The present study examined a range of circumstances for their effects on the vulnerability of hypnotic Ss to memory distortion. 26 high and 26 low hypnotizable Ss were tested individually in a design in which Ss received information that was either misleading or not misleading about a series of events depicting an apparent robbery. The information was presented prior to Ss being given hypnotic instructions, and low hypnotizability Ss were especially motivated for positive response in the session. Memory for the robbery was studied across a range of measures that included forced choice recognition, free recall, and response to leading questions. Results demonstrated predictably variable effects. The 2 groups performed appreciably differently in free recall, for example, while in recognition testing, data indicated that high and low hypnotizable Ss both incorporated misleading information into their memories to the same degree. Some implications of the data for the forensic context are discussed.

#### NOTES

1:

56 Ss were prescreened with Harvard Group Scale of Hypnotic Susceptibility, Form A, defining highs = 9-12, lows = 0-3. Used Loftus materials for testing memory (wallet snatching sequence, on a series of slides). Errors were classified as errors of fact, of inference, or conjectures. Highs had more intrusions that were errors of fact than lows did ( $p < .05$ ), confirming the earlier results published by Sheehan & Tilden, 1984. There was no significant association between hypnotizability level and intrusion of central detail (description of robber and victim), but 57% of highs and only 18% of lows intruded peripheral objects incorrectly into their own narrative reports (i.e. descriptions given of the surroundings),  $p < .01$ .

There were trends for high hypnotizable Ss to recall more objects correctly than low hypnotizable Ss during narrative reporting ( $p < .06$ ) and to recall more central objects ( $p < .06$ ), but not more peripheral objects. There may have been a loosening of criteria for memory among high hypnotizables, because they appeared to produce both greater accuracy and inaccuracy in recall of certain types of detail.

During the recognition testing, high hypnotizables exhibited significantly greater confidence in their responses than low hypnotizable Ss, but there was no group difference for accuracy. "Results for both tests of integration then (recognition and free recall) confirmed the prediction that hypnotic Ss incorporate false information into their memory, and the effect did not differentiate high from low hypnotizable Ss" (p. 131).

When a leading question implied that traffic lights were present in the scene, 34% responded in some way to that suggestion, and 20% said that they could see the lights in their minds eye; but 14% said that "although they could not see the lights, they nevertheless remembered they were there" (p. 132). Response to the leading question did not differ between high and low hypnotizable Ss.

In their discussion, the authors note that hypnosis did not enhance memory in this study. "Results overall suggest that hypnotic induction lowers the correspondence between confidence and accuracy. In the present study, hypnotic Ss were confident about their recall when the degree of accuracy of their reports suggested they should have been quite uncertain. Hypnotic instruction itself would appear, then, to establish conditions that spuriously facilitate a high degree of confidence in the reports that Ss produce.

"A major point to be made about the present study is that both general distortion and confidence effects observed here cannot necessarily be attributed to hypnosis. There was no independent comparison condition, for example, to contrast results for hypnotic Ss with results for Ss receiving no induction procedures. Effects, then, could be attributed to the hypnotic context as much as to the effects of induction per se, and context rather than state may be responsible for the vulnerability of hypnotic Ss that has been observed. The influence of context is seen at least in the clear evidence for an interaction between situational factors and hypnotizability. In free recall, hypnotizable Ss were more prone to distortions than un hypnotizable Ss, while in recognition, hypnotizable and un hypnotizable Ss were equally prone. Mode of testing is, therefore, a major contextual variable that is related to the nature of the distortion and confidence effects that can be observed. Present data further indicate that the hypnotic context is associated with memory distortion even in Ss who have little capacity for being hypnotized, but who are instructed to believe that they can, in fact, experience much of what is being suggested" (pp. 133-134).

Forensic implications need to be tempered because of difference between laboratory and real life, but practitioners nevertheless should be cautious. "While it is not true that hypnotized persons, by virtue of their hypnotizability level, will always distort their reports more obviously than nonhypnotic Ss, so as to bring their recollections into line with what is implied or suspected, parameters do exist that clearly increase the risks of distortion that can occur after hypnotic instruction. This is evidenced, for example, by the distinctive distortion effects that have been demonstrated for high hypnotizable Ss when they are given induction instructions and later requested to tell their story in their own way. Overall, the present data imply that the law needs to closely evaluate the impact of the different settings in which hypnosis takes place and the different ways in which misleading information can be communicated to persons who are later asked to testify. The potential risks of hypnosis--as well as its utility--will depend critically on how that information has been conveyed, and the way in which Ss' memories are tested" (pp. 134- 135).

Spanos, Nicholas P.; de Groh, Margaret M.; Bertrand, L. David (1986). Serial organization during posthypnotic amnesia using a modified version of the Stanford Hypnotic Susceptibility Scale. Psychological Reports, 58, 311-322.

A version of the SHSS:C modified for group testing was administered to 108 subjects. The final item on the scale was modified to enable (a) computation of a continuous amnesia score for each subject and (b) the measurement of serial organization on the recall trials during amnesia and after the cancellation of amnesia. Scores on the SHSS:C (computed without the amnesia item) and amnesia were significantly correlated. Furthermore, SHSS:C scores correlated significantly and negatively with three of four indexes of seriation during amnesia. Amnesia scores, however, correlated significantly with only one of the seriation measures, and in regression analyses the addition of amnesia to SHSS:C scores did not enhance prediction of any organization index. Methodological and theoretical implications are discussed.

Wilson, L.; Kihlstrom, J. F. (1986). Subjective and categorical organization of recall during posthypnotic amnesia. Journal of Abnormal Psychology, 95 (3), 264-73.

Conducted 2 experiments to determine the fate of organization of recall during posthypnotic amnesia. In both studies, amnesia suggestions were administered to undergraduate Ss of low, medium, and high hypnotic susceptibility who had learned a word list by the method of free recall while they were hypnotized. In Exp I (n = 44), words were unrelated to each other, and subjective organization was measured by raw and adjusted pair frequency. In Exp II (n = 59), words were drawn from various taxonomic categories, and category clustering was measured by repetition ratio, modified repetition ratio, and adjusted ratio of clustering. Results indicate that, compared to baseline levels, subjective organization and category clustering did not decrease reliably during the time the amnesia suggestion was in effect. Moreover, these aspects of strategic organization were not significantly correlated with the number of items recalled during amnesia. Both findings contrast with previous results concerning temporal organization of a word list memorized by the method of serial learning. Findings suggest that the disruption of retrieval processes in posthypnotic amnesia may be limited to certain organizational schemes. (43 ref).

1985

Coe, William C.; Yashinski, Edward (1985). Volitional experiences associated with breaching posthypnotic amnesia. Journal of Personality and Social Psychology, 48 (3), 716-722.

Highly responsive hypnotic subjects classified as having control over remembering (voluntaries) or not having control over remembering (involuntaries) during posthypnotic amnesia were compared during posthypnotic recall. Subjects reported their voluntariness after the experiment. Two contextual conditions were employed (2 x 2 design): a lie detector condition meant to create pressure to breach amnesia and a relax control condition. In contrast to earlier findings, the recall data showed that both voluntary and involuntary subjects breached under the lie detector condition compared with their counterparts in the relax condition; however, the degree of breaching was not great in any condition. The results are discussed as they

relate to studies attempting to breach posthypnotic amnesia and characteristics of the voluntary-involuntary dimension.

Eich, Eric; Reeves, John L.; Katz, Ronald L. (1985). Anesthesia, amnesia, and the memory/awareness distinction. Anesthesia and Analgesia, 64, 1143-1148.

Several studies have shown that surgical patients cannot consciously recall or recognize events to which they had been exposed during general anesthesia. Might evidence of memory for intraoperative events be revealed through the performance of a postoperative test that does not require remembering to be deliberate or intentional? Results of the present study, involving the recognition and spelling of semantically biased homophones, suggest a negative answer to this question and imply that intraoperative events cannot be remembered postoperatively, either with or without awareness.

#### NOTES

1:

"In this experiment, we attempted to apply the distinction between memory and awareness of memory to the question of whether adequately anesthetized and apparently unconscious patients can register and retain what is said in their presence during surgery. Prior research relating to this question has focused, for the most part, on the ability of postoperative patients to recall or recognize a specific item....The inference need not be drawn, however, that 'patients in so-called surgical planes of anesthesia cannot hear' (15, p. 89) or that anesthetized patients cannot encode and store in memory events that transpire during their surgery. The possibility remains that even though the effects of memory for intraoperative events may not--and probably cannot--be revealed in postoperative tests of retention that require remembering to be deliberate or intentional, such effects might be evident in the performance of tests that do not demand awareness of remembering.

"To explore the possible dissociation between memory and awareness of memory for intraoperative events, we modeled our experiment after a recent neuropsychological study by Jacoby and Witherspoon (5)" (p. 1143).

"...it appears that the prior presentation of a word has a substantial impact on its subsequent interpretation and spelling, regardless of whether or not the word is correctly classified as 'old' in a later test of recognition memory" (p. 1144).

"Approached from the standpoint of anesthesia theory and practice, the idea that recognition and spelling tap different memory processes or systems raises an interesting question for research. Specifically, suppose that during surgery, an anesthetized patient listens to a series of short, descriptive phrases, each consisting of a homophone and one or two words that bias the homophone's less common interpretation (e.g., war and PEACE, deep SEA). Suppose further that several days after surgery, the patient is read a list composed chiefly of old and new homophones (i.e., ones that either had or had not been presented intraoperatively) on two successive occasions. On one occasion, the patient is simply asked to spell each list item aloud; on the other occasion, the patient is asked to state aloud which list items he or she recognizes as having been presented during surgery. Given the situation sketched above, might the patient spell significantly more old than new homophones

in line with their less common interpretations, and yet fail to reliably discriminate between the two types of items in the test of recognition memory" (p. 1144).

Klatzky, Roberta L.; Erdelyi, Matthew H. (1985). The response criterion problem in tests of hypnosis and memory. International Journal of Clinical and Experimental Hypnosis, 33, 246-257.

Past experimental research on the effects of hypnosis on memory indicates both that hypnosis produces increases in correct recalls and that hypnosis produces increased vulnerability to misleading information and intrusions in recall. The present paper uses the framework of signal detection theory to account for this pattern of data. It suggests that the effects of hypnosis on memory cannot be ascertained from previous work, because of a general failure to discriminate between effects on the amount of information retrieved from memory and the criterion adopted by Ss for reporting what they remember.

#### NOTES

1:

Past experimental research indicates that hypnosis produces increases in correct recalls and as well as increased vulnerability to misleading information and intrusions in recall. This paper uses signal detection theory to account for the data. Signal detection theory describes performance as reflecting two underlying parameters--the information accessible to S at any point in time (designated as  $d'$ ) and the criterion adopted by S when making decisions about memory reports (report or decision criterion, response bias, or Beta). They review the recent literature on hypnosis and memory and conclude:

1. When the response output is not controlled, hypnotic instructions and/or hypnotizable have been found to produce increases in the number of correct recalls but this does not mean that the accessible information in memory has increased. What may be changing is the criterion for report.
2. When the response output is not controlled, hypnotic instructions and/or hypnotizable have been found to produce increases in incorrect recalls, i.e., intrusions, and compliance with leading questions, but this does not mean diminution or distortion of accessible memory ( $d'$ ). What may be changing is the criterion for report.
3. When response bias is controlled, hypnosis has been found to produce no enhancement of recognition but this does not imply that (a) Beta cannot change in recognition tests where it is allowed to vary, nor that (b) hypnosis has no effect on recall.
4. The proper experiment to determine whether hypnosis affects the accessibility of information in memory should place demands on the retrieval process and control the criterion for memory report.

The most decisive experimental outcome for the forensic situation would be a null or negative one: the demonstration that hypnosis does not enhance measures of memory accessibility. Then there would be no reason to use hypnosis to enhance memory.

1985-1986

Kunzendorf, Robert G.; Benoit, Michelle (1985-86). Spontaneous post-hypnotic amnesia and spontaneous rehypnotic recovery in repressors. Imagination, Cognition and Personality, 5 (4), 303-310.

The Salpêtrière school of hypnosis posited that true hypnotic effects occur spontaneously in people with repressive tendencies. Consistent with this early position, the current study indicates that both spontaneous amnesia after hypnosis and spontaneous recovery during rehypnosis are statistically associated with repression (but not with hypnotic suggestibility). In contrast, both suggested forgetting and suggested recovery are statistically associated with hypnotic suggestibility (but not with repression). Whereas the latter effects of suggestibility are attributable to the demand characteristics of hypnotic suggestions, the spontaneous effects of hypnosis on repressors' memories are not reducible to social psychological principles.

1985

Simon, Michael J.; Salzberg, Herman, C. (1985). The effect of manipulated expectancies on posthypnotic amnesia. International Journal of Clinical and Experimental Hypnosis, 33, 40-51.

The effects of manipulated S expectancy and direct suggestions for amnesia on posthypnotic amnesia were assessed. 120 undergraduate students were randomly assigned to 6 groups: negative expectancy (for amnesia)/suggestions (for amnesia); no expectancy/suggestions; negative expectancy/no suggestions; no expectancy/no suggestions; and 2 control groups. The results indicated that the expectancy manipulation had no effect on the occurrence of posthypnotic amnesia measured by the Stanford Hypnotic Susceptibility Scale, Form A (Weitzenhoffer & Hilgard, 1959), whereas suggestions for amnesia were found to have a significant effect. Hypnotized suggestion and no suggestion Ss remembered significantly less than Ss in the nonhypnotized control groups. The implications of the findings are discussed.

NOTES

1:

"The results of the study do not support Young and Cooper's (1972) earlier work which indicated that S expectancies play an important role in the occurrence of posthypnotic amnesia. [They do] support previous research (Hilgard & Cooper, 1965) which has shown that direct suggestions for amnesia play an important role in the occurrence of posthypnotic amnesia. It is also worth noting that forgetting was significantly greater for suggestion group Ss than for no suggestion Ss. In other words, the suggestion Ss could not remember as many items as the no suggestion Ss, even after the amnesia suggestions were lifted. This appears to be a replication of the 'residual amnesia' effect reported in previous studies (Hilgard & Hommel, 1961; Kihlstrom & Evans, 1977), in that Ss who showed a high level of initial amnesia (suggestion Ss) continued to display a persistence of the amnesia process, despite the cue to terminate amnesia" (p. 48).

"Although the nonstate theorists' argument cannot be completely dismissed, there are two points which tend to make the present findings particularly striking. Both concern the fact that the odds were actually stacked against the control group Ss remembering more than Ss in the hypnosis group, for reasons inherent in the design of the study. First of all, the control Ss were asked to engage in a set of routine and boring tasks. In contrast, the hypnosis group Ss were given instructions aimed at having them experience rather unusual phenomena which were significantly outside the realm of everyday experience. It seems logical to assume that such experience would be rather memorable. Second is the fact that the standardized scoring procedure which was used by the raters to score Ss' responses unavoidably favored the hypnosis group Ss. This was primarily because the number of acceptable responses was far greater for the hypnotized Ss, since in many cases a verbal description of the feelings or sensations which accompanied the task was sufficient to score the item as remembered. Thus, this finding suggests that the hypnotic state, in and of itself, may have had some inhibiting effect on memory. In other words, hypnotized Ss who did not receive any suggestions for amnesia may show more "forgetting" than nonhypnotized Ss due to some intrinsic characteristic of the hypnotized state. It is unlikely, however, that the extent of this "spontaneous" effect can ever be accurately determined because it will always be confounded by the internal expectations that Ss bring with them into the laboratory" (p. 49).

1984

Perry, Campbell (1984). Dissociative phenomena of hypnosis. Australian Journal of Clinical and Experimental Hypnosis, 12, 71-84.

Janet's concept of dissociation, Freud's notion of the Censor and Hilgard's multiple controls of consciousness are considered in relation to the hidden observer (HO) phenomenon. A review of reports of recent research, including that of the author and co-workers, indicates that the hidden observer effect occurs only in 40-50% of high susceptible subjects. It is speculated that subjects who show Hidden observer have maintained some contact with reality whilst those high susceptibles who do not show hidden observer are more deeply involved in hypnosis.

NOTES

1:

Author describes a series of experiments in their laboratory. Ss are double screened to select highly hypnotizable people, and accepted into the research only if they pass the amnesia item of SHSS:C and most of the other 11 items of that scale. Ss are told that hypnosis is a procedure which permits subjects to exercise various skills or abilities such as relaxation, imagination, imagery, absorption and selective attention--that everyone has some of these skills to varying degrees, and that hypnosis is one of many techniques (including yoga, etc.) for bringing out these skills and abilities. All sessions are videotaped for the Experiential Analysis Technique (EAT). The Hidden Observer (HO) procedure was modified so that E touched the S's shoulder lightly at the start of the item, and a second time to terminate the item. Whereas Hilgard used cold pressor pain, they used a mildly unpleasant shock provided by a Take-Me-Along electric stimulator.

Replying to Spanos and Hewitt (1980) in which data was interpreted as implying that the HO is an artifact of demand characteristics, "It struck me then, and still does, that people like Hilgard and ourselves, who believe that the HO is a phenomenon of hypnosis and not just some laboratory artifact, can only get it 40-50% of the time, whereas the investigators like Spanos and Hewitt, who believe it is all laboratory artifact, get the phenomenon almost 100% of the time. Usually it is the other way around, so it seems to me that if the HO is an artifact, it is unique in the history of psychology" (p. 77).

They found that all highs with the HO also reported subjective experiences similar to HO experience when they were not hypnotized. "For instance, one female subject who has the HO, insists that she is not hypnotized, despite compelling evidence to the contrary, because she feels the same way when she is not hypnotized. By contrast, another subject who is interested in creative writing reports HO type experiences when she is on a creativity binge and also when she is stoned" (p. 79).

They observed several consistent findings in their research: "(1) contrary to the belief that subjects who report HO's are more susceptible than those who do not, our findings are the reverse" (p. 79). The differences are not large enough to be significant, but that may be due to a ceiling effect on the scales since the subjects are already selected to be high hypnotizables. "(2) A second repeated observation is that when all the Ss were administered the HO instructions, they were given a second electric shock to the still analgesic hand, and asked to report the degree of pain they felt on a 1-10 scale where 1 = no pain and 10 = extreme pain. ... the HOs report having the HO experience and their pain reports on the 1-10 scale increase, in the manner described by Hilgard using cold pressor pain. The no HOS report no subjective difference, and their degree of analgesia actually increases" (p. 79).

The author describes further studies in which they obtained results in the opposite direction from what they had expected, based on the supposition that people who do not have the HO appear to set aside critical judgement more and to be more imaginatively involved. "So the finding of greater recall after reversal of amnesia for the no HOs both on number of items and on bits was a surprise" (p. 81). When they extended this research into the area of pseudo-memories, they found that "of the 8 subjects who had the HO, 7 of them believed the pseudo-memory was real. Of the 19 subjects who did not have the HO, only 6 of them accepted the pseudo-memory as real ... The effect was even stronger for duality in age regression. Of 12 subjects reporting duality, 10 reported the hallucinated noises as real; of the 15 with no duality, 3 accepted the reality of the pseudo-memory as actually having happened" (p. 81).

Spanos, Nicholas P.; Tkachyk, M.; Bertrand, L. D.; Weekes, J. R. (1984). The dissipation hypothesis of amnesia: More disconfirming evidence. Psychological Reports, 55, 191-196.

Hypnotic subjects were administered a suggestion to forget a previously overlearned word list. Before cancellation of the suggestion they were challenged twice to try and recall the words. Subjects in one group received a second challenge immediately after response to the first. Those in the second group were given a 15-min. delay before their second challenge. Subjects in both groups showed less amnesia after the

second challenge than after the first, but the length of delay between challenges had no effect on amnesia scores. These findings are inconsistent with the hypothesis that hypnotic amnesia involves an involuntary blockage of memory that decays spontaneously with time.

1983

Dillon, F. Richard; Spanos, Nicholas P. (1983). Proactive interference and the functional ablation hypothesis: More disconfirmatory data. International Journal of Clinical and Experimental Hypnosis, 31, 47-56.

According to the functional ablation hypothesis, memories for which amnesia has been hypnotically suggested do not interact with other information in memory. This hypothesis was tested in 2 interrelated experiments. In Experiment 1, Ss high and low in hypnotic susceptibility were administered a hypnotic induction procedure and tested on a Brown-Peterson (e.g., Wickens & Gittis, 1974) memory task designed to induce proactive interference (PI). Ss were exposed to 10 blocks of successive 3-word lists. Within each block, all words were strongly related, and, therefore, lists presented early in a block interfered with the retention of lists presented later (PI "buildup"). Following the "buildup" of PI, Ss were administered either a cue to be amnesic for the previous words of a block or a cue to relax. Contrary to the functional ablation hypothesis, the amnesia suggestion did not produce a "release" from PI in high susceptible hypnotic Ss. In other words, the amnesia suggestion did not prevent previously learned material from interfering with newly presented material. Experiment 2 demonstrated that the amnesia cues employed in the Brown-Peterson task produced a reversible recall deficit even though they failed to produce PI "release." These findings are consistent with the results of studies of the functional ablation hypothesis using the retroactive interference paradigms

1983

Geiselman, Ralph E.; Fishman, D. L.; Jaenicke, C.; Larnier, B. R.; MacKinnon, D. P.; et al. (1983). Mechanisms of hypnotic and nonhypnotic forgetting. Journal of Experimental Psychology: Learning, Memory, and Cognition, 9, 626-635.

40 undergraduates participated in 2 experimental sessions designed to study laboratory-induced amnesia, one using a standard hypnosis paradigm and one using a nonhypnotic directed forgetting paradigm. Two independent sources of variation were derived from the hypnotic amnesia data: retrieval inhibition and inhibition release. In the nonhypnotic directed-forgetting procedure, some items were cued to be either forgotten or remembered. At test, over 39% of the variance in the recall of the to-be-forgotten items could be accounted for by the inhibition and release constructs obtained with hypnosis. These relations between the 2 procedures were

not mediated by verbal ability (WAIS) or cognitive style (Hidden Figures Test). It is concluded that the mechanisms of forgetting involved in laboratory demonstrations of hypnotic and nonhypnotic amnesia are related, and the implication is that some of them are the same, namely, retrieval inhibition and inhibition release. Possible demand characteristics that accompany the hypnosis procedure were not apparent with the nonhypnotic procedure. Results provide evidence that hypnotically induced amnesia is not entirely the result of Ss' reactions to demand characteristics.

**Kihlstrom, John F.; Easton, Randolph D.; Shor, Ronald E. (1983). Spontaneous recovery of memory during posthypnotic amnesia. International Journal of Clinical and Experimental Hypnosis, 31, 309-323.**

Repeated testing of posthypnotic amnesia indicates that some Ss, initially responsive to the suggestion, show appreciable recovery of memory before the pre-arranged signal is given to cancel the amnesia. Comparison of Ss who received 2 successive memory tests during amnesia with others who received only a single test preceded by a distracting activity indicated that the recovery effect was attributable to the passage of time rather than to prior testing. There were wide individual differences in the extent of recovery, with some Ss maintaining a fairly dense amnesia on the second test. Those Ss who maintained amnesia were more hypnotizable, and showed a denser initial amnesia, than those who breached it. An analysis of subjective reports lent credence to the notion of partial response among some hypnotizable Ss who fail to meet a standard criterion of complete amnesia, and pseudoamnesia among some insusceptible Ss who appear to pass it. Some Ss reported voluntarily engaging in cognitive activity designed to induce forgetting, but these reports were related to neither the occurrence of initial amnesia nor its persistence. A failure of memory which reflects momentary disorientation upon transition from one mental state to another should be conceptually distinguished from a reversible amnesia initiated by hypnotic suggestion.

**Nogrady, Heather; McConkey, Kevin M.; Laurence, Jean-Roch; Perry, Campbell (1983). Dissociation, duality, and demand characteristics in hypnosis. Journal of Abnormal Psychology**

Examined hypnotic dissociation (as indexed by the "hidden-observer" method), duality in age regression, and the potential impact of situational cues on these phenomena. 12 high- and 9 low-susceptible undergraduates (as determined by the Stanford Hypnotic Susceptibility Scale) were tested in an application of the real-simulating paradigm of hypnosis; 10 high- to medium-susceptible Ss were also employed. Inquiry into Ss' experiences was conducted through the experiential analysis technique, which involves Ss viewing and commenting on a videotape playback of their hypnotic session. Results demonstrate that neither the hidden-observer effect nor duality could be explained solely in terms of the demand characteristics of the test situation. The hidden-observer effect was observed in high-susceptible Ss only; all Ss who displayed the hidden-observer effect also displayed duality in age regression. High-susceptible Ss were distinctive in their

reports of multiple levels of awareness during hypnosis. Findings are discussed in terms of the cognitive skills that Ss bring to hypnosis and the degree to which the hypnotic setting encourages the use of dissociative cognitive processes. (43 ref).

Simon, Michael J. (1983). The effect of manipulated expectancies on posthypnotic amnesia (Dissertation, University of South Carolina). Dissertation Abstracts International, 43 (n7-B), 2358. (Order No. DA 8228533)

"An attempt was made to determine the effects of manipulating subject expectancy on posthypnotic amnesia. The manipulation involved having Ss read an essay which included a paragraph informing them that they would have no trouble remembering what happened upon awakening from the trance. The effects of direct suggestions for amnesia were also assessed. "One hundred and twenty undergraduate students were randomly assigned to six groups: Negative Expectancy for amnesia/Suggestions for amnesia, No Expectancy for amnesia/Suggestions for amnesia, Negative Expectancy for amnesia/No Suggestions for amnesia, No Expectancy for amnesia/ No Suggestions for amnesia, and two control groups. "Subjects in the Suggestion conditions were administered the standard version of the Stanford Hypnotic Supports Scale Form A (SHSS-A). The No Suggestion subjects were administered a modified version of the SHSS-A which made no references to, and gave no suggestions for, posthypnotic amnesia. Finally, the control subjects were given a more drastically modified version of the scale in which the hypnotic induction as well as all references to hypnosis were eliminated. The control groups were employed to provide an estimate of the amount of forgetting exhibited by subjects who are not hypnotized. "The results indicated that the expectancy manipulation had no effect on the occurrence of posthypnotic amnesia as measured by the SHSS-A, while suggestions for amnesia were found to have a significant effect. Both Suggestion and No Suggestion subjects remembered significantly less than the subjects in the control groups. The implications of the findings were discussed" (p. 2358).

Schuyler, Bradley A. (1982). Further investigation of volitional and nonvolitional experience during posthypnotic amnesia (Dissertation, California School of Professional Psychology, Fresno). Dissertation Abstracts International, 44 (n6-B), 1977. (Order No. DA 8324472)

"Electrodermal responses were compared between highly responsive hypnotic Ss who were classified as having control over remembering (voluntaries) or not having control over remembering (involuntaries) during posthypnotic amnesia. Three contextual conditions were employed: Two were meant to create pressure to breach posthypnotic amnesia (lie detector instructions alone or with feedback that Ss had been detected as not having told all they could remember); the other provided feedback, in addition to the lie detector instructions, that Ss had told all they could remember. The recall data confirmed earlier findings of Coe and Yashinski and showed that voluntary and involuntary Ss did not differ in response to the

contextual conditions. However, lie detector instructions alone did not create pressure to breach as in previous studies. In addition, electrodermal results were insignificant. The results are discussed as they relate to (a) amnesia, (b) the physiological detection of deception and physiological activation, (c) the voluntary/involuntary classification of Ss, and (d) theories of hypnosis" (p. 1977).

St. Jean, Richard; MacLeod, Carrie; Coe, W. C.; Howard, M. L. (1982). Amnesia and hypnotic time estimation. International Journal of Clinical and Experimental Hypnosis, 30, 127-137.

Previous research has shown that hypnotic Ss tend to underestimate the duration of the hypnotic interval (Bowers, 1979; Bowers & Brenneman, 1979). Based on Ornstein's (1970) work, the present investigation tested the hypothesis that such underestimation occurs to the extent that Ss are amnesic for the events of the hypnotic session. Two separate studies, in which time estimates were collected in conjunction with administrations of the Harvard, failed to find a relationship between responses to the amnesia suggestion and time estimation. Ss in both studies substantially underestimated the duration of the hypnotic interval, but the degree of such underestimation was not related to hypnotic responsiveness. Thus, Ornstein's hypothesis that underestimation occurs to the extent that Ss are amnesic for the events of the hypnotic session was strongly disconfirmed.

1981

McConkey, Kevin M.; Sheehan, Peter W. (1981). The impact of videotape playback of hypnotic events on posthypnotic amnesia. Journal of Abnormal Psychology, 90 (1), 46-54.

Examined the breakdown of amnesia by showing 48 hypnotic and nonhypnotic undergraduates (Harvard Group Scale of Hypnotic Susceptibility) a videotape of the hypnotic events they had experienced. The extent of the amnesia for these events was defined precisely, and simulating procedures were employed to analyze the cues in the overall test situation. Videotape display of the hypnotic events was presented via the Experiential Analysis Technique and served to optimize conditions for breakdown. Some hypnotic Ss' amnesia could not be broken down even though they were exposed via videotape playback to the events to be recalled and when suggestions for the period of amnesia were quite explicit. Simulators showed breaching of amnesia but attributed their recall to the videotape rather than to the hypnotic session. Hypnotic Ss were distinctive in their inability to recall experiential aspects of their performance even though they could recall behavioral aspects. The data are discussed in relation to the hypothesis that dissociative cognitive mechanisms underlie posthypnotic amnesia. (22 ref).

Radtke, H. Lorraine; Spanos, Nicholas P. (1981). Temporal sequencing during posthypnotic amnesia: A methodological critique. Journal of Abnormal Psychology, 90, 476-485.

In studies by Evans and Kihlstrom (1973, 1975, 1979), high susceptibles were less likely than low susceptibles to recall the events of the hypnotic session in temporal sequence (i.e., temporal disorganization effect) following an amnesia suggestion. The primary measure of recall order was the rank-order correlation (rho scores) between the presentation order and the recall order of hypnotic experiences computed for each S. Following a suggestion for posthypnotic amnesia, HSs usually obtained lower rho scores than LSs. This research is critically examined, noting methodological shortcomings associated with the susceptibility-scale paradigm, inconsistent findings, and failures to replicate. Two studies are described that found no relationship between susceptibility level and rho scores. These null results held true for Ss who recalled new information after cancellation of the amnesia suggestion (reversers) as well as for those who did not recall new information (nonreversers). Nevertheless, the authors have replicated previous work on differential recall of the first item.

Kihlstrom, John F.; Evans, Frederick J.; Orne, Emily C.; Orne, Martin T. (1980). Attempting to breach posthypnotic amnesia. Journal of Abnormal Psychology, 89 (5), 603-616.

Traditionally, posthypnotic amnesia has been construed as a subjectively compelling deficit in memory retrieval. Alternatively, it may represent a motivated failure to utilize appropriate retrieval cues, lack of effort in recall, active suppression of memory, or unwillingness to verbalize the critical material. In an effort to test the alternative hypothesis of amnesia, 488 college students were presented with 4 kinds of instructions (using 4 modifications of the Harvard Group Scale of Hypnotizability, Form A) designed to overcome the effects of suggested posthypnotic amnesia. The instructions particularly affected Ss of low and moderate hypnotizability who failed the criterion for amnesia. For those of moderate and high hypnotizability who met the criterion for amnesia, however, explicit requests for temporal organization, exhortations to maximize recall, and demands for honesty in reporting produced no greater effect on memory than did a simple retest. Results place some boundaries on both the traditional and alternative views of posthypnotic amnesia and invite further exploration of both cognitive and contextual models of the phenomenon.

Spanos, Nicholas P.; Radtke-Bodorik, H. Lorraine; Stam, Henderikus J. (1980). Disorganized recall during suggested amnesia: Fact not artifact. Journal of Abnormal Psychology, 89 (1), 1-19.

In 3 experiments and a reanalysis of previous data, hypnotic and nonhypnotic Ss learned a 9-item categorized word list and were then given an amnesia suggestion for the list. Clustering of recall was measured on the recall trials immediately before the suggestion, during it, and after it was canceled. In Experiment I with 173 undergraduates, hypnotic Ss showed more amnesia than task-motivated Ss. However, partial nonrecallers in both of these treatments showed disorganized (i.e., less clustered) recall during the suggestion as compared to before it or after canceling it. Experiment II, with 100 university students, disconfirmed the

hypothesis that the greater amnesia of hypnotic as compared to task-motivated Ss, was due to high levels of relaxation in the hypnotic Ss. Disorganization was again found in partial nonrecallers. The reanalysis of clustering data from previous experiments with 196 Ss demonstrated that the disorganization effect was not an artifact produced by reduced recall during the suggestion period, and Experiment II (with 166 18-42 year old Ss) indicated that Ss who followed instructions and faked partial amnesia when explicitly asked to do so (simulators) showed no disorganization effect. An inattention-encoding specificity hypothesis was developed to account for these findings.

Stam, Henderikus J.; Radtke-Bodorik, Lorraine; Spanos, Nicholas P. (1980). Repression and hypnotic amnesia: A failure to replicate and an alternative formulation. Journal of Abnormal Psychology, 89 (4), 551-559.

In an attempt to replicate and extend a study by S. R. Clemes, 2 groups of 10 undergraduate hypnotic Ss learned a list of 18 words and were given an amnesia suggestion telling them they would be able to remember only 10 of these words. Half of the list words were critical (i.e., considered to be related to repressed conflictual material) and half were neutral (unrelated to conflictual material) as determined by Ss' responses to a word association test. Experimental Ss received their own critical and neutral words and yoked control Ss received the critical and neutral words of experimental Ss. Neither the experimental nor the yoked control group exhibited selective amnesia in favor of critical words, thus constituting a failure to replicate Clemes's result. However, variables affecting the degree to which words were initially learned (e.g., imagery value, serial position) predicted their resistance to amnesia. These findings are inconsistent with a repression hypothesis but congruent with an inattention hypothesis of suggested amnesia. (41 ref).

Weitzenhoffer, Andre M. (1980). Hypnotic susceptibility revisited. American Journal of Clinical Hypnosis, 22, 130-146.

The concept and measurement of hypnotic susceptibility are re-examined in their relation to hypnotizability, hypnotic depth and suggestibility. The Stanford Scales and similar instruments are found to have failed to take into account essential features defining traditional hypnosis and suggestibility and to have created confusion in the scientific inquiry into hypnotism. Other available measures have not been particularly successful, but some bear further attention. Recent claims that hypnotizability can be trained have failed to distinguish between hypnotizability proper and accessory processes, leaving some question about what is actually being trained. Possible future directions of work on susceptibility are considered. Attempts to distinguish between 'clinical' and 'laboratory' hypnotizability are examined and found to have been premature and loosely based on facts.

1979

Karlin, Robert A. (1979). Hypnotizability and attention. Journal of Abnormal Psychology, 88 (1), 92-95.

An attentional explanation of cognitive hypnotic phenomena (e.g., hallucinations and amnesia) based on the ability to shift the pertinence of stored information was developed. It was hypothesized that individuals who were successful at a difficult attentional task would also succeed on cognitive hypnotic items. The Harvard Group Scale of Hypnotic Susceptibility, Form A was used to assess hypnotizability. To measure pertinence-shift ability, two tape recordings made by the same person were played through a single sound source. One tape was designated the target tape. Amount remembered and perceived task ease were summed to form an additive score of task success. Subjects above the median on the task were assigned to the good pertinence shift group (GP); those below the median were assigned to the poor pertinence shift group (PP). As predicted, GP subjects passed significantly more cognitive hypnotic items than did PP subjects ( $p < .05$ ). When task difficulty and compliance were controlled for, the results remained significant ( $p < .05$ ). These results were replicated in a second study.

#### NOTES

1:

A brief version of this paper was presented at the Annual Meeting of the Society for Clinical and Experimental Hypnosis, Asheville, North Carolina, October, 1978

Orne, Martin T. (1979). The use and misuse of hypnosis in court. International Journal of Clinical and Experimental Hypnosis, 27, 311-341

The various forensic contexts in which hypnosis has been used are reviewed, emphasizing its advantages and pitfalls. The technique may be helpful in the context of criminal investigation and under circumstances involving functional memory loss. Hypnosis has no utility to assure the truthfulness of statements since, particularly in a forensic context, subjects may simulate hypnosis and are able to willfully lie even in deep hypnosis; most troublesome, actual memories cannot be distinguished from confabulations either by the subject or by the hypnotist without full and independent corroboration. While potentially useful to refresh witnesses' and victims' memories to facilitate eyewitness identification, the procedure is relatively safe and appropriate only when neither the subject, nor the authorities, nor the hypnotist have any preconceptions about who the criminal might be. If such preconceptions do exist -- either based on information acquired before the hypnotic procedure or on information subtly communicated during the hypnotic procedure -- hypnosis may readily cause the subject to confabulate the person who is suspected into his "hypnotically enhanced memories." These pseudomemories, originally developed in hypnosis, may come to be accepted by the subject as his actual recall of the original events; they are then remembered with great subjective certainty and reported with conviction. Such circumstances can create convincing, apparently objective "eyewitnesses" rather than facilitating actual recall. A number of minimal safeguards are proposed to reduce the likelihood of such an eventuality and other serious potential abuses of hypnosis.

1977

Chertok, Leon; Michaux, D.; Droin, M. C. (1977). Dynamics of hypnotic analgesia: Some new data. Journal of Nervous and Mental Disease, 164, 88-96.

Following two surgical operations under hypnotic anesthesia, it was possible, during subsequent recall under hypnosis, to elicit a representation of the past operative experience. It would seem that under hypnosis there is a persistence of the perception of nociceptive information and of its recognition as such by the subject. From an analysis of these two experiments in recall, it is possible to formulate several hypotheses concerning the psychological processes involved in hypnotic analgesia. In consequence of an affective relationship, in which the hypnotist's word assumes a special importance for the subject, the latter has recourse to two kinds of mechanism: a) internal (assimilation to an analogous sensation, not, however, registered as dangerous-- rationalization); and b) external (total compliance with the interpretations proposed by the hypnotist), which lead to a qualitative transformation of nociceptive information, as also the inhibition of the behavioral manifestations normally associated with a painful stimulus.

Fisher, R. (1977). On flashback and hypnotic recall. International Journal of Clinical and Experimental Hypnosis, 217-235.

This essay deals with both the intra-individual and inter-individual varieties of arousal state-bound experiences. The former are labelled as "flashbacks" while the latter embrace the great fantasies and repetitive schemes, the ever re-written plots and images of literature, art, and religion.

Flashbacks are both arousal-state and stage (i.e., set and setting) bound experiences. Flashback and hypnotic recall differ only in the ways by which they are induced. Induction methods should be distinguished from induced states on the hyperaroused perception-hallucination and hypoaroused perception-meditation continuum.

Flashbackers may be characterized by their (a) variability on perceptual-behavioral tasks; (b) tendency to minimize (or reduce) sensory input; (c) high resting heart rates; (d) hypnotizability; and, hence (e) preferential right-cerebral-hemispheric cognition; and (f) a display of EEG-alpha dominance in the resting, waking state.

1976

Coe, William C.; Basden, B.; Basden, D.; Graham, C. (1976). Posthypnotic amnesia: Suggestions of an active process in dissociative phenomena. Journal of Abnormal Psychology, 85, 455-458.

A retroactive inhibition design was used to examine the process of posthypnotic amnesia. The results supported the notion that "forgotten" material is as available to amnesic subjects at some level as it is to nonamnesic subjects. Further, so-called forgetting appears to be the result of an active process, that is, something the subject does. Implications for understanding dissociative phenomena in general are discussed.

Coe, William C.; Baugher, R. J.; Krimm, W. R.; Smith, J. A. (1976). A further examination of selective recall following hypnosis. International Journal of Clinical and Experimental Hypnosis, 24, 13-21.

29 Ss were tested for posthypnotic amnesia on SHSS:C. They rated each item for emotional tone (pleasant-unpleasant) and judged whether or not they had passed or failed it. There was some support for the notion that failed items are judged more unpleasant than passed items, but the emotional tone of an item was not related to its being recalled posthypnotically. There were minimal findings to suggest that Ss recall items which stand out in their experience. Discrepancies with earlier findings and the possible role of processes associated with normal memory are discussed.

Spanos, Nicholas P.; Spillane, Jeanne; McPeake, John (1976). Cognitive strategies and response to suggestion in hypnotic and task-motivated subjects. American Journal of Clinical Hypnosis, 18, 254-262.

Thirty-two male and 32 female subjects, exposed to an hypnotic induction or task-motivational instruction, were administered either three suggestions which provided a cognitive strategy (i.e., a goal-directed fantasy, GDF) for experiencing suggested effects, or three suggestions that did not provide such a strategy. Subjects provided with GDF strategies were more responsive overtly and subjectively to two out of the three suggestions. Subjects in the No GDF Strategy treatment who spontaneously devised their own goal-directed fantasies were more responsive to suggestions than subjects who failed to devise such a strategy. These results support the contention that goal-directed fantasy helps both hypnotic and non-hypnotic subjects experience suggested effects.

#### NOTES

The suggestions were for arm levitation, arm rigidity, and amnesia.

Stewart, C. G.; Dunlap, W. P. (1976). Functional isolation of associations during suggested posthypnotic amnesia. International Journal of Clinical and Experimental Hypnosis, 24, 426-434.

A search was made for functional isolation effects of hypnotic amnesia that do not derive directly from either the explicit content or simple demand characteristics of amnesia instructions. The frequency of response repetition on a word association task was investigated as a function of posthypnotically suggested recall amnesia during the normal waking state. A trace of evidence for predicted amnesia effects occurred with only 1 out of 6 intensively trained, highly susceptible subjects. The results are compatible with the view that (a) suggested recall amnesia produces a disturbance of the retrieval process similar to source amnesia, and (b) indirect associational measures then merely serve to stimulate retrieval.

Goldstein, M. S.; Sippelle, Carl N. (1970). Hypnotically induced amnesia versus ablation of memory. International Journal of Clinical and Experimental Hypnosis, **19** (3), 211-216. (Abstracted in Current Contents, 2, 35, 21)

Divided 33 hypnotizable undergraduates, all capable of achieving the criterion of amnesia for a 7-digit number, into 3 groups: 2 hypnotized and 1 pretend. The distributions of errors for an amnesic performance of these groups were compared with the theoretical chance distribution of errors expected in an amnesic performance. Both hypnotized groups differed significantly from the pretend group and from the theoretical distribution, while the performance of the pretend group did not differ significantly from the chance distribution. The performance of the pretend group conformed to the expectancy for amnesia significantly better than did the performance of either of the hypnosis groups. 1969

Barber, Theodore Xenophon (1969). An empirically-based formulation of hypnosis. American Journal of Clinical Hypnosis, **12** (2), 100-130.

A formulation is presented which does not invoke a special state of consciousness ("hypnosis" or "trance") to account for the behaviors that have been historically associated with the word hypnotism. Instead, so-called hypnotic behaviors - e.g., "analgesia," "hallucination," "age-regression," and "amnesia" - are conceived to be functionally related to denotable antecedent variables which are similar to those that control performance in a variety of interpersonal test-situations. The antecedent variables which determine behavior in a "hypnotic" situation include Ss' attitudes, expectancies, and motivations with respect to the situation, and the wording and tone of instructions- suggestions and of questions used to elicit subjective reports. The formulation is exemplified by several dozen experimental studies, and prospects for further research are delineated.

Raginsky, Bernard B. (1969). Hypnotic recall of air crash cause. International Journal of Clinical and Experimental Hypnosis, **17**, 1-19.

Discusses the use of hypnotic techniques to help a 33-yr-old male recall suppressed material which implicated him in an air crash. The cause was found after 2 short hypnotic sessions, where other methods used over 2 years had failed. The method can be used in all cases of amnesia. The S was made to hallucinate a threatening situation, and his hallucination gave a clue to the basic problem. He was then made to hallucinate a pleasant scene, which gave an indication of the method he used to escape from the problem. This was repeated at the 2nd session for confirmation. If the patient did not bring up the required material by free association under hypnosis, a dissociation of the personality induced in which the observing ego watched what the experiencing ego was doing to cause the accident. The results demonstrated that hypnotic techniques were more successful than sodium amytal interviews, free association, psychiatric interviews, physical and emotional isolation,

pressure by authorities, and kindness of friends. Reference was made to the problems involved when the interests of the S were in conflict with public safety. (Spanish & German summaries) (PsycINFO Database Record (c) 2002 APA, all rights reserved)

Thorne, D. Eugene (1969). Amnesia and hypnosis. International Journal of Clinical and Experimental Hypnosis, 17, 225-241.

Explored the relative effects of 2 factors on short-term memory for a paired-associate learning task. 36 undergraduate and graduate paid volunteers were stratified, according to their Harvard Group Scale of Hypnotic Susceptibility, Form A scores, into 3 groups of 12 Ss each. The Ss within each of the 3 groups were then evenly but randomly assigned to 3 treatment conditions, which differed in terms of the kind of motivational procedure in which suggestions of amnesia for a recently learned paired-associate task were given. Results did not directly support or were sometimes contrary to predictions derived from popular hypnosis theories, which assert that posthypnotic amnesia is a reliable behavioral criterion for the "hypnotic state." Barber, Theodore Xenophon; Calverley, David S. (1968). Toward a theory of 'hypnotic' behavior: Replication and extension of experiments by Barber and co-workers (1962-65) and Hilgard and Tart (1966). International Journal of Clinical and Experimental Hypnosis, 16, 179-195.

RESPONSES TO TEST SUGGESTIONS (E.G., HALLUCINATION AND AMNESIA) WERE ASSESSED UNDER THE FOLLOWING TREATMENTS: MOTIVATIONAL INSTRUCTIONS ALONE, HYPNOTIC PROCEDURE WITH MOTIVATIONAL INSTRUCTIONS, AND IMAGINATION-CONTROL. COMPARISONS WERE MADE ACROSS INDEPENDENT GROUPS, EACH TESTED UNDER 1 TREATMENT, AND ALSO WITHIN THE SAME SS TESTED TWICE UNDER VARIOUS COMBINATIONS OF THE TREATMENTS. ALTHOUGH SS WERE SUGGESTIBLE UNDER THE IMAGINATION-CONTROL TREATMENT, BOTH THE MOTIVATIONAL INSTRUCTIONS ALONE AND THE HYPNOTIC PROCEDURE GIVEN TOGETHER WITH THE MOTIVATIONAL INSTRUCTIONS RAISED SUGGESTIBILITY ABOVE THE CONTROL LEVEL. THE HYPNOTIC-MOTIVATIONAL TREATMENT TENDED TO PRODUCE AN INCREMENT IN SUGGESTIBILITY WHICH WENT SLIGHTLY BEYOND THAT ATTRIBUTABLE TO THE MOTIVATIONAL INSTRUCTIONS. THE LATTER INCREMENT IS INTERPRETED AS DUE TO THE SLIGHTLY GREATER EFFECTIVENESS OF THE HYPNOTIC PROCEDURE IN DEFINING THE SITUATION AS ONE IN WHICH UNUSUAL MANIFESTATIONS, SUCH AS HALLUCINATION AND AMNESIA, ARE WITHIN SS" CAPABILITIES AND

**Evans, Frederick J.; Thorn, Wendy A. (1966). Two types of posthypnotic amnesia: Recall amnesia and source amnesia. International Journal of Clinical and Experimental Hypnosis, 14 (2), 162-179.**

**Posthypnotic recall amnesia refers to S's inability to recall, when challenged posthypnotically, the events which occurred during hypnosis. Posthypnotic source amnesia, occurs when S subsequently remembers the experiences of hypnosis, but has no recollection of acquiring the experiences. Data from 3 samples are presented to support the distinction between the 2 types of amnesia. Of 243 Ss, 18 experienced recall amnesia, 26 displayed source amnesia, but only 4 developed both kinds. There were no differences in rated depth of hypnosis of these 3 subgroups. Recall amnesia and source amnesia correlated .37, .38, and .39, respectively ( $p < .001$ ) in the 3 samples. The evidence indicates the 2 types of amnesia are different phenomena. Similarities between source amnesia and certain (dissociative) normal and psychopathological memory processes are discussed. **Orne, Martin T. (1966). On the mechanisms of posthypnotic amnesia. International Journal of Clinical and Experimental Hypnosis, 2, 121-134.**

Reviews experimental and clinical evidence about posthypnotic amnesia. 2 interpretations are contrasted which seem sharply opposed: (1) posthypnotic amnesia may be seen as essentially like any other hypnotically suggested experience. It can be considered as an explicitly or implicitly administered posthypnotic suggestion. (2) Amnesia can be viewed as a form of dissociation. 1 possible mechanism of such dissociation may be a basic difference of the structure of thought processes involved in hypnosis compared to those of normal waking experience. In this sense amnesia should occur independently of suggestion and be different in kind from most other hypnotic phenomena. The former mechanism may occur more frequently in experimental situations and the latter, in clinical contexts. (Spanish & German summaries) (25 ref.) (PsycINFO Database Record (c) 2002 APA, all rights reserved)

**Stross, L. (1966). Impulse-defense implications in a case of amnesia. International Journal of Clinical and Experimental Hypnosis, 2, 89-103.**

An 18-yr-old girl with a delinquent history leading to several suicide attempts and a fugue is described as she was observed during shifting phases of her amnesic syndrome. Using the case study as a research tool, it is suggested that alteration of ego state might be an archaic, primitive means of defense against relatively unneutralized, intense drives. More speculative are the propositions, generated from this case, that the ego could employ different defensive means with regard to libidinal and aggressive drives and that alteration of ego state might be a specific defense against aggression. (Spanish & German summaries) (PsycINFO Database Record (c) 2002 APA, all rights reserved)

**1965**

**Field, Peter B.; Evans, Frederick J.; Orne, Martin T. (1965). Order of difficulty of suggestions during hypnosis. International Journal of Clinical and Experimental Hypnosis, 13, 183-192.**

This study tests the hypothesis that successful response to suggestion during hypnosis predisposes to further successful response, but failure leads to subsequent failure. The Harvard Group Scale of Hypnotic Susceptibility was administered to 2 groups of 51 volunteer students. For 1 group, 8 of the 12 items were administered in the order easy-to-difficult; for the 2nd group, in the order difficult-to-easy. Total

and 8-item mean scores, and frequency distributions, did not differ significantly between groups. Except for the item measuring posthypnotic amnesia, item difficulties for the 2 groups did not differ significantly. Although the difficult-to-easy group was more amnesic, the 2 groups recalled a similar number of additional items when amnesia was "lifted." The block of 4 easier items was relatively easier when preceded by a block of 4 harder items and, similarly, the harder items were relatively less difficult if preceded by a block of easier items. The magnitude of this effect was small, and the order effect hypothesis was basically not supported. Future research should consider the S's subjective impression of success and failure. (16 ref.) Hilgard, Ernest R.; Cooper, L. M. (1965). Spontaneous and suggested posthypnotic amnesia. International Journal of Clinical and Experimental Hypnosis, 13 (4), 261-274. (Abstracted in American Journal of Clinical Hypnosis, 1966, 1, 85)

This investigation was carried out to obtain comparable figures on the prevalence of spontaneous and suggested posthypnotic amnesia. 91 introductory psychology students were randomly assigned to 1 of 2 groups, and were required to serve as Ss for 2 consecutive days. The standard induction of the Stanford Hypnotic Susceptibility Scale, Form A was used on the 1st day, and that of Form B on the 2nd. Suggestibility items were then presented and served to appraise susceptibility and to test for amnesia. For 1 group, spontaneous amnesia was tested on the 1st day, and suggested amnesia on the 2nd day. This order was reversed for the 2nd group. Using as evidence of amnesia that 4 or fewer of the 10 possible items were recalled, 6 (7%) showed spontaneous amnesia on 1 of the 2 days, while a significantly larger number, 32 (35%), showed suggested amnesia. When the groups were subdivided on the basis of susceptibility scores, it was found that there is a marked advantage for suggested amnesia over spontaneous amnesia for highly susceptible hypnotic Ss, while this difference essentially disappears for low Ss. It was further found that (a) suggested amnesia is significantly greater than spontaneous amnesia whether or not 1 follows the other, (b) there is a small effect of the suggested posthypnotic amnesia for all levels of susceptibility, but this becomes pronounced with susceptibility scores of 6 and above, (c) the highly susceptible hypnotic Ss show no more spontaneous posthypnotic amnesia than do other Ss. Dorcus, Roy M. (1960). Recall under hypnosis of amnesic events. International Journal of Clinical and Experimental Hypnosis, 8 (1), 57-61.

NOTES

1:

The author reported on hypnosis work with eight cases, four dealing with attempts to recall misplaced or lost articles and four dealing with recall of information related to the commission of crimes. He concluded "that recall is not greatly improved under hypnosis. However, when strong emotional elements surround the events to be recalled some additional information may be secured" (p. 60).

1956

Dittborn, Julio M. (1956). Toward a semeiology of hypnosis. Journal of Clinical and Experimental Hypnosis, 4 (1), 30-36.

"19 subjects were chosen among two hundred that in the year the experiment took place (1954) were to be 20 years old. 11 of these subjects qualified themselves as good swayers, whereas the 8 others were considered somehow refractory to the postural swaying test.

"All 19 went under a standard hypnotic induction: the operator employed the same words in all cases, and requested from all the execution of the same acts.

"Several involuntary signs of standard induction are described, which reveal that the subject has attained a convenient degree of muscular relaxation after appropriate suggestions.

"Fatigue is apparently an important source of spontaneous amnesia in good swayers.

"In the analyzed cases no involuntary sign has been detected, that could reveal us whether the inducted subject will or not present spontaneous post-hypnotic amnesia" (p. 36).

1954

Schneck, Jerome M. (1954). The divided personality: A case study aided by hypnosis. International Journal of Clinical and Experimental Hypnosis, 2 (3), 220-232.

NOTES

1:

"Summary. Amnesia as a symptom assumes proportions more complex than would appear on the surface and the role of memory loss with specific reference to hypnotic recovery methods has been presented in several reports. Hypnotherapy would appear to be a preferred technique for resolving the symptom and at times for more extensive investigation of the underlying problems. The case reported now involved an extensive memory loss for past life, including personal identity. This was followed after nearly a year by recall and concurrent amnesia for the intervening time period. The latter amnesia was dispelled by recall at first under hypnosis and then by post-hypnotic extension and elaboration of the nuclear material. The patient's history was outlined and several facts of apparent importance in relation to the memory loss were revealed. The purposive and motivational features were stressed. Therapy was conducted in a medico-disciplinary setting with limitations based on administrative requirements. Military-legal complications of the patient's personality disorder and functioning were outlined. The concept of the divided personality was introduced and related to multiple personality and to another type of behavior which is quite similar to the divided personality except that periods of amnesia are not involved. The divided personality involves major cleavages in the continuity of living with amnesia and the

establishment of the individual in a setting where he undergoes extensive, significant operations relating to work, general activities, and even courtship and marriage. Unlike the generally accepted attributes of multiple personality involving considerable overt behavior, affect, and attitude alterations, the divided personality continues to function with his accustomed overt attitudes, interests, affect, and method of relating on an interpersonal level. Descriptively and overtly he is not too different if at all, but he seems to begin life anew in terms of setting and personal contacts. Cases of this type should be studied further with care, whenever possible, for further elicitation [sic] of psychodynamics. Hypnosis as a tool in treatment and investigation should prove helpful and is to be considered important.

## **ANALGESIA / ANESTHESIA**

**1995**

**Eastwood, John D.; Gaskaski, Peter; Bowers, Kenneth S. (1995, November). Frequency of pain reporting and analgesia: Exploration of a possible interaction. [Paper] Presented at the annual meeting of the Society for Clinical and Experimental Hypnosis, San Antonio, TX.**

### **NOTES**

**1:**

Two theories of pain control by hypnosis currently exist: 1. Socio-cognitive model - patient actively copes with noxious stimulus. Hypnotic analgesia should be like cognitive techniques like stress inoculation training. It requires deliberate effort. 2. Dissociative control model - pain reduction requires little cognitive effort.

These 2 theories have different predictions. He explains "ironic effects" theory, in which person must identify pain to reduce pain. Wagner's reflexivity constraint: any process of mental control must be consistent with state we are trying to create.

This investigation involved 25 Highs and 24 Lows who reported pain, produced by strain gauge. Taught either hypnotic analgesia or stress inoculation. Reported every 5 sec (high load) or 45 sec (low load). Subtracted report from baseline to make pain reduction scores. Highs in hypnosis had no difference in pain reduction under high or low mental load. For the other 3 groups (Highs under stress inoculation; Lows under either hypnosis or stress inoculation) the results were different. That is, for Highs in hypnosis the mean of pain reduction scores was the same even when challenged by frequent reports of how much pain was being experienced.

Results are congruent with Miller and Bowers' dissociative control model.

Wagner's ironic process theory is useful. Frequency of pain reporting moderates Ss reports of pain in analgesia. These results challenge the cognitive social model of hypnotic analgesia and support a dissociative control model. Unlike stress inoculation, hypnotic analgesia does not require cognitive effort for high hypnotizable subjects.

**1994**

**Crawford, Helen J. (1994). Brain dynamics and hypnosis: Attentional and disattentional processes. International Journal of Clinical and Experimental Hypnosis, 42 (3), 204-232.**

This article reviews recent research findings, expanding an evolving neuropsychophysiological model of hypnosis (Crawford, 1989; Crawford & Gruzelier, 1992), that support the view that highly hypnotizable persons (highs) possess stronger attentional filtering abilities than do low hypnotizable persons, and that these differences are reflected in underlying brain dynamics. Behavioral, cognitive, and neurophysiological evidence is reviewed that suggests that highs can both better focus and sustain their attention as well as better ignore irrelevant stimuli in the environment. It is proposed that hypnosis is a state of enhanced attention that activates an interplay between cortical and subcortical brain dynamics during hypnotic phenomena, such as hypnotic analgesia. A body of research is reviewed that suggests that both attentional and disattentional processes, among others, are important in the experiencing of hypnosis and hypnotic phenomena. Findings from studies of electrocortical activity, event-related potentials, and regional cerebral blood flow during waking and hypnosis are presented to suggest that these attentional differences are reflected in underlying neurophysiological differences in the far fronto-limbic attentional system.

Freeman, R.; Barabasz, A.; Barabasz, M. (1994, October). EEG topographic differences between dissociation and distraction during cold pressor pain in high and low hypnotizables. [Paper] Presented at the annual meeting of the Society for Clinical and Experimental Hypnosis, San Francisco

#### NOTES

1:

Hilgard once said we should study what is going on inside the skull when we study hypnotic behavior. Theta EEG was studied, in 3.5 and 5.5-7.5 band widths, based on Crawford's research (no differences between high and low hypnotizables in low range but significant differences in waking state, eyes closed condition).

Also employed new type of distraction procedure. Previously used as comparison conditions things like imagine a pleasant scene, do whatever you can do to reduce pain, or imagine an instructor giving a lecture. Barabasz theorized that highs, given the opportunity, may spontaneously get involved in imagery; so distraction used in some experiments may actually become hypnosis. Here, distraction involved using a storage box, with plexiglass covering front, and 3 lights--subjects were to recall sequence of light changes that occurred during 60 sec when arm was in the cold water.

Cold pressor pain. 3 immersions with simultaneous pain reporting and EEG monitoring. --Waking State --Light array distraction --Hypnotic induction and suggested analgesia (Distraction and hypnosis with analgesia were presented in a balanced design)

Pain Ratings ranged from 0 = no pain, 10 = level would very much like to remove arm from water (rating could exceed 10 however). After removing arm, subjects were to report the maximum amount of pain that they had felt. Pain Scores were obtained at 30 seconds and 60 seconds after immersion in the cold water.

Also got qualitative data. During recovery period after each arm immersion, Subjects were asked what if anything they had done to reduce the pain felt.

**30 second pain scores: Waking 7.60 vs 7.50 Distraction 8.60 vs 6.80 Hypnotic analgesia 7.80 vs 4.10 (Significantly different).**

**60 second pain scores: Showed same trend.**

**There was no difference whatsoever for the lows.**

**Results for the 2 EEG sites: P3 left hemisphere parietal in waking and hypnotic analgesia, high theta, had significantly different activity O1 left hemisphere in waking and hypnotic analgesia, was significantly different between highs and lows (same as above).**

**Results for two theta ranges: Low theta range, T4 temporal right hemisphere, for lows in waking and [missed words] condition--hard to interpret this finding.**

## **RESULTS.**

**Highs demonstrated pain reduction in hypnotic analgesia compared to waking and distraction conditions and compared to lows. Lows had no differences in any condition.**

**Enhanced EEG theta in left parietal area differentiated highs and lows. This suggests that highs generate enhanced disattention that may be controlled by these areas.**

**P3 area regulates the integration and association of somatic perceptions. The O1 area controls processing of visual imagery. Perhaps high hypnotizables have more ability to alter afferent sensory information through focused attentional processes. Also, the ability to alter the suffering portion of pain experience may involve visual imagery activity.**

**State and trait differences are apparent.**

**The low theta range may be more closely related to slower delta range 0-3.5 that is associated with sleep and drowsiness. High theta = low arousal and attention capacity. That's why theta seems associated with wide range of behaviors that appear contradictory**

**The qualitative data shows highs reported they spontaneously preferred strategies that were more than distraction (associating colors with warmth, thinking of warm water) and the most frequent responses of lows were "nothing" or "told myself it would be over soon."**

**Highs in analgesia condition used no specific strategy: 8/10 reported the arm simply felt more numb.**

**Kiernan, Brian; Dane, Joseph R. (1994, October). Hypnoanalgesia reduces new physiologic index of pain, the R-III Index, but the role of hypnotic susceptibility remains unclear. [Paper] Presented at the annual meeting of the Society for Clinical and Experimental Hypnosis, San Francisco.**

## **NOTES**

**Stimulated by work of Basil Finer, and following upon the Neodissociation theory of Hilgard; pain is registered by the body but dissociation that produces analgesia is a function of higher brain centers.**

Could hypnotic analgesia be mediated lower, at the level of the spinal cord? Gate at dorsal horn could be open or shut; subject to descending modulation. Is hypnosis involved in descending modulation of activity in the dorsal horn?

Hypothesis: reduced pain intensity would be associated with reduced activity at dorsal horn. From Price & Barber, we wanted to look at affect and intensity aspects of pain. Polysynaptic reflex, R-III, latency consistent with conduction velocity (when hand touches a hot stove); even with severed spinal cord injury we still demonstrate the reflex. The magnitude of reflex is linearly related to the pain sensation. The stronger the electrical pulse, the greater the magnitude of the reflex. Magnitude of reflex is linearly related to subjective pain. It is an index of nociceptive activity.

Procedure: Evoke reflex with electrical stimulus at ankle; measure signal at muscle with EMG. We anticipated that at dorsal horn, descending modulation would dampen signal.

15 healthy volunteers. Sural nerve was stimulated. R III reflex measured via EMG response. Used the visual analogue scale (VAS) to assess pain.

NOTES

1:

Presents point of view of a private practice anesthesiologist in Santa Barbara, California. Used hypnosis for 20 years.

Use of hypnosis as hypnoanesthesia is rare since Esdaile, with brief resurgence in 50's, because surgery techniques advanced before anesthetics did in areas that were very risky. Now it is a matter of choice, and may be undertaken because of a patient's extreme fear of anesthesia, previous bad experience with anesthesia, fervent belief in holistic method, allergy, or previous experience with hypnosis. Still advised to use hypnosis for MRIs, radiation procedures, former drug addicts (who may have problems with drugs), burn patients, release of neck contractions, and medical procedures--especially with children--like lumbar puncture.

She disagrees with Kroger's estimate of only 10% of patients being able to use hypnoanesthesia; she does not believe it requires a lot of training, or profound muscle relaxation.

There is no indication of how many cases are actually done with hypnosis. Also, published cases are not representative of the quantity or complexity of cases; most published cases have a few extraordinary characteristics. The Irish surgeon Jack Gibson has done more than 4000 cases, some very complicated.

I have used it for D & Cs, and complex cases that were not published. Most of my patients elected to be alert during the hypnosis and conversed with their surgeons. The most common benefit is that recovery from anesthesia is not necessary; but these days with newer anesthetics recovery from anesthesia is rapid anyway. However, if as we suspect anesthesia affects immune function, that would be another reason to use hypnosis.

Preparation for surgery may be of three types: 1. formal hypnosis techniques 2. "hypnoidal" techniques that aren't formal 3. unprepared patients in whom hypnosis is used at last moment.

Examples. 1. Formal hypnosis: This symposium deals with this type of approach. Three groups derive particular benefit -- those requiring prolonged artificial ventilation postoperatively (because otherwise sedation must be used, which leads to complications), where prepared patients tolerate interventions calmly and comfortably -- cancer patients, for whom this can be first experience of patient to see self as active participant in care rather than a victim of the illness and of complicated technology -- pediatric patients. 2. Hypnoidal (hypnosis like) techniques: This is the most important application. Time doesn't permit much discussion here. Patients are in an altered state when they come for surgery, highly suggestible, and suggestions appear to be as effective as during formal trance state. The doctor can elicit positive responses during "casual conversation" while seemingly giving information to the patient. (The reverse is true also, with inadvertent negative suggestions, to the detriment of the patient.) Scrupulous adherence to medical facts is important during this type of conversation.

Operating room fixtures are useful for focus of attention, and I have published this information in an article.

Recovery room also is place where case specific information and appropriate suggestions can be given. Patient can experience his ability to alter sensations, for the first time, following suggestions.

Remainder of the hospitalization offers opportunity for reinforcing case specific positive suggestions.

Bennett, Henry L. (1993, October). Hypnosis and suggestion in anesthesiology and surgery. [Paper] Presented at the annual meeting of the Society for Clinical and Experimental Hypnosis, Arlington Heights, IL.

## NOTES

1:

He began by saying that he is opposed to using hypnosis for surgery, though he favors a theory of how hypnosis effects physiological change, and cites T. X. Barber's classic "Changing Unchanging Bodily Processes."

Relaxation puts patient in a "psychological strait jacket" because surgery is so highly stressful. He gives information "about how to go through the surgery more comfortably," gets across the idea about coping style, tells them surgery is exertional and that they are tired afterward, that he can help them "using things you already know how to do," and specifies exactly what they can do--using model of himself as a trainer.

In some recent research he used pairs of pictures, some of which lead to pupillary constriction (blood pressure goes down) or dilation (blood pressure goes up). Instructing them to look, patients looked twice as long at the pictures than they did during free gaze. When not instructed to look, heart rate went down; when told to look, heart rate went up. So the researchers went back to free gaze. He uses this as a metaphor for many of the pre- surgery preparation activities that encourage relaxation "inappropriately."

He cites Cohen & Lazarus re vigilant copers, Price et al (1957), and some other studies on epinephrine effects. He uses examples of work patients may have done (e.g. planting a garden) when talking with patients prior to surgery, that gives them a sense of accomplishment later.

You have to give specific instructions or suggestion, not general relaxation suggestions.

Question from the audience: Can preoperative instructions (not hypnosis) diminish blood loss.

In Bennett's answer he seems to be reporting the earlier study: they found 150- 4000 cc blood loss, high variability. Extent of blood loss was determined by extent of surgery, by instructions to patients vs no instructions.

This study was replicated by Enqvist, Bystedt, & von Konow in the Anesthesia conference at Emory University in 1992.

May 1993 Western Journal of Medicine article, Disbrow, Bennett, & Owinos, with 40 lower abdominal surgery patients who got specific instructions or not. The SHCS was used to measure hypnotizability: highs resolved quicker than low hypnotizable patients. They also found that instructed patients did better than those who did not get specific instructions.

There are now 3 replications of McClintock's study: people use less medications after surgery, when tapes about rapid recovery are played \*during\* surgery.

Bennett is now using tapes with suggestions for recovery during surgery.

Blankfield, Robert P. (1993, October). Suggestion, hypnosis, and relaxation as adjuncts for surgery patients: Lessons from studies involving cardiac surgery patients. [Paper] Presented at the annual meeting of the Society for Clinical and Experimental Hypnosis, Arlington Heights, IL

## NOTES

1:

The author stated that his research and the few other studies of cardiac surgery patients do not support idea that cardiac surgery patients benefit from hypnosis and suggestion.

Types of intervention have varied: hypnosis, suggestion, relaxation; pre-op, during, or post-op; with many different outcome variables.

Aiken & Henrichs (1971) study was nonrandomized, nonblinded, for 30 patients getting open heart surgery. Treated patients had benefits.

Surman, Hackett, Silverberg, & Behrendt (1974) had a randomized, single-blind design for 40 patients taught Self Hypnosis (S-H), for elective mitral valve surgery. No difference in benefits. But 45% of patients taught S-H reported a subjective sense of benefit (though objective indicators didn't support that). [He says the difference between subjective/objective outcome ratings is important.]

Hart (1980) used randomized, single-blind design for 40 patients who had open heart surgery. No differences found except initial 3 days post surgery.

Greenleaf et al (1992) - see her paper presentation of this date.

Blankfield et al (presented at Society of Clinical and Experimental Hypnosis meeting in 1992) used a randomized, single-blind design for 95 patients, who were

randomly assigned to taped suggestions, music, or controls. No differences were found in benefits.

Our data were re-analyzed: patients who felt tape was helpful were compared to the remaining 62 patients, but there again were no differences in amount of narcotics used for pain, though there was a trend in the right direction; nursing assessments failed to identify less anxiety.

The point is, whereas the bulk of publications suggest benefits, there is little evidence with this population. Could these patients be different in personality, ability to respond to intervention, amount of external stimuli? They should be studied because there are a lot of these patients with only a few surgeons and you don't have to gain the cooperation of a lot of different surgeons to do this kind of research. Also, there is uniformity in cardiac surgery whereas standard operating surgery is in a state of flux in other areas (e.g. movement from generous incisions to micro procedures, and patients receiving this type of surgery remain in hospital for a week whereas this opportunity to study them during inpatient post-surgical period is disappearing in other areas). It is my opinion that cardiac patients may not be highly receptive to suggestion.

Curiously, according to Surman and my research, 1/2 the subjects report benefits. Either some benefits are subtle, or they are reporting a placebo effect.

Future studies need more patients, and the investigators must stratify on personality inventory variables such as Type A personality, hypnotizability, motivation, anxiety, depression, family support, social support systems. This is labor intensive, to determine which characteristics determine differing outcomes. The patients used in this type of research require more presurgery evaluation than previously has occurred.

The MMPI can be self administered and is widely acceptable, but is cumbersome, not well suited to people who are acutely ill. Assessment of Type A personality is important because Type A's might be less receptive to suggestion. Structured interview is time consuming, but a 52-item questionnaire can be self administered. Other factors listed above are important.

Crawford, Helen J.; Gur, Ruben C.; Skolnick, Brett; Gur, Raquel E.; Benson, Deborah M. (1993). Effects of hypnosis on regional cerebral blood flow during ischemic pain with and without suggested hypnotic analgesia. International Journal of Psychophysiology, 15, 181-195.

Using <sup>133</sup>Xe regional cerebral blood flow (CBF) imaging, two male groups having high and low hypnotic susceptibility were compared in waking and after hypnotic induction, while at rest and while experiencing ischemic pain to both arms under two conditions: attend to pain and suggested analgesia. Differences between low and highly-hypnotizable persons were observed during all hypnosis conditions: only highly-hypnotizable persons showed a significant increase in overall CBF, suggesting that hypnosis requires cognitive effort. As anticipated, ischemic pain produced CBF increases in the somatosensory region. Of major theoretical interest is a highly-significant bilateral CBF activation of the orbito-frontal cortex in the highly-hypnotizable group only during hypnotic analgesia. During hypnotic

analgesia, highly-hypnotizable persons showed CBF increase over the somatosensory cortex, while low-hypnotizable persons showed decreases. Research is supportive of a neuropsychophysiological model of hypnosis (Crawford, 1991; Crawford and Gruzelier, 1992) and suggests that hypnotic analgesia involves the supervisory, attentional control system of the far-frontal cortex in a topographically specific inhibitory feedback circuit that cooperates in the regulation of thalamocortical activities.

Everett, John J.; Patterson, David R.; Burns, G. Leonard; Montgomery, Brenda; Heimbach, David (1993). Adjunctive interventions for burn pain control: Comparison of hypnosis and Ativan. Journal of Burn Care and Rehabilitation, 14, 676-683.

Thirty-two patients hospitalized for the care of major burns were randomly assigned to groups that received hypnosis, lorazepam, hypnosis with lorazepam, or placebo controls as adjuncts to opioids for the control of pain during dressing changes. Analysis of scores on the Visual Analogue Scale indicated that although pain during dressing changes decreased over consecutive days, assignment to the various treatment groups did not have a differential effect. This finding was in contrast to those of earlier studies and is likely attributable to the low baseline pain scores of subjects who participated. A larger number of subjects with low baseline pain ratings will likely be necessary to replicate earlier findings. The results are argued to support the analgesic advantages of early, aggressive opioid use via PCA or through careful staff monitoring and titration of pain drugs.

NOTES

1:

"Surgical patients can absorb information while they're knocked out, and even learn tips that help with recovery, researchers reported Friday at a symposium on memory and anesthesia.

"Researchers at Papworth Hospital in Cambridge, England, studied 51 cardiac patients, one-third of whom heard a tape of positive 'therapeutic suggestions' during surgery. Another third heard batches of word associations; the rest heard a blank tape.

"Patients who were played the suggestion tape - which told them they were doing well, or wouldn't feel much pain - left the hospital 1 1/2 days earlier on average than other patients.

"Another study, from the University of Arizona College of Medicine, found that surgical patients who heard specific pain-relief suggestions recovered more easily than those hearing vague advice such as, 'Think of being well.'

"'These are still early days to invest in every operating suite buying a tape recorder to play for the patients,' said Dr. Sunit Ghosh, a researcher with the Papworth team. 'But this definitely does hold promise.'

"Scholars at the second annual Symposium on Memory and Awareness in Anesthesia said patients rarely wake up recalling - unprompted - something that happened during anesthesia.

"But several studies showed subconscious learning while the patients were out cold.

"Not everyone accepted the findings.

"It shows an enormous sensitivity on the part of the brain, if it can be shown,' said Eugene Winograd, an Emory University psychologist and organizer of the Emory-sponsored conference. 'I'm not confident it has been shown yet.'

"Some researchers in other studies found no association between messages heard during anesthesia and learning.

"Dr. Alan Aitkenhead, professor of anesthesia at the University of Nottingham in England, found no significant difference between patients who heard recuperative suggestions and patients who were treated to a deliberately dull history of the hospital where they were.

"Aitkenhead said his study kept all patients quite deeply anesthetized, and that may be why they might not have learned as much as patients in other studies.

"By far, most likely, it's a difference in levels of anesthesia,' he said.

"The Papworth researchers, in another study, found that some patients showed strong word associations after hearing tapes of groups of words during surgery; but other patients under a different anesthesia didn't.

"There needs to be standardization of our testing,' Ghosh said. 'I think it's partly related to the anesthesia technique and partly related to the way in which material is presented to the patient.'

Blankfield, Robert; Scheurman, Kathleen; Bittel, Sue; Alemagno, Sonia; Flocke, Sue; Zyzanski, Stephen (1992, October). Taped therapeutic suggestions and taped music as adjuncts in the care of coronary artery bypass graft patients. [Paper] Presented at the annual meeting of the Society for Clinical and Experimental Hypnosis, Arlington, VA.

## NOTES

1:

18 studies have explored the issue with an experimental design; half used tapes, half didn't; majority of studies found benefits; 2 were of heart surgery patients.

This study used taped suggestions with coronary bypass patients. Used tape recorder rather than person delivering suggestions because it was more convenient; used tape intra-surgery and post-operatively for more impact.

We hypothesized: shorter length of stay, less narcotic analgesia, less anxiety, faster recovery, more positive mental outlook, resume activities sooner, have less symptoms postoperatively, etc.

Used a prospective, randomized, single-blind trial in 2 community hospitals in Cleveland with coronary artery bypass graft surgery patients. Study was done between Dec 1989 - Feb 1992.

3 groups were involved: (1) Suggestion, (2) music, and (3) tape. Control subjects had a blank tape. Tapes were played continuously and repeatedly with headphones. Postoperatively, a different tape was played.

Excluded: Patients with emergent surgery, hearing impairment, poor comprehension of English, patients who died in hospital, patients whose hospital

stay lasted longer than 14 days (3 of them). 5% of sample were eliminated for last 2 reasons.

**Music:** Herb Ernst, Dreamflight II. Suggestions: Music background, permissive, based on Evans & Richardson's study.

**Outcome Measures:** Nurse assessment of anxiety and progress post operatively, Symptom scale, Depression scale.

Mean age 62, 3/4 men, 92% white, 75% married. The groups were same on a variety of preoperative variables (status of heart and arteries). Length of stay was 6.5 in all 3 groups. No difference in narcotics use, in nurse assessment of anxiety or of progress; of depression scale, or activities of daily living.

Recategorized data into patients who said the tapes were helpful (both music and suggestion) N = 33 vs the other patients N = 62. No difference in the variables evaluated.

Hajek, P.; Jakoubek, B.; Kyhos, K.; Radio, T. (1992). Increase in cutaneous temperature induced by hypnotic suggestion of pain. Perceptual and Motor Skills, 74, 737-738.

Eight patients with atopic eczema and six healthy subjects were given hypnotic suggestion to feel pain in the upper part of the back and in one case on the palm. An average local increase in skin temperature of 0.6 degrees centigrade (detected by thermovision) occurred under this condition. For some patients cutaneous pain threshold was increased before the experiment by means of repetitive hypnotic suggestion of analgesia. These subjects reported feeling no pain subjectively, but the local change in skin temperature was equal in both cases. The results suggest a central mechanism induced by measuring changes in pain threshold in the skin, which changes are independent of local changes in blood flow. Local pain in the middle of the upper part of the back, and in one subject for comparative purposes in the region of the right palm, was induced during a single hypnotic session by specific suggestion which emphasized a subjective feeling of local pain lasting for 6 minutes. In four of the eczema patients long-lasting cutaneous analgesia was induced before this experiment by a different suggestion which stressed the impossibility of conducting pain from the skin to the brain and which was repeated in ten consecutive hypnotic sessions. The spatial thermal reaction of the skin surface was monitored, with consecutive recordings taken at 20-sec. intervals before and after finishing the hypnotic suggestion of pain. There was a gradual increase in temperature (1.08 degrees Fahrenheit). In the four eczema patients with long-lasting cutaneous analgesia treated equally, the thermal reaction of the skin was similar to that described above although no subjective feeling of pain was reported. These subjects reported feeling only that their skin was getting warmer at the specified place.

Hargadon, Robin M.; Bowers, Kenneth S. (1992, October). High hypnotizables and hypnotic analgesia: An examination of underlying mechanisms. [Paper] Presented at the annual meeting of the Society for Clinical and Experimental Hypnosis, Arlington, VA.

## NOTES

1:

Bowers' dissociated control adaptation of Hilgard's neodissociation theory of hypnosis posits that higher control systems are not used if lower systems are activated.

Imagery may be less important for achieving hypnotic effects. It also may contribute differently than previously thought, an uncorrelated factor. If imaginal involvement and imagery is integral to the production of analgesia using hypnosis, one would get results different than if not integral.

Research: 65 Ss rated as high on two hypnotizability tests participated.

### Session 1:

Procedure entailed finger pressure pain: baseline, followed by 2 hypnosis treatment trials. Ss were not informed of the second trial before they did the first.

Standard suggestions: imagery congruent with the suggestion (hand like block of wood, protected by a glove)

Imageless condition: your hand will remain comfortably nonresponsive to the pressure; you will not allow other things to come into your mind.

### Outcome Measures

Analogue scale for pain 0-10

Nonvoluntary experience rated 0-4

### Session 2:

Administered Tellegen Scale, Woody & Oakman Scale, Marks Vividness of Imagery, Bowers' Effortless Experiencing, and Duality of Experience during age regression.

## RESULTS.

No difference was found between the standard and imageless conditions in amount of pain reduced. So in high hypnotizables, use of imagery or not doesn't matter for controlling pain. Some Ss had a clear preference however, for one or the other method (even counter to their own expectations).

Feelings of nonvolition did not differ as a function of imagery use.

Multiple regression showed effects of hypnotizability and effortless experiencing. Ss who have an effortless experiencing of imagery benefit from using it to reduce pain; those who find it more effortful do better without imagery when attempting to reduce pain.

Contrary to last year's results reported by Bowers, high imagery was related to duality of experiencing in age regression.

Dissociated control theory is consistent with the results but not necessarily demonstrated. It is important to discriminate between imagery as a mediator rather than as a co-occurrence. This research suggests, as did Zamansky's work on counter suggestions, that imagery is not as critical for hypnotic response as we previously thought.

## 1991

Block, Robert I.; Ghoneim, M. M.; Sum Ping, S. T.; Ali, M. A. (1991). Efficacy of therapeutic suggestions for improved postoperative recovery during general anesthesia. Anesthesiology, 75, 746-755.

There have been claims that the postoperative course of patients may be improved by presentation during general anesthesia of therapeutic suggestions which predict a rapid and comfortable postoperative recovery. This study evaluated the effectiveness of such therapeutic suggestions under double-blind and randomized conditions. A tape recording predicting a smooth recovery during a short postoperative stay without pain, nausea, or vomiting was played during anesthesia to about half the patients (N = 109), while the remaining, control patients were played a blank tape instead (N = 100). The patients were primarily undergoing operations on the fallopian tubes, total abdominal hysterectomy, vertical banding gastroplasty, cholecystectomy, and ovarian cystectomy or myomectomy. The anesthesia methods consisted of either isoflurane with 70% nitrous oxide in oxygen to produce end-tidal concentrations of 1.0, 1.3, or 1.5 MAC; or 70% nitrous oxide in oxygen combined with high or low doses of opioids. Assessments of the efficacy of the therapeutic suggestions in the recovery room and throughout the postoperative hospital stay included: the frequency of administration of analgesic and antiemetic drugs; opioid doses; the incidence of fever; nausea, retching, and vomiting; other gastrointestinal and urinary symptoms; ratings of pain; ratings of anxiety; global ratings of the patients' physical and psychological recoveries by the patients and their nurses; and length of postoperative hospital stay. There were no meaningful, significant differences in postoperative recovery of patients receiving therapeutic suggestions and controls. These negative results were not likely to be due to insensitivity of the assessments of recovery, as they showed meaningful interrelations among themselves and numerous differences in recovery following different types of surgery. Widespread utilization of therapeutic suggestions as a routine operating room procedure seems premature in the absence of adequate replication of previously published positive studies. (Key words: Anesthesia, depth: Awareness, Memory, Recall, Learning.)

#### NOTES

1:

Patients ages 19-55 were accepted into the study and they were paid for participation. (Older patients were excluded to guard against memory or hearing problems.) Other criteria for exclusion were: ASA physical status 4 or 5 indicating significant systemic disease, visual or hearing problems, middle ear disease (because it increases probability of nausea and vomiting), if their condition might require heavy sedation, if they were currently taking medication that interferes with memory (e.g. benzodiazepines, if there were intolerance to opioids, or if there were a likelihood of using postoperative pain treatment other than opioids).

The Spielberger State-Trait Anxiety Inventory was administered before surgery. Either suggestions (lasting 6 minutes) or a blank tape were played through headphones, starting 5 minutes after the surgical incision. The tape was played once for the first 59 patients, continuously for the remaining 150 patients. The first 139 patients received additional verbal materials on the tape, for memory tests to test possibility of learning under anesthesia. Operating room sounds were recorded by a tape recorder near the patient's head, throughout period of unconsciousness (except when tape was being played).

After the first 25% of cases, the team decided that lack of effect on therapeutic suggestions attributable to type of anesthesia did not warrant restriction to a single anesthetic method; also, multiple presentations of the suggestions on tape did not show an effect different from a single presentation.

After the patient regained consciousness and was reoriented, pain, nausea, retching, and vomiting were assessed every 30 minutes. Pain was rated orally on a scale from 1 to 10 in the recovery room, then on visual analogue scales every 2 hours on the day of surgery and the second day, and every 4 hours on subsequent hospital days during waking hours. Variables that were rated by staff every 24 hours included: opioids, other analgesics, antiemetics, nausea, vomiting, retching, presence or absence of nasogastric tube, passage of flatus, bowel movement, fluid intake, solids intake, urination. Temperature was recorded every 4 hours for the first 2 days after surgery, and after that less often. The anxiety measures were repeated on Day 3 postsurgery, as well as self ratings and nurse ratings on physical and psychological recovery. Staff recorded length of postoperative hospital stay and reasons for any delay of discharge. Separate analyses were performed for patients receiving opioids via patient-controlled analgesia (52%) vs traditional administration (48%), but no differences were found for effects of therapeutic suggestions except on postoperative Day 8.

"The inability to detect beneficial effects of therapeutic suggestions probably was not due to insensitivity of the measures of recovery. These measures were sensitive enough to show numerous significant differences in recovery after different types of surgery" (p. 751). The authors supported their contention that the measures were sufficiently sensitive by demonstrating meaningful correlations among the measures themselves; and by demonstrating adequate statistical power for detecting the effects of theoretical interest—at least 1 day in postoperative hospital stay or one half day in fever.

Discussion: The authors note that a recent investigation that found positive results in a double-blind, randomized design with 39 hysterectomy patients (Evans & Richardson, 1988. Improved recovery and reduced postoperative stay after therapeutic suggestions during general anaesthesia. *Lancet*, 2:491-493) may not have controlled for variables such as presence of malignancy, physical status of patients before surgery, or ethnicity. Authors note that Evans and Richardson observed shorter periods of pyrexia despite there being no relevant suggestions, but no differences in pain intensity, nausea, vomiting, or urinary difficulties despite there being suggestions relating to those symptoms. There also were no differences in mood and anxiety test scores postoperatively for the experimental and control groups.

The authors note that McLintock, Aitken, Downie, & Kenny (Postoperative analgesic requirements in patients exposed to positive intraoperative suggestions. *Br M J* 301:788-790. 1990) reported a 23% reduction in opioids by patients receiving suggestions, but no reduction in pain, nausea, or vomiting. They contrast the present study with these earlier studies that had obtained positive results.

"We studied patients who had more than one type of surgery to obtain a large sample size and to assess the possibility that beneficial effects of therapeutic suggestions would be restricted to certain types of operations. Had this been the

case, interactions of therapeutic suggestions with type of surgery would have been significant in the overall analyses, and follow-up analyses would have indicated that they were attributable to beneficial effects of therapeutic suggestions for certain surgeries. This did not occur. The two types of surgeries involving the largest numbers of patients seemed particularly promising for demonstrating beneficial effects. It has been reported that therapeutic suggestions presented during anesthesia are likely to be less successful with major and extensive surgery. Certainly, surgery on the fallopian tubes and gastric stapling did not involve a great deal of tissue trauma and blood loss. Patients were motivated to have the surgery and to recover quickly; particularly motivated were those having operations on the fallopian tubes, who were very eager to become pregnant, and those having vertical banding gastroplasties, who wanted desperately to lose weight" (pp. 753-754).

"In practice, we observed no beneficial effects of therapeutic suggestions, and there was no hint that anesthesia methods influenced the efficacy of the therapeutic suggestions. Interestingly, anesthetic methods also did not influence learning under anesthesia in the implicit memory tests we have used previously. Patients anesthetized with nitrous oxide and opioids did not differ from those anesthetized only with inhalational agents. In general, implicit or unconscious memory occurs in patients regardless of anesthesia methods or dosages of drugs" (p. 754).

"The few significant effects of therapeutic suggestions in our study did not point toward a beneficial influence of these suggestions. We found, in fact, an increased frequency of retching (but not nausea or vomiting) in the experimental group. The multiple variables examined in this study increased the likelihood of significant differences arising by chance, such that the null hypothesis was rejected when it should have been accepted. This is the way we interpret the effect on retching---i.e., as a type I error. We used in our therapeutic suggestions one negative or exclusionary sentence, 'You won't feel nauseous or have to vomit', among several positive or affirmative statements, e.g., 'You will enjoy eating, drinking...You will swallow to clear your throat and everything will go one way, straight down. . . The food will taste good...Your stomach will feel fine.' We do not think that the negative sentence led to paradoxical results. Evans and Richardson (personal communication) used in their therapeutic suggestions a negative sentence ('You will not feel sick'), which they repeated, yet the reported incidence of nausea and vomiting did not differ between the experimental and control groups" (p. 754).

1990

NOTES

1:

Sensory and pain thresholds to laser stimulation were determined, and the laser-pain evoked brain potentials were measured for 8 highly hypnotizable (Harvard Scores 10-11) student volunteers in 3 conditions: (1) waking, (2) suggestion of hyperaesthesia during hypnosis, (3) suggestion of analgesia during hypnosis.

The investigators used a laser beam 3 mm in diameter, with a 200 msec stimulus duration; the same area (but different points within the area) was used for consecutive stimulations. Ss were otherwise maintained in low stimulus conditions so they would not have visual or auditory cues about laser beam onset; they wore

**goggles, had eyes shut, and had earphones on. Sensory threshold was defined as warmth; pain threshold was defined as a distinct sharp pin prick.**

**The laser intensity used for stimulation corresponded to strong pain. Interstimulus intervals averaged 15 sec (but were randomly varied between 10-20 sec). Sensory and pain thresholds as well as two evoked potential measurements were taken during waking, hypnotized hyperaesthesia, and hypnotized analgesia conditions in a single 1 1/2 hour session.**

**The evoked potential component of interest was the negative complex N1 with latency of 300 msec; amplitude (P1=N1-P2) and latency of this complex (N1) were measured. EEG epochs contaminated by eye movement were omitted from analysis. The standardized induction and deepening of hypnosis required 15-20 minutes; then the suggestion was given that Ss could alter their perception of stimuli such as pain. Hyperaesthesia suggestions were to imagine the right hand was in very hot water, then taken out but still very red, hot, sensitive so that even the vaguest stimulus would be detectable and unpleasant. They were told that they would receive a series of painful but tolerable stimuli, and to raise the left index finger if they could just perceive a laser pulse (sensory threshold), and again if they felt pricking pain (pain threshold).**

**Suggestions for analgesia were to imagine that their right hand was placed on their chest, and that their 'former right hand' was no longer their own but was made of some heavy and completely insensitive material like wood or stone. Sensory and pain threshold measures were then taken. During the evoked potential measurement period they received continuous suggestions of analgesia. They also were told to relax and imagine they were in a pleasant place, ignoring everything except the pleasant, relaxed feelings and imagining pleasant sights, sounds, feelings and the imagined place. They were told that though they would receive stimuli, they probably would be able to ignore the stimuli completely.**

**Results were as follows.**

**1. In the hypnotic hyperaesthesia condition, sensory and pain thresholds decreased significantly by 47% and 48%, respectively. Three Ss reacted to laser intensities far below what normally can be perceived in the waking state. [The authors ran a separate small control experiment to make sure that the Subjects were not using any other cues, but mention the possibility of light-sensitive skin reacting to the blue laser light, creating evoked potentials.]**

**2. In the hypnotic analgesia condition, sensory and pain thresholds increased by 316% and 190%, respectively. 7 of 8 Ss did not even respond to pain threshold when the laser intensity was increased to the noxious level of 3W, which is the level at which tissue damage can occur.**

**3. Pain-related evoked potentials. Amplitude of the first pain-related potential was increased significantly by 14% in the hyperaesthesia condition and reduced significantly by 31% in the analgesia condition. Changes in the evoked potentials were considered minor however compared to those observed for thresholds, which are subjective response measures. Even in Subjects who reported complete analgesia, the experimenters observed the laser pain evoked responses. There were no differences in latencies of the first pain-related potentials for the three conditions**

(indicating that peripheral and central afferent conduction velocities were the same).

**Discussion.** "There has been some dispute concerning the experimental design and the reliability of the data obtained in studies dealing with hypnotic suggested analgesia [Spanos & Chaves, 1970]. In our design 2 'opposite' conditions were induced, and the 2 inductions gave 'opposite' results.

"The experience of pain can be significantly altered by suggestions of analgesia, which is in accordance with a number of other studies (for review see [Barber & Adrian, 1982; Hilgard & Hilgard, 1975]). The finding that suggestions of hyperaesthesia can decrease the sensory and pain thresholds and increase the amplitude of the pain evoked potential is a new observation. Since synchronized auditory and visual stimuli from the laser were blocked, and the stimulus was given at random intervals, the changes might be induced by the hypnotic suggestions" (p. 247).

The authors discuss their results in terms of (1) four pain modulation systems (neural/opiate, hormonal/opiate, neural/non-opiate, and hormonal/non-opiate) and (2) focusing and defocusing attention. Because in their pilot study it was necessary to give suggestions continually in order to affect the laser evoked potentials, they conclude that endogenous substances or hormonal/non-opiates would play a minor role, if any, in hypnotic analgesia. (Price and Barber [25] had also found it important to give suggestions continuously.)

On the other hand, "event-related potentials [7, 26] and pain-related potentials have, previously, been shown to be sensitive to focused and de-focused attention. Recently, Miltner et al. [23] showed the influence of attention on the late pain-related component of potentials, evoked by painful intracutaneous electrical stimulation. The degree to which the subject paid attention to the painful stimulus had a powerful effect on the pain-related complex. When subjects ignored the pain, it was still possible to record the pain-related complex although all the subjects consistently reported less or no pain. In wakeful subjects where cutaneous pain was abolished by lignocaine infiltration, the pain-related evoked potentials were abolished [4]. In our study, we could also record evoked potentials although the subject subjectively did not feel pain. The reason might be that the S acted as if there was full analgesia to the stimuli, in order to satisfy the hypnotist. During suggested hyperaesthesia the thresholds declined below what normally could be perceived in the wakeful state. The volunteers could, therefore, not act hypersensitive, so something did happen.

"The discrepancy in subjective and objective responses might, however, be useful when investigating levels of the neuroaxis at which hypnosis might work" (pp. 248-249).

The authors note that this laser induced pain and the tooth pulp stimulation pain of Mayer & Barber both use the A-delta fibers. Barber & Mayer found it impossible to elicit pain within the output range of the stimulator (up to 150 microA) and reached maximal intensity for all volunteers during suggested analgesia. Using cutaneous laser stimulation the authors found that the skin damage level (3W) could be reached in 7 of 8 volunteers without any reaction of pain.

During the hyperaesthesia condition the sensory threshold was sometimes lower than can be detected in the waking state. Although some researchers have suggested that red light from a helium-neon laser might activate cutaneous photosensitive receptors and thereby elicit brain potentials, the authors were unable to elicit potentials in waking Subjects using their blue and green argon laser light with below sensory threshold intensity.

The authors also note that previous attempts to use physiological correlates of pain such as heart rate, blood pressure, respiration, and galvanic skin response have yielded confusing results. The physiological indicators are present even when Subjects report analgesia, leading some investigators to conclude that the subjective reports are due to illusion [Sutcliffe, 1961], compliance [Wagstaff, 1986], or a placebo induced by the hypnosis context [Wagstaff, 1986]. "These confusing results lead to the conclusion that both the traditional methods used for induction of pain and the monitored physiological responses have been unsatisfactory. The present study has sought to eliminate some of the methodological difficulties by (1) using brief well-defined argon laser stimuli which in awake volunteers induce very stable perceptions between trials [Arendt-Nielsen & Bjerring, 1988], and (2) recording psychophysical thresholds and objective parameters quantitatively related to the intensity of the pain perceived (1, 3)" (p. 249).

Harmon, Teresa M.; Hynan, Michael T.; Tyre, Timothy E. (1990). Improved obstetric outcomes using hypnotic analgesia and skill mastery combined with childbirth education. Journal of Consulting and Clinical Psychology, 58, 525-530.

Studied the benefits of hypnotic analgesia as an adjunct to childbirth in 60 nulliparous women. Subjects were divided into high- and low-susceptibility groups before receiving six sessions of childbirth education and skill mastery using an ischemic pain task. Half of the subjects in each group received a hypnotic induction at the beginning of each session; the remaining control subjects received relaxation and breathing exercises typically used in childbirth education. Both hypnotic subjects and highly susceptible subjects reported reduced pain. Hypnotically prepared births had shorter Stage 1 labors, less medication, higher Apgar scores, and more frequent spontaneous deliveries than control subjects' births. Highly susceptible, hypnotically treated women had lower depression scores after birth than women in the other three groups. The authors believe that repeated skill mastery facilitated the effectiveness of hypnosis in the study.

Boeke, S.; Bonke, B.; Bouwhuis-Hoogerwerf, M. L.; Bovill, J. G.; Zwaveling, A. (1988). Effects of sounds presented during general anaesthesia on postoperative course. British Journal of Anaesthesia, 60, 697-702.

In a double-blind, randomized study, patients undergoing cholecystectomy were administered one of four different sounds during general anaesthesia: positive suggestions, nonsense suggestions, seaside sounds or sounds from the operating theatre. The effect of these sounds on the postoperative course was examined to

assess intraoperative auditory registration. No differences were found between the four groups in postoperative variables

**NOTES**

**1:**

Postoperative course was evaluated by 5 variables: pain, nausea and vomiting, evaluation by nursing staff, subjective well-being, and duration of postoperative hospital stay. From the chart they used amount of postoperative analgesia, volume of nasogastric suction or drainage and fluid lost through vomiting over 6 days post-operatively; duration of postoperative hospital stay was registered after discharge. See p. 699 for details, including wording of questions. They cite their own earlier study that got positive results, and explain the difference as possibly due to use of only male voices on tapes, lack of difference in the sounds on tapes in this study, insensitivity of outcome measures (patients stayed longer in first study than in this one), and sample too small in this study (106).

Boeke et al. (1988) report that this double-blind, randomized study of positive suggestions, noise or sounds from the operating theatre presented to 3 groups of patients undergoing cholecystectomy during general anaesthesia had positive results for older patients. patients > 55 years who received positive suggestions had a significantly shorter postoperative hospital stay than the other patients in this age category.

**Goldmann, Les; Ogg, T. W.; Levey, A. B. (1988). Hypnosis and daycase anaesthesia. A study to reduce preoperative anxiety and intraoperative anaesthesia requirements. Anesthesia, 43, 466-469.**

52 female patients having gynecological surgery as day cases received either a short preoperative hypnotic induction or a brief discussion of equal length. Hypnotized patients who underwent vaginal termination of pregnancy required significantly less methohexitone for induction of anesthesia and were significantly more relaxed as judged by their visual analogue scores for anxiety. Less than half the patients were satisfied with their knowledge about the operative procedure even after discussions with the surgeon and anesthetist. A significant correlation was found between anxiety and perceived knowledge of procedures. Results suggest that preoperative hypnosis can provide a quick and effective way to reduce preoperative patient anxiety and anesthetic requirements for gynecological daycase surgery.

**NOTES**

**1:**

This article is a reply to Wagstaff's (1984) critique of the McGlashan, Evans & Orne (1969) article which was entitled "The nature of hypnotic analgesia and the placebo response to experimental pain," published in *Psychosomatic Medicine*, 31, 227-246. The paper to which the authors are replying is Wagstaff, G. F. (1984). Is

hypnotherapy a placebo? Paper given at the First Annual Conference of the British Society of Experimental and Clinical Hypnosis, University College, London. An abridged version appeared in the British Journal of Experimental and Clinical Hypnosis, 1987, 4, 135-140.

The closing comments of this Evans & McGlashan 1987 paper read as follows: "The strategy in this study [i.e. McGlashan, Evans & Orne, 1969] was quite different from the usual experimental design. Our goal was to maximize all of those non-specific factors that we could build into the experimental procedure. Only by attempting to maximize non-specific effects is it possible to see whether hypnosis in appropriately responsive subjects can exceed that degree of pain control which occurs due to the maximal operation of these non-specific effects. These non-specific components of the hypnotic situation may account for a great deal of clinical change. ... The critical finding was that hypnosis did add a level of pain control that occurred after maximizing clinically related non-specific factors contributing to change in pain tolerance, and that this increased tolerance occurred only in subjects markedly responsive to hypnosis, in contrast to the significant non-specific effects which were uncorrelated with measured hypnotizability" (pp. 143-144).

The principal findings of the McGlashan, Evans & Orne (1969) study were: "(a) The improved ability to tolerate pain following the ingestion of placebo was roughly the same for high hypnotizable and low hypnotizable subjects. (b) The response to the non-specific aspects of taking a 'drug' among low hypnotizable subjects was identical to, and highly correlated (.76) with, their response to the legitimized expectation that change would occur under hypnosis for low hypnotizable subjects. The placebo component of a believe-in 'drug' ingestion was the same as the placebo component of a believed-in hypnotic experience for these low hypnotizable subjects. (c) The performance of the highly hypnotizable subjects was significantly greater under hypnotic analgesia conditions than it was under placebo conditions.

"This last finding is important conceptually, though of less clinical relevance. It should be noted that not all high hypnotizable subjects showed this result. Even among highly hypnotizable subjects, not all of them had the experience that profound analgesia had occurred! Thus, based on their subjective experience of the relatively small degree of analgesia, 6 of the 12 highly hypnotizable subjects behaved exactly as the low hypnotizable subjects had -- their placebo and hypnotic responses were small, significant, but equal. Only 6 out of 12 carefully screened hypnotizable subjects who subjectively experienced marked analgesia showed dramatic objective changes in pain endurance. Dr. Wagstaff might consider the physiological implications of the observation that we became somewhat frightened about the possibility of tissue damage with two of these six subjects. We had to stop their performance at a point where physiologists had assured us that tissue damage could be expected. They had also assured us, wrongly for these subjects, that we did not have to worry about such a critical point because nobody could endure such a degree of occlusion with this procedure. In fact, for these two subjects, anoxia and muscle cramping were not even apparent!" ( p. 144).

Goldmann, Les (1987, October). Ways of maximizing patient memory for events during anesthesia. [Paper] Presented at the annual meeting of the Society for Clinical and Experimental Hypnosis, Los Angeles.

#### NOTES

1:  
Reported a series of experiments: 1. Under atropine, we did not get an orienting response to things having to do with the operation, but did get an orienting response to jokes, dogs barking, and the name of a polite anesthetist. 2. Replicated the research by Bennett and didn't get ear pulling response. 3. Studied cardiac patients. Gave subjects a pre-anesthesia speech of importance [of hearing under anesthesia? Notes here are not clear.] and a chin touch suggestion that was successful. 7 of 30 subjects gave reports of recall - usually recalled something of particular interest to them. These 7 subjects appeared more anxious postoperatively than previously. 4. Recognition study: Pre-op "IQ" test. Gave subjects answers to the questions while they were under anesthesia, and postoperatively they had better performance than previously. 5. Recall study, double blind. Interviewer learned something about the patient, and told them something about what was learned about the patient during anesthesia e.g., You have a lovely garden. After surgery they were hypnotized by someone who did not know what information was given, and then recall for information "heard" under anesthesia was tested. 6. 10 female patients who were good hypnotic subjects, all received the same statement under anesthesia, that they would believe for a moment that they had green hair. During the interview, one said she was fascinated by green things, one wanted to go home and wash her hair.

Goldmann, Les; Shah, M. V.; Hebden, M. W. (1987). Memory of cardiac anesthesia: Psychological sequelae in cardiac patients of intra-operative suggestion and operating room conversation. Anesthesia, 42 (6), 596-603.

Thirty elective cardiopulmonary by-pass surgery patients were interviewed pre- and postoperatively. A random selection of patients heard a prerecorded audio tape toward the end of surgery after they were rewarmed to 37 degrees C. The tape contained suggestions for patients to touch their chin during the postoperative interview, to remember three sentences, and to recover quickly. The interviewers were blind to the experimental conditions. The experimental group touched their chins significantly more often than the control group ( $p = .015$ ). Sentence recognition did not reach significance, perhaps due to the small numbers and low salience of the stimuli. Seven patients (23%) recalled intraoperative events, five with the aid of hypnosis. Three reports (10%) were corroborated. Preoperative medication ( $p < .01$ ) and postoperative anxiety ( $p < .05$ ) were significant predictors of those patients who reported recall.

Hilgard, Ernest R. (1987). Research advances in hypnosis: Issues and methods. International Journal of Clinical and Experimental Hypnosis, 35, 248-264

There are substantial areas of agreement upon the classical phenomena of hypnosis, illustrated by what we now have learned about hypnotic talent, amnesia,

hallucinations, analgesia, and dissociative processes. While genuine advances in knowledge about hypnosis have been made in recent decades, differing orienting attitudes have kept some controversy alive, particularly in the interpretation of empirical findings. Differences of interpretation of the phenomenal and behavioral facts are to be expected in the present stage of developmental, cognitive, and social psychology.

## NOTES

1:

The author writes of the "domain of hypnosis" as within the larger domain of social psychology (because it is usually interpersonal); cognitive psychology (because of alterations in perception, imagination, memory, and thought); developmental and personality psychology (because of individual differences); and physiological psychology (because of neurophysiological aspects).

In terms of what we know about hypnotic talent, he notes that high hypnotizability is not generally associated with psychopathology; that it may however be associated with a personality measure called absorption; and that there may be some inherited ability (Morgan, 1973). In the author's view, hypnosis is no longer considered simply a response to suggestion, since imagination and/or fantasy are very important.

In reviewing evidence of posthypnotic amnesia the author writes, "Subtleties in language require making careful distinctions among concepts such as compliance, suggestion, compulsivity, belief, self-deception, automaticity, the voluntary, the involuntary, and a happening. If these distinctions are glossed over, the choice of words (e.g., substituting compliance for response to suggestion) may give the impression that a finding departs more widely from conventional views than it does. We, too, have found that Ss used varied strategies or skills during amnesia, but this need not deny augmentation by suggestion.

"It takes genuinely high Ss to illustrate truly high posthypnotic amnesia... Many of the truly high hypnotizable individuals cannot break amnesia, no matter how hard they try" (p. 253).

Regarding the evidence for hypnotic hallucinations and trance logic, the author suggests that trance logic is not a clear concept because the Subject is capable of good logic while tolerating some inconsistencies. "It is ordinary logic to assume that if your hallucination is your own construction, it is you who can influence it by your own wishes. In the rare cases of transparent or diaphanous hallucinations there is still an 'out there' quality. People who report that they see wispy ghosts also see them as 'out there,' so that they qualify as hallucinations. The distinction appears to be one of perception and perception-like experiences within hypnosis rather than of logic" (p. 256).

In reviewing the evidence for hypnotic analgesia, the author acknowledges that pain relief is available with other kinds of interventions, or by using other kinds of psychological processes, but that does not diminish the contribution of hypnosis (which has a long and impressive clinical history). Following laboratory studies, it is noted that "the amount of alleviation of pain through hypnosis is positively correlated with the hypnotizability of the candidate for pain reduction. This result is not universally accepted, because some clinicians are convinced that those unsuccessful in hypnotic pain reduction are resisting hypnosis" (p. 256-257). In the

present paper he acknowledges but does not review physiological literature on hypnoanalgesia.

Regarding the concept of dissociation, the author indicates that he considers it a more useful concept than the concept of trance or hypnotic state "when a person is only slightly or moderately involved in hypnosis ... . The advantage is that dissociations, as compared with altered states, can be described according to limited or more pervasive changes in the cognitive or motor systems that are being activated or distorted through suggestion in the context of hypnosis. Perhaps when all-inclusive enough, such changes can justify the use of the term trance or altered state, but I believe that these terms should be used, if at all, only for those for whom the immersion in the hypnotic experience is demonstrably pervasive" (pp. 258-259). The author goes on to describe his initial discovery of the 'hidden observer' in an experimental context, and to relate the 'hidden observer' to others' earlier observations of a secondary report of an experience previously concealed from S's consciousness (Binet, 1889-1890/1896; Estabrooks, 1957; James, 1899; Kaplan, 1960). "The issues are still being worked on, but as in the case of trance logic the heart of the problem is not whether to speak of a hidden observer, but to recognize that there may be cognitive distortions in hypnosis even while some more realistic information is being processed in parallel, so that everything is not reportable by S" (p. 260).

1986

Farthing, G. William; Venturino, Michael; Brown, Scott W.; Lazar, Joel D. (1986, April). Internal vs. external distraction in the control of pain as a function of hypnotic susceptibility. [Paper] Presented at the annual meeting of the Eastern Psychological Association, New York.

NOTES

This study tested the prediction, derived from their 1984 study: for highly hypnotizable subjects, pain reduction methods involving either attention to external distracting stimuli or attention to internally generated distracting images will be effective in reducing pain. However, for low hypnotizables only external stimulus distraction will be effective, and internal images will not be effective distractors for reducing pain.

Used independent groups of college students, with 1/3 highs, 1/3 mediums, and 1/3 lows. Used five conditions: (n=12 per subgroup 3H x 5T) 1. Suggestion - Subjects told "to image as vividly as you can that your hand is numb and insensitive, as if it were made of rubber." (No hypnotic induction was used.) 2. Guided imagery - Subjects told to listen to a story that would be read to them, and to try to imagine the scenes as vividly as possible. (Story included scenes where the s was the main character.) 3. Word memory - Subjects told to listen to a list of words that would be read to them and try to remember them for later recall test (30 abstract nouns, at rate of 1 every 2 seconds. 4. Pursuit rotor - which subjects did during the ice water immersion. 5. Placebo control - included suggestion, "For this test you will find that you can succeed in not being disturbed by the cold water if you carefully follow the following instructions. While your hand is in the water you should not try to control

your thoughts. Just let your mind wander freely to whatever feelings or thoughts or ideas happen to come to you."

1985

Eich, Eric; Reeves, John L.; Katz, Ronald L. (1985). Anesthesia, amnesia, and the memory/awareness distinction. Anesthesia and Analgesia, 64, 1143-1148.

Several studies have shown that surgical patients cannot consciously recall or recognize events to which they had been exposed during general anesthesia. Might evidence of memory for intraoperative events be revealed through the performance of a postoperative test that does not require remembering to be deliberate or intentional? Results of the present study, involving the recognition and spelling of semantically biased homophones, suggest a negative answer to this question and imply that intraoperative events cannot be remembered postoperatively, either with or without awareness.

#### NOTES

1:

"In this experiment, we attempted to apply the distinction between memory and awareness of memory to the question of whether adequately anesthetized and apparently unconscious patients can register and retain what is said in their presence during surgery. Prior research relating to this question has focused, for the most part, on the ability of postoperative patients to recall or recognize a specific item....The inference need not be drawn, however, that 'patients in so-called surgical planes of anesthesia cannot hear' (15, p. 89) or that anesthetized patients cannot encode and store in memory events that transpire during their surgery. The possibility remains that even though the effects of memory for intraoperative events may not--and probably cannot--be revealed in postoperative tests of retention that require remembering to be deliberate or intentional, such effects might be evident in the performance of tests that do not demand awareness of remembering.

"To explore the possible dissociation between memory and awareness of memory for intraoperative events, we modeled our experiment after a recent neuropsychological study by Jacoby and Witherspoon (5)" (p. 1143).

"...it appears that the prior presentation of a word has a substantial impact on its subsequent interpretation and spelling, regardless of whether or not the word is correctly classified as 'old' in a later test of recognition memory" (p. 1144).

"Approached from the standpoint of anesthesia theory and practice, the idea that recognition and spelling tap different memory processes or systems raises an interesting question for research. Specifically, suppose that during surgery, an anesthetized patient listens to a series of short, descriptive phrases, each consisting of a homophone and one or two words that bias the homophone's less common interpretation (e.g., war and PEACE, deep SEA). Suppose further that several days after surgery, the patient is read a list composed chiefly of old and new homophones (i.e., ones that either had or had not been presented intraoperatively) on two successive occasions. On one occasion, the patient is simply asked to spell each list item aloud; on the other occasion, the patient is asked to state aloud which list items he or she recognizes as having been presented during surgery. Given the situation

sketched above, might the patient spell significantly more old than new homophones in line with their less common interpretations, and yet fail to reliably discriminate between the two types of items in the test of recognition memory" (p. 1144).

**Gillett, Penny L.; Coe, William C. (1984). The effects of rapid induction analgesia (RIA), hypnotic susceptibility and the severity of discomfort on reducing dental pain. American Journal of Clinical Hypnosis, 27, 81-90.**

**ACT** The study was designed to address three issues involved in hypnotic analgesia for dental pain: 1) The effectiveness of J. Barber's (1977) hypnotic procedure for producing analgesia in its usual form and a shortened form, 2) the relationship of hypnotic susceptibility to analgesic responsiveness, and 3) the effect of dental procedure discomfort level on hypnotic analgesia. Sixty unselected dental patients were administered either J. Barber's (1977) RIA or a shortened version of it (SI) before their dental treatment. Measures of hypnotic susceptibility were obtained as were dentists' ratings of the discomfort levels involved in the various dental procedures administered. The 52% success rate of the present study failed to replicate Barber's very high (99%) success rate, although procedural differences might explain the lower rate. RIA and SI were equally effective. Hypnotic susceptibility level did not relate significantly to success with hypnotic analgesia. The level of dental procedure discomfort was the clearest predictor of success with hypnotic analgesia. The greater the discomfort rating of a procedure the less likely that hypnotic analgesia would be successful.

**Edwards, William Henry (1980). Direct versus indirect hypnosis for the relief of chronic pain in spinal cord injured patients (Dissertation, United States International University). Dissertation Abstracts International, 40 (10-B), 4996.**

**NOTES**

**1:**

This study compared effectiveness of direct hypnosis and indirect hypnosis (Rapid Induction Analgesia, developed by Joseph Barber) in reducing experimental and clinical pain in spinal cord injured patients. The 30 male paraplegic patients who had chronic benign pain volunteered for the study. They were administered three tests: the Pain Estimate Scale (Sternbach, 1974), Ischemic Muscle Pain Test (IMPT), and the Stanford Profile Hypnotic Susceptibility Scale, Form II -- SPHSS -- (Weitzenhoffer and Hilgard, 1967). Each patient experienced three sessions: (1) Baseline Control, (2) Direct Hypnosis, and (3) Indirect Hypnosis. Patients were randomly assigned to Sessions (2) and (3). The results indicated no significant statistical difference in the effectiveness of direct versus indirect hypnotic analgesia in these chronic pain patients. Direct and indirect hypnosis were equally effective; hypnotizability was not associated with outcome. Furthermore, there was no

interaction between treatment effects and pretreatment pain level. The results were similar for both clinical and experimental pain.

1979

Barber, Joseph; Donaldson, David; Ramras, Susan; Allen, Gerald D. (1979). The relationship between nitrous oxide conscious sedation and the hypnotic state. Journal of the American Dental Association, 99, 624-626.

NOTES

1:

Nitrous oxide-oxygen produces a state of consciousness in the patient that is reported to be similar to the hypnotic state. In this investigation, the authors test the hypothesis that nitrous oxide-oxygen heightens a patient's responsiveness. This study apparently did not have a control group receiving nitrous oxide but no suggestions, to evaluate the amnesia and analgesic effects of the drug alone.

Bennett, Henry L.; Giannini, Jeffrey A.; Kline, Mark D. (1979, September). Consequences of hearing during general anesthesia. [Paper] Presented at the annual meeting of the American Psychological Association, New York.

A double blind 2X2 study exposed 23 herniorrhaphy and cholecystectomy patients to either a 45 minute suggestion tape or to the actual sounds of the operation. Structured interviews conducted postoperatively assessed hypnotic susceptibility and regressed patients under hypnosis to operative events. Ten patients accurately recalled significant events from surgery but only under hypnosis. Recall was greater and more accurate in patients scoring high on the Stanford Clinical Hypnosis Scale. Fewest number of pain medications were given postoperatively to patients receiving the suggestion tape. Hernia patients showed better recall than gallbladder patients.

1977

Chertok, Leon; Michaux, D.; Droin, M. C. (1977). Dynamics of hypnotic analgesia: Some new data. Journal of Nervous and Mental Disease, 164, 88-96.

Following two surgical operations under hypnotic anesthesia, it was possible, during subsequent recall under hypnosis, to elicit a representation of the past operative experience. It would seem that under hypnosis there is a persistence of the perception of nociceptive information and of its recognition as such by the subject. From an analysis of these two experiments in recall, it is possible to formulate several hypotheses concerning the psychological processes involved in hypnotic analgesia. In consequence of an affective relationship, in which the hypnotist's word assumes a special importance for the subject, the latter has recourse to two kinds of mechanism: a) internal (assimilation to an analogous sensation, not, however, registered as dangerous-- rationalization); and b) external (total compliance with the interpretations proposed by the hypnotist), which lead to a qualitative transformation of nociceptive information, as also the inhibition of the behavioral manifestations normally associated with a painful stimulus.

1976

Chaves, John F.; Barber, Theodore Xenophon (1976). Hypnotic procedures and surgery: A critical analysis with applications to 'acupuncture analgesia'. American Journal of Clinical Hypnosis, 18 (4), 217-236.

Although hypnotic procedures are useful for reducing the anxiety of surgery and helping patients tolerate surgery, they do not consistently eliminate pain. Six factors that are part of or associated with hypnotic procedures help patients tolerate surgery. These factors pertain to patient selection, the patient-physician relationship, the preoperative 'education' of the patient, the adjunctive use of drugs, and the use of suggestions of analgesia and distraction. It appears that the same factors account for the apparent successes of 'acupuncture analgesia' as well. A frequently-overlooked fact, that most internal tissues and organs of the body do not hurt when they are cut by the surgeon's scalpel, is also important in understanding how surgery can be performed with either 'hypnoanesthesia' or 'acupuncture analgesia.'

1975

Carli, G. (1975). Some evidence of analgesia during animal hypnosis [Abstract]. Experimental Brain Research, 23, 35.

The purpose of this study was to investigate the response to painful stimuli during animal hypnosis. The experiments were performed on unanesthetized, free-moving rabbits carrying implanted electrodes for recording the EEG and EMG activity and nerve stimulation. Injection of formaline into the dorsal region of the foot produced long lasting EEG desynchronization and motor pain reactions. In some rabbits a procedure of habituation was used to reduce hypnosis duration below 45 sec. Hypnosis was induced by inversion. The following results were obtained: 1) Polysynaptic reflexes elicited [sic] by electrical stimulation of cutaneous and muscle afferents were depressed during hypnosis. 2) Hypnosis transitorily suppressed all the painful manifestations due to formaline injection and was characterized by high [sic] voltage slow wave activity in the EEG, 3) In habituated rabbits, a significant increase in hypnotic duration and EEG synchronization was observed when hypnosis was preceded by formaline injection. Hypnosis duration was not potentiated by painful stimuli when Naloxone (5mg/Kg i.v.) was injected before hypnosis induction. 4) In habituated rabbits a recovery in hypnotic duration coupled to EEG synchronization was obtained, in absence of painful stimuli, following subanalgesic injection of Morphine (1mg/Kg). It has been previously shown that in the rabbit administration of 5-20 mg/Kg of Morphine produces EEG synchronization and strong reduction of pain reactions. It is suggested that, during animal hypnosis in a condition of continuous nociceptive stimulation, the pain response is blocked by a mechanism which exhibit [sic] similar effects of Morphine both at spinal cord (polysynaptic reflexes) and at cortical levels (EEG synchronization).

1974

Chaves, John F.; Barber, Theodore Xenophon (1974). Acupuncture analgesia: A six-factor theory. Psychoenergetic Systems, 1, 11-21.

The dramatic successes claimed for acupuncture suggest that Western medicine has failed to identify important factors that pertain to the nature of pain and its control. This may not be the case, as there are at least six factors which are often overlooked by writers describing the absence of pain (i.e., analgesia) during acupuncture: (a) the patients accepted for surgery under acupuncture usually believe that it will work, (b) drugs are frequently used in combination with acupuncture, (c) the pain associated with surgical procedures is less than is generally assumed, (d) the patients are prepared in special ways for surgery under acupuncture, (e) the acupuncture needles distract the patient from the pain of surgery and, (f) suggestions for pain relief are present in acupuncture treatment. It is concluded that more research is needed to determine whether additional factors are needed to help explain the phenomenon of acupuncture analgesia.

Chaves, John F.; Barber, Theodore Xenophon (1974). Cognitive strategies, experimenter modeling, and expectation in attenuation of pain. Journal of Abnormal Psychology, 83 (4), 356-363.

Verbal reports of pain were obtained from 120 subjects during a base-level pretest and also during a posttest conducted under one of several experimental treatments. The pain stimulus was a heavy weight applied to a finger for two minutes. During the posttest, subjects who had been asked to utilize cognitive strategies for reducing pain (to imagine pleasant events or to imagine the finger as insensitive) showed a reduction in pain as compared to uninstructed control subjects. Subjects led to expect a reduction in pain, but not provided with cognitive strategies, also showed reduced pain during the posttest as compared to control subjects, but the reduction was smaller than for subjects using cognitive strategies. An experimenter modeling procedure, used with one half of the subjects under each experimental treatment, was effective in reducing verbal reports of pain only for subjects with high pretest levels who were asked to imagine pleasant events.

1970

Evans, Michael B.; Paul, Gordon L. (1970). Effects of hypnotically suggested analgesia on physiological and subjective responses to cold stress. Journal of Consulting and Clinical Psychology, 35 (3), 362-371.

Relative effects of suggested analgesia and hypnotic induction were evaluated with regard to reduction of stress responses (self-report, heart rate, pulse volume) to the physical application of ice-water stress. Four groups (N = 16 each) of undergraduate female Ss, equated on hypnotic susceptibility, were run individually, receiving (a) hypnotic induction plus analgesic suggestion, (b) hypnotic induction alone, (c) waking self-relaxation plus analgesic suggestion, or (d) waking self-relaxation alone. The major findings were that suggestion, not hypnotic induction procedures, produced reductions in the self-report of distress, and that the degree of reduction

was related to hypnotic susceptibility in both "hypnotic and "waking" conditions. Neither suggestion nor hypnotic induction procedures resulted in reduction of the physiological stress responses monitored in this study. Several methodological issues are discussed. Although findings add to the bulk of evidence supporting the "skeptical" view of hypnotic phenomena, results are related to other literature, suggesting that an adequate evaluation of hypnotic analgesia as used clinically has not yet been undertaken.

**1969**

**Barber, Theodore Xenophon (1969). An empirically-based formulation of hypnosis. American Journal of Clinical Hypnosis, 12 (2), 100-130.**

A formulation is presented which does not invoke a special state of consciousness ("hypnosis" or "trance") to account for the behaviors that have been historically associated with the word hypnotism. Instead, so-called hypnotic behaviors - e.g., "analgesia," "hallucination," "age-regression," and "amnesia" - are conceived to be functionally related to denotable antecedent variables which are similar to those that control performance in a variety of interpersonal test-situations. The antecedent variables which determine behavior in a "hypnotic" situation include Ss' attitudes, expectancies, and motivations with respect to the situation, and the wording and tone of instructions- suggestions and of questions used to elicit subjective reports. The formulation is exemplified by several dozen experimental studies, and prospects for further research are delineated.

**1965**

**Barber, Theodore Xenophon (1965). Physiological effects of 'hypnotic suggestions': A critical review of recent research (1960-64). Psychological Bulletin, 201-222.**

Recent studies are reviewed which were concerned with the effectiveness of suggestions given under "hypnosis" and "waking" experimental treatments in alleviating allergies, ichthyosis, myopia, and other conditions and in eliciting deafness, blindness, hallucinations, analgesia, cardiac acceleration and deceleration, emotional responses, urine secretion to sham water ingestion, narcotic-like drug effects, and other phenomena. The review indicates that a wide variety of physiological functions can be influenced by suggestions administered under either hypnosis or waking experimental treatments, and direct and indirect suggestions to show the particular physiological manifestations are crucial variables in producing the effects.

**Bernstein, Norman R. (1965). Observations on the use of hypnosis with burned children on a pediatric ward. International Journal of Clinical and Experimental Hypnosis, 13 (1), 1-10.**

Several cases are described and observations made about the interplay of forces between staff, patient, and therapist, as well as the expectations of the patients to assess how these factors influenced the use of hypnosis. Hypnosis appears to be a

particularly useful means for reaching isolated and depressed children with burns and for improving the morale of the staff team working with these children. The results may be along specific lines in terms of pain tolerance and improved eating, or in general improvement of cooperativeness and mood on the part of the child. 1964

Attar, A.; Muftic, M. (1964). Narcohypnosis in abdominal surgery. British Journal of Medical Hypnotism, 16 (1), 29-32.

Effectiveness of a relaxation technique to increase the comfort level of patients in their first postoperative attempt at getting out of bed was tested on 42 patients, aged 18 to 65, who were hospitalized for elective surgery. Study group patients were taught the relaxing technique; control group patients were not taught the technique. Each group had an equal distribution of cholecystectomy, herniorrhaphy, and hemorrhoidectomy patients. Blood pressure, pulse, and respiratory rates of subjects in both groups were compared prior to surgery and after the postoperative attempt to get out of bed. Subjects' reports of incisional pain and bodily distress were measured via a pain and distress scale after their attempt at getting out of bed. Amount of analgesics used in the first 24 hrs following surgery was examined. Mean differences in report of incisional pain and body distress, analgesic consumption, and respiratory rate changes were statistically significant, supporting the hypothesis that use of a relaxation technique to reduce muscular tension will lead to an increased comfort level of postoperative patients.

1961

Hilgard, Josephine R.; Hilgard, Ernest R.; Newman, Martha (1961). Sequelae to hypnotic induction with special reference to earlier chemical anesthesia. Journal of Nervous and Mental Disease, 133, 461-478.

## NOTES

Although a review of relevant literature turned up little in the way of statistical studies, some case studies were located in which unintended or unexpected results of hypnosis were observed. The authors located 15 cases in which the symptoms that developed subsequent to symptom removal using hypnosis were more disturbing than the original symptom. This type of response occurred in patients with extensive psychiatric history, prior to the hypnosis experience. However, it could not be determined whether the undesired response was due to hypnosis or to the psychotherapy that was provided to these patients.

In order to avoid the complications introduced by studying undesired sequelae in psychiatric patients receiving posthypnotic suggestions for therapeutic purposes, this investigation used a sample of non-patient university students (114 male and 106 female) who volunteered for research. Subjects were asked about "aftereffects" in followup interviews. Aftereffects that might be considered sequelae are exemplified by statements such as, "I was 'in a fog' for one hour" and "Things were hazy and vague for four hours."

Of the 220 Subjects, 17 (7.7%) reported sequelae, many of them "minor and fleeting." None of the sequelae was of psychotic proportions. Only 2.3% of the sample experienced sequelae that lasted as long as a few hours. Although the relationship of sequelae to hypnotizability was slight, there seemed to be a relationship to having had a difficult experience with chemical anesthesia in early childhood. They present six case studies, three who had difficulty with chemical anesthesia and three for whom the sequelae appeared to relate to a different kind of childhood experience.

The investigators concluded that "a routine experience of hypnosis is generally harmless in a student population, but E (or therapist) should be alert for possible aftereffects, and provisions should be at hand for occasional brief psychotherapy, even though the experiments themselves are not oriented toward therapy" (p. 477).

The authors present a psychodynamic explanation for the sequelae observed. "It is conjectured that the conflicts within the induction phase of hypnosis that produce either immediate or delayed symptoms are primarily those having to do with the exercise of power and the reaction to authority, hence, conflicts between the conscious willingness to be hypnotized and the unconscious resistance to or fear of the submissive role required. The individual forms that such conflicts take are highly varied.

"The conflicts within the established state differ, in that the state is not reached unless the conflicts of the induction are at least temporarily resolved. The new state, which has regressive characteristics, makes S vulnerable to conflicts based on reality distortions (as in suggested hallucinations) or ethical-social issues (as in suggested behavior violating his moral code or superego demands). Sometimes specific suggestions revive early experiences that were traumatic or provocative of fear.

"While the language of psychodynamics is appropriate in the discussion of these cases, the many redintegrative factors also suggest that learning theory can have much to say in explanation of them. Because learning theory has ways of dealing with conflict and conflict resolution, it can also encompass some of the problems discussed as conflicts over authority, commonly treated in psychodynamics as transference problems.

"The many reflections of earlier childhood experiences in the sequelae, including some of the dreams, suggest the promise of a developmental theory of hypnosis" (p. 477).

1960

Hernandez-Peon, R.; Dittborn, J.; Borlone, M.; Davidovich, A. (1960). Changes of spinal excitability during hypnotically induced anesthesia and hyperesthesia. American Journal of Clinical Hypnosis, 3, 64. (From 21st International Congress of Physiology, Buenos Aires, 1959, pg. 124, Abstracts)

Although hypnosis is well established, the physiological mechanisms of the hypnotic state and their related sensory phenomena are far from clear. Hernandez-Peon and Donoso have found that the magnitude of photic evoked potentials in the optic radiations of awake human subjects changed in response to previous verbal suggestions concerning the intensity of the expected photic stimulus. This striking

observation led the cited authors to propose that certain hypnotic sensory phenomena might be explained, at least partially, by changes occurring as far down as second-order sensory neurons by centrifugal mechanisms controlling the sensory input to the brain. In the intact subject it is impossible to record uncontaminated electrical indexes of afferent impulses from those lower sensory neurons. However, it is possible to gain indirect evidence of tactile sensory inflow to the spinal cord by recording cutaneous reflexes. In young males, a forearm skin reflex evoked by a single square pulse of 0-.1 msec. duration was recorded with cathode- ray oscilloscope. The amplitude of the evoked potentials was often reduced during the hypnotic state, and it was further reduced by verbally suggesting to the hypnotized subject complete anesthesia of the forearm. Reciprocally, during hypnotically suggested hyperesthesia the cutaneous reflex was enhanced. It is concluded that during hypnotic anesthesia and hyperesthesia excitability changes occur at the spinal level, and it is suggested that these changes probably involve the spinal internuncial system interposed between the dorsal root ganglion cells and the motoneurons. (From Abstracts, 21st Internat. Cong. Physiol., Buenos Aires, 1959, p. 124.)

ABSTRACT: No Abstract available

## NOTES

1:

"Summary and Conclusions

"Six 'good' hypnotic Ss were given a ten-minute 'hypnotic induction' and a series of 'hypnotic tests.' Both basic skin conductance and momentary variations in skin conductance (GSR) were recorded during the experiment.

"The results were as follows:

1. There was no significant variation in skin conductance during the 'hypnotic induction procedure.'
2. Skin conductance generally increased throughout the remainder of the experiment, i.e., when the Ss were given suggestions of 'sensory hallucinations,' 'age-regression,' 'analgesia,' 'negative hallucinations,' and 'post'-hypnotic behavior.
3. The Ss usually showed a GSR when they were given 'hallucinatory' suggestions, i.e., when they were told that they were becoming 'itchy,' 'thirsty,' and 'very hot.'
4. The GSR to a pinprick was essentially the same before the experiment and during 'hypnotic analgesia.' Also, the GSR was essentially the same, during 'hypnotic analgesia,' (a) when three Ss were told they would receive a pinprick but did not receive the pinprick, (b) when they were told they would receive a pinprick and did receive the pinprick, and (c) when they received a pinprick without being told they would receive it.
5. Four Ss showed a GSR each time they were asked to look at a 'negatively hallucinated' object and person. Two Ss did not show a GSR when they were asked to look at the 'negatively hallucinated' object (or person). The four Ss who showed a GSR stated, during or after the experiment, that they were by no means

convinced that the person or object was no longer in the room. The two Ss who did not show GSR stated, after the experiment, that they had been 'certain' that the object (or person) was not present in the room.

6. Although the Ss stated that they did not 'remember' the 'post'-hypnotic suggestion (or anything else about the experiment), they usually showed a GSR when the E made the preliminary movements to give the signal for the 'post'-hypnotic behavior. (They also showed a GSR when E gave the signal for the 'post'-hypnotic behavior.)

"Since skin conductance is an index of the S's level of 'activation,' 'arousal,' or 'excitation,' these results indicate the following:

1. Ss do not necessarily become more 'passive' or 'relaxed' during the 'hypnotic induction procedure.'
2. Ss often become more and more 'excited' and 'aroused' when they are given a series of 'active' suggestions such as 'sensory hallucinations,' 'age-regression,' etc.
3. Ss often show momentary 'excitement' when they are 'hallucinating.'
4. A pinprick can 'arouse' a S to the same extent during 'hypnotic analgesia' as it can during 'normal waking.' In addition, 'hypnotic analgesic' Ss are often just as much 'aroused' by the threat of a pinprick as they are by an actual pinprick.
5. Many Ss become momentarily 'excited' when they are asked to look directly at an object (or person) which they have been told they will not be able to see. However, some Ss do not show this momentary 'excitement.'
6. Although Ss may state that they do not 'remember' the 'post'-hypnotic suggestion, they often become momentarily 'excited' when the E makes preliminary motions to give the signal for the 'post'-hypnotic act" (pp. 90-92).

Ament, Phillip (1955). A psychosomatic approach to the use of anesthesia for a hysterical dental patient: A case history. Journal of Clinical and Experimental Hypnosis, 3, 120-123. (Abstracted in Psychological Abstracts 56: 1280)

NOTES

1:

Author describes a case highly resistant both to anesthesia and dentistry. Although very responsive to hypnosis, she continued moaning and moving from side to side (later determined to be her way of preventing dental work even though anesthetized). Ultimately a combination of hypnosis and multiple anesthetics was needed, including nembutal, sodium pentothal, nitrous oxide and novocain. In the author's experience, most other patients require only hypnosis or hypnosis plus novocaine.

ANIMAL MAGNETISM/MESMERISM

2001

Gravitz, M.A. (2001, August). The historical role of hypnosis in the theoretical conceptualization of transference. [Paper] Presented at the Annual Meeting of the American Psychological Association, San Francisco.

Long before Freud incorporated rapport and transference into his psychoanalytic theories, Mesmer and a number of his followers had recognized the significance of relationship factors in animal magnetism. While the mesmerists generally held that animal magnetism was transmitted as a physical force (i.e., fluidum) from one person to the other, later dynamic therapists emphasized the importance of psychological factors. This paper documents the contributions over several centuries of these early theoreticians, leading eventually to the work of Freud, Janet, Erickson, and others.

1997

Chaves, John F. (1997). The state of the state debate in hypnosis: A view from the cognitive-behavioral perspective. International Journal of Clinical and Experimental Hypnosis, 45 (3), 251-265.

For most of the past 50 years, hypnosis research has been driven by a debate about whether hypnotic phenomena can be best described and understood as the product of an altered state of consciousness. The meanings of some of the pivotal concepts in this debate and the nature of the phenomena that gave rise to them were ambiguous at the outset and led to misconceptions and surplus meanings that have obscured the debate through most of its history. The nature of the posited hypnotic state and its assumed consequences have changed during this period, reflecting the abandonment of untenable versions of hypnotic state theory. Carefully conducted studies in laboratories around the world have refined our understanding of hypnotic phenomena and helped identify the critical variables that interact to elicit them. With the maturation of the cognitive-behavioral perspective and the growing refinement of state conceptions of hypnosis, questions arise whether the state debate is still the axis about which hypnosis research and theory pivots. Although heuristic value of this debate has been enormous, we must guard against the cognitive constraints of our own metaphors and conceptual frameworks. - Journal Abstract

NOTES

1:

Author notes that mesmerism is not hypnotism because induction techniques are different and psychological and physiological results are different. Esdaile used mesmerism, not hypnotic suggestion. "If the essential differences between mesmerism and hypnotism were to be generally recognized and acknowledged, a lot of modern writing would be outmoded, hence recognition will be tardy and reluctant, but I think it will come" (p. 25). However, research on mesmerism would be difficult because "it seems likely that successful mesmerism may require not only very lengthy manipulations but subjects in a very real state of heightened emotion or acute fear, such as obtained before surgery in the last century, or was artificially (sic) engendered in the salons of the early mesmerists. It has certainly been

demonstrated that the nearest thing to a mesmeric trance that we are likely to witness, the states of tonic immobility that can be produced in animals, are potentiated by stimuli that arouse fear (Gallup et al., 1970)" (p. 27).

**Spanos, Nicholas P.; Gottlieb, Jack (1979). Demonic possession, Mesmerism, and hysteria: A social psychological perspective on their historical interrelations. Journal of Abnormal Psychology, 88 (5), 527-546.**

Provides a social psychological interpretation of the interrelations among demonic possession, mesmerism, and hysteria. It is argued that the reciprocal role relationship of mesmerist and magnetized S in the 18th and 19th centuries involved the secularization of the role relation that had existed between exorcist and demonically possessed. The commonalities between these 2 sets of social roles are delineated, some of the variables leading an individual to learn and enact the possessed role are outlined, and several lines of historical evidence pertaining to the influence of the exorcist-demoniac relationship on the mesmeric relationship are outlined. The influence of the possessed role in shaping the role of the hysterical patient is also discussed. The use of hysteria as a modern explanatory concept in histories of possession and mesmerism, however, is criticized. (198 ref).

**1978**

**Schneck, Jerome M. (1978). Benjamin Rush and animal magnetism, 1789 and 1812. International Journal of Clinical and Experimental Hypnosis, 26, 9-14.**

Little information is available about animal magnetism in the United States during the late eighteenth and early nineteenth centuries. An early assessment of animal magnetism in the United States was provided by Benjamin Rush in 1789 and 1812. Unlike Benjamin Franklin and his colleagues on the 1784 French commission who recognized the role of imagination yet without its potential benefits, Rush discerned the value of both suggestion and imagination in their constructive potential and incorporated them into his medical practice while rejecting Mesmer's theories and techniques. This is of additional interest because of Rush's fame as an early American physician and his position as the father of American psychiatry.

## **ANXIETY**

**Ashton C Jr. Whitworth GC. Seldomridge JA. Shapiro PA. Weinberg AD. Michler RE. Smith CR. Rose EA. Fisher S. Oz MC. Self-hypnosis reduces anxiety following coronary artery bypass surgery. A prospective, randomized trial. Journal of Cardiovascular Surgery 1997;38(1):69-75** **OBJECTIVE:** The role of complementary medicine techniques has generated increasing interest in today's society. The purpose of our study was to evaluate the effects of one technique, self-hypnosis, and its role in coronary artery bypass surgery. We hypothesize that self-hypnosis relaxation techniques will have a positive effect on the patient's mental and physical condition following coronary artery bypass surgery.

**EXPERIMENTAL DESIGN:** A prospective, randomized trial was conducted. Patients were followed beginning one day prior to surgery until the time of discharge from the hospital. **SETTING:** The study was conducted at Columbia Presbyterian Medical Center, a large tertiary care teaching institution. **PATIENTS:** All patients undergoing first-time elective coronary artery bypass surgery were eligible. A total of 32 patients were randomized into two groups. **INTERVENTIONS:** The study group was taught self-hypnosis relaxation techniques preoperatively, with no therapy in the control group. **MEASURES:** Outcome variables studied included anesthetic requirements, operative parameters, postoperative pain medication requirements, quality of life, hospital stay, major morbidity and mortality. **RESULTS:** Patients who were taught self-hypnosis relaxation techniques were significantly more relaxed postoperatively compared to the control group ( $p=0.032$ ). Pain medication requirements were also significantly less in patients practising the self-hypnosis relaxation techniques than those who were noncompliant ( $p=0.046$ ). No differences were noted in intraoperative parameters, morbidity or mortality. **CONCLUSION:** This study demonstrates the beneficial effects self-hypnosis relaxation techniques on patients undergoing coronary artery bypass surgery. It also provides a framework to study complementary techniques and the limitations encountered.

Benson H. Frankel FH. Apfel R. Daniels MD. Schniewind HE. Nemiah JC. Sifneos PE. Crassweller KD. Greenwood MM. Kotch JB. Arns PA. Rosner B. Treatment of anxiety: a comparison of the usefulness of self-hypnosis and a meditational relaxation technique. An overview. *Psychotherapy & Psychosomatics*. 1978;30(3-4):229-42 We have investigated prospectively the efficacy of two nonpharmacologic relaxation techniques in the therapy of anxiety. A simple, meditational relaxation technique (MT) that elicits the changes of decreased sympathetic nervous system activity was compared to a self-hypnosis technique (HT) in which relaxation, with or without altered perceptions, was suggested. 32 patients with anxiety neurosis were divided into 2 groups on the basis of their responsiveness to hypnosis: moderate-high and low responsiveness. The MT or HT was then randomly assigned separately to each member of the two responsiveness groups. Thus, 4 treatment groups were studied: moderate-high responsiveness MT; low responsiveness MT; moderate-high responsiveness HT; and low responsiveness HT. The low responsiveness HT group, by definition largely incapable of achieving the altered perceptions essential to hypnosis, was designed as the control group. Patients were instructed to practice the assigned technique daily for 8 weeks. Change in anxiety was determined by three types of evaluation: psychiatric assessment; physiologic testing; and self-assessment. There was essentially no difference between the two techniques in therapeutic efficacy according to these evaluations. Psychiatric assessment revealed overall improvement in 34% of the patients and the self-rating assessment indicated improvement in 63% of the population. Patients who had moderate-high hypnotic responsiveness, independent of the technique used, significantly improved on psychiatric assessment ( $p = 0.05$ ) and decreased average systolic blood pressure from 126.1 to 122.5 mm Hg over the 8-week period ( $p = 0.048$ ). The responsiveness

scores at the higher end of the hypnotic responsivity spectrum were proportionately correlated to greater decreases in systolic blood pressure ( $p = 0.075$ ) and to improvement by psychiatric assessment ( $p = 0.003$ ). There was, however, no consistent relation between hypnotic responsivity and the other assessments made, such as diastolic blood pressure, oxygen consumption, heart rate and the self-rating questionnaires. The meditational and self-hypnosis techniques employed in this investigation are simple to use and effective in the therapy of anxiety.

**Boutin GE. Tosi DJ. Modification of irrational ideas and test anxiety through rational stage directed hypnotherapy RSDH. Journal of Clinical Psychology 1983;39(3):382-91** Examined the effects of four treatment conditions on the modification of Irrational Ideas and test anxiety in female nursing students. The treatments were Rational Stage Directed Hypnotherapy, a cognitive behavioral approach that utilized hypnosis and vivid-emotive-imagery, a hypnosis-only treatment, a placebo condition, and a no-treatment control. The 48 Ss were assigned randomly to one of these treatment groups, which met for 1 hour per week for 6 consecutive weeks with in-vivo homework assignments also utilized. Statistically significant treatment effects on cognitive, affective, behavioral, and physiological measures were noted for both the RSDH and hypnosis group at the posttest and at a 2-month follow-up. Post-hoc analyses revealed the RSDH treatment group to be significantly more effective than the hypnosis only group on both the post- and follow-up tests. The placebo and control groups showed no significant effects either at post-treatment or at follow-up.

**Goldmann L. Ogg TW. Levey AB. Hypnosis and daycase anaesthesia. A study to reduce pre-operative anxiety and intra-operative anaesthetic requirements. Anaesthesia 1988;43(6):466-9** Fifty-two female patients who underwent gynaecological operations as day cases received either a short pre-operative hypnotic induction or a brief discussion of equal duration. Hypnotized patients who underwent vaginal termination of pregnancy required significantly less methohexitone for induction of anaesthesia. They were also significantly more relaxed as judged by their visual analogue scores for anxiety. Less than half of the patients were satisfied with their knowledge about the operative procedure even after discussions with the surgeon and anaesthetist. A significant correlation was found between anxiety and perceived knowledge of procedures. The results suggest that pre-operative hypnosis can provide a quick and effective way to reduce pre-operative patient anxiety and anaesthetic requirements for gynaecological daycase surgery.

**Hurley JD. Differential effects of hypnosis, biofeedback training, and trophotropic responses on anxiety, ego strength, and locus of control. Journal of Clinical Psychology 1980;36(2):503-7** Pretested 60 college students on three scales: The IPAT Anxiety Scale, the Barron Ego-strength scale, and the Rotter I-E scale. The Ss then were assigned randomly to one of four treatment groups designated: Hypnotic treatment, biofeedback treatment, trophotropic treatment, and control. Three of these groups met separately for 60 minutes once a week for 8 weeks. The control

group did not meet during this time. During the sessions, each group was trained in a different technique for self-regulation. At the end of the 8-week period the scales were readministered to all groups. A series of covariance analyses indicated that hypnosis was a more effective self-regulatory technique for lowering anxiety levels when compared to biofeedback or trophotropic response procedures. With regard to increasing ego strength, both the hypnotic training group and the biofeedback training group proved to be significant. No significant difference was found between the experimental and control groups on the I-E scores.

## **ANXIETY (DENTAL SURGERY)**

**1984**

**Katcher A. Segal H. Beck A. Comparison of contemplation and hypnosis for the reduction of anxiety and discomfort during dental surgery. American Journal of Clinical Hypnosis 1984;27(1):14-21** Used complex moving visual stimuli to induce states of relaxation, hypnosis, and reverie in 42 dental patients (aged 21-60 yrs). To test the efficacy of using aquarium contemplation to induce relaxation, Subjects were randomly assigned to 1 of 5 treatments prior to elective oral surgery: contemplation of an aquarium, contemplation of a poster, poster contemplation with hypnotic induction, aquarium contemplation with hypnosis, and a nonintervention control. Subjects were administered 5 tests of susceptibility adapted from the Stanford Hypnotic Susceptibility Scale; blood pressure, heart rate, and subjective and objective measures of anxiety were also taken. It was found that pretreatment with aquarium contemplation and hypnosis, either alone or in combination, produced significantly greater degrees of relaxation during surgery than poster contemplation or the control procedure. Two-way ANOVA demonstrated that a formal hypnotic induction did not augment the relaxation produced by aquarium contemplation. Findings suggest that aquarium contemplation can alter patients' subjective experiences and overt behavior during oral surgery. Other clinical applications of the contemplation procedure are discussed.

**1976**

**Melnick J. Russell RW. Hypnosis versus systematic desensitization in the treatment of test anxiety. Journal of Counseling Psychology 1976;23(4):291-295.** Assessed the comparative effectiveness of systematic desensitization (SD) and the directed experience hypnotic technique (HT) in reducing self-reported test anxiety and increasing the academic performance of 36 test-anxious undergraduates. Subjects were assigned randomly to either the HT or SD conditions or to 1 of 2 control groups. All Subjects had previously scored above the 50th percentile on Sarason's Test Anxiety Questionnaire (TAQ) and below the 85th percentile on a midterm exam. Results indicate that only the SD treatment significantly reduced TAQ scores. No significant improvement in academic performance was observed for either treatment. An additional analysis of high- vs moderate-anxious subgroups failed to show differential treatment effects on either dependent measure.

**Podolnick EE. Field PB. Emotional involvement, oral anxiety, and hypnosis. International Journal of Clinical & Experimental Hypnosis 1970;18(3):194-210. 48**

undergraduates were randomly assigned to either a high or low emotional arousal manipulation and then underwent a tape-recorded hypnotic induction and test of depth. The high-arousal group was exposed to infantile oral objects and were led to believe that they would have to suck on them as part of a physiological psychology experiment in which the cutaneous sensitivity of the human mouth was being mapped. The low-arousal group believed they only had to blow on whistles or pipes. While both groups were anticipating these experiences, hypnosis was induced. Subjects in the high-arousal group were significantly more hypnotizable ( $p < .001$ ) than their counterparts in the low-arousal group. Subjects in the high-arousal group were significantly less anxious after hypnosis than they were before hypnosis, while the low-arousal Subjects did not show a reduction in anxiety. The groups did not differ on several background personality tests given as checks on the randomization. (Spanish & German summaries)

Rankin EJ. Gilner FH. Gfeller JD. Katz BM. Efficacy of progressive muscle relaxation for reducing state anxiety among elderly adults on memory tasks. *Perceptual & Motor Skills* 1993;77(3 Pt 2):1395-402 Cognitively intact anxious elderly subjects were randomly assigned to either a progressive muscle relaxation-training condition or control condition ( $ns = 15$ ) and then completed selected subtests from the Wechsler Memory Scale--Revised. Despite significant reductions in state anxiety in the relaxation group, no significant differences were detected between the two groups on memory measures. These results are discussed within the context of previous research, and suggestions for further research are made

Amigo, Salvador (1994, August). New approach to self-regulation therapy--treatment strategies. [Paper] Presented at the annual meeting of the American Psychological Association, Los Angeles.

## NOTES

Training programs demonstrate that hypnotizability can be improved. Use individualized treatment programs. Cognitive behavioral treatment can be improved by hypnotic suggestions. Emphasis is on alertness and relaxation, not sleepiness; on conversation with the clinician rather than just listening.

Emotional self regulation is the procedure studied most. They used three phases: Phase 1: Sensory recall exercises (smell, taste, heaviness provoked by lifting a book). Phase 2: Reproduce sensations (hand stiffness, smell) without therapist stimulus. Phase 3: Generalization. Any demand generates the suggested effects. (Tell Subject his brain is very activated, that he can respond without training. Give therapeutic suggestions.)

Case of nicotine addiction presented.

Brown, Gail W.; Riddell, Rodney; Summers, David; Coffman, Brent (1994, August). Use of hypnosis by practitioners in the school setting. [Paper] Presented at the annual meeting of the American Psychological Association, Los Angeles.

## NOTES

Hypnosis is a therapeutic procedure that is appropriate for some school-age clients. Through the use of hypnosis that utilizes metaphors and imagery, children can be empowered to find unique solutions to their problems. Children enjoy the feeling of power and mastery that they have when able to perform hypnotic phenomena. They like to play magic and can be told that a finger or other body part will become numb. Because a major goal of hypnotherapy is to teach a child to be an active participant in his or her own behalf, the focus is on creating solutions and mastering the situation rather than enduring the problems. Four case studies demonstrate the utility of hypnosis in the treatment of phantom pain and nausea, sleep terror disorder, school phobia, and spider phobia. In each case, treatment goals were realized. Because the solutions were self-generated, the behavioral changes maintained over time and situation.

**Case #1:** Hypnosis was used to help alleviate phantom limb pain and nausea during chemotherapy following amputation of the right leg at the knee due to cancer in a thirteen-year-old male. The client had indicated that he loved nature and enjoyed the mountains. The metaphor described a young tree that has just begun to grow small silvery leaves. The spring floods tear the limbs and branches from the stump. The deep roots and stump of the tree are all that remain. The tree is not the same as before the flood. Its roots are stronger, its base more sturdy compared to the branches and limbs. The young tree has withstood the catastrophe of the torrent of waters and is even stronger than before. To counter the nausea and vomiting associated with chemotherapy a switch mechanism metaphor was used. The client was adroit with computers and had no difficulty picturing a switch located in his brain which could "turn off" the nausea from chemotherapy. A room contained all the unpleasant feelings that were being experienced. In this room is a light of a particular color that represents all the unpleasant sensations. Press the key on the computer that controls the switch to turn off the colored light in that room. Suggestions for healing were also given. Your body has known for years how to heal. Visualize the battle between good and bad cells and the victory of the good cells.

**Case #2:** Hypnosis was used to alleviate sleep terror disorder in a ten-year-old female. The onset of the subject's parasomnic symptomatology appeared to coincide with her starting kindergarten and her family's relocation shortly before. The initial treatment consisted of progressive relaxation, deep breathing, and the visual image of her "secret safe place." An induction utilizing a variety of images was presented. Hiking barefoot on a cool moss covered mountain trail, sitting in an alpine meadow on a warm summer afternoon, and flying proved most effective in facilitating trance. The participant was told to "Visualize all your anxiety and tension as hard grey rocks. Pick up these rocks and place them in your pockets. Go to the front porch of your "secret safe place and on the porch is a "magic hefty bag." Place your hard grey rocks that contain all your anxiety and tension in the magic bag. Once in the bag, the rocks will no longer weight you down, you will be free of any feelings of stress or tension. Your bed is magic; it is covered with a

special glue which will keep you in a reclining position until you are fully rested and ready to awaken."

**Case #3:** Hypnosis was used in the treatment of school phobia in a nine-year-old male. The student experienced intense anxiety whenever separation from the primary caretaker occurred. The teacher stated that this boy experienced frequent absences and crying spells that were only relieved by phone calls to his mother or the presence of his mother next to him in class. In preparation for the intervention, the student was asked to draw a picture of how he felt inside during a panic attack. He drew a fire. He also said that only his mother could put that fire out. This information was utilized in creating a metaphor that described a house in a small town. "The mother had left, and a young boy was left alone. While at home, the boy looked out the window and saw several boys trying to burn a neighbor's yard! Acting quickly, he called the fire department, grabbed the fire extinguisher and unraveled the garden hose. He was able to extinguish the fire. The neighbors and friends were very happy and praised the boy's performance. When his mother heard the good news, she quickly returned home and held a celebration in his honor." Following the metaphor, hypnotherapy continued with suggestions about fire extinguishers that the subject could use to put out emotional fires.

**Case #4:** Hypnosis was used in the treatment of spider phobia. Diagnosis of phobia was made in this eleven-year-old female when the fear or avoidance behavior was distressing. The child's strained facial expressions occurred even at the thought of seeing what she described as "a creepy, crawly creature with 8 legs." Preparatory to her first induction the participant was read the story of Charlotte's Web (White, 1980) to facilitate the imagery for future hypnotic work. In the following session systematic desensitization was accomplished using characters from the story of Charlotte's Web. During the third session the subject was age regressed to the first time she remembered seeing a spider. She recalled playing in the woods outside her family home on an island and seeing a large web stretched between two trees with a very large spider in the center of its web. She was then asked to remain at that place to look closely at that spider as it was most likely Charlotte or one of Charlotte's family. Upon closer investigation she saw not only Charlotte but "teeny-tiny babies." The event was reconstructed as a happy experience. The imagery provided by Charlotte's Web permitted the subject to fantasize her previous frightful experience and reframe spiders as cute little "teeny-tiny" babies with admirable human qualities.

**1993**

**Morgan, William P. (1993, October). Use of hypnosis in exercise and sport psychology. [Paper] Presented at the annual meeting of the Society for Clinical and Experimental Hypnosis, Arlington Heights, IL.**

**NOTES:** Performance of exercise is rated as equal effort with hypnosis and waking conditions; but with hypnotic suggestion they will perceive it as more or less effortful (uphill exercise vs going down the hill). When they think they are going up hill both cardiac and respiratory response increase physiologically, with catecholamine differences.

Mitchell (1981) suggests that respiration changes with exercise do not result from muscle feedback, but that central motor brain signals go to both the cardiovascular centers and to exercising muscle. Actually, it appears that both muscle and cortex give signals, and their synergy governs whether ventilation or heart rate increase.

Wang & Morgan, Psychophysiological responses to imagined exercise, Sport Psychology Lab, University of Wisconsin-Madison. Reported that both external (watching someone else) and internal (imagining oneself) visualizing give responses similar to actual exercise.

We have done research on the prediction of respiratory distress (dyspnea) - work we have done with fire fighters. The best predictor of this on treadmill with air supply is trait anxiety. Sometimes the firefighters who took off face mask even though they had air did not know why they did. It is an opportunity to use hypnotic age regression. SCUBA divers described in Lynn & Rhue also were age regressed to obtain information that was repressed. They have demonstrated stress responses like panic in a 12 foot tank also.

For active people and athletes there is an "iceberg" profile on the POMS, below average on tension, depression, anger, fatigue, and confusion, but higher on vigor. But the divers who panic have a flat profile, around the 50th percentile on all POMS scales.

Middleman et al used Navy divers in 25 degree C. water and used hypnosis to increase and decrease their body temperature--one of the best papers on the topic. Ss who were best able to use imagery, to think of a beach, had the poorest responses; the ones who could relax did poorest, because shivering produces heat and keeps you warm. It is opposite of what is needed.

In our work, we took 5 highest and 5 lowest anxiety Ss; the latter had higher rates of respiration than the former.

All Ss are similar in oxygen use whether volunteers or not. When people volunteer for research before they know hypnosis will be used, the males are lower than females [on hypnotizability?] when they finally volunteer. [He presents a lot of different tests on which volunteers do not differ from nonvolunteers personality wise.]

Ikai & Steinhaus is a classic study of Disinhibition of Inhibitory Mechanisms. Taking Ss up to their maximum (in weight training) to a plateau, Ikai & Steinhaus said this is a pseudomaximum. They showed that strength increases if - you fire a starter pistol behind them - you ask them to shout just as they do it - they have alcohol - they have amphetamine sulfate - they have hypnosis It is disinhibition of the inhibitory mechanisms.

[He referred to the book Mind of the Marathoner.]

In Tibet an anthropologist was amazed to see a man running into their camp, and he ran straight through--a monk carrying messages. He created a non-cultic form of meditation in the laboratory (trained to visually "fix" on mountaintop, to have respiration in synchrony with locomotion, and to use a pseudo mantra "down" each time they put their foot down). Placebo condition was used also. Ss were tested by blinded lab assistants. Endurance time increased from 16 minutes to 20, while controls decreased a minute.

Now we can predict who will win a race. Elite runners do not dissociate; they use association strategy. They pay close attention to race strategy, they monitor themselves constantly (they slow down when they feel bad), and attempt informally to stay loose, not get tight, and relax. Dissociation has, however, been used for the last 300 meters of a marathon (New Zealander Dixon).

1992

Bindler, Paul (1992, October). Hypnosis and Psychotherapy: The clinical utility of altered states of consciousness. [Paper] Presented at the annual meeting of the Society for Clinical and Experimental Hypnosis, Arlington, VA.

#### NOTES

Author assesses state, especially attentional changes, with Multidimensional Consciousness Scale (receptivity, arousal, .... etc.)

Clinical management of anxiety is goal. Cites Nash as characterizing anxiety disorders with cognitive/affective characteristics similar to hypnotized state. Wickramasekera's model has people high in neuroticism and high in hypnotizable being hypersensitive to stress, with physiological hyperarousal. Lows have alexithymia, may be unresponsive to symbolic events but very responsive to concrete events; poor verbalization of alexithymics leads to somatization.

Author focuses on relaxation and anxiety reduction. Suggests that Crawford's attention model (highs better able to shift cognitive and attentional strategies) is useful.

Instructions facilitate focusing attention inward so external stimuli become irrelevant. Therapist helps patient focus attention on the link between cognitions and tension.

Garssen, Bert; de Ruiter, Corine; Van Dyck, Richard (1992). Breathing retraining: A rational placebo?. Clinical Psychology Review, 12, 141-153

Breathing retraining of patients with Hyperventilation Syndrome (HVS) and/or panic disorder is discussed to evaluate its clinical effectiveness and to examine the mechanism that mediates its effect. In relation to this theoretical question, the validity of HVS as a scientific model is discussed and is deemed insufficient. It is concluded that breathing retraining and related procedures are therapeutically effective, but probably due to principles other than originally proposed, namely decreasing the tendency to hyperventilate. An alternative principle is the induction of a relaxation response, presenting a credible explanation for the threatening symptoms, giving a distracting task to practice when panic may occur, and promoting a feeling of control.

NOTES: Goal of treatment is to (1) reduce respiratory rate, and (2) cognitive reattribution of physical symptoms to hyperventilation instead of other more catastrophic causes. Reviews a number of studies, mostly small sample, including panic disorder studies, and concludes that the majority point to a therapeutic effect of breathing retraining and cognitive reattribution of physical symptoms to

hyperventilation for patients suffering HVS and the closely related panic disorder with or without agoraphobia. However, the specificity of these techniques for HVS is questionable. Vlaander-van der Giessen (1986) found relaxation training just as effective as breathing retraining; and Hibbert & Chan (1989) found breathing retraining equally effective as a placebo treatment, and not more effective with patients who had recognized symptoms at a hyperventilation provocation test than with those who had not.

Levitan, Alexander A. (1992). The use of hypnosis with cancer patients. Psychiatric Medicine, 10, 119-131.

Hypnosis has proven to be extremely valuable in the treatment of cancer patients. Specific applications include: establishing rapport between the patient and members of the medical health team; control of pain with self-regulation of pain perception through the use of glove anesthesia, time distortion, amnesia, transference of pain to a different body part, or dissociation of the painful part from the rest of the body; controlling symptoms, such as, nausea, anticipatory emesis, learned food aversions, etc.; psychotherapy for anxiety, depression, guilt, anger, hostility, frustration, isolation, and a diminished sense of self-esteem; visualization for health improvement; and, dealing with death anxiety and other related issues. Hypnosis has unique advantages for patients including improvement of self-esteem, involvement in self-care, return of locus of control, lack of unpleasant side effects, and continued efficacy despite continued use.

Morse, Donald R.; Martin, John; Moshonov, Joshua (1992). Stress induced sudden cardiac death: Can it be prevented?. Stress Medicine, 8, 35-46.

Previously, psychosomatically induced death relative to stress, hypnosis, mind control, and voodoo was discussed. In this article, emphasis is on one aspect of that - stress induced sudden cardiac death (SCD). A brief review is presented of the sympathetic aspects of the acute stress response and stress induced SCD. Findings from previous studies are presented to highlight sympathetic aspects of the acute stress response. This is followed by a presentation of various strategies to prevent or decrease the possibilities for stress induced SCD. These include long-term measures (e.g. diet control, smoking control, hypertension control, stress management strategies) and immediate measures (e.g. calm, controlled approach, elicitation of the relaxation response, selected use of drugs, and heart rate variability monitoring). Relative to prevention strategies, findings are presented both from previous studies and new investigations.

1991

Bodden, Jack L. (1991). Accessing state-bound memories in the treatment of phobias: Two case studies. American Journal of Clinical Hypnosis, 34, 24-28.

Two cases of simple phobia demonstrate the inadequacies of both behavioral and psychodynamic theories. These cases and their treatment outcomes provide support for the state-dependent memory and learning theory. Hypnosis and ideomotor

signaling proved to be not only effective treatments but also useful means of illuminating the role and nature of symptom function. Issues of symptom removal and substitution are also discussed in relation to these cases

**NOTES:** The authors state that Rossi and Cheek (1988) summarize a number of experimental studies on animal memory that demonstrate that different information substances are involved in different learning situations. For example, ACTH and cortisol are involved in avoidance learning while angiotensin is involved in operant conditioning. In hypnosis, state dependent memory seems to be implicated. "Hilgard (1977) interpreted the state-dependent memory studies by Overton and others as entirely consistent with and supportive of his theory of hypnosis. Milton Erickson (1948) has also strongly suggested that it is the altered levels of arousal and affect that are responsible for the encoding and recall of stress-related problems with hypnosis" (p. 26).

"Affective experiences are apparently stored independently from their intellectual counterparts, or the emotional unit from one set may attach itself to a constellation of cues that make up a totally different cognitive set. Hypnosis may facilitate recall by providing relevant cues during an altered state of consciousness" (p. 27).

"In commenting upon [one of Erickson's cases], Rossi (1986) states that Erickson was effective because he helped the patient access state-bound memories by reviewing the context and sensory-perceptual cues that surrounded their original acquisition" (p. 27).

"When traditional behavior therapy fails it may be because the original fear stimulus is state bound or unconscious. What is conscious to the patient are those stimuli that are similar in some important respect to the original phobic stimulus and are acquired by stimulus generalization. Desensitization may reduce the patient's reactivity to the associated or acquired stimuli but cannot desensitize the original stimulus until it can be accessed consciously" (p. 27).

"The two main psychological explanations of phobic behavior are psychodynamic and behavioral. The psychodynamic approach is built upon the early writings of Freud (1956) on the traumatic basis of neurosis. Freud speculated that the intense anxiety (psychic pain) associated with the emotional trauma lead to dissociation, repression, and amnesia. Symptoms represented a dissociated or symbolic vestige of the repressed ('forgotten') trauma.

"Behavioral explanations (e.g., Rimm & Masters, 1974) are built upon classical and operant conditioning models of learning. Classical conditioning explains how a neutral stimulus (e.g., a bridge) can acquire reactivity and elicit a fear response. Avoidant behavior, which preserves the phobia, is acquired and maintained by operant conditioning. Treatment apparently involves gradual extinction of the fear response.

"These two divergent explanations have spawned quite different therapeutic approaches, with the behavioral approach (systematic desensitization) demonstrating greater empirical support for its effectiveness (Kaplan & Sadock, 1986). The problem is made complex theoretically by the fact that desensitization doesn't always work, even when applied in a competent fashion" (p. 25).

"Freud's early work on the traumatic basis of neurosis pointed to but offered an incorrect explanation of phobias whose origins were unconscious or state bound (i.e., not available to recall during the normal conscious state)" (p. 25).

Cochrane, Gordon J. (1991). Client-therapist collaboration in the preparation of hypnosis interventions: Case illustrations. American Journal of Clinical Hypnosis, 33, 254-262.

Therapists can use hypnosis in a variety of situations to help clients utilize their own resources effectively. In both heterohypnosis and tape-assisted self-hypnosis, the respectful collaboration of therapist and client in the development of specific intervention strategies can be effective. I have described four cases to illustrate the collaborative aspect of heterohypnosis in a surgical setting and tape-assisted self-hypnosis for anxiety, tinnitus, and situational depression. In each case the clients were willing and able participants.

#### NOTES:

"Hypnotic interventions as adjunctive therapeutic modalities for a variety of surgical procedures have been well documented (Frankel, 1987; Gravitz, 1988; Nathan, Morris, Goebel, & Blass, 1987). The availability, relative safety, dependability, and ease of use have made chemical agents the anesthetic of choice in the majority of surgical situations, but hypnosis, either alone or in conjunction with chemical agents, can have a number of advantages for some patients (Udolf, 1987, p. 248). Some patients who have extreme preoperative pain and anxiety can learn to use self-hypnosis (Frankel, 1987); others may use hypnosis when experiencing postoperative nausea and other uncomfortable side effects of chemical anesthetics. Some may fear death under general anesthesia or react to a previous trauma arising from general anesthesia and the operating room procedures in general (Udolf, 1987, p. 250) and therefore choose hypnotic strategies. In the following case illustration the patient feared general anesthesia because of a previous negative postoperative experience" (p. 255).

While collaboratively planned hypnosis often empowers the patient, contributing to a sense of personal control and well being, some patients are not able to participate in that manner. Cochrane cites patients who are severely depressed or "who struggle with narcissism and other severe pathologies" (p. 260). He notes that audiotapes are useful for supplementing in-session therapy, contributing to skill development, attitude change, and a sense of self-worth. He cites Eisen and Fromm (1983) as indicating that self hypnosis is also useful for clients "who struggle with issues of control and intimacy" (p. 260).

Mauer, D. R. (1991, October). A comparison of cognitive-behavioral and hypnotic techniques in the management of electromyography pain (Dissertation, University of Iowa). Dissertation Abstracts International, 53 (4), 1070-B. (Order No. DA 9217180)

"Compared a cognitive behavioral technique that included providing specific sensory and procedural information combined with relaxation with a hypnotic

technique (relaxation with guided imagery) and a control group for management of acute EMG pain and anxiety. Pain and anxiety ratings were gathered from 45 EMG patients and observers for both nerve conduction and needle electrode components of the EMG exam. It was found that only the hypnosis group significantly reduced pain and anxiety during the needle electrode portion of the procedure. Patients with unexplained or functional symptoms reported more EMG pain and anxiety than patients who had an organically based disease. Because having had a prior EMG seemed to have an effect on the efficacy of treatment, the data were reexamined. Results determined that inexperienced EMG patients who were treated had less pain and anxiety than patients who experienced EMG before, but inexperienced control patients had an increase in pain and anxiety over experienced patients" (p. 1070).

### 1990-1991

Avants, S. Kelly; Margolin, Arthur; Salovey, Peter (1990-91). Stress management techniques: Anxiety reduction, appeal, and individual differences. Imagination, Cognition and Personality, 10, 3-23.

### NOTES

Four stress management techniques were evaluated for their general appeal, their immediate benefits, and the subjective experiences they evoke. One hundred undergraduates were randomly assigned to one of five treatment groups: (1) progressive muscle relaxation (PMR); (2) distraction imagery; (3) focused imagery; (4) listening to music; (5) sitting quietly (control). Distraction imagery and listening to music were the only techniques found to reduce anxiety to a greater extent than simply sitting quietly. The techniques differed in the way they made subjects feel, but not in their general appeal. Individuals with a 'blunting' coping style were more likely to find all five techniques appealing.

Tests used included the Miller Behavioral Style Scale, Cognitive-Somatic Anxiety Questionnaire of Schwartz, Davidson & Golman, Life Orientation Test of Scheier & Carver, Somatic Perception Questionnaire of Landy and Stern, Body Consciousness Questionnaire of L. C. Miller, Murphy, & Buss, Betts' Questionnaire Upon Mental Imagery, Shortened Form, State-Trait Anxiety Inventory, and Technique Evaluation Questionnaire of the authors.

Progressive muscle relaxation was according to Bernstein & Borkovec. Distraction imagery involved successively imagining a walk along a beach, a stroll across a flower filled meadow, sitting by a stream, a walk into the woods, sitting in a cabin in the woods listening to the rain against the windowpane, all including images in a variety of sense modalities. Focused imagery involved creating an image of a stressor, then through symbolic imagery experiences Ss were guided through a typical day's events that might lead up to the stressor, reinterpreting cues associated with the stressor as signals that they are in control, visualizing encountering the stressor feeling strong and determined, and any physical sensations reinterpreted as 'energy' that would help them to cope, visualizing enjoying their success (from

Crits-Cristoph & Singer. Music was a 20-min tape (10 min of music used in the distraction imagery tape--Natural Light by Steve Halpern & David Smith) and 10 min of music used in background of the focused imagery tape (Structures of Silence by Michael Lanz). A 5th group, Control, was instructed to sit quietly with eyes closed.

This data can be used in support of imagery-suggestion types of hypnosis (as in surgery study) reducing anxiety. It shows particularly strong effects for people high in cognitive anxiety or low in optimism, pre-treatment.

Discussion: "... we feel confident that our distraction techniques were more effective for the immediate relief of anxiety than was PMR. This conclusion is consistent with the Suls and Fletcher meta-analysis (29) that suggested that 'avoidance' is an effective short-term coping strategy. That distraction (positive) imagery may be a more useful clinical technique than focused (active involvement) imagery was concluded in a study comparing these two techniques in the treatment of phobias (24)" (p. 19. [Ref #24 is Crits-Cristoph & Singer (1983) in *Imagination, Cognition, and Personality*.])

"Pessimism and cognitive anxiety emerged as the only individual difference variables to influence anxiety reduction. Pessimism as measured by the LOT is cognitive in nature, with most of the items relating to expectations of negative outcomes; similarly, cognitive anxiety is characterized by worry and an inability to control negative thoughts and images. That individuals who perceive their world somewhat negatively should have entered the study more anxious than individuals who do not is hardly surprising. What is surprising is that despite an inverse relation between cognitive anxiety and the ability to relax, these individuals were able to benefit from whatever technique they performed to a greater extent than were individuals with a more positive outlook. In fact, after performing the technique, pessimists had reduced their anxiety to the level of optimists" (p. 19).

"The stress management techniques used in the current study did not differ in their appeal" (p. 20). "Our finding that PMR produced more somatic effects than did focused imagery and less cognitive effects than did distraction imagery, listening to music, or sitting quietly is consistent with the model of anxiety proposed by Davidson and Schwartz (17). Our findings are also generally consistent with a conclusion reached by Woolfolk and Lehrer (4): that although various techniques are generally stress reducing, they seem to have highly specific effects. However, we found no support for the hypothesis that individuals who express anxiety cognitively (or somatically) prefer and benefit most from techniques that produce cognitive (or somatic) effects. In fact, the extremely high correlation found between the cognitive and somatic anxiety subscales of the Schwartz et al. measure (5) casts some doubt on the usefulness of a cognitive-somatic distinction, as does the corr between the experience of physical symptoms under stress (the Somatic Perception Questionnaire) with the cognitive, as well as the somatic, anxiety subscale.

"The finding that blunterners experiences more 'somatic effects' regardless of the technique they were assigned may have been the result of a single response--'how much did mind-wandering interfere with performing the technique'--which was the only Factor 2 item that was highly inversely related to blunting. Since blunterners are more likely to perceive mind wandering as the essence of stress management rather

than as 'interference,' we do not view this main effect as particularly illuminating" (p. 20). "However, our finding that blunters experienced all techniques as appealing is consistent with the results of Martelli et al. (1) who found that individuals with low information-preference benefitted from what the authors labeled an 'emotion-focused' intervention, but which, in fact, included many of the quite diverse stress management techniques that we compared in the current study. That 'avoiders' failed to benefit from any intervention in the Scott and Clum study (11) may be due to the nature of the stressor [postsurgical pain]. Our undergraduates may have been more like the Martelli dental patients in terms of their level of distress than were the Scott and Clum subjects who were patients undergoing major surgery (hysterectomy or cholecystectomy). Future research needs to examine possible three-way, technique by patient by stressor-type, interactions (cf. 19)" pp 20-21.

**Kaye, J. M.; Schindler, B. A. (1990). Hypnosis on a consultation-liaison service. General Hospital Psychiatry, 12, 379-383.**

Studied the use of hypnosis on a consultation-liaison service with a broad spectrum of medically hospitalized patients. Autohypnosis tapes were used for reinforcement. Twenty-nine women and eight men from 24-75 years of age were hypnotized for relief of depression, pain, anxiety, or side effects of chemotherapy. Results were excellent (total to almost total relief of symptoms) in 68%, fair in 22%, and poor in 11%, with no differences among the results with the various conditions. This demonstrates that hypnotherapy is an extremely useful tool in medical management of patients in consultation-liaison psychiatry.

**Lazarus, A. A.; Mayne, T. J. (1990). Relaxation: Some limitations, side effects, and proposed solutions. Psychotherapy, 27, 261-266**

Deep-muscle relaxation has been widely regarded as anxiety inhibiting, and the relaxation response an antidote to tension and stress. However, some relaxation techniques have been shown to have negative effects. These include relaxation-induced anxiety and panic, paradoxical increases in tension, and parasympathetic rebound. Specific indications and contraindications are discussed.

#### NOTES

1:

The following unpleasant side effects have been observed: "unpleasant sensations of heaviness, warmth, perspiration, tingling, numbness, dizziness, floating, coolness; paradoxical increases in tension; rapid heart rate; feelings of physical and psychological vulnerability; depression; fear of losing control; depersonalization; dissociation; myoclonic jerks; spasms; headache; akathisia; negative auditory, gustatory, and olfactory reactions; intrusive images and thoughts; anxiety; irritability; guilt; regressive urges; hallucinations; and panic" (p. 261).

People have been observed to have "negative or untoward reactions to meditation ([Lazarus, 1976]; French, Schmid & Ingalls, 1975; Kennedy, 1976), relaxation (Borkovec & Grayson, 1980; Carrington, 1977; Edinger & Jacobsen, 1982), and

biofeedback (Miller & Dworkin, 1977). In his doctoral dissertation Heide (1981) found that more than half of his subjects under focused relaxation reported increased tension due to the relaxation session. Recently, the concept of RIA--relaxation-induced anxiety--has appeared in the literature (Heide & Borkovec, 1983; 1984). Clients suffering from generalized anxiety appear to be especially prone to RIA" (pp. 261-262).

Others have suggested that relaxation may be counterindicated for asthmatics, because the small airways dilate with sympathetic nervous system arousal. The specific instructions of autogenic training may be counterindicated for patients with gastrointestinal disease because focusing on a sense of warmth in the abdomen tends to produce more peristalsis, increased blood flow in the gastric mucosa, and acidity in the gastric juice (Luthe & Schultz, 1979). Even the standard relaxation therapy for tension headache (as well as other pain problems) is being replaced with cognitive behavioral therapy, which may have relaxation as only one component. "The point again is that relaxation is not a panacea, and that an informed selection and administration of treatments is mandated, even in disorders where relaxation has traditionally been held second only to medication" (p. 264).

Interviews suggest people with relaxation induced anxiety (RIA) fear losing control. "Some are afraid of heightened arousal; others refer to helplessness, depression, some unidentified internal or external danger, a fear of going crazy, a negative association with anesthetics, a fear of falling from heights, plus any number of catastrophic expectations (Chambless & Goldstein, 1980)" (p. 264). Lazarus recommends that if someone displays RIA, the therapist may try alternative techniques, which might include for example tensing-relaxing muscles, passive receptivity, positive or pleasant imagery, focus on breathing, subvocal monotonous chant or mantra, or the Vipassana meditation practice of achieving awareness of spontaneous sensations and thoughts. The relationship with the therapist, differences in room illumination, amount of time per session, and sitting or reclining may be important.

"If a therapist deduces that a client is likely to derive benefit from relaxation training, three obvious questions arise: (1) Which of the many types of relaxation training programs is this particular client likely to respond to? (2) How frequently, and for what length of time, should the client practice the selected relaxation sequence? (3) Will treatment adherence be augmented or attenuated by the supplementary use of cassettes for home use?" (P. 262).

The authors describe their Structural Profile Inventory (SPI; Lazarus, 1989), a 35-item questionnaire, which may be used to predict the preferred sequences and forms of relaxation to employ with individual clients. "A predominantly imagery/sensory reactor, for example, may do well with visualization and autogenic training, whereas a highly active/cognitive client might be better advised first to engage in strenuous exercise followed by calming self-statements (Zilbergeld & Lazarus, 1988)" (p. 265). They suggest that for those patients who are perfectionistic and simply can't "just let go," they might simply fill a bathtub with warm water and sit in it for 10-20 minutes and rest with a magazine (rather than "relax") once or twice a day.

**McNally, Richard J. (1990). Psychological approaches to panic disorder: A review. Psychological Bulletin, 108 (3), 403-419.**

Panic disorder has been the subject of considerable research and controversy. Though biological conceptualizations have been predominant, psychological theorists have recently advanced conditioning, personality, and cognitive hypotheses to explain the etiology of panic disorder. The purpose of this article is to provide an empirical and conceptual analysis of these psychological hypotheses. This review covers variants of the "fear-of-fear" construal of panic disorder (i.e., Pavlovian interoceptive conditioning, catastrophic misinterpretation of bodily sensations, anxiety sensitivity), research on predictability (i.e., expectancies) and controllability, and research on information-processing biases believed to underlie the phenomenology of panic. Suggestions for future research are made.

**1987**

**Katz, Ernest R.; Kellerman, Jonathan; Ellenberg, Leah (1987). Hypnosis in the reduction of acute pain and distress in children with cancer. Journal of Pediatric Psychology, 12, 379-394.**

Hypnosis has been used as a behavioral approach to help children tolerate aversive medical procedures more effectively, but empirical longitudinal research evaluating the outcome of such interventions has been limited. In the present study, 36 children with acute lymphoblastic leukemia between the ages of 6 and 12 years of age undergoing repeated bone marrow aspirations (BMAs) were randomized to hypnosis or play comparison groups. Subjects were selected on their behavioral performance on baseline procedures and received interventions prior to their next three BMA procedures. Major results indicated an improvement in self-reported distress over baseline with both interventions, with no differences between them. Girls exhibited more distress behavior than boys on three of four dependent measures used. Suggestions of an interaction effect between sex and treatment group were noted. The role of rapport between patient and therapist in therapeutic outcome was also evaluated. Results are discussed in terms of potential individual differences in responding to stress and intervention that warrant further research.

**1986**

**Belicki, Kathryn; Belicki, Denis (1986). Predisposition for nightmares: A study of hypnotic ability, vividness of imagery, and absorption. Journal of Clinical Psychology, 42 (5), 714-718.**

The relationships of nightmare frequency to hypnotic ability, vividness of visual imagery, and the tendency to become absorbed in fantasy-like experiences were examined. Subjects were 841 undergraduate university students who participated in group tests of hypnotic ability, after which they estimated the number of nightmares that they had experienced in the prior year. In addition, 406 of the subjects completed Marks' Vividness of Visual Imagery Questionnaire, and Rotenberg and Bowers' Absorption scale. Of the subjects, 76% reported experiencing at least one

nightmare in the prior year; 8.3% indicated one or more per month. Individuals with frequent nightmares scored higher on hypnotizability, vividness of visual imagery, and absorption.

#### NOTES

1:  
620, Belicki & Bowers, 1982 ABSTRACT: Investigated the role of demand characteristics in dream change by comparing dream report change following pre- and postsleep administrations of instructions to pay attention to specific dream content. This design was based on the assumption that if presleep instructions merely distort dream reports rather than influence actual dreams, report change should be observable following a postsleep instruction. 42 undergraduates were prescreened with the Harvard Group Scale of Hypnotic Susceptibility (Form A), which allowed experimenters to examine the role of hypnotizability in dream change. Significant differences were observed only following the presleep instructions. It is concluded that report distortion as a result of paying attention to a dimension of dream content was insufficient to account for dream report change following presleep instructions. Hypnotic ability correlated significantly with the amount of dream change.

Billotti, Thomas J. (1984, August). The effects of rational emotive imagery and rational emotive imagery plus hypnosis in reduced public speaking anxiety (Dissertation). Dissertation Abstracts International, 46 (2), 633-634-B.

"Previous investigations have demonstrated the effectiveness of rational emotive therapy in reducing public speaking anxiety and the increased benefit derived by combining rational emotive procedures with hypnosis. The present study examined the effectiveness of rational emotive imagery and rational emotive imagery plus hypnosis in reducing public speaking anxiety in subjects with high and low levels of imaginative ability. The dependent measures employed included self report, behavioral and physiological measures of anxiety. "47 undergraduate students who reported anxiety while speaking in public served as subjects in the study. The subjects were divided into high and low levels of imaginative ability and randomly assigned to one of three experimental groups as follows: rational emotive imagery, rational emotive imagery plus hypnosis, and an instructional control group. It was hypothesized that subjects in the rational emotive imagery plus hypnosis group would evidence significantly less anxiety than subjects in the rational emotive imagery and instructional control group, and that subjects with high pre-treatment levels of imaginative ability would evidence significantly less anxiety than subjects with low pre- treatment levels of imaginative ability. "The results of this study provided some support for the efficacy of combining rational emotive imagery with hypnosis. Subjects in the rational emotive imagery plus hypnosis group evidenced significantly less anxiety than subjects in the rational emotive imagery and instructional control group on the two self-report measures. There were no significant differences as between subjects in the rational emotive imagery group and instructional control group or between subjects with high and low imaginative

ability on post-treatment assessments. Subjects tended to have their highest pulse rates at the start of the speeches, their lowest pulse rate just after the speeches, and moderate pulse rates just before and during the speeches. "Factors contributing to these results and interpretations of the data were discussed. Suggestions regarding the direction of future research were offered" (p. 633- 634).

**Katcher, Aaron; Segal, Herman; Beck, Alan (1984). Comparison of contemplation and hypnosis for the reduction of anxiety and discomfort during dental surgery. American Journal of Clinical Hypnosis, 27, 14-21.**

Complex moving visual stimuli are used to induce states of relaxation, hypnosis and reverie. To test the efficacy of using aquarium contemplation to induce relaxation, 42 patients were randomly assigned to one of five treatments prior to elective oral surgery: 1) contemplation of an aquarium, 2) contemplation of a poster, 3) poster contemplation with hypnotic induction, 4) aquarium contemplation with hypnosis, and 5) a non intervention control. Blood pressure, heart rate, and subjective and objective measures of anxiety were used as dependent measures. Pretreatment with aquarium contemplation and hypnosis, either alone or in combination, produced significantly greater degrees of relaxation during surgery than poster contemplation or the control procedure. Two-way ANOVA demonstrated that a formal hypnotic induction did not augment the relaxation produced by aquarium contemplation.

#### **NOTES**

**1:**  
The consent form was designed to reduce anxiety about hypnosis by stating that if hypnosis was used, it would be used only to induce relaxation. Patients were then randomly assigned to one of the 5 pretreatment groups, with 8 in each of the four contemplation groups and 10 in the nonintervention control.

**1. Aquarium contemplation.** Ss contemplated it for 40 minutes; during the 1st 25 min, 5 tests of suggestibility were administered (from the Stanford) which eliminated all tests the authors considered anxiety-provoking such as suggested hallucination. Also, the terms hypnotically relaxed or hypnotic relaxation replaced the term hypnosis throughout the protocol.

**2. Poster contemplation** was the same, using a color photo of a mountain waterfall.

**3. Poster contemplation with hypnosis** used a protocol derived from Stanford, with visual fixation on poster, then the 5 tests, then Ss contemplated the poster for 10 minutes under hypnosis and were given post hypnotic suggestion that they could reenter hypnosis during the dental procedure by closing their eyes and visualizing the poster

**4. Aquarium contemplation with hypnosis** was like #3 except that Ss were asked to look at "either one fish or a portion of the aquarium" during induction and were told to reenter hypnosis during treatment by closing their eyes and visualizing the aquarium

**5. Nonintervention control** Ss were given no tests of suggestibility; they were seated in a chair and told to "relax."

During surgery, an observer recorded overt signs of anxiety or agitation on a check list, making entries at five-minute intervals.

The surgeries took variable lengths of time (5-90 minutes) and variable kinds of procedures (multiple injections, removal of bone, etc.) Surgeons varied in management-- gentleness, etc.

Blood pressure fell significantly during all 5 pretreatments without any significant differences between groups. Analysis of interaction effects, significant at the 0.1 level for all 3 dependent variables, indicated that hypnosis had a major effect on relaxation only when the S was contemplating a poster. Hypnosis had no significant influence on the levels of relaxation obtained by contemplation of the aquarium.

There were no significant differences between groups in the number of suggestions accepted.

1983

Boutin, Gerald E.; Tosi, Donald J. (1983). Modification of irrational ideas and test anxiety through rational stage directed hypnotherapy (RSDH). Journal of Clinical Psychology, 39 (3), 382-391.

Examined the effects of four treatment conditions on the modification of Irrational Ideas and test anxiety in female nursing students. The treatments were Rational Stage Directed Hypnotherapy, a cognitive behavioral approach that utilized hypnosis, and vivid emotive imagery, a hypnosis-only treatment, a placebo condition, and a no-treatment control. The 48 Ss were assigned randomly to one of these treatment groups, which met for 1 hour per week for 6 consecutive weeks with in-vivo homework assignments also utilized. Statistically, significant treatment effects on cognitive, affective, behavioral, and physiological measures were noted for both the RSDH and hypnosis group at the posttest and at a 2-month follow-up. Post-hoc analyses revealed the RSDH treatment group to be significantly more effective than the hypnosis only group on both the post- and follow-up tests. The placebo and control groups showed no significant effects either at posttreatment or at follow-up.

Harris, Gina M.; Johnson, Suzanne Bennett (1983). Coping imagery and relaxation instructions in a covert modeling treatment for test anxiety. Behavior Therapy, 14, 144-157.

The present study compared the efficacy of instructing test anxious subjects to use personalized coping imagery based on nonacademic experiences of competence with coping imagery based on academic experiences of competence. The effect of relaxation was also examined and the relationship of imagery elaborateness and content to treatment effectiveness was assessed. Sixty-three subjects were randomly assigned to one of four treatments or a waiting list control group. Test anxiety as measured by a self-report instrument significantly decreased in all treatment groups. Improvement in grade point average occurred for all treatment groups except for academic coping imagery without relaxation which was also the least efficient treatment. The waiting list control group significantly deteriorated in academic performance. Relaxation training did not appear to enhance treatment

effectiveness or influence the elaborateness or content of the imagery used. Test anxiety scenes elicited highly response-oriented images by all subjects. However, the stimulus/response content of the subjects' images was not influenced by treatment outcome. In contrast, successful treatment was primarily associated with reduction in negative coping imagery descriptions, although an increase in positive coping statements cured as well.

Heide, F. J.; Borkovec, T. D. (1983). Relaxation-induced anxiety: Paradoxical anxiety enhancement due to relaxation training. Journal of Consulting and Clinical Psychology, 51, 171-182.

The present study was designed to document the occurrence of relaxation-induced anxiety. Fourteen subjects (7 male, 7 female) suffering from general tension and significant levels of anxiety were given one session of training in each of two relaxation methods, progressive relaxation and mantra meditation; order of presentation was counterbalanced. Four of the subjects plus one other who terminated prematurely displayed clinical evidence of an anxiety reaction during a preliminary practice period, while 30.8% of the total group under progressive relaxation and 53.8% under focused relaxation reported increased tension due to the relaxation session. Progressive relaxation produced greater reductions in subjective and physiological outcome measures and less evidence of relaxation-induced anxiety, and the phenomenon was not clearly evident from physiological measures and from subjective ratings even in this clinical population.

1982

Hilgard, Josephine R.; LeBaron, Samuel (1982). Relief of anxiety and pain in children and adolescents with cancer: Quantitative measures and clinical observations. International Journal of Clinical and Experimental Hypnosis, 30, 417-442.

Children and adolescents with cancer, chiefly forms of leukemia, aged 6 to 19 years, underwent medical treatments which required repeated bone marrow aspirations, normally a painful and anxiety-provoking experience. Data were obtained in baseline bone marrow observations on 63 patients, who were then offered the opportunity to volunteer for hypnotic help in pain control. Of the 24 patients who accepted hypnosis, 9 were highly hypnotizable. 10 of the 19 reduced self-reported pain substantially by the first hypnotic treatment (the prompt pain reducers) and 5 more reduced self-reported pain by the second treatment (the delayed pain reducers) while none of the 5 less hypnotizable patients accomplished this. The latter benefitted by reducing anxiety. Short case reports illustrate the variety of experiences.

Analysis of baseline observations before any therapeutic intervention revealed age and sex differences. The difference between self-reported and observed pain was not statistically significant for patients under age 10 but was significant for the patients age 10 and older ( $p < .001$ ). There were minor but significant sex differences both in

observed pain ( $p < .01$ ) and in self-reported pain ( $p < .05$ ), with the females reporting more pain.

1981

Fling, Sheila; Thomas, Anne; Gallaher, Michael (1981). Participant characteristics and the effects of two types of meditation vs. quiet sitting. Journal of Clinical Psychology, 37 (4), 784-790.

Randomly assigned 61 undergraduate volunteers to Clinically Standardized Meditation (CSM), quiet sitting (SIT), or wait list1 and 19 others to Open Focus (OF) or wait list2. Ss were tested before training and again 8 weeks later. All groups but wait list2 decreased significantly on Spielberger's trait anxiety. All groups became nonsignificantly more internal on Rotter's locus of control. On the Myers-Briggs Type Indicator, meditation volunteers were more introverted than extraverted, intuitive than sensing, feeling than thinking, and perceiving than judging. All groups became more intuitive, approaching significance for CSM only. OF became significantly more extraverted than both CSM and SIT, and CSM significantly more so than wait list1. Practice time correlated with anxiety reduction for the combined treatment groups. More evidence was found for correlations of practice time and outcome with growth motivation than with either new experience motivation or expectancy of benefit.

1980

Heide, Frederick J.; Wadlington, W. L.; Lundy, Richard M. (1980). Hypnotic responsivity as a predictor of outcome in meditation. International Journal of Clinical and Experimental Hypnosis, 28 (4), 358-385.

This study tested the hypothesis that measures of hypnotic responsivity would predict outcome from brief meditation training. 58 Ss were matched on hypnotic responsivity and randomly assigned to meditation and control conditions. The Ss in the meditation group displayed significantly greater decreases in trait anxiety than control Ss following a 1-week treatment period. The Ss highest in hypnotic responsivity showed the most substantial decrements in anxiety. It is concluded that hypnotic responsivity is moderately predictive of outcome in meditation. Findings were also consistent with reports that hypnotic responsivity is not increased by practice in meditation.

NOTES

1:

Subjects in the Meditation condition received 1 hour of group instruction-- a lecture which discussed physiological benefits, guidelines for practice, and possible side-effects. "The technique consisted of the passive, subvocal repetition of a mantra, 'Om,' for a period of 20 minutes. It was emphasized that the mantra should be allowed to 'repeat itself' in a gentle, effortless fashion. The Ss were told that when they found themselves distracted by thoughts, they should not try to block them out but should simply return to repeating the mantra" (p. 360). Ss practiced the

technique for 20 minutes and were asked to meditate twice daily for 7 days, keeping a log for that period.

**Hurley, John D. (1980). Differential effects of hypnosis, biofeedback training, and trophotropic responses on anxiety, ego strength, and locus of control. Journal of Clinical Psychology, 36 (2), 503-507.**

Pretested 60 college students on three scales: the IPAT Anxiety Scale, the Barron Ego-strength scale, and the Rotter I-E scale. The Ss then were assigned randomly to one of four treatment groups designated: hypnotic treatment, biofeedback treatment, trophotropic treatment, and control. Three of these groups met separately for 60 minutes once a week for 8 weeks. The control group did not meet during this time. During the sessions, each group was trained in a different technique for self-regulation. At the end of the 8-week period the scales were readministered to all groups. A series of covariance analyses indicated that hypnosis was a more effective self-regulatory technique for lowering anxiety levels when compared to biofeedback or trophotropic response procedures. With regard to increasing ego strength, both the hypnotic training group and the biofeedback training group proved to be significant. No significant difference was found between the experimental and control groups on the I-E scores.

**Lamb, Douglas H.; Strand, Kenneth H. (1980). The effect of a brief relaxation treatment for dental anxiety on measures of state and trait anxiety. Journal of Clinical Psychology, 36 (1), 270-274.**

Used a brief deep muscle relaxation procedure to reduce patient (N = 39) anxiety during a dental appointment. State anxiety decreased significantly for a relaxed (treated) group from the waiting room period to the actual contact with the dentist. This reduction in state anxiety was maintained for the duration of the dental visit. There were no changes in trait anxiety. Implications for the reduction of state and trait anxiety in an in vivo situation were discussed.

**Lundy, Richard M.; Heide, Frederick J.; Wadlington, W. L. (1980). Hypnotic responsivity as a predictor of outcome in meditation. International Journal of Clinical and Experimental Hypnosis, 28 (4), 358-366.**

## NOTES

1:

TM reportedly diminishes Trait Anxiety (not State Anxiety). Spielberger's Anxiety Scale was administered. Non-analytical attention is increased in TM. Spanos, et al. found a relationship between sustained attention in a meditation task and hypnotizability. Both load on the same factor.

Used Control and Experimental groups pretested on a scale of hypnotizability (Harvard Scale?): Lows = 1-4; Mediums = 5-7; Highs = 8-12.

Subjects were given instructions for modified TM, including a lecture on physiological benefits. "Let the sound 'OM' repeat itself; let that sound pass through and return to the mantra." Subjects logged practice on their 20 minute

meditation twice a day, for 7 days. They were given pre- and posthypnotic tests of State and Trait anxiety.

**RESULTS.** Meditators decreased Trait anxiety but not State anxiety. But anxiety was reduced more for high hypnotizables than for other levels. There was greater change in anxiety for High hypnotizables who practiced meditation . No difference in pre- and posthypnotic test on Harvard, confirming Spanos, et al.

**CONCLUSIONS.** This provides more evidence that the skill of hypnotizability has more utility than we had thought, in therapy. Spanos, et al. also found that improvement in meditation was correlated with hypnotizability (in terms of number of intrusions) and Benson, Frankel, et al., found Lows benefit less in blood pressure change with either meditation or hypnosis.

**1978**

Benson, Herbert; Frankel, Fred H.; Apfel, Roberta; Daniels, Michael D.; Schniewind, Henry E.; Nemiah, John C.; Sifneos, Peter E.; Crassweller, Karen D.; Greenwood, Martha M.; Kotch, Jamie B.; Arns, Patricia A.; Rosner, Bernard (1978). Treatment of anxiety: A comparison of the usefulness of self-hypnosis and a meditational relaxation technique. Psychotherapy and Psychosomatics, 30, 229-242.

We have investigated prospectively the efficacy of two nonpharmacologic relaxation techniques in the therapy of anxiety. A simple, meditational relaxation technique (MT) that elicits the changes of decreased sympathetic nervous system activity was compared to a self-hypnosis technique (HT) in which relaxation, with or without altered perceptions, was suggested. 32 patients with anxiety neurosis were divided into 2 groups on the basis of their responsivity to hypnosis: moderate-high and low responsivity. The NIT or HT was then randomly assigned separately to each member of the two responsivity groups. Thus, 4 treatment groups were studied: moderate-high responsivity MT; low responsivity MT; moderate-high responsivity HT; and low responsivity HT. The low responsivity HT group, by definition largely incapable of achieving the altered perceptions essential to hypnosis, was designed as the control group. Patients were instructed to practice the assigned technique daily for 8 weeks. Change in anxiety was determined by three types of evaluation: psychiatric assessment; physiologic testing; and self-assessment. There was essentially no difference between the two techniques in therapeutic efficacy according to these evaluations. Psychiatric assessment revealed overall improvement in 34% of the patients and the self-rating assessment indicated improvement in 63% of the population. Patients who had moderate- high hypnotic responsivity, independent of the technique used, significantly improved on psychiatric assessment ( $p = 0.05$ ) and decreased average systolic blood pressure from 126.1 to 122.5 mm Hg over the 8-week period ( $p = 0.048$ ). The responsivity scores at the higher end of the hypnotic responsivity spectrum were proportionately correlated to greater decreases in systolic blood pressure ( $p = 0.075$ ) and to improvement by psychiatric assessment ( $p = 0.003$ ). There was, however, no consistent relation between hypnotic responsivity and the other assessments made, such as diastolic blood pressure, oxygen consumption, heart rate and the self-rating

questionnaires. The meditational and self- hypnosis techniques employed in this investigation are simple to use and effective in the therapy of anxiety.

Counts, D. Kenneth; Hollandsworth, James G., Jr.; Alcorn, John D. (1978). Use of electromyographic biofeedback and cue-controlled relaxation in the treatment of test anxiety. Journal of Consulting and Clinical Psychology, 46 (5), 990-996.

The effect of using electromyographic (EMG) biofeedback to increase the efficacy of cue-controlled relaxation training in the treatment of test anxiety was studied. Forty college undergraduates scoring in the upper third on a self-report measure of test anxiety were randomly assigned to one of four treatment conditions - EMG-assisted cue- controlled relaxation, cue-controlled relaxation alone, attention-placebo relaxation, and no-treatment control. Pre-post self-report measures of test anxiety, state anxiety, and trait anxiety were obtained. In addition, a performance measure in the form of a mental abilities test was administered. Subjects from the three relaxation groups received six 45- minute individual sessions over a period of 2 weeks. All treatments were conducted using audiotape recordings. The results indicate that cue-controlled relaxation is effective in increasing test performance for test anxious subjects, that EMG biofeedback does not contribute to the effectiveness of this procedure, and that self-report measures of anxiety are susceptible to a placebo effect.

Lehrer, Paul M. (1978). Psychophysiological effects of progressive relaxation in anxiety neurotic patients and of progressive relaxation and alpha feedback in nonpatients. Journal of Consulting and Clinical Psychology, 46 (3), 389-404.

Gave 10 anxiety neurotic patients 4 sessions of individual instruction in progressive relaxation; 10 patients served as waiting list controls. 10 nonpatients were assigned to each of the same conditions, and an additional 10 nonpatients were given 4 sessions of alpha feedback. Nonpatients showed more psychophysiological habituation over sessions than patients in response to hearing 5 very loud tones and to a reaction time task. Patients, however, showed greater physiological response to relaxation than did nonpatients. After relaxation, the autonomic responses of the patients resembled those of the nonpatients. The effects of relaxation were more pronounced in measures of physiological reactivity than in measures of physiological activity. Defensive reflexes yielded to orienting reflexes more readily in nonpatients than in patients. There was also a tendency for progressive relaxation to generalize to autonomic functions more than alpha feedback.

1977

Dillbeck, Michael C. (1977). The effect of the transcendental meditation technique on anxiety level. Journal of Clinical Psychology, 33 (4), 1076-1078.

Two weeks of twice-daily practice of the Transcendental Meditation (Transcendental meditation) technique was compared with 2 weeks of twice-daily practice of passive relaxation as a means of reduction of anxiety, as measured by the

Trait scale of the State-Trait Anxiety Inventory. Thirty-three graduate and undergraduate students were assigned randomly to a relaxation group and a Transcendental meditation group. After a 2-week experimental interval, the relaxation Ss began Transcendental meditation. As hypothesized, in the comparison between the relaxation and meditation Ss, as well as between conditions of the relaxation-meditation group, Transcendental meditation was significantly more effective in reducing anxiety level. Thus, the anxiety-reducing effect of the practice of Transcendental meditation cannot be attributed merely to sitting quietly twice daily, although additional research must determine the extent to which S expectations for change contributed to this effect.

Gatchel, Robert J.; Hatch, John P.; Watson, Paur J.; Smith, Dan; Gaas, Elizabeth (1977). Comparative effectiveness of voluntary heart rate control and muscular relaxation as active coping skills for reducing speech anxiety. Journal of Consulting and Clinical Psychology, 1093-1100.

The present study investigated whether heart rate biofeedback training is as effective as muscular relaxation training in reducing speech anxiety. Also, a combined muscle relaxation/biofeedback treatment group was included in this study. All treatment groups were compared to a false-biofeedback placebo control group. This investigation also assessed whether the degree of autonomic nervous system awareness significantly influences the treatment process. Ten speech-anxious subjects, half of whom scored high on the Autonomic Perception Questionnaire (APQ) and half of whom scored low on the APQ, were assigned to each group. Results indicated that all four groups demonstrated a decrease in self-reported anxiety. Assessment of physiological measures (heart rate and skin conductance) indicated that the three treatment groups were associated with less physiological responding during the posttreatment assessment of anxiety, relative to the false-biofeedback group. Moreover, among the three treatment groups, the combined relaxation/biofeedback group demonstrated the lowest level of responding. The degree of autonomic awareness was not found to be related to therapeutic improvement

Lick, John R.; Heffler, David (1977). Relaxation training and attention placebo in the treatment of severe insomnia. Journal of Consulting and Clinical Psychology, 45 (2), 153-161.

This study compared the effectiveness of progressive relaxation training with and without a supplementary relaxation recording, which the subjects played at home, and an attention placebo manipulation in the modification of severe insomnia in adult volunteers. The results indicated that the relaxation training procedures were significantly more effective than placebo and no-treatment controls in modifying several parameters of sleeping behavior, in reducing consumption of sleep-inducing medication, and in influencing a self-report anxiety measure. The supplementary relaxation tape did not increase the effectiveness of relaxation training conducted in

the clinic, and there was no difference in the efficacy of the placebo and no-treatment conditions. Physiological data gathered during the last treatment session indicated few significant correlations between reductions in arousal associated with relaxation training and treatment outcome.

1976

Gatchel, Robert J.; Proctor, Janet D. (1976). Effectiveness of voluntary heart rate control in reducing speech anxiety. Journal of Consulting and Clinical Psychology, 381-389.

The effects of learned control of heart rate deceleration and therapeutic expectancy set in reducing speech anxiety were investigated in a factorial design employing 36 speech-anxious subjects. Heart rate control training and no heart rate control training were each paired with high-therapeutic-expectancy and neutral-expectancy instructions, in order to assess the individual and combined effects of the two factors. Results demonstrated that learning to control heart rate deceleration led to a significant reduction in self-report, physiological (heart rate and skin conductance level), and overt signs of anxiety, relative to the no-heart-rate control condition. High-therapeutic-expectancy instructions also contributed to a reduction in self-reported anxiety. These results demonstrate that learned heart rate control is an effective therapeutic technique for reducing anxiety.

Hemme, Robert; Boor, Myron (1976). Role of expectancy set in the systematic desensitization of speech anxiety: An extension of prior research. Journal of Clinical Psychology, 32 (2), 398-404.

#### SUMMARY

The influence of expectancy set with regard to therapy outcome on the effectiveness of systematic desensitization (SD) for reducing public speaking anxiety was investigated. The 7 Ss given a high expectancy set for favorable therapy outcome were informed about psychological research that indicates that SD is effective to reduce public speaking fears. SD was administered with the standard instructions to the 11 Ss given a neutral expectancy set. This expectancy manipulation did not require deception and perhaps could be used with actual SD therapy clients. As in previous research by Woy and Efran, the expectancy set manipulation significantly modified Ss' self-report of subjective perceptions of anxiety from pretreatment to posttreatment speeches, but did not affect overt behavioral or physiological indices of anxiety. Since subjective perceptions of anxiety responses are psychologically significant behaviors, these data suggest the importance of conveying a high expectation of improvement to SD and perhaps also to other types of therapy clients. SD sessions administered to small groups of clients on consecutive days, as in this study, appeared to be as effective to reduce speech anxiety as SD sessions administered to each client individually at 1-week intervals, as in the Woy and Efran study" (pp. 403-404).

Lawlor, E. D. (1976). Hypnotic intervention with 'school phobic' children. International Journal of Clinical and Experimental Hypnosis, 24, 74-86.

Case studies are used to illustrate the use of hypnosis in working with children who exhibit symptoms of "school phobia." Responses obtained during and after hypnosis are utilized to uncover underlying conflicts and fears.

The literature (Ansbacher, 1956; Friedman, 1959; Johnson, 1957; Johnson, Falstein, Szurek, & Svendsen, 1941; Kessler, 1966; Waldfogel & Gardner, 1961) confirms the findings that a child through his symptoms has fears which he is unable to bring to consciousness and talk about. Typical are fears of abandonment by parents; fears of disaster befalling parents, especially the mother; fears based on destructive wishes toward siblings due to severe rivalry for the mother's love and attention; fears that exhibiting angry feelings will be punished by the parents; and fears of annihilation and starvation.

Hypnosis has aided in restoring these children to a school environment more quickly than more traditional methods. One case is reported with excerpts from a session. The perceptions uncovered through the use of hypnosis can be utilized with children in various school settings

1973

McReynolds, William T.; Barnes, Allan R.; Brooks, Samuel; Rehagen, Nicholas (1973). The role of attention-placebo influences in the efficacy of systematic desensitization. Journal of Consulting and Clinical Psychology, 41 (1), 86-92.

Systematic desensitization was compared with two attention- placebo control treatments - one taken from Paul and one currently devised as an elaborate, highly impressive "therapeutic" experience - and no treatment. It was hypothesized that (a) fear reductions following desensitization would be no greater than those associated with an equally compelling placebo treatment and (b) fear and control measure changes following the previously used attention-placebo treatment would be less than those following desensitization and the present placebo control manipulations. Both hypotheses were supported, although support for the first was more consistent than for the second.

1971

McAmmond, D. M.; Davidson, P. O.; Kovitz, D. M. (1971). A comparison of the effects of hypnosis and relaxation training on stress reactions in a dental situation. American Journal of Clinical Hypnosis, 13, 233-242.

NOTES

1:

Compared the effectiveness of relaxation, hypnosis, and a control condition in reducing in dental phobics the reaction to pressure-algometer stimulation and the injection of anesthesia. For subjects with high baseline skin-conductance levels, relaxation was most effective in reducing stress reactions. Hypnosis did not differ from the control condition. For subjects with a medium or low skin-conductance baseline, relaxation was not effective. The hypnosis group rated their treatment as most effective, and the controls rated their treatment as least effective. Five-month follow-up indicated that all subjects in the hypnosis group returned for dental

treatment and that 5 of 10 in the control group and only 1 of the relaxation group returned for care.

1970

Davis, Daniel; McLemore, Clinton W.; London, Perry (1970). The role of visual imagery in desensitization. Behaviour Research and Therapy, 8 (1), 11-13.

#### NOTES

Summary: a measure of visual imagery ability was obtained for 33 females who and participated in desensitization therapy for snake phobia. Visual imagery was positively related to pretherapy performance (closeness of approach to a live snake), but not to improvement. On the basis of these results and the results of two other studies, it was hypothesized that the fear of good imagers tends to be based on imagination while that of poor imagers tends to be based on sensory experience.

Most psychologists now recognize behavior therapy as effective in alleviating a wide variety of fears, but the nature of the processes underlying the various methods remains an open issue. Imagery has been of particular interest as a possible common denominator among various desensitization techniques. Lazarus (1961), for example, asserts that a "prerequisite for effective application of desensitization is the ability to conjure up reasonably vivid images," and Wolpe (1961) claims, "it is essential for visualizing to be at least moderately clear." London suggests that theoretically opposed treatments such as reciprocal inhibition (Wolpe, 1958) and implosion (Stampfl and Levis, 1967) may both be facilitated by repeated imagery which "produces a discrimination set such that the patient learns to distinguish between the imaginative, cognitive, affective aspects of experience, and the sensory and overt muscular aspects" (1964, p. 130). However, no systematic studies linking visual imagery to desensitization have been reported. This study examined the relationship between visual imagery and success in desensitization therapy.

1968

Nuland, William (1968). The use of hypnotherapy in the treatment of the postmyocardial infarction invalid. International Journal of Clinical and Experimental Hypnosis, 16 (3), 139-150.

DEALS WITH THE PSYCHOLOGICAL ASPECTS OF CONVALESCENCE AND REHABILITATION OF PATIENTS FOLLOWING CORONARY INFARCTION. THE FOCUS IS ON THE SITUATIONAL FACTORS WHICH THE PATIENT ENCOUNTERS DURING CONVALESCENCE THAT SERVE TO PROLONG AND REINFORCE THE INVALIDISM. IT IS CONCERNED ESPECIALLY WITH THE VALUE OF HYPNOTHERAPY AS COMPARED WITH OTHER PSYCHOTHERAPEUTIC METHODS IN TREATING THESE CASES. THE ANXIETY AND EMOTIONAL STRESS WHICH CAN BE RELIEVED THROUGH THE USE OF HYPNOSIS IS DIRECTED PRIMARILY TOWARD REDUCING EMOTIONAL TURMOIL WHICH RESULTS FROM THE CORONARY ATTACK WITH THE CONSEQUENT FEAR OF PHYSICAL ACTIVITY AND OF SUDDEN DEATH. SPECIFICALLY, HYPNOSIS IS USED

EFFECTIVELY IN REASSURANCE, REEDUCATION, DESENSITIZATION, GUIDANCE, AND OTHER DIRECT SUPPORT TECHNIQUES IN ACCORDANCE WITH THE PATIENT'S SYMPTOMS AND NEEDS. (SPANISH + GERMAN SUMMARIES) (PsycINFO Database Record (c) 2002 APA, all rights reserved)

Davison, Gerald C. (1965, June). Anxiety under total curarization: Implications for the role of muscular relaxation in the desensitization of neurotic fears. [Paper] Presented at the annual meeting of the Western Psychological Association, Honolulu.

NOTES

1:

I began by describing the Jacobson-Wolpe position on the use of deep muscular relaxation as an anxiety-inhibitor: these writers assume that the considerable reduction in proprioceptive feedback from muscles which are in a relaxed state is incompatible with a state of anxiety. Then I mentioned the evidence that at least modern neuromuscular blocking-agents operate solely at the myoneural junction, with no direct central effects. I went on to discuss the various studies which have used paralytic drugs, primarily d- tubocurarine chloride, to show the learning of fear-responses under complete striate muscle paralysis: the fact that these animals are able to acquire classically-conditioned fear-responses under curare was taken as evidence inconsistent with the views of Jacobson and Wolpe. Several studies were then reviewed which purport to furnish confirmatory evidence for the Jacobson position: these studies showed considerable central depression during curare paralysis. I re-interpreted these studies in the light of the over-riding importance of exteroceptive stimulation, stressing that the animals in the curare learning experiments were likewise deprived of proprioceptive feedback and yet were hardly non- anxious: the important difference was that the animals in the conditioning experiments were stimulated frequently from the environment while curarized, this stimulation maintaining an alert, often anxious state. Finally, two hypotheses were put forward as to why training in muscular relaxation does, in fact, inhibit anxiety: the one suggested that relaxing one's muscles generates strong positive affect states, which in turn inhibit anxiety; the other hypothesis called attention to the fact that the states of muscular relaxation under curare versus under self-induced relaxation differ in the important respect that only with self-induced relaxation is there a reduction in efferent activity--perhaps this elimination of efferents, rather than afferents, inhibits anxiety.

1955

Jacoby, James D. (1955). A statistical report on the practical use of hypnosis in dentistry. Journal of Clinical and Experimental Hypnosis, 3 (2), 117-119.

NOTES

1:

This is a description of one dentist's office practice employing hypnosis: 197 hypnodontic subjects experienced 776 hypnodontic sessions (about 4 sessions per

patient). Appointments included: 107 surgical (exodontics), 527 operative, 15 prosthetic, 46 periodontic surgery, 14 endodontics, and 67 "for suggestive conditioning only." The average depth of trance estimated from the first "conditioning" appointment was: 4 refused all instruction following introduction of the subject; 4 were refractory -- did not enter a trance or relaxed mood; 43 reached hypnoidal stage; 41 reached light trance; 65 reached medium trance; 40 reached somnambule stage. The author concludes, "we might also remind ourselves that all patients do not survive surgical or anesthesia intervention. The hypnodontist or hypnotherapist has a 100% clean record for the survival of his patient or even of any deleterious side effects of his treatment. No other specialty of medical-dental therapy is so fortunate" (p. 119).

1994

Amigo, S. (1994). Self-regulation therapy and the voluntary reproduction of stimulant effects of ephedrine: Possible therapeutic applications. Contemporary Hypnosis, 11 (3), 108-120.

## NOTES

1:

"Emotional self-regulation therapy is comprised of three phases. In the first phase, several sensory recall exercises are used to teach subjects how to voluntarily reproduce various physical sensations (hand numbness and heaviness, smell and taste) that are initially provoked by real stimuli (cold water, a heavy book, cigarette ashes, and lemon juice). Subjects are asked to associate these sensations with images, words, or other cues that will help them to later reproduce the sensations without the physical stimuli.

"In the second phase, subjects reproduce these sensations without the physical stimuli and are asked to generate them in response to various cues suggested by the therapist (e.g., touching a pencil, pen, book, etc.) ....

"In the last phase ... a demand of any kind generates the suggested effects. In the beginning of this phase, subjects are told that because of previously performed exercises, their minds are highly activated and receptive, so that they can respond to the therapist's verbal suggestions, without needing training for each new sensation. At this point, therapeutic suggestions are given to the patient" (p. 109).

1993

Harris, Ruth M.; Porges, Stephen W.; Carpenter, Myrna E. Clemenson; Vincenz, Lilli M. (1993). Hypnotic susceptibility, mood state, and cardiovascular reactivity. American Journal of Clinical Hypnosis, 36 (1), 15-25.

In this study we explored the relationship between hypnotic susceptibility measured with the Harvard Group Scale of Hypnotic Susceptibility (HGSHS) and cardiovascular parameters. After assessing their degree of hypnotic susceptibility, we induced 21 female students into happy mood states and into sad mood states. During the mood state induction we monitored blood pressure, heart rate, and

cardiac vagal tone continuously. The study demonstrated a strong relationship between hypnotic susceptibility and both cardiac vagal tone and heart rate reactivity. Subjects with lower heart rate and greater vagal tone during baseline and greater heart rate increases during mood induction were more susceptible to hypnosis. Multiple regression analyses indicated that approximately 40% of the individual difference variance of hypnotic susceptibility was accounted for by baseline cardiac vagal tone and heart rate reactivity during mood state. The data demonstrate that autonomic tone, assessed by cardiac vagal tone and heart rate reactivity, are related to hypnotic susceptibility as measured by the HGSHS. - Journal Abstract

**1991**

Crowson, J. Jeffrey, Jr.; Conroy Aileen M.; Chester, Traci D. (1991). Hypnotizability as related to visually induced affective reactivity: A brief communication. International Journal of Clinical and Experimental Hypnosis, 39 (3), 140-144.

Numerous studies have explored the relationship between hypnotizability and individual differences in imaginative involvement and creativity. Most have assessed imaginative or affective involvement by involving Ss in a variety of imaging tasks. Unlike these earlier studies, however, the present study made no attempt to actively involve Ss in the film viewing task. Rather, individuals assessed as high, medium, or low in hypnotizability were exposed to either a violent film, a neutral film, or no film. Results provided tentative evidence to indicate that the level of negative affect reported was significantly greater for highly hypnotizable Ss. Results were discussed in terms of the limitations of the present study and implications for future studies.

**1990**

Arendt-Nielsen, Lars; Zachariae, Robert; Bjerring, Peter (1990). Quantitative evaluation of hypnotically suggested hyperaesthesia and analgesia by painful laser stimulation. Pain, 42, 243-251.

**NOTES:**

Sensory and pain thresholds to laser stimulation were determined, and the laser-pain evoked brain potentials were measured for 8 highly hypnotizable (Harvard Scores 10-11) student volunteers in 3 conditions: (1) waking, (2) suggestion of hyperaesthesia during hypnosis, (3) suggestion of analgesia during hypnosis.

The investigators used a laser beam 3 mm in diameter, with a 200 msec stimulus duration; the same area (but different points within the area) was used for consecutive stimulations. Ss were otherwise maintained in low stimulus conditions so they would not have visual or auditory cues about laser beam onset; they wore goggles, had eyes shut, and had earphones on. Sensory threshold was defined as warmth; pain threshold was defined as a distinct sharp pin prick.

The laser intensity used for stimulation corresponded to strong pain. Interstimulus intervals averaged 15 sec (but were randomly varied between 10-20 sec). Sensory and pain thresholds as well as two evoked potential measurements were taken during waking, hypnotized hyperaesthesia, and hypnotized analgesia conditions in a single 1 1/2 hour session.

The evoked potential component of interest was the negative complex N1 with latency of 300 msec; amplitude (P1=N1-P2) and latency of this complex (N1) were measured. EEG epochs contaminated by eye movement were omitted from analysis.

The standardized induction and deepening of hypnosis required 15-20 minutes; then the suggestion was given that Ss could alter their perception of stimuli such as pain. Hyperaesthesia suggestions were to imagine the right hand was in very hot water, then taken out but still very red, hot, sensitive so that even the vaguest stimulus would be detectable and unpleasant. They were told that they would receive a series of painful but tolerable stimuli, and to raise the left index finger if they could just perceive a laser pulse (sensory threshold), and again if they felt pricking pain (pain threshold).

Suggestions for analgesia were to imagine that their right hand was placed on their chest, and that their 'former right hand' was no longer their own but was made of some heavy and completely insensitive material like wood or stone. Sensory and pain threshold measures were then taken. During the evoked potential measurement period they received continuous suggestions of analgesia. They also were told to relax and imagine they were in a pleasant place, ignoring everything except the pleasant, relaxed feelings and imagining pleasant sights, sounds, feelings and the imagined place. They were told that though they would receive stimuli, they probably would be able to ignore the stimuli completely.

Results were as follows.

1. In the hypnotic hyperaesthesia condition, sensory and pain thresholds decreased significantly by 47% and 48%, respectively. Three Ss reacted to laser intensities far below what normally can be perceived in the waking state. [The authors ran a separate small control experiment to make sure that the Subjects were not using any other cues, but mention the possibility of light-sensitive skin reacting to the blue laser light, creating evoked potentials.]

2. In the hypnotic analgesia condition, sensory and pain thresholds increased by 316% and 190%, respectively. 7 of 8 Ss did not even respond to pain threshold when the laser intensity was increased to the noxious level of 3W, which is the level at which tissue damage can occur.

3. Pain-related evoked potentials. Amplitude of the first pain-related potential was increased significantly by 14% in the hyperaesthesia condition and reduced significantly by 31% in the analgesia condition. Changes in the evoked potentials were considered minor however compared to those observed for thresholds, which are subjective response measures. Even in Subjects who reported complete analgesia, the experimenters observed the laser pain evoked responses. There were no differences in latencies of the first pain-related potentials for the three conditions (indicating that peripheral and central afferent conduction velocities were the same).

**Discussion.** "There has been some dispute concerning the experimental design and the reliability of the data obtained in studies dealing with hypnotic suggested analgesia [Spanos & Chaves, 1970]. In our design 2 'opposite' conditions were induced, and the 2 inductions gave 'opposite' results.

"The experience of pain can be significantly altered by suggestions of analgesia, which is in accordance with a number of other studies (for review see [Barber & Adrian, 1982; Hilgard & Hilgard, 1975]). The finding that suggestions of hyperaesthesia can decrease the sensory and pain thresholds and increase the amplitude of the pain evoked potential is a new observation. Since synchronized auditory and visual stimuli from the laser were blocked, and the stimulus was given at random intervals, the changes might be induced by the hypnotic suggestions" (p. 247).

The authors discuss their results in terms of (1) four pain modulation systems (neural/opiate, hormonal/opiate, neural/non-opiate, and hormonal/non-opiate) and (2) focusing and defocusing attention. Because in their pilot study it was necessary to give suggestions continually in order to affect the laser evoked potentials, they conclude that endogenous substances or hormonal/non-opiates would play a minor role, if any, in hypnotic analgesia. (Price and Barber [25] had also found it important to give suggestions continuously.)

On the other hand, "event-related potentials [7, 26] and pain-related potentials have, previously, been shown to be sensitive to focused and de-focused attention. Recently, Miltner et al. [23] showed the influence of attention on the late pain-related component of potentials, evoked by painful intracutaneous electrical stimulation. The degree to which the subject paid attention to the painful stimulus had a powerful effect on the pain-related complex. When subjects ignored the pain, it was still possible to record the pain-related complex although all the subjects consistently reported less or no pain. In wakeful subjects where cutaneous pain was abolished by lignocaine infiltration, the pain-related evoked potentials were abolished [4]. In our study, we could also record evoked potentials although the subject subjectively did not feel pain. The reason might be that the S acted as if there was full analgesia to the stimuli, in order to satisfy the hypnotist. During suggested hyperaesthesia the thresholds declined below what normally could be perceived in the wakeful state. The volunteers could, therefore, not act hypersensitive, so something did happen.

"The discrepancy in subjective and objective responses might, however, be useful when investigating levels of the neuroaxis at which hypnosis might work" (pp. 248-249).

The authors note that this laser induced pain and the tooth pulp stimulation pain of Mayer & Barber both use the A-delta fibers. Barber & Mayer found it impossible to elicit pain within the output range of the stimulator (up to 150 microA) and reached maximal intensity for all volunteers during suggested analgesia. Using cutaneous laser stimulation the authors found that the skin damage level (3W) could be reached in 7 of 8 volunteers without any reaction of pain.

During the hyperaesthesia condition the sensory threshold was sometimes lower than can be detected in the waking state. Although some researchers have suggested that red light from a helium-neon laser might activate cutaneous photosensitive

receptors and thereby elicit brain potentials, the authors were unable to elicit potentials in waking Subjects using their blue and green argon laser light with below sensory threshold intensity.

The authors also note that previous attempts to use physiological correlates of pain such as heart rate, blood pressure, respiration, and galvanic skin response have yielded confusing results. The physiological indicators are present even when Subjects report analgesia, leading some investigators to conclude that the subjective reports are due to illusion [Sutcliffe, 1961], compliance [Wagstaff, 1986], or a placebo induced by the hypnosis context [Wagstaff, 1986]. "These confusing results lead to the conclusion that both the traditional methods used for induction of pain and the monitored physiological responses have been unsatisfactory. The present study has sought to eliminate some of the methodological difficulties by (1) using brief well-defined argon laser stimuli which in awake volunteers induce very stable perceptions between trials [Arendt-Nielsen & Bjerring, 1988], and (2) recording psychophysical thresholds and objective parameters quantitatively related to the intensity of the pain perceived (1, 3)" (p. 249).

**Pekala, Ronald J.; Bieber, Stephen L. (1989-90). Operationalizing pattern approaches to consciousness: An analysis of phenomenological patterns of consciousness among individuals of differing susceptibility. Imagination, Cognition and Personality, 9 (4), 303-320.**

Pattern differences in subjective experience, as assessed by a self-report inventory, the Phenomenology of Consciousness Inventory (PCI), were compared across low, low-medium, high-medium, and high hypnotically susceptible individuals during hypnosis and eyes-closed. A hierarchical factor analytic approach was utilized that allowed for the determination of pattern differences among PCI dimensions as a function of hypnotic susceptibility. The factor analyses found that the four susceptibility (sic) groups were 'pattern equivalent' during eyes-closed, partially pattern dissimilar during hypnosis, and partially pattern dissimilar when comparing hypnosis against eyes-closed. The nature of these results support previous analyses (1) which compared pattern structure differences as a function of correlational matrices. The results suggest the complementarity of Bieber's (2) and Pekala's (3) approaches for assessing pattern differences in consciousness and are congruent with the theorizing of Tart (4), Izard (5), and the PDP researchers on the importance of pattern structure changes in understanding states of consciousness.

**Pekala, Ronald J.; Kumar, V. K. (1989). Phenomenological patterns of consciousness during hypnosis: Relevance to cognition and individual differences. Australian Journal of Clinical and Experimental Hypnosis, 17 (1), 1-20.**

Relationships among phenomenological subsystems of consciousness associated with a baseline condition and an hypnotic induction condition were compared across individuals of differing hypnotic susceptibility. Phenomenological experience on 12 subsystems of consciousness was quantified by means of the Phenomenology of

Consciousness Inventory (PCI) and the relationships between dimensions were statistically assessed. The results replicated previous findings and suggested that hypnosis has differential effects upon the reported organization of phenomenological structures of consciousness across subjects of differing susceptibility. The data from the previous and present studies were pooled and the combined data were reanalyzed. The results provided further support for the differential pattern structure across low and high susceptibles during hypnosis. Furthermore, differences in pattern structure were augmented when comparing very low versus very high susceptible individuals.

#### NOTES

1:

This paper is based on a paper presented to Division 30, Psychological Hypnosis, at annual meeting of the American Psychological Association, Aug 1987.

1988

Kumar, V. K.; Pekala, Ronald J. (1988). Hypnotizability, absorption, and individual differences in phenomenological experience. International Journal of Clinical and Experimental Hypnosis, 36, 80-88.

The phenomenological effects associated with a baseline condition of eyes- closed and a hypnotic induction condition were compared across individuals of differing absorption capacity and hypnotizability. The results indicated that individuals of differing absorption capacity and hypnotizability reported different intensities of phenomenological experience during the baseline eyes-closed condition. The induction further augmented intensity differences for low, medium, and high absorption and hypnotizable Ss, but more so for high (and medium) than low hypnotizable Ss. The results support both a trait and state interpretation of hypnotizability, and highlight the importance of the interaction between these factors on the resulting hypnotic experience of S.

#### NOTES

1:

Based on a review of relevant literature, the authors predicted that (1) during hypnosis and a baseline condition (eyes-closed), high absorption and high hypnotizable Ss will report the phenomenological effects at greater intensity relative to low absorption and low hypnotizable Ss, respectively; (2) hypnotic induction will be associated with increased absorption; greater alterations in awareness and experience; and decreased volitional control, rationality, and memory; (3) phenomenological intensity differences (hypnosis compared to eyes-closed) will be significantly greater for high than for low hypnotizable Ss.

They used the Phenomenology of Consciousness Inventory (PCI) developed by Pekala (1982), which is a 53 item self-report instrument that is completed retrospectively in reference to a preceding stimulus condition. The PCI measures the following dimensions and subdimensions: internal dialogue; self-awareness; state of awareness; imagery (amount, vividness); positive affect (joy, sexual excitement, love); negative affect (anger, fear, sadness); altered experience (time

sense, body image, perception, unusual meanings); attention (absorption, direction); memory; rationality; volitional control; and arousal.

The 217 Ss were administered the Tellegen Absorption Scale, then sat quietly with eyes closed for four minutes, then completed the PCI, Form 1, relative to that 4-minute period. They were administered a slightly shortened version of the Harvard Group Scale of Hypnotic Susceptibility, Form A (HGSHS:A); before the posthypnotic suggestion and amnesia suggestion they experienced another 4-minute silent period during which they were told to 'continue to experience the state you are in right now.' After the HGSHS:A they completed PCI, Form 2, in reference to the silent period during the HGSHS:A, before they completed the 11-point questionnaire on the HGSHS:

A Subjects who did not have reliable PCI response forms were removed from the sample, leaving 173 Ss who were divided into high, medium, and low Absorption groups, and high, medium, and low hypnotizability groups. The statistical analysis employed MANOVA on intensity scores for first the major PCI dimensions and then the 14 subdimensions using Conditions (eyes closed, hypnosis) and Groups. There were significant main and interaction effects. Subsequent ANOVAs for each (sub)dimension, Conditions by Hypnotizability Groups (2 x 3) were then performed. Hypnosis "was associated with significantly less positive affect (joy, sexual excitement, love); negative affect (anger, sadness); visual imagery (amount, vividness); self-awareness, internal dialogue, rationality, volitional control, and memory; and significantly more altered experience (time sense, perception) and altered state of awareness.

"Significant main effects for Hypnotizability Groups were found for positive affect (joy, love); altered experience (body image, time sense, perception, meaning); attention (direction, absorption); self-awareness; altered state of awareness; rationality; volitional control; and memory.

"Post-hoc comparisons for the eyes-closed condition revealed that high relative to low, hypnotizables reported significantly greater alterations in body image, time sense, meaning, and altered state of awareness. Medium hypnotizable Ss, compared to low hypnotizables, reported significantly increased alterations in body image and state of awareness.

"Post-hoc comparisons for the hypnotic induction condition revealed that high, viz-a-viz low, hypnotizables reported significantly increased absorbed attention; greater altered experience (body image, time sense, perception, meaning); and increased alterations in state of awareness. High hypnotizables also reported significantly less imagery vividness, self-awareness, rationality, volitional control, and memory. Medium hypnotizable Ss, vis-a-vis low hypnotizables, reported significantly more altered experience (body image, time sense, perception, meaning); absorbed attention; and altered state of awareness; and significantly less imagery vividness, self-awareness, rationality, volitional control, and memory. High hypnotizable Ss, relative to medium hypnotizables, reported significantly more altered experience (perception, meaning) and absorption, and significantly less rationality, volitional control, and memory.

"Concerning the significant interactions ( $\alpha = .01$ ), graphs of the means indicated significant ordinal interactions between Conditions and Hypnotizability

Groups for altered experience (perception), imagery (vividness), self-awareness, altered state of awareness, rationality, volitional control, and memory. For all of the PCI (sub)dimensions, the hypnotic induction condition (compared to eyes-closed) was associated with a significantly greater increase in altered experience (perception), and altered state of awareness; and a significantly greater decrease in imagery (vividness), rationality, volitional control, and memory for the high (and medium) hypnotizable groups relative to the low hypnotizable group.

"Significant disordinal interactions were found for absorption and unusual meanings. Whereas high hypnotizable Ss reported a more absorbed attentional focus and more unusual meaning during hypnosis, low hypnotizable Ss reported being less absorbed (or more distracted) during the induction than eyes-closed. Low hypnotizables reported more unusual meanings in reference to eyes closed" (pp. 84-85).

Correlations among the major PCI dimensions, absorption, and hypnotizability differ between the two conditions. In hypnosis, the hypnotizability correlations that reached the .001 level were: --Self Awareness -.55 --State of Awareness .60 --Altered Experience .56 --Inward Absorbed Attention .44 --Rationality -.41 --Volitional control -.65 --Memory -.41 --Arousal -.28

In the eyes closed condition, the only PCI variables that Hypnotizability correlated with, at the .001 level, were: --Positive Affect .26 --Altered Experience .32

MANOVAs and ANOVAs were computed for Absorption groups in a similar fashion. Main effects but not interaction effects were significant. Results are not abstracted here.

In their Discussion, the authors note that "The three hypotheses were supported by the results. Several of the absorption group comparisons obtained in previous research (Pekala et al., 1985) involving alterations in subjective experience (body image, perception, meaning); state of awareness; and volitional control were replicated in the present research" (p. 85).

Neiss, Rob (1988). Reconceptualizing arousal: Psychobiological states in motor performance. *Psychological Bulletin*, 103 (3), 345-366.

This review of research dealing with psychologically induced arousal and motor performance focuses on the hypothesized inverted-U function relating arousal to performance. The inverted-U hypothesis is supported only in a weak and psychologically trivial fashion. More useful research in human motor performance would investigate discrete psychobiological states, which include affect and cognition as well as physiology. Examination of profound individual differences in response to incentive and threat suggests that psychobiological states have their genesis in response expectancies and hypnotic-like self-inductions. The cognitive and affective components of these states are highly interactive and perhaps not profitably separated. Because performance anxiety is a central problem in the motor realm, it is carefully delineated and the test anxiety literature is scrutinized. Psychophysiological test batteries and other investigations in the area are described, and guidelines for future research are provided.

Neiss, Rob (1988). **Reconceptualizing relaxation treatments: Psychobiological states in sports.** Clinical Psychology Review, 8 (2), 139-159

Reviews studies relating relaxation treatments to motor performance and attempts to explain these treatments from a psychological perspective. The inverted-U hypothesis is based on arousal, which has construct validation problems and is a physiological, rather than a psychological, construct. Arousal cannot distinguish among fear, anger, sexuality, and other psychobiological states; predictive validity is low in the area of motor performance. The inverted-U hypothesis is effectively refutable in current usage, and empirically weakly supported. Relaxation treatments are reconceptualized as relatively nonspecific psychological therapies, potentially useful in alleviating dysphoric, debilitating psychobiological states. These treatments are particularly apt for athletics, where performance anxiety is a pervasive problem..

1984

Pekala, Ronald J.; Kumar, V. K. (1984). **Predicting hypnotic susceptibility by a self-report phenomenological state instrument.** American Journal of Clinical Hypnosis, 114-121.

In an attempt to predict hypnotic susceptibility (as measured by the Harvard Group Scale of Hypnotic Susceptibility, HGSHS) the phenomenological experiences of an hypnotic induction (HI) procedure and a baseline comparison condition (eyes closed, EC, sitting quietly) were assessed. After each experience the subjects (n=217) completed the Phenomenology of Consciousness Inventory (PCI), a self-report phenomenological state instrument, dealing with that condition. Step-wise multiple regression and discriminant analyses were then performed on data using the subject's HGSHS score as the dependent variable and the PCI (sub)dimensions as the independent variables. Regression analyses that held up under cross-validation during HI suggest that the PCI may be an appropriate instrument for predicting susceptibility. The possible clinical usefulness of this approach is discussed.

1982

Blum, Gerald S.; Nash, John K. (1982). **EEG correlates of posthypnotically controlled degrees of cognitive arousal.** Memory and Cognition, 10, 475-478.

Experimental control over five degrees of cognitive (as opposed to organismic) arousal has been developed by hypnotic programming techniques. Previously these posthypnotic manipulations have been applied to the investigation of diverse topics such as visual discrimination, performance on the Stroop test, selective concentration on color versus form of consonants, and cognitive "reverberation." The present study explored EEG correlates of the five degrees of cognitive arousal in a task requiring participants to visualize objects for one-minute periods while lying on a couch with eyes closed. Analysis of data from the occipital area in left and right hemispheres revealed that the highest degree of arousal was accompanied by larger amplitudes of alpha and beta power and smaller amplitudes of theta. This

pattern of results was similar in both hemispheres, although more marked in the left. The findings, which provide an independent source of support for validity of the hypnotic programming, are discussed in relation to EEG literature on cognitive activity.

#### NOTES

1:

Hypnosis doesn't enhance imagery. It provides the conditions under which mental alertness may be manipulated, and very clear imagery is associated with the alert condition whereas blurry imagery is associated with the lowest cognitive arousal condition. The other impression comes from clinical work, i.e. that hypnosis enhances imagery. This article is an example of hypnosis used in other research--see last page.

1981

De Piano, F. A.; Salzberg, H. C. (1981). Hypnosis as an aid to recall of meaningful information presented under three types of arousal. International Journal of Clinical and Experimental Hypnosis, 29 (4), 383-400.

This study was designed to examine the effect of hypnotic induction on recall of information which was incidental, meaningful, and contextually presented. A hypnotic induction with task motivating suggestions was found to enhance recall to a greater extent than were task motivating suggestions alone. It was argued that the positive findings of this study might be due to (a) the types of information used for recall in this study, (b) confidence/motivational factors felt to be facilitated by hypnotic induction, and (c) reduction in critical judgment which allows for the reporting of partial memories. Film-induced arousal resulted in physiological measures and self-reports of arousal which varied with the content of the films. The effects of arousal on recall, however, were less clear but with only slight indications that traumatic arousal had a deleterious effect on recall. Support for the contention that a hypnotic induction would aid recall of information learned under traumatic arousal to a greater extent was not found. The range of arousal produced, however, was probably restricted in comparison to "natural" arousal. Greater differences in recall might be found in real world situations.

#### NOTES

1:

Hypnosis was not mentioned during recruitment of subjects. They were connected to equipment to measure physiological changes, and then shown a film. Each S saw one of 3 films: Low Arousal (depicting scenes of horses running in the distance, landscape, people socializing), Sexual Arousal (two lovers in romantic encounter, culminating in sexual intercourse), or Traumatic Arousal (a transorbital surgical lobotomy of the brain).

1979

Quall, Penelope J.; Sheehan, Peter W. (1979). Capacity for absorption and relaxation during electromyograph biofeedback and no-feedback conditions. Journal of Abnormal Psychology, 88 (6), 652-662.

The present research examined the relation between absorption capacity and relaxation during electromyograph biofeedback and no-feedback (instructions only) conditions. Sixteen high absorption and 16 low absorption female subjects underwent a biofeedback and no-feedback session with the order of conditions counterbalanced. For high absorption subjects in the first session, EMG reductions were greater during no- feedback than during biofeedback, although the performance of biofeedback subjects improved in the second session. For low absorption subjects, no differences in EMG reductions were apparent across experimental conditions. Postexperimental self-report data demonstrated differences between absorption groups in subjects' state of arousal and quality of consciousness. It was concluded that for subjects with high capacity for absorbed attention, experimental conditions that allow for a withdrawal from the external environment are most conducive to relaxation, whereas for subjects with limited capacity for absorbed attention, conditions such as biofeedback that place an attentional demand on subjects may be preferable.

1978

Parker, Jerry C.; Gilbert, Gary S.; Thoreson, Richard W. (1978). Reduction of autonomic arousal in alcoholics: A comparison of relaxation and meditation techniques. Journal of Consulting and Clinical Psychology, 46 (5), 879-886.

To investigate and compare the effects of progressive relaxation training and meditation training on autonomic arousal in alcoholics, 30 subjects were selected from a population of alcoholics in a Veterans Administration hospital substance-abuse program. The subjects were randomly assigned to one of the following three experimental conditions: (a) progressive relaxation training group, (b) meditation training group, or (c) quiet rest control group. All groups met for 3 weeks during which state anxiety, blood pressure, heart rate, and spontaneous galvanic skin responses were measured. The measures were designed to assess the treatment effects following the first training session and at the end of the total training period. The results indicate that both progressive relaxation training and meditation training are useful for reducing blood pressure in alcoholics. In addition, significant differences between the groups in the effectiveness of the relaxation procedures were found. Meditation training induced blood pressure decreases at an earlier point in the 3-week training period and affected decreases in systolic blood pressure that progressive relaxation training did not. These results support the idea of considerable specificity of response to relaxation techniques.

1977

Fisher, R. (1977). On flashback and hypnotic recall. International Journal of Clinical and Experimental Hypnosis, 217-235.

This essay deals with both the intra-individual and inter-individual varieties of arousal state-bound experiences. The former are labelled as "flashbacks" while the

latter embrace the great fantasies and repetitive schemes, the ever re-written plots and images of literature, art, and religion.

Flashbacks are both arousal-state and stage (i.e., set and setting) bound experiences. Flashback and hypnotic recall differ only in the ways by which they are induced. Induction methods should be distinguished from induced states on the hyperaroused perception-hallucination and hypoaroused perception-meditation continuum.

Flashbackers may be characterized by their (a) variability on perceptual-behavioral tasks; (b) tendency to minimize (or reduce) sensory input; (c) high resting heart rates; (d) hypnotizability; and, hence (e) preferential right-cerebral-hemispheric cognition; and (f) a display of EEG-alpha dominance in the resting, waking state.

1974

Bloom, Richard F. (1974). Validation of suggestion-induced stress.

NOTES

1:

Technical Memorandum 23-74 (October 1974), US Army Human Engineering Laboratory, Aberdeen Proving Ground, Maryland 21005, AMCMS Code 5910.21.68629, Contract No. DAAD05-73-C-0243, Dunlap and Associates, Inc. (now Stamford, CT), AD002557.

Sixty college men, divided into three equal groups, each attended two induced stress sessions in which their physiological, psychological and performance reactions were measured. Their responses were compared to determine if valid stress reactions could be induced through suggestion in an altered state (in this case, hypnosis), and also to determine the validity of such reactions if the subject had never before experienced that stress situation. It was demonstrated that valid stress reactions can be induced in an individual with the aid of suggestions, especially if the real stress situation has been experienced before. If no previous experience with that real situation exists, the subject still exhibits stressful reactions; however, the closest resemblance to real stress is found in the subjective or psychological measures, less similarity is found in the physiological measures, and the least similarity is found in the performance measures.

**NOTES**

**1:**

**An adolescent with questionable diagnosis (mental retardation due to organic brain damage or functional psychological disorder) was given the E-G-Y test for an estimate of verbal intelligence. After initial testing, in which attention span was limited and she was very negativistic, she was re-tested in light hypnosis. Her mental age "more than doubled -- went up by six years -- "in the intervening 24 hours. The author ascribes improvement to relaxation from light hypnosis and opined that the 10 year level achieved under hypnosis was close to her "true" level of functioning. Subsequent attempts to hypnotize her were not successful, possibly due to short attention span and negativistic tendencies.**

arber, Theodore Xenophon; Coules, John (1959). Electrical skin conductance and galvanic skin response during 'Hypnosis'. International Journal of Clinical and Experimental Hypnosis, 7 (2), 79-92.

#### NOTES

1:

##### "Summary and Conclusions

"Six 'good' hypnotic Ss were given a ten-minute 'hypnotic induction' and a series of 'hypnotic tests.' Both basic skin conductance and momentary variations in skin conductance (GSR) were recorded during the experiment.

"The results were as follows:

1. There was no significant variation in skin conductance during the 'hypnotic induction procedure.'

2. Skin conductance generally increased throughout the remainder of the experiment, ie., when the Ss were given suggestions of 'sensory hallucinations,' 'age-regression,' 'analgesia,' 'negative hallucinations,' and 'post'-hypnotic behavior.

3. The Ss usually showed a GSR when they were given 'hallucinatory' suggestions, i.e., when they were told that they were becoming 'itchy,' 'thirsty,' and 'very hot.'

4. The GSR to a pinprick was essentially the same before the experiment and during 'hypnotic analgesia.' Also, the GSR was essentially the same, during 'hypnotic analgesia,' (a) when three Ss were told they would receive a pinprick but did not receive the pinprick, (b) when they were told they would receive a pinprick and did receive the pinprick, and (c) when they received a pinprick without being told they would receive it.

5. Four Ss showed a GSR each time they were asked to look at a 'negatively hallucinated' object and person. Two Ss did not show a GSR when they were asked to look at the 'negatively hallucinated' object (or person). The four Ss who showed a GSR stated, during or after the experiment, that they were by no means convinced that the person or object was no longer in the room. The two Ss who did not show GSR stated, after the experiment, that they had been 'certain' that the object (or person) was not present in the room.

6. Although the Ss stated that they did not 'remember' the 'post'-hypnotic suggestion (or anything else about the experiment), they usually showed a GSR when the E made the preliminary movements to give the signal for the 'post'-hypnotic behavior. (They also showed a GSR when E gave the signal for the 'post'hypnotic behavior.)

"Since skin conductance is an index of the S's level of 'activation,' 'arousal,' or 'excitation,' these results indicate the following:

1. Ss do not necessarily become more 'passive' or 'relaxed' during the 'hypnotic induction procedure.'

2. Ss often become more and more 'excited' and 'aroused' when they are given a series of 'active' suggestions such as 'sensory hallucinations,' 'age-regression,' etc.

3. Ss often show momentary 'excitement' when they are 'hallucinating.'

4. A pinprick can 'arouse' a S to the same extent during 'hypnotic analgesia' as it can during 'normal waking.' In addition, 'hypnotic analgesic' Ss are often just as much 'aroused' by the threat of a pinprick as they are by an actual pinprick.

5. Many Ss become momentarily 'excited' when they are asked to look directly at an object (or person) which they have been told they will not be able to see. However, some Ss do not show this momentary 'excitement.'

6. Although Ss may state that they do not 'remember' the 'post'-hypnotic suggestion, they often become momentarily 'excited' when the E makes preliminary motions to give the signal for the 'post'-hypnotic act" (pp. 90-92).

**1998**

**Eimer, Bruce; Freeman, Arthur (1998). Pain management psychotherapy: A practical guide. New York NY: John Wiley & Sons, Inc..**

### **NOTES**

**1:**

"Pain Management Psychotherapy" (PMP) provides a clear and methodical look at pain management psychotherapy beginning with the initial consultation and work-up of the patient and continuing through termination of treatment. It is a thoughtful and thorough presentation that covers methods for psychologically assessing the chronic pain patient (structured interviews, pain assessment tests and rating scales, instruments for evaluating beliefs, attitudes, pain behavior, disability, depression, anxiety, anger and alienation), treatment planning, cognitive-behavioral therapy techniques, and a range of hypnotic approaches to pain management. The book covers both traditional (cognitive and behavior therapy, biofeedback, assessing hypnotizability, choice of inductions, designing an individualized self-hypnosis exercise) as well as newer innovative techniques (e.g., EMDR, pain-relief imagery, hypno-projective methods, hypno-analytic reprocessing of pain-related negative experiences). An extensive appendix reproduces in their entirety numerous forms, rating scale, inventories, assessment instruments, and scripts.

The senior author, Bruce Eimer, states in his online comments on Amazon.com that "most therapists hold the belief that 'real' chronic pain patients are quite impossible to help. This book attempts to dispel these misguided beliefs by providing a body of knowledge, theory, and techniques that have proven value in understanding and relieving chronic physical pain." He also states that "the challenge for the therapist is to persuade the would-ne patient/client that he or she has something to offer that can help take way pain and bring back more pleasure. This challenge is negotiated through the therapeutic relationship. However, the therapist just can't be 'warm, accepting, non-judgmental and empathic'. The therapist must also have knowledge and skills relevant to relieving pain. Only then can the therapist impart such knowledge, and in teaching these skills to the pain patient, help the patient become something of a 'self-therapist'. . . I dedicate this book to everyone who wants to find ways to make living with pain more comfortable, and to the ongoing search for better ways to relieve pain."

**1996**

Holroyd, Jean (1996). Hypnosis treatment of clinical pain: Understanding why hypnosis is useful. International Journal of Clinical and Experimental Hypnosis, 44 (1), 33-51.

Clinical and experimental research literature indicates hypnosis is very useful for severe and persistent pain, yet reviews suggest hypnosis is not widely used. To encourage more widespread clinical application, the author reviews recent controlled clinical studies in which hypnosis compares favorably with other interventions; links advances in understanding endogenous pain modulation to a neurophysiologic view of hypnosis and hypnoanalgesia; relates the neurophysiology of hypnoanalgesia to management of chronic pain; challenges the view that hypnotic pain control is only for the highly hypnotizable patient; and raises issues about how people learn to control pain with hypnosis. Training in hypnotic analgesia may usefully enhance nervous system inhibitory processes that attenuate pain.

#### NOTES

1:

Hypnosis has been more effective for pain management than other cognitive behavioral interventions in studies of fibromyalgia (Haanen, Hoenderdos, Van Romunde, Hop, Malle, Terwiel, & Hekster, 1991); burn treatment (Patterson, Everett, Burns, & Marvin, 1992); and cancer bone marrow transplant procedures (Syrjala, Cummings, & Donaldson, 1992). Central nervous system gating or downward modulation of pain impulses may account for hypnotic pain control. "Hypnosis enables both amplification and attenuation of cortical response subsequent to sensory registration and prior to consciousness, depending on whether suggestions are for increasing or decreasing awareness (Blum & Barbour, 1979)" (p. 36). This type of inhibition may even be observed in the peripheral nervous system (see Hernandez-Peon, Dittborn, Borlone, & Davidovich, 1959/1960; Sharev & Tal, 1989; Kiernan, Dane, Phillips, & Price, 1995). Work by Helen Crawford (1994) suggests that frontal and limbic areas of the brain are involved in inhibitory patterns of brain activity, and that generation of theta EEG rhythms by lower centers is associated with the suppression of awareness of pain.

Some very low hypnotizable people have been able to learn to control pain with hypnosis, suggesting that it is a skill that can be learned. However, few investigations of improvement of hypnoanalgesia were located. Rather, one must generalize from the fact that other kinds of hypnosis skills have been improved using special training programs, such as the Carleton University program developed by Gorassini & Spanos, 1986). Although most research on improving hypnotic response has been based on operant learning principles, a model that incorporates respondent (classical conditioning) principles might be more useful when it comes to understanding the training of a neurophysiological response, such as inhibitory brain patterns associated with hypnoanalgesia. "Historical success with clinical pain, taken together with newer findings in the neurophysiology of hypnosis, indicate that we should be spending more energy investigating how learning may improve hypnotic analgesia" (p. 43). "We should acknowledge that there are advantages to hypnosis beyond those of relaxation, a good placebo, and psychotherapy. ... Responsible care demands that we provide training or practice in

hypnotic analgesia when treating pain, and especially whenever a chronic pain patient initially appears to be nonresponsive" (p. 43).

1991

Haanen, Huub C.M.; Hoenderdos, Henk T.W.; Van Romunde, Leo K.J.; Hop, Win C.J.; Malle, Constant; Terwiel, Jack P.; Hekster, Gideon B. (1991). Controlled trial of hypnotherapy in the treatment of refractory fibromyalgia. Journal of Rheumatology, 18 (1), 72-75.

In a controlled study, 40 patients with refractory fibromyalgia were randomly allocated to treatment with either hypnotherapy or physical therapy for 12 weeks with followup at 24 weeks. Compared with the patients in the physical therapy group, the patients in the hypnotherapy group showed a significantly better outcome with respect to their pain experience, fatigue on awakening, sleep pattern and global assessment at 12 and 24 weeks, but this was not reflected in an improvement of the total myalgic score measured by a dolorimeter. At baseline most patients in both groups had strong feelings of somatic and psychic discomfort as measured by the Hopkins Symptom Checklist. These feelings showed a significant decrease in patients treated by hypnotherapy compared with physical therapy, but they remained abnormally strong in many cases. We conclude hypnotherapy may be useful in relieving symptoms in patients with refractory fibromyalgia.

#### NOTES

1:

The patients in this study were 38 women and 2 men, ages 30-65, who had had fibromyalgia for an average of 8.5 years (range 1.5 - 40 years). Of these, 25 were on sick leave or incapacitated, and 6 were unemployed. Patients were randomly assigned to hypnotherapy, or to training in muscle relaxation plus massage (designated "physical therapy"). They were withdrawn from analgesics, except for paracetamol (like Tylenol), at the beginning of this program. Hypnotizability was not measured.

Hypnosis treatment consisted of an arm levitation induction, imagery deepening techniques, ego strengthening suggestions, and suggestions for control of muscle pain, relaxation, and improved sleep. Patients received eight one-hour sessions in decreasing frequency over three months; after Session 3 they were given a 30-minute audiotape to assist in daily self hypnosis. Seventeen patients completed hypnotherapy but three were dissatisfied and withdrew after 3 sessions.

Patients did self ratings on (1) duration of morning stiffness, (2) muscle pain, (3) fatigue on awakening, (4) sleep disturbance, and (5) global assessment, the last four using visual analog scales (VAS). Patient assessment at 12 and 24 weeks was the primary outcome measure, since fibromyalgia is diagnosed principally from patient's self described symptoms.

Independent observers did not know to which group the patient belonged. The physician's evaluation included (1) dolorimeter measures of point tenderness (for a Total Myalgic Score, TMS), (2) presence of tender points at 30 points, with 5 control points, (3) overall pain rating with visual analogue scale.

The Hopkins Symptom Checklist (HCL-90) also was used to evaluate outcome.

Using analysis of variance techniques and correcting for initial values, the study found significantly more favorable values in the hypnosis group than in the physical therapy group for muscle pain, fatigue on awakening, sleep disturbance, patient's overall assessment, and HCL total score. However, differences were not significant for morning stiffness, physician's overall assessment, or T.S. There were no differences between Weeks 12 and 24 for both groups; therefore the mean value for weeks 12 and 24 for each patient were used to calculate percentage change relative to baseline.

The reduction in pain medication used by the hypnosis group was quite remarkable. "Median (range) analgesic drug use at the initiation of the study (mostly paracetamol) was in the hypnotherapy group 3.0 (0-42) tablets/week and in the physical therapy group 4.5 (0-21)/week. At Week 12 this was 1.0 (0-21) tablet/week for the hypnotherapy group and 7.0 (0-34) tablets/week for the physical therapy group. At the end of the study, 10 of 12 patients in hypnotherapy group and 3 of 12 patients in the physical therapy group had reduced their paracetamol use (Fisher exact test:  $p = 0.006$ )" (pp. 73-74).

Although it was observed that the total number of tender points decreased (regardless of treatment group), the Total Myalgic Score assigned by the physician had not changed either at week 12 or at week 24. In fact, even the control points were tender in 44% of the patients; most patients showed some pain response to a control point in one or two sessions of the three. "Only 12 of 40 patients had consistently nontender control points, 4 in hypnotherapy group and 8 in the physical therapy group. ... No relation was found between the initial HCL total score and the changes in the other variables studied" (p. 74).

Figures taken from Table 2, showing percent change as compared to baseline:

Physical Therapy (%)	Hypnotherapy (%)	Morning stiffness (minutes)	0.0	-25.0	
Muscle pain (VAS)	-6.8	-10.2**	Fatigue on awakening (VAS)	-0.3	-16.7**
Sleep disturbance (VAS)	-1.0	-23.1**	Overall assessment patient	-8.4	-33.2**
	+5.7	-3.2	T.S. (kg/3 cm <sup>2</sup> )	-11.1	-2.4
			HCL total score	-0.9	-13.0**

In their Discussion, the authors write, "In this controlled therapeutic trial in patients with refractory fibromyalgia hypnotherapy was more successful than physical therapy in improving complaints. The assessment of fatigue on awakening, sleep disturbance, muscle pain, the patient's overall assessment and the total score of the HCL showed a significant decrease in the hypnotherapy group at the end of the hypnotherapy at 12 weeks. This decrease persisted for 3 months after finishing the hypnotherapy. The variables studied in the physical therapy group had not changed significantly at 12 and 24 weeks.

"However, the patients in the hypnotherapy group improved only subjectively. This improvement was not seen via more objective variables (T.S. and number of tender points), in accordance with others [Carette et al., 1986]. This suggests that coping with the disease may be positively influenced by hypnotherapy though the underlying disorder is still present.

"Correction of the sleeping disturbance by hypnotherapy was the most consistent finding and possibly played an important role in the subjective improvement of fibromyalgia" (p. 74).

The authors noted that the HCL yielded scores in the pathological range during the baseline period. "Thus, in our study, patients with long-standing fibromyalgia often showed pathological feelings of discomfort. In the hypnotherapy group the total score of the HCL decreased significantly suggesting that the physical disturbance may be secondary to long-standing fibromyalgia. It is worth noting that only 3 of the 57 questions on the HCL-90 concern fibromyalgia" (p. 74).

The authors express the opinion that their data do not support a distinction between fibromyalgia and psychogenic rheumatism [Simms, Goldenberg, Felson, & Mason, 1988; Campbell, Clark, & Tindall, 1983] based on pain reported at control points. "Most patients in our study had variable tender control points. The finding of tender control points in fibromyalgia is consistent with others [Wolfe, Smythe, Yunus, et al., 1990; Scudds, Rollman, Harth, & McCain, 1987]. Also we found a positive correlation between the number of tender points and the presence of tender control points. Therefore, it seems more likely that there is a fairly large overlap between fibromyalgia and psychogenic rheumatism (tender all over)" (p. 75).

1990

Gil, Karen M.; Williams, David A.; Keefe, Francis J.; Beckham, Jean C. (1990). The relationship of negative thoughts to pain and psychological distress. Behavior Therapy, 21 (3), 349-362.

Examined the degree to which negative thoughts during flare-ups of pain are related to pain and psychological distress in 3 pain populations: sickle cell disease, rheumatoid arthritis, and chronic pain. 185 adults completed the Inventory of Negative Thoughts in Response to Pain (INTRP), a pain rating scale, the SCL-90 (revised), and a coping strategies questionnaire. Factor analysis of the INTRP revealed 3 factors: Negative Self-Statements, Negative Social Cognitions, and Self-Blame. High scorers on Negative Self-Statement and Negative Social Cognitions reported more severe pain and psychological distress. Ss with chronic daily pain had more frequent negative thoughts during flare-ups than those having intermittent pain secondary to sickle cell disease or rheumatoid arthritis. The INTRP appears to have adequate internal consistency and construct validity.

1989

Yousufzai, N. M. (1989). Rheumatoid arthritis and hypnosis: Case report. British Journal of Experimental and Clinical Hypnosis, 6 (3), 178-181.

In this study we aimed to assess the effectiveness of clinical hypnosis on the symptoms and disease activity of rheumatoid arthritis (RA). 66 RA patients participated in a controlled group design. 26 patients learnt the hypnosis intervention, 20 patients were in a relaxation control group, and 20 patients were in a waiting-list control group. During hypnosis, patients developed individual visual imagery aimed at reducing the autoimmune activity underlying the RA and at reducing the symptoms of joint pain, swelling, and stiffness. Subjective assessments of symptom severity and body and joint function, using standardized questionnaires

and visual analogue scales, were obtained. Objective measures of disease activity via multiple blood samples during the therapy period and at the two follow-ups were also taken. These measurements were of erythrocyte sedimentation rate, C-reactive protein, hemoglobin, and leukocyte total numbers. Results indicate that the hypnosis therapy produced more significant improvements in both the subjective and objective measurements, above relaxation and medication. Improvements were also found to be of clinical significance and became even more significant when patients practiced the hypnosis regularly during the follow-up periods.

#### NOTES

1:

"The effect of hypnotic suggestion on pain and mobility of joints was remarkable. On the fifth session there was hardly any pain, and shoulder movements were almost normal" (p. 179).

1985

Domangue, Barbara B.; Margolis, Clorinda; Lieberman, D.; Kaji, H. (1985). Biochemical correlates of hypnoanalgesia in arthritic pain patients. Journal of Clinical Psychiatry, 46, 235-238.

Self-reported levels of pain, anxiety, and depression, and plasma levels of beta-endorphin, epinephrine, nor-epinephrine, dopamine, and serotonin were measured in 19 arthritic pain patients before and after hypnosis designed to produce pain reduction. Correlations were found between levels of pain, anxiety, and depression. Anxiety and depression were negatively related to plasma norepinephrine levels. Dopamine levels were positively correlated with both depression and epinephrine levels and negatively correlated with levels of serotonin. Serotonin levels were positively correlated with levels of beta-endorphin and negatively correlated to epinephrine. Following hypnotherapy, there were clinically and statistically significant decreases in pain, anxiety, and depression and increases in beta-endorphin-like immunoreactive material.

1984

Elkins, Gary R. (1984). Hypnosis in the treatment of myofibrositis and anxiety: A case report. American Journal of Clinical Hypnosis, 27, 26-30.

A 38-year-old woman with chronic myofibrositis pain was treated by the use of hypnosis and psychotherapy. Hypnotherapeutic techniques, including symptom alteration, relaxation, and insight, are described. This regimen resulted in reduction in pain and emotional distress, which was maintained at three months and one year after treatment.

#### ASORPTION

2003

Holroyd, Jean (2003). The science of meditation and the state of hypnosis. American Journal of Clinical Hypnosis, 46 (2), 109-128.

Two aspects of Buddhist meditation -- concentration and mindfulness -- are discussed in relationship to hypnosis. Mindfulness training facilitates the investigation of subjective responses to hypnosis. Concentration practice leads to altered states similar to those in hypnosis, both phenomenologically and neurologically. The similarities and differences between hypnosis and meditation are used to shed light on perennial questions: (1) Does hypnosis involve an altered state of consciousness? (2) Does a hypnotic induction increase suggestibility? It is concluded that a model for hypnosis should include altered states as well as capacity for imaginative involvement and expectations.

Sapp, Marty; Hitchcock, Kim (2003). Creative imagination, absorption, and dissociation with African American college students. Sleep and Hypnosis, 5 (2), 95-104.

The purpose of this study was to assess creative imagination, absorption, and dissociation with African American college students. Two hundred thirty-six undergraduate African American students ranging between the ages of 18 to 22 participated in this study. Students were assigned to the following experimental manipulation: (a) Creative Imagination Scale (CIS), a cognitive-behavioral measure of hypnotizability; and (b) Dissociative Experiences Scale (DES), General Dissociation Scale (GDS), and Tellegen Absorption Scale (TAS) embedded within the CIS. Results indicated that dissociation and absorption were affected by the CIS. Finally, this sample was compared with the European American sample obtained by Barber and Wilson (1978) and Wilson and Barber (1978), and clearly the two samples differed on creative imagination,  $t(405)=7.00$ ,  $p<.005$ . The African American sample had a significantly lower mean CIS score than the European American sample.

Key words: imagination, hypnosis, absorption, dissociation, adolescents, cultural differences, African American college students, cognition.

2002

Manmiller, Jessica L.; Kumar, V. K.; Pekala, Ronald J. (2002). Hypnotizability, creative capacity, creativity styles, absorption and phenomenological experience. [Paper] Presented at the annual meeting of the American Psychological Association, Chicago.

"The study investigated relationships between creative capacity, styles of creativity, hypnotizability, and absorption. Participants were 429 students enrolled in Introduction to Psychology classes. Students first completed questionnaires pertaining to creative capacity, creativity styles, and absorption (Tellegen's Absorption Scale). They were subsequently hypnotized using the Harvard Group Scale of Hypnotic Susceptibility and completed the Phenomenology of Consciousness Inventory. The pattern of results suggests that creative capacity is

more closely related to absorption than hypnotizability. The support for P. G. Bowers' assertion that effortless experiencing while engaged in creative tasks and hypnotic tasks is a process that is common to both high creative and high hypnotizable subjects was weak. Hypnotizability was more strongly and negatively correlated with volitional control for suggestions experienced during hypnosis, than both absorption and creative capacity. Creativity styles of belief in unconscious processes, use of techniques, final product orientation (intrinsic/extrinsic) motivation, environmental control and behavioral self-regulation, and superstition were negatively correlated with volitional control (feeling of effortlessness experiencing) during hypnosis, but the correlations were small in magnitude" (Bulletin of Division 30, Psychological Hypnosis, Fall, 2002, Vol. 11, No. 3, P. 14).

**2000**

Eimer, Bruce. N. (2000). Clinical applications of hypnosis for brief and efficient pain management psychotherapy. American Journal of Clinical Hypnosis, 43 (1), 17-40. (July)

This paper describes four specific clinical applications of hypnosis that can make psychotherapy for pain management briefer, more goal-oriented, and more efficient: (1) the assessment of hypnotizability; (2) the induction of hypnotic analgesia and development of individualized pain coping strategies; (3) direct suggestion, cognitive reframing, hypnotic metaphors, and pain relief imagery; and (4) brief psychodynamic reprocessing during the trance state of emotional factors in the patient's experience of chronic pain. Important theoretical and clinical issues regarding the relationship between hypnotizability to the induction of hypnotic analgesia are presented, and attempts to individualize pain treatment strategies on the basis of assessed differences in hypnotizability and patients' preferred coping strategies are described. Some ways are also presented of integrating direct hypnotic suggestion, COGNITIVE-EVALUATIVE reframing, hypnotic metaphors, and imagery for alleviating the SENSORY and AFFECTIVE-MOTIVATIONAL components of pain, with an exploratory, insight-oriented, and brief psychodynamic reprocessing approach during trance for resolving unconscious sources of resistance to treatment, and reducing the emotional overlay associated with chronic pain. Some basic assumptions underlying the use of this approach are discussed, and a brief step-by-step protocol is outlined.

Lichtenberg, P.; Bachner-Melman, R.; Gritsenko, I.; Ebstein, R. P. (2000). Exploratory association study between catechol-O-methyltransferase (COMT) high/low enzyme activity polymorphism and hypnotizability. American Journal of Medical Genetics, 96, 771-774.

Only recently have studies of electrocortical activity, event-related potentials, and regional cerebral blood flow begun to shed light on the anatomical and neurobiological underpinnings of hypnosis. Since twin studies show a significant heritable component for hypnotizability, we were prompted to

examine the role of a common, functional polymorphism in contributing to individual differences in hypnotizability. A group of 109 subjects (51 male, 58 female) were administered three psychological instruments and tested for the high/low enzyme activity COMT val/met polymorphism. We observed a significant correlation between hypnotizability measured by the Stanford Hypnotic Susceptibility Scale (SHSS:C), ability to partition attention (Differential Attentional Processes Inventory or DAPI), and absorptive capacities (Tellegen Absorption Scale or TAS). The effect of COMT on the various dependent variables was initially examined by multivariate analysis that corrects for multiple testing. The dependent variables were SHSS:C hypnotizability scores, four attentional subscales of the DAPI, and TAS total score grouped by the COMT genotype (val/val, val/met, met/met) as the independent variable. Hotelling's Trace statistic was significant when scores were grouped by the COMT genotype (Hotelling's  $T^2 = 1.88$ ,  $P = 0.04$ ). Post-hoc testing using the Bonferroni correction shows that the only significant difference is between the val/met vs. the val/val COMT genotypes on hypnotizability. This association was significant for men but not for women. As for all case-control studies, these results need to be interpreted cautiously and require replication.

**Hillig, Justine A.; Holroyd, Jean (1997-98). Consciousness, attention, and hypnoidal effects during firewalking. Imagination, Cognition and Personality.**

Subjective experiences of individuals who walked on hot coals during a firewalking ceremony were investigated. This study extended and partially supported an investigation reported by Pekala and Ersek in this Journal [1]. Twenty-three participants completed retrospective questionnaire assessments concerning their subjective experiences while walking on hot coals. Results from twelve participants were compared with the participants' own experiences during a baseline condition. The data suggested that attention during firewalking is significantly more "one-pointed" than during a baseline condition, and that consciousness may be characterized as more "hypnoidal" than during a baseline condition. Walking on hot coals was further characterized by trends toward reporting increased altered awareness, altered experience, and absorbed attention. Participants who developed a greater degree of blistering reported significantly greater hypnoidal effects during the firewalk than those who developed a lesser degree of blistering.

**Dixon, Mike; Labelle, Louise; Laurence, Jean-Roch (1996). A multivariate approach to the prediction of hypnotic susceptibility. International Journal of Clinical and Experimental Hypnosis, 44 (3), 250-264.**

The present study examined the relation between various self-report measures and two measures of hypnotizability within a multivariate framework. A group of 748 participants was tested on the Harvard Group Scale of Hypnotic Susceptibility, Form A (HGSHS:A), the Tellegen Absorption Scale (TAS), as well as the Preference for an Imagic Cognitive Style (PICS) questionnaire. One hundred ninety of these participants also completed the Paranormal Experiences Questionnaire (PEQ). Data were analyzed using hierarchical multiple regression equations, and the results of the analyses indicated that both the TAS and PICS accounted for significant amounts of unique variance in each of two 373-member samples of HGSHS:A scores. A further sub-sample of participants (n = 161) was tested on the Stanford Hypnotic Susceptibility Scale, Form C (SHSS:C) to see if these results would generalize to another measure of hypnotizability. Hierarchical multiple regression analyses revealed that although the PEQ predicted significant amounts of unique SHSS:C variance over and above that predicted by the TAS, the PICS failed to do so. This inconsistency in results may be due in part to the generally low

intercorrelation between the different hypnotizability scales and points to the need to develop new predictor variables that are orthogonal to each other. - Journal Abstract

Kumar, V. K.; Pekala, Ronald J.; Cummings, James (1996). Trait factors, state effects, and hypnotizability. International Journal of Clinical and Experimental Hypnosis, 44 (3), 232-249.

This study examined the relationship of 15 trait (e.g., absorption, ego-permissiveness) and 21 phenomenological variables (assessed by the Phenomenology of Consciousness Inventory) with performance on the Harvard Group Scale of Hypnotic Susceptibility, Form A. Factor analyses suggested three trait factors (absorption-permissiveness, general sensation seeking, and social desirability) and five state factors (dissociated control state, positive affect, negative affect, attention to internal processes, and visual imagery). The factors correlated to hypnotizability were absorption-permissiveness, dissociated control, positive affect, and attention to internal processes. In predicting hypnotizability, the amount of variance accounted for by the trait factors was approximately 9%; an additional 22% was accounted for by state factors. The interactions did not account for any additional variance in predicting hypnotizability.

Wickramasekera, Ian; Price, Daniel C. (1996, November). Morbid obesity, absorption, neuroticism, and the high risk model of threat perception. [Paper] Presented at the annual meeting of the Society for Clinical and Experimental Hypnosis, Tampa, FL.

We studied seventy morbidly obese patients, candidates for gastric exclusion surgery. We found that their mean absorption score was significantly lower and that their mean neuroticism score significantly higher than a matched control group. These results are consistent with predictions from the High Risk Model of Threat Perception (Wickramasekera, 1979, 1988). People high in neuroticism are hypothesized to be hypersensitive to threat at a behavioral and biological level, and therefore, at greater risk for stress related psychobiological disorders. People low in absorption are hypothesized to have poor perception of psychosocial sources of threat have a more restricted range of psychological methods of coping with threat. Therefore, they may be at greater risk during stress of not recognizing psychosocial sources of threat of unconsciously using substances to self-soothe and of perceiving medical surgical solutions to weight gain as more credible than psychosocial therapy programs. We found that low absorption and high neuroticism as predicted by the HRMTP were significantly more prevalent among the morbidly obese seeking surgical therapy than a matched community control group.

1995

Bryant, Richard A. (1995). Fantasy proneness, reported childhood abuse, and the relevance of reported abuse onset. International Journal of Clinical and Experimental Hypnosis, 43 (2), 184-193.

This study investigated the relationship between fantasy proneness and the age at which reported childhood sexual abuse occurs. Seventeen adult females who reported having been sexually abused before the age of 7 years, 20 females who reported having been abused after the age of 7 years, and 20 females who reported having never been abused were administered two measures of imaginative involvement (Tellegen Absorption Scale [TAS] and Inventory of Childhood Memories and Imaginings [ICMI]). Participants who were reportedly abused early in childhood obtained higher scores on the TAS and ICMI than participants who were reportedly abused later in childhood, who in turn obtained higher scores than the control participants. Findings are discussed in terms of factors that mediate fantasy proneness and reports of childhood abuse.

Crawford, Helen J.; Kapelis, Lia; Harrison, David W. (1995). Visual field asymmetry in facial affect perception: Moderating effects of hypnosis, hypnotic susceptibility level, absorption, and sustained attentional abilities. International Journal of Neuroscience, 82 (n1-2), 11-23.

Effects of hypnotic level, affect valence and cerebral asymmetry on reaction time (RT) in the discrimination of Ekman and Friesen (1978) stimuli of angry and happy faces were studied in counterbalanced conditions of waking and hypnosis. Assessed previously on two hypnotic susceptibility scales (Harvard Group Scale of Hypnotic Susceptibility; Stanford Hypnotic Susceptibility Scale, Form C (SHSS:C)), non-depressed subjects were 16 low (0-4 SHSS:C) and 17 highly (10-12 SHSS:C) hypnotizable, right-handed college students. Subjects were required to identify affect of faces, presented tachistoscopically to left (LVF) or right (RVF) visual fields, by using a forced-choice RT paradigm. Highs were significantly faster than lows in angry and happy affect recognition. Hypnosis had no significant effects. For highs only, angry emotional valence was identified faster when presented to the right hemisphere (RVF), but there were no significant hemispheric effects for happy emotional valence. For lows there were no hemispheric differences. Gender was a nonsignificant factor. Significant correlations showed that faster reaction times to angry and happy stimuli, in both LVF and RVF in waking and hypnosis, were obtained by subjects who reported more deeply absorbed and extremely focused and sustained attention on the Tellegen (1982) Absorption Scale and a subscale of the Differential Attentional Processes Inventory (Grumbles & Crawford, 1981). Vividness of Visual Imagery Questionnaire (Marks, 1973) and Affect Intensity Measure (Larsen, 1985), in general, did not correlate with RTs. The potential role of the fronto-limbic attentional system in the recognition of external visual sensory affect is discussed.

Glisky, Martha L.; Tataryn, Douglas J.; Kihlstrom, John F. (1995). Hypnotizability and mental imagery. International Journal of Clinical and Experimental Hypnosis, 43 (1), 34-54.

Two studies investigated the relationship between mental imagery and hypnotizability, with the imagery measures administered in a hypnotic context. The

correlation of hypnotizability with vividness of imagery was significant in one study, but not in the other; both correlations were significantly lower than that obtained between hypnotizability and absorption, assessed in the same samples. The correlations with control of visual imagery, and with various measures of the vividness of motor imagery, were even lower and rarely significant. Except for an aggregate index of motor imagery, a search for significant nonlinear relationships with hypnotizability yielded nothing that was consistent across studies. Future studies of imagery and hypnotizability should make use of better measures of vividness of mental imagery and consider the relevance of aspects of imagery other than vividness.

Repka, Renee J.; Nash, Michael R. (1995). Hypnotic responsivity of the deaf: The development of the University of Tennessee Hypnotic Susceptibility Scale for the Deaf. International Journal of Clinical and Experimental Hypnosis, 43 (3), 316-331.

The purpose of these two studies was to develop and test a measure that assesses the hypnotic responsivity of deaf individuals. The University of Tennessee Hypnotic Susceptibility Scale for the Deaf (UTHSS:D) is a signed, videotaped version of a standard hypnotic induction with 12 standard suggestions. Experiment 1 compared the behavioral and subjective hypnotic responsivity of deaf and hearing individuals using the UTHSS:D and the Field Depth Inventory (FDI), respectively. As compared to hearing subjects, deaf participants were found to be less responsive to hypnosis when assessed behaviorally (UTHSS:D) and equally responsive to hypnosis when assessed subjectively (FDI). Experiment 2 undertook a more comprehensive examination of the hypnotic responsivity of deaf individuals, using hearing individuals as controls. Three dimensions of hypnosis responsivity were assessed: behavioral (UTHSS:D), subjective (FDI), and interpersonal (Archaic Involvement Measure). Additionally, correlates of hypnotic responsivity (absorption, attitudes, expectations) were examined for the two groups. In Experiment 2, no significant differences were found between the deaf and hearing participant groups on any measures of hypnotic responsivity or on any measure of the correlates of hypnotic responsivity.

Atkinson, Richard P. (1994). Relationships of hypnotic susceptibility to paranormal beliefs and claimed experiences: Implications for hypnotic absorption. American Journal of Clinical Hypnosis, 37, 34-40.

This study examined the relationship of hypnotic susceptibility level to belief in and claimed experience with paranormal phenomena. The Harvard ... and the Inventory of Paranormal Beliefs and Experiences [developed for this study] were administered on consecutive days to 43 undergraduate students (14 men, 29 women) ... . a significant multiple correlation was obtained ( $r = .55, p < .001$ ). A partial correlation between hypnotic susceptibility and belief in paranormal phenomena was also significant ( $r = .53, p < .001$ ), while hypnotic susceptibility was not found to be

significantly related to claimed paranormal experiences. Implications of these relationships for the role of absorption in hypnosis are discussed.

**NOTES**

**1:**

Discusses relationship to Absorption, and the fact that Labelle, Dixon, Laurence, & Nadon (1990) got correlation of hypnotizability with paranormal experience.

Csoli, Karen; Ramsay, Jason T.; Spanos, Nicholas P. (1994, August). Psychological correlates of the out-of-body experiences--a reexamination. [Paper] Presented at the annual meeting of the American Psychological Association, Los Angeles.

**NOTES**

**1:**

**NOTES:** 12% of population reports an out-of-body experience (OBE) sometime in their lives. They leave their body and can see self from the outside. Awareness is confined to the new point of view, not fragmented; there is unimpaired intellectual ability; feelings of detachment, completeness, well being, and profound relaxation. Can occur under stress or deep relaxation; not while driving a car.

Psychological correlates aren't known. Studies are inconclusive with respect to belief systems (religious, death anxiety, etc.); measures of absorption, hypnosis, imaginative ability, imagery controls. Recent Carlton study with 87 Ss (33 had OBE) got results we didn't expect. They completed questionnaires, were tested for hypnotizability, had an interview re OBE experience.

This study found the OBE-experiencing people had higher levels of anxiety, psychosomatic symptoms, and panic attacks. They were also higher on magical thinking, perceptual aberration, and Schizophrenia scores. They didn't differ on mysticism, levels of drug or alcohol use, or level of self esteem.

Grant, Carolyn (1994). The Computer-Assisted Hypnosis Scale: Standardization and norming of a computer-administered measure of hypnotic ability (Dissertation). Dissertation Abstracts International, 54 (10/B), 5387.

**ABSTRACT:** "In a counterbalanced, within-subjects, repeated measures design, 130 subjects were administered both the Computerized Assisted Hypnosis Scale (CAHS) and the Stanford Hypnotic Susceptibility Scale, Form C (Stanford Hypnotic Susceptibility Scale: C). For each hypnotic procedure responsiveness was assessed along three dimensions: behavioral (CAHS, Stanford Hypnotic Susceptibility Scale: C), subjective depth (Field Depth Inventory), and relational involvement (Archaic Involvement Measure). Subjects also completed a Stanford Hypnotic Susceptibility Scale: C self scoring measure and the Tellegen Absorption Scale. The CAHS was shown to be a psychometrically sound instrument for measuring hypnotic ability. The various dimensions of CAHS hypnotic responsiveness were highly positively related, and the CAHS compared favorably with the Stanford Hypnotic Susceptibility Scale: C across the three dimensions assessed. Results are discussed in terms of the theory and practice of clinical assessment, noting directions for future research" (p. 5387).

Wain, Harold J.; Wollman, K. (1994, October). A comparison of the hypnotic capacity of psychiatric outpatients and psychiatric consultation liaison patients. [Paper] Presented at the annual meeting of the Society for Clinical and Experimental Hypnosis, San Francisco.

NOTES

1:

NOTES: We used the Hypnotic Induction Profile (HIP) in our studies. HIP Scores (eyeroll and arm levitation) for Psychiatric Consultation Liaison patients (PCLA group) and Psychiatric Outpatient Clinic (POC) group are significantly different, as are the total scores on the HIP.

Eyeroll Scores: PCLA = 2.625, POC = 2.205 HIP Scores: PCLA = 7.330 POC = 5.920

Thus there is higher hypnotizability in Consultation Liaison patients. Engel and Romano suggested that 75% of patients going to a physician have a psychological component to their illness.

Once a person recognizes they have a medical condition there is a sense of trauma, a sense of anxiety, which contributes to an altered state. Components of hypnosis (absorption, decreased vigilance, suggestion, dissociation, assimilation of data, trance logic, time distortion) may affect how they then assimilate a symptom.

Why is hypnosis (absorption) so effective in an emergency room? Patients in the emergency room feel panicked, thinking "physiologically and psychologically I'm out of control." By using hypnosis you give them an anchor. Maybe hypnotizability enhances medical symptomatology, but it can also facilitate treatment.

We use the HIP because the eye roll component is observable by medical colleagues and patients.

1993

Atkinson, Richard P. (1993, October). Shifts in Muller-Lyer Illusion difference thresholds: Are high hypnotizables more sensitive than lows in hypnosis?. [Paper] Presented at the annual meeting of the Society for Clinical and Experimental Hypnosis, Arlington Heights, IL.

NOTES

1:

NOTES: Refers to Wallace (1979) finding that hypnotizability correlates with afterimage persistence. Atkinson showed highs perform better than lows in perceptual tasks in hypnosis only. Also studies indicate highs are more susceptible to illusions. Our study showed difference in threshold and point of subjective equality for highs and lows.

32 undergraduates had Harvard and Group Stanford Form C, were 9-12 or 0-3 on both scales. Counterbalanced conditions of waking and hypnosis. Used computer monitor to compare length of lines. Waking condition Ss had to close eyes for 15 minutes before the trials, same length of time as for hypnosis condition.

Significant interaction between hypnotizability and sessions was observed: highs had significantly decreased difference thresholds in hypnosis compared to waking, and significantly decreased difference thresholds compared to lows in hypnosis. Thus they had greater sensitivity than lows.

The point of subjective equality ANOVA did not yield significant effects. Highs show higher sensitivity to illusion in hypnosis than in waking, and more than the lows.

Nadon, Robert (1993, October). Nomothetic and idiographic approaches to hypnosis. [Paper] Presented at the annual meeting of the Society for Clinical and Experimental Hypnosis, Arlington Heights, IL.

## NOTES

1:

Scientists and practitioners are not benefitting from each other's contributions. The central contribution to hypnosis, both basic and applied, is the logic and validity of study designs. The false memory issue is an example. Clinicians supply an answer the public likes, but scientist provide data based on nomothetic (group average) models that are not useful here.

Most of my own work is nomothetic, but it can work together with case study approach. We use a synergistic model: the combined effects of traits, cognitive, social, and affective factors are investigated. Interactions are tricky to detect, but we need a spirit of enquiry that encourages designs sensitive to interactions.

One example is Radke & Spanos' study that used a scale rating whether subject was hypnotized and another indicating degree of absorption-and-hypnotized vs absorption-and-not-hypnotized. Nadon's reanalysis showed a scale by Ss interaction: mediums were different on the 7 point scale but highs were not. (Highs were less manipulated by the scale manipulation).

Jean-Roche Laurence and Nadon replicated the interaction. Then Nadon did a study to test the idea that highs were less affected by scale manipulation because they relied more on subjective experience. They measured Absorption in a different context and hypothesized that the highs here would be less affected on the 7 point scale in the other context; it was validated. There seemed to be a linear absorption by a quadratic hypnotizability interaction.

Another simple example of interaction at work: there are different lines predicting hypnotic ability based on the Absorption scale, representing need for control on the scale. Those low in need for control have a stronger prediction of hypnotizability from Absorption scale. With high need for control, Absorption doesn't predict hypnotizability. This may explain why the correlation isn't stronger between Absorption and hypnotizability.

Nadon investigated how level of relaxation could be affected by an interaction. Measured muscle tension of masseter (?) while listening to music (half of Ss) or focusing on relaxing (50%). In an experiential condition there was a negative correlation between Absorption and muscle tension (highs relaxed more); in an Instrumental condition it was the opposite. So both high and low Absorption people were capable of relaxation, but to get the best relaxation you would have to know their Absorption score.

A second study hypothesized that predispositions for certain kinds of affect (Tellegen's positive affect, like extroversion) and negative affect (like neuroticism). High Absorption extraverts low in neuroticism worked best with music; and [missed words]. This supports Tellegen's hypothesis re the effects of positive and negative affect and Absorption.

Now we can discuss individual characteristics that suggest which relaxation strategy will benefit. The practical implications can be validated by case studies.

**Pekala, Ronald J.; Ersek, Barrett (1993). Firewalking versus hypnosis: A preliminary study concerning consciousness, attention, and fire immunity. Imagination, Cognition and Personality, 12, 207-229.**

This study assessed the subjective effects associated with firewalking, and compared them with the subjective effects associated with hypnosis and a baseline condition (eyes closed sitting quietly). Twenty-seven subjects, who walked over hot coals during a firewalk ceremony, completed questionnaires about what they subjectively experienced during the firewalk. Their experiences were subsequently compared with those of subjects (n = 246) who experienced hypnosis and a baseline condition. The data suggested that firewalking, as assessed across all subjects, is characterized by high levels of volitional control and rationality, and a very absorbed attentional style wherein the mind is one-pointed, and consciousness is characterized by strong feelings of joy and high levels of internal dialogue. Firewalking was also found to be associated with significantly more joy, one-pointedness of thought, absorption, and internal dialogue than hypnosis or the baseline condition. In addition, a cluster analysis suggested two subgroups of firewalkers based on their subjective experiences of the firewalk. Interestingly, analyzing the attentional experiences among these firewalkers who got slightly burned, versus those who did not, revealed significant differences. A one-pointed and absorbed attentional focus may be the critical variable for the fire immunity observed in firewalking.

#### NOTES

1:

About 500 people walked across coals, in 3-4 steps. At end of weekend, 71 said they would complete a questionnaire and it was mailed to them. Of those, 27 responded (25 of 26 in an average of 23 days). Hence, 5% of the population who walked responded to the questionnaire, and it was some time later. Three of 24 reported minor blisters. Those who didn't get burned reported less detachment, less of a feeling of being out of their bodies, and more thoughts than the firewalkers who got slightly burned.

Pekala has defined an altered state of consciousness as associated with the perception of being in an altered state of awareness (the \_subjective sense of \_altered state\_ --SSAS [30]), and a change in the patterning or configuration of the subsystems or dimensions of consciousness. A discrete state of consciousness, as defined by Pekala, is associated with a significant pattern change but no perceived alteration in state of consciousness (no SSAS). An identity state of consciousness, on the other hand, is defined as having neither a significantly perceived alteration in state of awareness nor a perceived pattern change among dimensions of consciousness in reference to another state of consciousness. Since the PCI can measure both intensity and pattern effects, it can be used to assess for altered, discrete, and identity states of consciousness. Using a cluster analysis they found that one group of 16 subjects reported the firewalk experience to be characterized by a significant alteration in awareness and experience (body image, time sense, etc.), and significant intensities of internal dialogue, positive and negative affect, and

arousal, while a second group of six subjects reported little alteration in consciousness or experience, little losses in rationality or control, and less internal dialogue, positive and negative affect or arousal than the larger group. Whereas hypnosis is usually associated with a loss in control (the classic suggestion effect), firewalking was found to be associated with increased control, a more aroused state, and more fear! Firewalking appears to be a more absorbed and one-pointed state than even hypnosis.

The nature of attentional experience is similar across firewalkers (DAQ results).

Both firewalking and hypnosis meet the criteria for altered states of consciousness (different pattern and different subjective experience), but they are not altered states in reference to each other; they are discrete states of consciousness in reference to each other, because there is a significantly different patterning of PCI dimensions between the two conditions, but no significant SSAS. This suggests that the firewalk state is qualitatively different from the hypnotic state (as induced by the induction procedure to the Harvard Scale) and probably represents a different type of state of consciousness than hypnosis. Firewalkers obtained a lower mean hypnoidal state score than hypnosis subjects, so it does not appear that the fire immunity is due to being in a "hypnotized" state.

The fact that there appears to be two groups of successful firewalkers, one of which did not report much alteration in consciousness, calls into question the theorizing concerning the importance of alteration in state of consciousness as being etiologically related to successful firewalking. Since about 25 percent of the firewalkers clustered into what appears to be a nonaltered state of awareness, this suggests a sizable percentage of subjects who did not report any significant alteration in consciousness and experience.

Hence, what may be important is not an alteration in consciousness, but rather an alteration in attention. The cluster analysis revealed a relatively unitary attentional state across all subjects suggesting that attention was deployed in a rather similar manner across all subjects, that is, with very high absorption and one-pointedness. It was also the DAQ dimensions, and not the PCI dimensions, that successfully discriminated a trend between the blistered and nonblistered firewalkers. Hence, high levels of one-pointedness and absorption, that is, how attention is deployed during firewalking may be more critical (than an alteration in consciousness in general) for the fire immunity observed during firewalking.

1992

Balthazard, Claude G.; Woody, Erik Z. (1992). The spectral analysis of hypnotic performance with respect to 'Absorption'. International Journal of Clinical and Experimental Hypnosis, 40, 21-43.

In factor analyses of the hypnosis scales, the essential result is that the items form a continuous, 2-dimensional fan-shaped pattern. This continuum is referred to as the "spectrum of hypnotic performance." "Spectral analysis" is introduced as an exploratory procedure which makes use of this notion of continuum or spectrum. Spectral analysis consists of a graphical display of the level of latent correlation between a variable and individual hypnotic performances when the latter are arranged according to their position in the spectrum. The spectral analysis of

hypnotic performance with respect to absorption is illustrated using data from a sample of 160 Ss. The results indicate that absorption is more strongly related to difficult hypnotic performances than to easy ones. In particular, illustrative item characteristic curves are presented to show that although easy hypnotic performances do not require the processes tapped by individual differences in absorption, a certain level of absorption is necessary to pass difficult hypnotic items. In addition, a high level of absorption may be sufficient in and of itself for difficult hypnotic performances. These results are discussed in light of some speculations by Shor, M. T. Orne, and O'Connell (1962) and Tellegen (1978/1979) concerning the differential contribution of ability components to performance on difficult hypnotic suggestions. The results are also related to a variety of work in social psychological models of hypnotic performance.

#### NOTES

1:

Spectral analysis "consists of a graphical display of the level of latent correlation between a variable and individual hypnotic performances when these hypnotic performances are arranged according to their position in the spectrum--which is indexed by item difficulty" (p. 25). Difficulty (the proportion of Ss that pass a given item) is on the X-axis; the degree of latent correlation is on the Y-axis. "It is necessary to differentiate between the manifest and the latent relationship of a variable to a dichotomously scored hypnotic performance. The manifest relationship is given by the point biserial correlation and the latent relationship is given by the biserial correlation. ... By inspecting the overall pattern of these biserial correlations as a function of item difficulty, it is possible to overcome the difficulty-content confound, because the biserial correlations are not affected by item difficulty" (p. 25).

"Throughout the easy and middle ranges [of item difficulty], the biserial correlation of hypnotic performance with absorption remains slightly above .2, then it rises sharply in the difficult range--beginning roughly where only one in four Ss can pass the item--to a value slightly above .5 " (p. 27). "In essence, the proportion of Ss that pass a particular hypnosis suggestion given a particular score on the absorption scale is being plotted" (p. 30).

In their discussion, the authors relate their position to that of other theorists. Shor, Orne, & O'Connell (1962) proposed that both ability and nonability components contributed to hypnosis, with ability being the primary determinant of hypnotic performance at deeper levels. Shor et al. found a correlation between depth ratings and a questionnaire that tapped 'hypnotic-like experiences' to be .45; the correlation was .84 when computed for only the Ss who became deeply hypnotized, but only .17 for Ss who were only lightly or medium-level hypnotized. They concluded that their questionnaire predicted hypnotizability only for the "deeper region" of hypnosis.

Tellegen (1978/1979) proposed a two-factor model, one factor being genuine responsiveness and the other being compliance . He suggested that various hypnosis test items draw on the two factors in differing degrees. Tellegen's genuine responsiveness factor would be similar to Shor et al.'s ability components, and Tellegen's compliance factor would be similar to Shor et al.'s non-ability components. (The Shor model goes farther than Tellegen in positing a gradual shift

in the relative contributions of the two components as one moves from easy to difficult items, and this gradualness is part of the authors' spectrum model.)

The two-factor model is different from the general factor (plus special factors) model suggested by E. R. Hilgard (1965)); Hilgard's general factor would probably correspond better to the Tellegen genuine responsiveness factor and the Shor et al. ability component than to the compliance factor or nonability component, which probably would correspond more to the easier items on hypnotizability scales.

Spanos et al. (1980) suggested that cooperativeness and expectation might be more important with ideomotor and challenge suggestions, and ability to treat imaginings as real (i.e. absorption) more important for more difficult cognitive items. Sarbin (1984) developed a typology with two types of individuals--those who respond to the hypnosis context by "joining the game" and knowingly create an illusion that their response is involuntary (the compliance kind of response), and those who convince themselves and others that their response is involuntary (the genuine responsiveness factor kind of response).

[Speaking of the context effects observed but not replicated 100% of the time, on the correlation between absorption and hypnotizability.] "It is possible that context effects may depend on the difficulty of the hypnotic suggestions and the latent abilities of the sample used. For relatively good hypnotic Ss performing relatively difficult suggestions, the correlation of absorption with hypnotizability may be stable across different contexts; however, for less able Ss performing relatively easy suggestions, the correlation, depending more on the 'non-ability' component, may be quite responsive to context manipulations. It might also be mentioned parenthetically that details of the instructions used to introduce the particular hypnosis scale employed may differentially pull for one kind of component or the other" (p. 39).

Goodman, Linda; Holroyd, Jean (1992). Ego receptivity and hypnotizability. International Journal of Clinical and Experimental Hypnosis, 40 (2), 63-67.

Ego receptivity has been described as important for the psychotherapy process and as a characteristic of hypnosis (Deikman, 1974; Dosamantes-Alperson, 1979; Fromm, 1979). Receptivity also has been associated with a measure of absorption (Tellegen, 1981). In the first pilot study with 6 dance/movement therapy students, higher observer ratings of receptivity were associated with greater hypnotizability ( $r = .79$ ,  $df = 4$ ,  $p < .05$ , 2-tailed test). In the second pilot study, the correlation was replicated ( $r = .51$ ,  $df = 12$ ,  $p = .06$ , 2-tailed test) with 14 dance/movement therapy students. In the second pilot study, receptivity did not correlate with absorption. Receptivity and absorption, however, accounted for 54% of hypnotizability population variance in a step-wise multiple regression. Receptivity accounted for a unique part of the variance after the effects of absorption were removed. It was concluded that receptivity should be explored as a potential predictor of hypnotizability, and that a reliable scaled measure of receptivity should be developed.

## NOTES

1:

Receptivity was rated by dance instructor on the following scale. "TABLE 1 Criteria for Ranking Ss on Receptivity A. Individuals were rated high if they could consistently do the following most of the time:

1. If they moved with emotional involvement.
  2. If they could readily verbally describe their movement experience in terms of sensations or feelings.
  3. If they were able to image while moving. That is, their movement experience could be transformed into representational visual images.
  4. In their describing their movement experience verbally, if they readily alluded to the images which were generated from their body movement.
  5. If they could relate their movement experiences to other contexts outside of the therapeutic one.
  6. If they could develop a working alliance with the therapist (based on students' capacity to risk experiencing self with increased emotional depth).
- B. Individuals were rated low, if they were not able to do the above most of the time. C. Individuals were rated in the mid-range if they were able to do the above some of the time" (p. 65).

Kvaal, Steven; Lynn, Steven Jay; Myers, Brian (1992, October). The Gulf war: Effects on hypnotizability. [Paper] Presented at the annual meeting of the Society for Clinical and Experimental Hypnosis, Arlington, VA.

## NOTES

We did a study that follows the line that volunteers may differ from nonvolunteers for hypnosis experiments (Authors cite 3 studies, including one with Hilgard as later author; Brodsky; Zamansky). Also, Ss who volunteer early in the quarter at the university are motivated for hypnosis; later volunteers want course credit. The former want to experience hypnosis.

Previously we did a study on authoritative vs permissive suggestions with Ss who volunteered early or late in the quarter; Ss were tested twice. For Ss who volunteered in first 2 weeks of the quarter, scores decreased across testing; for Ss volunteering late, scores remained stable across testing. This implies that if an experiment were conducted late in a quarter we would conclude that repeated testing has no effect; if done earlier, we would have concluded repeated testing decreases scores.

This result has been replicated. It is therefore important to run Ss across an entire quarter or year.

The present study differs from the foregoing study. It addresses the question: Do life events affect scores on the Harvard Scale? Do tension, uncertainty, etc. affect scores? Would they depress scores? Are scores reactive to environmental events?

On January 14 the U.S. issued an ultimative to Iraq; that very day we administered a tape recorded version of the Harvard Scale of Hypnotic Susceptibility, preceded by the Tellegen Absorption Scale. The hypnotizability tests were self-scored for involvement and involuntariness. Tension throughout the day escalated, culminating with bombing 2 hours before the hypnosis screening. The graduate

student announced war had started and told Ss they could leave if they wanted. All 52 Ss stayed!

Control group was 58 Ss tested at same time of the quarter, one year before (10 days into the quarter).

Analysis was by a 3 x 2 ANOVA. There was no main effect for time of testing, sex, or interaction for any measures on hypnotizability, or subjective involvement.

The Tellegen Absorption scale showed a significant timing x sex interaction: males on outbreak of war scored lower than all other groups (15 vs 21 or more for all other groups). Tensions had no effect on subjective or objective scores of hypnotizability. Thus the males were affected on the Absorption Scale by outbreak of war. The fact the Tellegen Scale was more reactive suggests hypnotizability may be more stable than Absorption. Absorption might have been depressed because males were more upset by images of military services. Little research has been conducted to examine the possible positive effects on hypnotizability of positive events in real life.

## NOTES

1:

These notes are taken only from the section of this chapter that deals with Hypnotic Responding, Imaginative Activity, and Expectancies, and they treat of the concept of nonvoluntary responding (pp 315-316). Other topics covered in the chapter include: Imagination, Fantasy, and Hypnosis Theories; The Hypnotizable Subject as Creative Problem-Solving Agent; Hypnosis and Subjects' Capability for Imaginative Activity; Goal-Directed Fantasy: Patterns of Imaginative Activity during Hypnosis; Hypnosis and Creativity; and a Conclusion.

Several studies manipulated expectancies re the relationship between imagination and involuntariness. When Ss were told that "good" hypnotic subjects could (or could not) resist suggestions, "this information affected their ability to resist the hypnotist and tended to affect subjects' report of suggestion-related involuntariness ... [Lynn, Nash, Rhue, Frauman, & Sweeney, 1984]. Furthermore, subjects who successfully resisted suggestions and subjects who failed to do so reported comparable levels of hypnotic depth and imaginative involvement in suggestions.

"Spanos, Cobb, and Gorassini (1985) conducted a similar experiment in which they found that hypnotizable subjects who were instructed that they could become deeply involved in suggestions and yet resist them successfully resisted 95% of the suggestions and rated themselves as maintaining voluntary control over their behavior. Thus, subjects are able to resist nearly all of the suggestions when resistance is facilitated by situational demands. It is worth noting that subjects in this research who resisted hypnotic suggestions rated themselves as just as deeply involved in the suggestions as Ss who failed to resist suggestions after being informed that deeply hypnotized subjects were incapable of resisting suggestions" (pp. 315-316).

Lynn, Snodgrass, et al. (1987). showed that hypnotizable Ss who were just "imagining" along with suggestions but instructed to resist responding to motoric suggestions acted the way hypnotized Ss did in their earlier countersuggestion research: imagining subjects tended to move in response to suggestion (that "good" Ss responded in certain ways), despite being instructed to resist. In this study, with instructions designed to increase the use of goal directed fantasies (GDFs), low and high hypnotizable subjects reported equivalent GDF absorption and frequency of GDFs. However, highs responded more and reported greater involuntariness than lows, even when their GDFs were equivalent.

"A number of other studies have examined the effects of expectancies on imaginings and hypnotic behavior. Spanos, Weekes, and de Groh (1984) informed subjects that deeply hypnotized individuals could imagine an arm movement in one direction while their unconscious caused the arm to move in the opposite direction. Even though subjects so informed moved in the opposite direction, they imagined suggested effects and described their countersuggestion behavior as involuntary" (p. 317).

Lyons, Larry C. (1992, October). Absorption and hypnotizability: Meta-analysis of studies to determine if contextual effects are important. [Paper] Presented at the annual meeting of the Society for Clinical and Experimental Hypnosis, Arlington, VA.

#### NOTES

1:

Correlations between hypnotizability and Absorption range from .20 to .40; Council et al. suggest the correlation between these variables is a context effect (expectancy). In our review there was no statistically significant difference between correlations that were found in and out of context (.26 and .23, weighted means) in more than 40 studies with more than one correlation per study.

When Absorption was measured before hypnosis experience the  $r = .25$ ; after the hypnosis experience,  $r = .32$  (significantly different), which also was different from what context hypothesis would predict. Any context difference may be a function of length of time between the Absorption and hypnosis sessions.

Data does not support the context hypothesis. Measuring Absorption after hypnosis resulted in higher mean correlations with susceptibility. However, the magnitude of this relationship was small. Variation due to test reliability and small sample size are likely explanations of the differences in the magnitude of the correlations across studies. We also must consider scale reliability and sample error (samples less than 1000 have departures from the population correlation that are fairly large).

CONCLUSION. We should construct confidence intervals around observed correlations and look at the overlap; don't look only at the significance of the difference between correlations.

Author is in the process of conducting a mail survey to obtain unpublished results on context effect.

Perry, Campbell (1992). Theorizing about hypnosis in either/or terms. International Journal of Clinical and Experimental Hypnosis, 40, 238-252.

The present paper addresses 3 issues raised by Coe (1992). First, it maintains that the "altered state" issue of the 1960s remains buried in current dichotomous classifications of hypnosis theories as involving either "special processes" or the social- psychological position. Given the current diversity of the field, it appears imprudent to classify theorizing in either/or terms; additionally, despite a history of using the term "altered state" in a circular way, it is not an inherently circular formulation. It can be used descriptively simply to point to the observation that some individuals in hypnosis report subjective alterations. A second issue broached concerns the metaphorical status of the term "hypnosis"; it is accepted as a misleading metaphor inherited from 19th century investigators such as Braid, Faria, Puysegur, and Liebeault. Provided that it is recognized that this metaphor refers to a "domain" (E. G. Hilgard, 1973) of characteristically elicited behaviors, no problem ensues in retaining this metaphor derived from nocturnal sleep. A subsequent discussion of current conceptualizations of hypnosis indicates considerable agreement among investigators; there is much consensus that hypnosis is an individual differences phenomenon, in which imagination may, in some individuals, become so intense and so vivid, as to take on "reality value," to the extent that a hypnotized person may have difficulty in distinguishing fantasy from reality. The S abilities of imagery/imagination, absorption, dissociation, and automaticity (which may be proved to be an index of dissociation) are proposed as being the main ingredients of the hypnotic experience. Finally, a synergistic approach is proposed as a means of progressing beyond the current impasse of either/or theorizing.

Price, Simani M.; Crawford, Helen J.; Plantier, Mary E.; Jones, Elizabeth P. (1992, October). Sustained attention, selective attention, and automaticity: Relationships to hypnotic responsiveness. [Paper] Presented at the annual meeting of the Society for Clinical and Experimental Hypnosis, Arlington, VA.

#### NOTES

1:

There are four dimensions of attention: 1. focused & sustained attention 2. selective attention 3. divided or dual attention 4. ambient attention (the ability to attend to one thing but have floating attention also)

Ss had Harvard and Group Stanford scales of hypnotizability, to divide them into low, medium, and high groups. They were recruited for a study of attentional correlates with no mention of hypnosis, in order to reduce expectancy effects.

In this study, 57 Ss had two 45 second trials on the Stroop test; the higher scores mean less Stroop-type interference. We studied the effects of distraction on ability to do mental arithmetic. (There were to ignore a word in the sum column.) Then Ss were tested for implicit memory of the words.

Necker Cube task was administered (to replicate Crawford & Wallace): four trials, 60 sec. each Absorption Scale

Crawford & Gumbles scale

RESULTS. There were no differences on most of the tests for high, medium, and low groups. Hypnotizability correlated with extremely focused attentional ability as

measured by the DAPI Extremely Focused Attention factor, and the Tellegen Absorption Scale. Moderately Focused Attention loaded on DAPI Moderate Focus. Necker Cube and Implicit Memory (for words) loaded on the Dual Ambient Attention factor.

Spiegel, Herbert; Greenleaf, Marcia (1992). Personality style and hypnotizability: The fix-flex continuum. Psychiatric Medicine, 10, 13-24.

Since Mesmer, there has been much confusion about the inter-relationship between an individual's degree of hypnotizability, the personality style of the individual, and the importance of the therapeutic strategy. Empirical and experimental research supports the hypotheses that there are: 1) biopsychosocial components of hypnotizability on a continuum ranging from ecologically insensitive (not modifiable by external stimuli) to ecologically sensitive (very modifiable by external stimuli); 2) biopsychosocial components that can be measured to identify an individual's degree of hypnotic capacity and responsivity; 3) distinct personality styles which correlation with low, mid-range and high hypnotizability on a fix (ecologically insensitive) - flex (ecologically sensitive) continuum; and 4) different clinical syndromes which correlation with these categorical distinctions. We propose that measuring hypnotizability and personality style is a way to clarify diagnosis and choose appropriate treatment strategies to maximize existing biopsychosocial resources of an individual with a specific problem in a particular context.

Spiegel, David (1992, October). Dissociation during trauma. [Paper] Presented at the annual meeting of the Society for Clinical and Experimental Hypnosis, Arlington, VA.

NOTES

1:

Spiegel & Spiegel's theory of hypnosis involves: 1. absorption 2. suggestion 3. dissociation

Traumatic memories may be out of consciousness yet may influence consciousness. Thus, rape victim may not be able to continue to enjoy sex with her husband or may hyperventilate when near the place it occurs. This conceptualization is consistent with Kihlstrom's evidence using priming in verbal learning; and Ken Bowers' research on hypnosis for pain control.

Hypnotizability is higher in childhood than in adults, so if children are traumatized they may resort to dissociation more easily.

Certain dissociative disorders may be associated with high hypnotizability (forgetting the causal arrow, as association does not imply causation).

The diagnosis of post traumatic stress syndrome (PTSD) in the current diagnostic manual, DSM III-R, parallels the three characteristics of hypnosis, except that the diagnosis also includes a history of trauma. (In the upcoming revision, DSM IV will remove the language of "beyond the range of normal human experience" when characterizing the trauma in patient's history. The traumas referred to will be physical traumas.)

## NOTES

1:

Balthazar and I pointed out that different psychological processes are implicated in hypnotizability scale items, depending on the difficulty of the item. One process is more important on easy items, the other on difficult items.

We correlated an external variable as a function of difficulty of the items. Used the Absorption scale as the non-hypnotic measure for the latent correlation (biserial correlations). As item difficulty increases, the correlation with Absorption increases (from .2 to .5).

This suggests a high level of Absorption is needed to pass difficult items on the hypnotizability scale. We argued that Absorption is connected to true hypnotic responsiveness.

Now we are looking for indicators of easy item responsiveness. Last year I tried to explain anomalies in the data, anomalies that disappeared with a full complement of Ss.

Another possible external variable to correlate with item difficulty is a social compliance type of attribute, but in the history of hypnosis those variables are not found. Therefore we used a model from alcohol research that investigates an expectancy type of suggestion.

In that model, Ss drank two drinks that were alcohol free, but one drink purportedly had alcohol. Ss were told that large amounts of alcohol affect changes in perception, and that we were testing whether small amounts did. They were tested for "feeling of sluggishness in limbs," etc. They rated a list of experiences they might be having. The 109 Ss had been tested on Harvard A scale in separate research.

Ratings in the alcohol model had high internal consistency; this suggestion score correlated with hypnotizability in .2-.3 range.

The pattern of latent correlations would be predicted to be a graph with a negative slope, which the researchers obtained.  $R = -.77$

The easier the hypnosis item, the stronger the correlation with the expectancy measure. The easiest Harvard A scale items tap little more than those expectancy effects, and the hardest items have almost nothing to do with the expectancy effect.

What does this mean? We thought it was evidence of a social influence factor. Further work suggests we need to be more specific.

We measured the other putative variables: 1. Compliance Questionnaire (Gudjonsson, 1989); it evaluates the tendency to comply with requests, and to obey instructions; e.g., "I tend to go along even when someone is wrong." It has correlated with a measure of social conformity. 2. Suggestibility Questionnaire (which we developed). Items were based on interviews in which Ss told about everyday suggestible things--e.g. "When I hear about an illness I tend to get it. When someone tells me they smell something, I tend to also."

These Compliance and General Suggestibility tests correlated .12 and .07 respectively with the alcohol expectancy measure; nor did they correlate with each other. They do not measure the same trait. Also, though they correlated .18 and .26 with hypnotizability, neither variable showed the spectral pattern on latent correlation analysis. Thus, we need to be more specific in linking the alcohol expectancy measure to hypnosis. Most items on Harvard A scale are motor items of either direct suggestion or inhibition (challenge) type. The relationship of alcohol expectancy to direct motor items is strong; the relationship is weaker with motor challenge items (for which another process must be important). We can think of will vs automatic control of behavior, as in the theory presented by Normal and Shallice. For well-learned behavior there are two levels of control: 1. low level - doesn't require conscious attention and control 2. higher level - relevant to initiation of action, planning Direct motor suggestion response requires little attentional effort and the role of will is not important. There exists ambiguity for indeterminacy of the role of will and attention. Ambiguity offers an opportunity to attribute one's action to hypnosis. What happens in alcohol expectancy is different, but an ambiguous experience is happening due to "alcohol" in the drink--ambiguous experience is interpreted according to the context. This differs from the neodissociation theory explanation, according to which the suggested behavior is enacted voluntarily but the voluntary aspect is separated from consciousness. To me, for simple motor acts the causality is inferred rather than perceived. For simple motor acts, no such higher level control is needed. Motor challenge items have instructions to "try" to overcome; S must exert will. "Try to raise your arm" is different from "Raise your arm." The S could remain role consistent and not try; ambiguity is maintained and the S could look to the context for an explanation.

In the Normal and Shallice model, hypnosis weakens the higher system relative to the lower system. The S might be trying to exert will but experience it as less [influential] than in the normal state. Such capacity would not be tapped by an alcohol expectancy measure. We think of individual differences in hypnotizability as multiple processes, like a tree that consists of more than one healthy branch but has plenty of dead wood to be pruned out.

1991

Campbell, Laura; St. Jean, Richard (1991, August). Attentional processing and hypnotic time estimation. [Paper] Presented at the annual meeting of the American Psychological Association, San Francisco.

The tendency of subjects to substantially underestimate the duration of the hypnotic period is, by now, well-documented (St. Jean, 1989). Recent attempts to account for this phenomenon have focused on the attentional processing requirements of the hypnotic role and hypnotic task. St. Jean, McInnis, and Swainson (1990) presented a "busy-beaver" hypothesis which views the hypnotic subject as so occupied with the demands of task and role that little attention may be spared for the processing of unrelated stimuli. Consequently, when stimuli such as contextual changes, or other cues denoting the passage of time, are unattended the result is a reduction in subjective duration. St. Jean et al. (1990) reported a study in which the attentional

demands of a listening task, presented in a hypnotic context, were varied by placing additional processing demands, in the form of a complex problem-solving task, on some subjects, but not on others. Subjects in the attentionally-demanding condition underestimated the duration of the listening period to a far greater degree than their passive listening counterparts. Estimates were not related to hypnotic susceptibility. St. Jean et al. (1990) did not employ a waking comparison condition. Such a comparison is important in determining whether the hypnotic role, or context, apart from the processing demands they usually impose, contribute to the underestimation effect. The present study provides such a comparison by presenting the same attentional manipulation in both a waking and a hypnotic context. The findings of the previous study were strongly corroborated; subjects in the attentional condition gave significantly shorter duration estimates than those who passively listened. The nature of the context, hypnotic or waking, did not, however, influence the magnitude of time estimates. These results, together with similar findings in the time-perception literature, appear to lend considerable support to the "busy-beaver" hypothesis. (ABSTRACT from Bulletin of Division 30, Psychological Hypnosis, Provided by former Editor, James Council.)

#### NOTES

1:

"In summary, some of our recent data suggest that there are a number of interacting reliable correlates of hypnotizability ... . None relate to suggestibility in the traditional sense. ... Hypnotizability is related to the ability to process cognitive information during sleep, to the physiological ease of falling asleep, and to a dimension of subjective sleep characteristics we have labeled the 'control of sleep' (involving ... the ability to fall asleep easily and readily at will, and the tendency to take naps). Additional data have suggested that the concept of absorption can be meaningfully divided into subfactors that reflect the volitional control over the absorption process that correlates with hypnotizability in both normal and patient populations. ... (C)ontrolled absorption correlates significantly with hypnotizability in both normal and patient populations--a result that might be predicted from the concept of multiple pathways as correlates of hypnotizability (J. R. Hilgard, 1970). ... Finally, both the control-of-sleep dimension and hypnotizability relate to the reductions of symptoms and psychopathology even when psychiatric patients are not treated with hypnotic techniques" (pp. 164-165).

Glicksohn, Joseph; Mourad, Boaz; Pavell, Eyal (1991-92). Imagination, absorption and subjective time estimation. Imagination, Cognition and Personality, 167-176.

We report an exploratory study that investigated the interaction of trait and task in determining duration judgment. High and low absorption subjects (determined by median split along the Absorption Scale) viewed a series of paired slides, and were

required to relate to each pair in one of two tasks: A metaphor-production task, and a story-production one. These tasks were carried out for an objective interval of fifteen minutes, following which the subject was required to verbally estimate this duration, retrospectively. In addition, from the individual protocols we measured the average time till response and the average time of response. A significant interaction between absorption and task was obtained for the latter two variables. In addition, a main effect for task was found for the duration estimation. These and other results are assessed in terms of both a cognitive-timer model for time estimation and a contextualistic approach to temporal processing.

## NOTES

1:

The authors used a model for subjective time estimation (STE) that involves a cognitive timer (or internal clock) that encodes temporal information. STE purportedly may be correlated with the amount of attention directed at the passage of time, and negatively correlated with attention paid to other kinds of tasks. They used tasks that aroused Subjects' imagination--a series of pairs of slides. One group was to produce a metaphor relating the two slides, while the other group was to produce a short story relating the two--theoretically an easier task. The authors hypothesized that high absorption Ss would be more engrossed in the task than low absorption Ss, and therefore would underestimate the amount of time used for the task irrespective of task difficulty. For the low absorption Ss they predicted that time estimates for the more difficult metaphor task should be longer, because the task itself demanded more attention than the other task. (High absorption Ss would not exhibit such a difference.) As another measure, Subjects were required to produce four short time intervals (4, 8, 16, and 32 seconds) to assess whether there might be a different rate of the cognitive timer for the two types of Ss, irrespective of nontemporal task involvement. 26 Ss were randomly allocated to one of two conditions (metaphor task or story task). Since this number of Ss is too small for an adequate evaluation of the interaction effect (absorption x task) of particular interest, the authors regard the experiment as exploratory only. The results suggest that high absorption Ss view the tasks as easy and pleasant relative to the lows, and have larger STE values. Shorter time estimates are associated with the metaphor task than the story task, for both highs and lows--an unexpected finding. While highs take the same amount of time for metaphor production as for story production, lows take longer to produce a metaphor than a story (and of course, the metaphor is shorter in length!) The high absorption Ss provided larger estimations of time for the task in which they produced a required number of seconds (4, 8, etc.), indicating a slower baseline rate of functioning of the cognitive timer. The authors in their discussion find the results supportive of the cognitive timer model. They cite the finding that duration estimate was predicted from STE, task, and interaction of absorption with average time to response. (1) remembered duration was positively correlated with baseline functioning of the cognitive timer (STE) (2) remembered duration was negatively correlated with task difficulty (3) remembered duration was an interactive function of absorption and average time to response.

Nadon, R.; Hoyt, I. P.; Register, P. A.; Kihlstrom, J. F. (1991). Absorption and hypnotizability: Contextual effects re-examined. Journal of Personality and Social Psychology, 60, 144-153.

Two independent studies failed to find evidence consistent with Council, Kirsch, and Hafner (1986), who argued that the repeatedly observed correlations between Tellegen's (1981) Absorption Scale (TAS) and hypnosis measures were artifacts of testing context, and de Groot, Gwynn, and Spanos (1988), who claimed evidence for a Gender x Context moderator effect. In the present studies, subjects completed the TAS and other personality questionnaires during an independent survey and later immediately prior to an assessment of hypnotizability. In Experiment 1 (N = 475), the effect of context on the relation between questionnaire scores and hypnotizability was weak and variable; in Experience 2 (N = 434), these weak effects were reversed. The results reaffirmed the construct validity of absorption as both a major dimension of personality and as a predictor of hypnotic responsiveness.

Neill, W. Trammell (1991, August). Consciousness and the inhibitory control of cognition. [Paper] Presented at the annual meeting of the American Psychological Association, San Francisco.

#### NOTES

1:

This review mentions an association between Tellegen's Absorption Scale and a cognitive inhibitory process called negative priming. Westberry and colleagues, including Anker and Neill, found that people high on the Absorption Scale show an extremely large negative priming effect.

Attention is usually attributed to facilitation (selectively processing stimuli that meet our needs) but might also be due to inhibition of competing stimuli. If, after stimulus S2 has been ignored, we now require a response to either S2 or a new stimulus, S3, according to the facilitation theory S2 should be processed as easily as S3; according to the inhibition theory, processing of the recently ignored stimulus may be hampered by the persistence of inhibition. Dalrymple-Alford provided evidence of inhibition using a Stroop color naming task in which each printed word in a list named the ink color of the next word in the list. Dalrymple-Alford concluded that the response to each word had to be suppressed in order to name its ink color, thereby making it harder to make that same response to the next item. Neill replicated it: color naming was slower when the current color matched the previous distractor (e.g., YELLOW in green ink, after GREEN in red ink) than when the current and previous trial were unrelated (e.g., YELLOW in green ink, after BLUE in red ink).

Tipper, Weaver, Cameron, Brehaut, & Bastedo (1991) had subjects name a picture at fixation, ignoring another picture to the left or right, and Tipper (1985) had subjects ignore picture drawn in another color. If the ignored picture subsequently becomes the target, it is named more slowly than an unrelated target. A particularly interesting finding is that the inhibition generalizes to semantic associates (e.g. if a picture of a dog is ignored, a picture of a cat will then be named more slowly). Yee (1991) demonstrated the effect with ignored words. Tipper (1985) called the inhibitory effects "negative priming".

Neill used a task in which S is shown a string of five letters, and is instructed to judge the second and fourth letters as "same" (e.g., ABABA) or "different" (e.g., ABACA). Negative priming was shown by slower reaction time to target letters that matched the previous ignored distractors (in case below, ABABA):

ABABA - Reaction times are 779 for CACAC and 766 for CDCDC because the A appears in both ABABA and CACAC.

Negative priming does not appear to be perceptual, since it occurs between physically dissimilar stimuli, e.g. in the Stroop task ignoring a printed word inhibits responding to a color. And Tipper and Driver (1988) found negative priming between pictures and corresponding words. By default, the locus of inhibition appears to be at the level of a central cognitive representation. That is, it occurs at a level in which the word GREEN and the color green are related to the same abstract concept, but have not yet accessed an overt response.

However, in the letter-matching task, negative priming occurred only if the ignored distractor letter and subsequent target shared the same letter case. If the ignored distractor and subsequent target were in opposite case (e.g., ABABA, then cacac), positive priming was obtained instead. Because the letter-matching task could be performed on the basis of perceptual similarity, it appears that inhibition can be specific to the perceptual representation when attention is directed to that level of processing. Individual differences in negative priming appear to be related to more global cognitive effectiveness. N.B. Stroop interference is greatest at age 7, decreasing to adolescence, then plateaus through adulthood (Comalli,

Wapner & Werner, 1962). Children in second grade also show less negative priming than young adults in picture naming task (Tipper et al. 1989). (Same thing was found for the elderly, and it is associated with distractibility).

Negative priming research suggests the inhibition of irrelevant processing that is critical for effective functioning. Beech, Baylis & Claridge, 1989, and Beech & Claridge, 1987, studied schizophrenics and college students with schizotypal traits using negative priming task, where these appear to be associated with a failure to inhibit distracting information.

Broadbent et al's (1982) Cognitive Failures Questionnaire measures self-reported lapses of perception, memory, and motor function. Tipper and Baylis (1987) found that negative priming was negatively correlated with cognitive failures; i.e. cognitive failures are associated with less inhibition of distracting information.

Westberry, 1984; Westberry, Anker & Neill, in preparation - found that people high on the Absorption Scale show an extremely large negative priming effect, while the effect for "low absorbers" was negligible.

Nelson, Peter L. (1991-92). Personality attributes as discriminating factors in distinguishing religio-mystical from paranormal experients. Imagination, Cognition and Personality, 11, 389-406.

In the first section of this article, an operationalized notion of preternatural experience is described which includes two general classes of experience: religio-mystical (Ontic) and paranormal (Perceptual). The exploratory study which follows

uses the personality measures of the complete Tellegen Differential Personality Questionnaire taken from 120 subjects who reported having had spontaneous religio- mystical and/or paranormal experiences at some time in the past. The scores on all eleven primary dimensions, three higher order affect factors, and two validity scales were used individually, in univariate ANOVAs, and together, in a Direct Discriminant Function Analysis, to successfully separate two classes of preternatural experients from non- experients and from each other.

**Persinger, M. A.; Makarec, Katherine (1991-92). Interactions between temporal lobe signs, imaginings, beliefs and gender: Their effect upon logical inference. Imagination, Cognition and Personality, 11, 149-166.**

**Rotton's Paralogic Test, Wilson-Barber's Inventory of Childhood memories and Imaginings (ICMI) and the PPI (Personal Philosophy Inventory) were administered to 100 male and 100 female university students. Both sexes displayed moderately strong (0.50) correlations between content-selected and factor analyzed clusters of possible temporal lobe signs, exotic beliefs and the numbers of childhood imaginings. Although there were no sex differences between the accuracy of logical statements that contained paranormal or neutral content, males who displayed more temporal lobe signs were more accurate for logical items that contained paranormal content. Females who displayed more imaginings were more accurate for valid than for invalid items. Accuracy for items with paranormal content increased with exotic beliefs but not with conservative religious beliefs for both sexes. The relationship between exotic beliefs and accuracy for items with paranormal content was especially strong for females. These results suggest: 1) gender differences in the neurocognitive processes that contribute to logical problem solving and 2) accuracy may depend upon the degree to which the subject matter is commensurate with the person's history of enhanced temporal lobe signs, capacity for fantasy and imaginings and beliefs in exotic concepts.**

**NOTES**

**1:**

**Review of related literature indicates that Personal Philosophy Inventory (PPI) temporal lobe signs are correlated with temporal lobe EEG alpha but not occipital lobe alpha (Makarec & Persinger, 1990), with increased suggestibility (Persinger & DeSano, 1986; Ross & Persinger, 1987), with creativity and proneness towards fantasy (Persinger & DeSano, 1986; Ross & Persinger, 1987; Makarec & Persinger, 1987), and with reports of psi experiences and beliefs in such things as reincarnation and aliens in UFOs ('exotic themes') (Persinger & Makarec, 1987; Persinger & Makarec, 1990). This experiment was designed to answer four questions: " 1) Do imagery and temporal lobe signs emerge from the same source of variance?; 2) Do males and females differ significantly in their incidence of imaginings and temporal lobe signs?; 3) Do males and females differ in their ability to solve logical problems?; and 4) Is the accuracy of problem solving affected by the subject matter of the problem and the problem solver's temporal lobe signs and capacity for imagery?" (p. 151). The PPI consists of 140 true-false items that were selected with a goal of discerning temporal lobe signs within a normal population. One 30-item**

subscale has items that are similar to experiences reported by patients with verified electrical foci in the temporal lobes, albeit milder (the TLS or temporal lobe sign scale). Of these 30 items, 16 refer to ictal-like experiences (the CPES, or complex partial epileptic signs), and 14 refer to interictal-like behaviors (ILB). CPES items are items like "Sometimes an event will occur that has special significance for me only," and "While sitting quietly, I have had uplifting sensations as if I were driving over a rolling road." ILB items are items like "People tell me I blank out sometimes when people are talking," and "When I lose an argument I spend a lot of time thinking about what I should have said." Wilson and Barber's Inventory of Childhood Memories and Imaginings (ICMI) has 52 true-false items that include reports of paranormal experiences (5 items), moderate imaginings (18 items) such as "When I was a child I enjoyed fairytales," and extreme imaginings (15 items) such as "When I was a child or teenager, at times I was afraid my imagining would become so real to me that I would be unable to stop it."

Rotton's Paralogic Test [unpublished, at Florida International University, Miami] has 16 syllogisms, each with major premise, minor premise, and conclusion. "The person must decide if the argument is valid ( $n = 8$ ) or invalid ( $n = 8$ ). Half of each of the valid and invalid arguments refer to mundane material while the other half of the arguments refer to paranormal-related material. An example of the former is 'If a president is a crook, he would be impeached; Congress did not impeach Nixon. Therefore Nixon is not a crook' and 'If flying saucers really existed, somebody would have photographed one. Nobody has ever photographed a flying saucer. Therefore, flying saucers do not exist'" (p. 153). Correlations were computed separately for males and females. Both groups increased in accuracy for paranormal items as their belief in things like reincarnation and UFOs ('exotic concepts') increased. Males with a higher number of temporal lobe signs demonstrated more accuracy for logic test items with paranormal (psi) content than logic test items with mundane content. "The single most important correlation was between exotic beliefs and the interaction term for the Rotton scale; the coefficient was unusually strong (0.54) and highly statistically significant ( $p < 0.001$ ) for females only. Because of the manner in which the interaction term was calculated, this correlation meant that females who reported more exotic beliefs were also more accurate for valid items that contained paranormal content only" (p. 159). In their Discussion, the authors write, "The significant positive correlations between exotic beliefs and the clusters of CPES items and extreme Wilson-Barber imagining items are expected associations according to Bear's concept of sensory-limbic hyperconnectionism [Temporal Lobe Epilepsy: A Syndrome of Sensory-Limbic Hyperconnectionism, *Cortex*, 15, pp. 357-384. It would predict that concepts (or word trains) that are unusual, strange or infrequent would be charged with emotional significance and personal value. Ideas that generate substantial imagery, such as time- travel, reincarnation and alien intelligence, would be particularly prone to this affective infusion from limbic sources. Induction of such unique or intensified affective states, especially during childhood, would facilitate the development of more frequent or more extreme periods of dissociation in the adult. We have collected (unpublished) clinical evidence to suggest that the emergence of this pattern is found in the propensity for creative thinkers, including writers, poets,

musicians, artists and scientists, to have had developmental histories that could have promoted temporal lobe lability without overt seizure activity; clusters of such "promoters" include mild physical abuse, febrile episodes, minor head injuries and likely hypoxic periods during extreme physical exertion (competitive athletics)" (pp. 161-162). Another conclusion of the study is that males and females do not differ in their accuracy in solving syllogisms, but "the neurocognitive processes, as inferred from inventories of temporal lobe signs or childhood imaginings, by which the two sexes arrive at solutions may be quite different" (p. 162).

1991

Radtke, H. Lorraine; Stam, Henderikus J. (1991). The relationship between absorption, openness to experience, anhedonia, and susceptibility. International Journal of Clinical and Experimental Hypnosis, 39, 39-56.

Examination of the absorption (Tellegen Absorption Scale [TAS] of Tellegen & Atkinson, 1974), openness to experience (OTE Inventory of Costa & McCrae, 1978), and anhedonia (ANH Scales of L. J. Chapman, J. P. Chapman, & Raulin, 1976) scales suggested that they might be conceptually related. Given the reliable relationship between TAS and hypnotic susceptibility, the authors were interested in studying OTE and ANH as possible personality correlates of hypnotic susceptibility. 2 studies, 1 involving a community sample and the other a sample of university students, were conducted to assess the relationships between the TAS, OTE, and ANH scales and hypnotic susceptibility. As predicted, in Study 1 (community sample) the TAS and OTE inventories were positively correlated with one another and both were negatively correlated with the ANH scale. This pattern of correlations was replicated in Study 2 (university sample), but only TAS correlated significantly with hypnotic susceptibility. Factor analyses further confirmed these findings. It was concluded that the conceptual relationship among the TAS and the OTE and ANH scales resides in some dimension other than hypnotic susceptibility.

#### NOTES

1:

Two studies used Tellegen Absorption Scale (TAS), Costa & McCrae's (1978) Openness to Experience Inventory (OTE), and Chapman, Chapman, & Raulin's (1976) Anhedonia scales (ANH). One involved a community sample, the other involved university students.

OTE and TAS  $r = .42$  and  $.62$

TAS and HGSHS:A  $r = .22$  ( $p < .10$ ) in one study "Thus, while there is a significant overlap in variability between TAS and the other person variables, the variance shared between TAS and hypnotic susceptibility is unique to those two measures. Further research is needed to determine the role of expectancies in contributing to this pattern of findings and the extent to which item overlap may be responsible for the observed correlations (Nicholls et al., 1982). Inspection of the items included in the three scales indicated that only TAS assesses involvement in experiences; items on the ANH and OTE instruments focus on interest or willingness to engage in various experiences" (p. 51).

"Notably, the correlations between TAS and the 2 subjective indices of hypnotic susceptibility, SUB and O-I, were slightly stronger than the correlations between TAS and the two indices reflecting overt behavior (OBJ and HGSHS:A scores). This pattern of relationships is consistent with recent arguments that objective indices alone do not fully capture the hypnotic experience (e.g., Spanos et al., 1983).

"Interestingly, the correlations among the three personality scales tended to be stronger in Study 1 where a community sample was assessed in a nonhypnotic context than in Study 2 where a sample of university undergraduates was assessed in a hypnotic context. The two samples differed significantly on all three scales both in terms of mean level and variability, indicating possible ceiling effects and restricted range problems in the university sample. Given that almost all of the research on hypnotic susceptibility and its correlates has been conducted on university students, these findings point to the utility of obtaining research participants from a greater cross-section of the population" (pp. 51- 52).

"Of particular importance, these results indicate that the relationships among TAS and the OTE and ANH scales do not depend upon the hypnotic context and are not the product of expectancies generated by the anticipation of being hypnotized. Nevertheless, the conceptual relationship among the three scales resides in some dimension that is unrelated to hypnotic susceptibility. At this point, we can only speculate as to what this dimension might be. One possibility is that TAS and the OTE and ANH scales reflect an openness to various experiences; what absorption and hypnotic susceptibility uniquely share is the willingness to become involved in imaginal and sensory experiences" (p. 52).

Ross, Colin A.; Joshi, S.; Currie, R. (1991). Dissociative experiences in the general population: A factor analysis. Hospital and Community Psychiatry, 42, 297-301.

The 28-item Dissociative Experiences Scale was administered to a stratified cluster sample of 1055 respondents in a general population of Winnipeg. Dissociative experiences were common in the sample and were not related to socioeconomic status, sex, education, religion, or place of birth, although they declined with age in both sexes. A principal components analysis identified three factors accounting for 47.1% of the combined variance of scores. The first factor, absorption-imaginative involvement, is composed of common, benign experiences such as missing part of a conversation, being able to ignore pain, staring into space, absorption in a television program or movie, not being sure if you did something or only thought about it, and remembering things so vividly one seems to be reliving it. The other two factors, activities of dissociated states and depersonalization-derealization, composed of less common experiences such as not recognizing friends or family members and not recognizing one's own reflection in a mirror, may be powerful predictors of DSM-III-R dissociative disorders.

1990

Bartis, Scott P.; Zamansky, Harold S. (1990). Cognitive strategies in hypnosis: Toward resolving the hypnotic conflict. International Journal of Clinical and Experimental Hypnosis, 38, 168-182.

Two experiments were carried out to assess the relative contributions of dissociation and absorption as cognitive strategies employed by high and low hypnotizability Ss

in responding successfully to hypnotic suggestions. Of special interest was the manner in which Ss deal with conflicting information typically inherent in hypnotic suggestions. In the first experiment, Ss rated their attentional focus and the involuntariness of their experience after responding to a number of hypnotic suggestions administered in the usual manner. In the second experiment, the level of conflict was varied by instructing some Ss to imagine a circumstance that was congruent and other Ss to imagine a circumstance that was incongruent with the suggested behavioral response. The results of the 2 experiments were consistent in suggesting that, depending upon the nature of the hypnotic suggestion, high hypnotizability Ss are able to employ dissociation or absorption in order to respond successfully. Low hypnotizability Ss, on the other hand, seem to be relatively ineffective dissociators. When the structure of the hypnotic suggestion precludes the use of absorption, the performance of low hypnotizables deteriorates.

1990-1991

Drake, Stephen D.; Nash, Michael R.; Cawood, Glenn N. (1990-91). Imaginative involvement and hypnotic susceptibility: A re-examination of the relationship. Imagination, Cognition and Personality, 10, 141-155.

Several researchers have reported that significant correlations between hypnotic susceptibility and absorption result from the reactive effects of administering scales immediately before measurement of hypnotizability. The present study was conducted to determine whether interview measures of imaginative involvement are similarly reactive. Three groups of 48, 43, and 43 Ss each were first administered 3 scales of absorption/imaginativeness. This was followed by administration of a hypnotizability scale. Ss in Group 1 who were administered the 3 scales immediately prior to hypnosis evidenced the usual significant positive correlation between each of the 3 scales and hypnotizability. Ss in Groups 2 and 3 were administered the 3 scales 24 to 36 hours prior to hypnosis. Group 2 Ss were informed that administration of these scales was part of a hypnosis experiment. Group 3 Ss were not aware that the scales were part of a hypnosis experiment. No significant correlation between hypnotizability and the 3 measures of imagination/absorption was evidenced for either Group 2 or Group 3. Our findings suggest that any relationship between these two constructs may be quite dependent on how and when the measures are administered.

1990

Freeman, William B., Jr.; Kessler, Marc; Vigne, Jeffery (1990). Random number generation, absorption, and hypnotizability: A brief communication. International Journal of Clinical and Experimental Hypnosis, 38, 10-16.

Graham and Evans (1977) found that a measure of random number generation (RNG) was related to hypnotizability. In 2 studies, the relationship between hypnotizability and Graham and Evans' RNG (1977) index was examined. In Study 1 Evans' (1981) measures of controlled and automatic absorption were also evaluated. In Study 1 no relationship was found between the measures of absorption

or RNG and hypnotizability. Since Study 1 was carried out primarily to evaluate methods for modifying hypnotizability, Study 2 was designed to evaluate RNG measure directly. Study 2 found no consistent relationship between RNG and hypnotizability, or between RNG and measures of the experience of hypnotic depth and nonvolition.

Pekala, Ronald J.; Forbes, Elizabeth J. (1990, Spring). Subjective effects of several stress management strategies: With reference to attention. Behavioural Medicine, 39-43.

This study assessed variations in reported attentional experience associated with several stress management techniques (hypnosis, progressive relaxation, deep abdominal breathing) and baseline (eyes closed) as a function of hypnotic susceptibility. Three hundred nursing students experienced the stress management conditions and afterward completed a self-report inventory, the Dimensions of Attention Questionnaire (DAQ), in reference to each condition. The DAQ quantifies 12 aspects of attentional experience in a reliable and valid manner. The results demonstrated that progressive relaxation, hypnosis, and deep abdominal breathing are characterized by differences in reported attentional experience that are further moderated by an individual's hypnotic susceptibility. The clinical implications of these results are discussed.

#### NOTES

1:

"Significant main effects were found for conditions for perspicacity, absorption, and control, with progressive relaxation associated with increased perspicacity and absorption, but with decreased control vis-a-vis hypnosis.

"Significant main effects for groups were found for perspicacity, locus, direction of attention, absorption, control, and vigilance. ... [Post-hoc comparisons] revealed that high susceptibles (vis-a-vis low susceptibles) reported increased perspicacity, absorption, a more inward-focused attention, more feelings of being out of their bodies, and decreased control and vigilance. High-mediums were also different from lows (in the same direction) for all of the above comparisons except for direction of attention. Low-mediums, along with lows, were different from highs for absorption and control.

"Significant interactions between conditions and groups were found for absorption, control, and vigilance. Whereas low susceptibles reported significantly increased absorption but significantly decreased control and vigilance during progressive relaxation than during hypnosis, high susceptibles reported no significant differences between relaxation and hypnosis for absorption, control, or vigilance" (p. 41).

The authors describe the differences found for deep abdominal breathing on p. 41.

"The interaction effects suggest that the experience of hypnosis and progressive relaxation are moderated by a person's hypnotic susceptibility--low susceptibles experience significantly greater absorption, but decreased control and vigilance during progressive relaxation than during hypnosis, although there are no such differences for high susceptibles. This suggests that progressive relaxation may be a

'better' procedure than hypnosis to use with low susceptibles, at least if one wants to increase absorption and decrease vigilance and control" (p. 42).

The authors also note that "deep abdominal breathing is associated with increased 'calmness of mind,' in reference to a baseline condition, as demonstrated by increased attentional detachment and equanimity, and decreased vigilance and density (the 'amount' of thoughts going through one's mind)" (p. 42).

Tenenbaum, Steven J.; Kurtz, Richard M.; Bienias, Julia L. (1990). Hypnotic susceptibility and experimental pain reduction. American Journal of Clinical Hypnosis, 33 (1), 40-49.

We exposed 24 subjects high in hypnotic susceptibility and 24 subjects low in hypnotic susceptibility to a cold-pressor pain stimulus under either hypnotic or waking conditions, using each of two pain-reduction strategies (analgesia and distraction) separately. Trance depth level was held constant for hypnotized subjects. We used pain-tolerance levels as measures of pain, and we analyzed them by survival analysis. High susceptibles reported significantly lower pain ratings and kept their hands immersed longer in the cold water than low-susceptible subjects. There were no significant differences between hypnotic and waking condition subjects or between the different strategies. We have discussed the results in terms of a relationship in the literature between choice of experimental design (between-subjects or within-subjects) and the effectiveness of a hypnotic induction for suggested pain reduction.

#### NOTES

1:

High hypnotizable Subjects scored 25 or above on the Wilson & Barber (1977) Creative Imagination Scale--the CIS (out of 40) and 4 or above on the Morgan & Hilgard (1979) Stanford Hypnotic Clinical Scale--SHCS (out of 5); Lows scored 15 or lower on the CIS and 2 or lower on the SHCS. Depth ratings during hypnosis were 7.4 for Highs, 2.3 for Lows; Tellegen Absorption scores were 25 and 18, respectively.

Subjects were assigned to either waking suggestion group or hypnosis group to avoid carryover effects across sessions, hence there were four groups: highs/waking procedure, highs/hypnotic procedure, lows/waking procedure, lows/hypnotic procedure. Each group was taught two strategies--analgesia or distraction--in a counterbalanced order, with administration of the Absorption Scale during a 15 minute rest in between the two procedures.

For hypnotic inductions, Experimenters provided an audiotape of an induction based on the SHCS, and had Ss report trance depth. When self-reported depth became less than baseline, following either strategy training period, deepening procedures were used to re-establish the earlier depth level. Analgesia testing was not done blind as to subgroup membership and/or susceptibility.

The analgesia condition involved a suggestion of numbness in the hand and arm exposed to the cold pressor (Bassman & Wester, 1983). The distraction condition involved a suggestion to imagine a pleasant beach scene (Turk, Meichenbaum, and Gnest, 1984).

The number of individuals dropping out (removing their hands from the bath) at any one time period was measured, providing 'survival curves.' Pain tolerance was the same for Highs and Lows during baseline; also pain tolerance was the same for the hypnotic group as for the waking group. However, Low hypnotizable Ss removed their hands from the cold water faster than High hypnotizables: after 90 seconds only 60% of Lows, compared with 85% of Highs, remained. The same results occurred for distraction.

"In summary, both treatments allowed subjects to tolerate the cold pressor longer. There were no significant differences between subjects receiving or not receiving a hypnotic induction, and high-susceptibility subjects appeared to derive significantly greater benefit from treatment than did low-susceptibility subjects, as reflected by their tendency to tolerate exposure to the cold bath for greater lengths of time" (p. 46).

"High-susceptible subjects appeared to derive significantly greater benefit from treatment than did low-susceptible subjects, as reflected by their tendency both to tolerate exposure to the cold bath for greater lengths of time and to produce lower pain ratings" (p. 46).

"One issue that remains unresolved concerning the relationship between susceptibility and pain reduction is whether susceptibility is a transsituational capacity that is accessed by suggestion, or as Spanos, Hodgins, Stam, and Gwynn (1984) have asserted, simply an expectancy effect created by the susceptibility screening process, in which susceptibility screening appeared to act as a 'primary effect,' generating a successful experience related to hypnosis. The hypothesis that susceptibility is a capacity that can be accessed by suggestion is supported by the bulk of the literature on susceptibility and pain reduction, including research generated by both social-cognitive and neo-dissociation theorists (e.g., Hilgard, 1975; Spanos & Hewitt, 1980). In addition, susceptibility has proved to be a relatively stable trait, resistant to clinically significant modification (Crouse & Kurtz, 1984; Hilgard, 1975).

"Empirical resolution of this question would seem to require extension and replication of the Spanos, Hodgins, Stam, and Gwynn (1984) study, including exploration of whether screening at the end of the treatment phase of a suggestion experiment wipes out the relationship between susceptibility and successful suggestion for other hypnotic phenomena, such as amnesia, hallucination, time distortion, and so forth" (pp. 47-48).

1989

Balthazard, Claude G.; Woody, Erik Z. (1989). Bimodality, dimensionality and the notion of hypnotic types. International Journal of Clinical and Experimental Hypnosis, 37 (1), 70-89.

The notion of hypnotic types -- of qualitative differences in the mechanisms by which people respond to hypnotic suggestions -- is examined with respect to the kind of evidence that has traditionally been seen to support it. Bimodality in the distribution of hypnosis scores has been taken as evidence for two "types" of hypnotizability. It is argued that little can be said about the nature of underlying

processes from the distribution of raw scores. The relationship of factor analytic results to possible underlying typologies is examined. It is concluded that the present evidence simply does not allow an evaluation of the merits of current typological formulations.

Carlson, Eve Bernstein; Putnam, Frank W. (1989). Integrating research on dissociation and hypnotizability: Are there two pathways to hypnotizability?. Dissociation, 2, 32-38.

Attention to the relationship between hypnotizability and dissociation has been limited to date. Reviews recent studies implying a relationship between "dissociativity" and hypnotizability, and places in context of J. Hilgard's theory of two developmental pathways to hypnotizability (imagination/absorption and punishment). This might imply two subsets of hypnotizable persons, as Nadon et al. (1988) postulate--one with a dissociative style and one with an absorption style. Also, high capacity for imaginative involvement may be a necessary condition for a dissociative response to trauma. Branscomb (1988; unpublished) posits a genetic-stressor model for PTSD in which a history of dissociative-proneness and child abuse predispose one to PTSD when a trauma occurs in a non-supportive environment. Relates this theory to hidden observer research and to dissociative patients.

Hoyt, Irene P.; Nadon, Robert; Register, Patricia A.; Chorny, Joseph; Fleeson, William; Grigorian, Ellen M.; Otto, Laura; Kihlstrom, John F. (1989). Daydreaming, absorption and hypnotizability. International Journal of Clinical and Experimental Hypnosis, 37, 332-342

#### NOTES

1:

NOTES: It appears that the consistent correlation between hypnotizability and positive-constructive day dreaming is carried largely by three subscales--Acceptance of Daydreaming, Positive Reactions to

Day dreaming, and Problem-Solving. Number other subscales consistently correlated with hypnotizability. When absorption was taken into account, daydreaming activity made no independent contribution to the prediction of hypnotizability. "The present results differ from Crawford's (1982) somewhat, however, in terms of the specific aspects of daydreaming activity that are associated with hypnosis. Crawford found that hypnotizability correlated consistently (i.e., in both men and women) with three subscales tapping imagery variables: the presence of visual and auditory imagery in daydreams and the hallucinatory vividness of daydream imagery. In the present study, the imagery subscale, including both visual and auditory items, did not correlate significantly with hypnotizability; unfortunately, the hallucinatory vividness subscale is not represented on the short form (SIPI) of the daydreaming questionnaire used in this study. Crawford (1982) did not find consistent correlations between hypnotizability and scales measuring acceptance, positive reactions, and problem solving--the subscales that consistently yielded significant correlations in the present study. Not too much interpretive

weight should be given to any of the correlations between hypnotizability and daydreaming subscales, until a full replication with reliable subscale measurements (such as those provided by the long, original IPI) has been completed. The important point made by Crawford (1982), and confirmed in the present study, is that hypnotizability is related to positive-constructive rather than guilty-dysphoric daydreaming" (p. 338). The two studies agree that absorption and hypnosis are not correlated with daydreaming scales reflecting poor attentional control. Given the theoretical emphasis in both domains on the narrowing of attention and exclusion of potentially distracting input, negative correlations with this aspect of daydreaming might have been expected.

**Johnson, Blair; Eagly, Alice H. (1989). Effects of involvement on persuasion: A meta-analysis. Psychological Bulletin, 106 (2), 290-314.**

Defines involvement as a motivational state induced by an association between an activated attitude and the self-concept. Integration of the available research suggests that the effects of involvement on attitude change depended on the aspect of message recipients' self-concept that was activated to create involvement: (a) their enduring values (value-relevant involvement), (b) their ability to attain desirable outcomes (outcome-relevant involvement), or (c) the impression they make on others (impression-relevant involvement). Findings showed that (a) with value-relevant involvement, high-involvement subjects were less persuaded than low-involvement subjects;

**Kihlstrom, John F.; Register, Patricia A.; Hoyt, Irene P.; Albright, Jeanne Sumi; Grigorian, Ellen M.; Heindel, William C.; Morrison, Charles R. (1989). Dispositional correlates of hypnosis: A phenomenological approach. International Journal of Clinical and Experimental Hypnosis, 37, 249-263.**

Attempted to construct and validate a questionnaire measure of hypnotic-like experiences based on Shor's (1979) 8-dimension phenomenological analysis of hypnosis. Separate item pools were developed to measure each disposition: Trance, Nonconscious Involvement, Archaic Involvement, Drowsiness, Relaxation, Vividness of Imagery, Absorption, and Access to the Unconscious. Based on preliminary testing (total Number - 856), a final questionnaire was produced containing 5 items measuring normal, everyday experiences in each domain. Results from a standardization sample (Number - 468) showed that each of the subscales, except for Archaic Involvement, possessed satisfactory levels of internal consistency and test-retest reliability. Factor analysis indicated that 6 subscales loaded highly on a common factor similar to the absorption construct (Tellegen & Atkinson, 1974), while items pertaining to Relaxation and Archaic Involvement formed separate factors. Validation testing on 4 samples receiving the Harvard Group Scale of Hypnotic Susceptibility, Form A (HGSHS:A) of Shor and E. Orne (1962) (total Number = 1855) showed that the Absorption and Trance dimensions correlated most strongly with HGSHS:A; the correlations with Drowsiness, Relaxation, and Nonconscious Involvement approached 0. The scales derived from Shor's analysis,

however, did not improve the prediction of hypnotizability over that obtained with the absorption scale (Tellegen & Atkinson, 1974).

Rhue, Judith W.; Lynn, Steven Jay (1989). Fantasy proneness, hypnotizability, and absorption--a re-examination: A brief communication. International Journal of Clinical and Experimental Hypnosis, 37, 100-106.

In a previous study (Lynn & Rhue, Journal of Personality and Social Psychology, 1986) of fantasy-prone persons, "fantasizers" participated in an 8-10 hour, multi-session study. Group selection was based on scoring in the upper 4% of the college population on the Inventory of Childhood Memories and Imaginings (ICMI) of Wilson and Barber (1981) and conforming to the fantasy-prone personality syndrome (Wilson & Barber, 1981) during an interview. Fantasizers differed from nonfantasizers (lower 4% of population) and medium range scorers on measures of hypnotizability (Harvard Group Scale of Hypnotic Susceptibility, Form A, Shor & E. Orne, 1962) and absorption (Tellegen Absorption Scale, Tellegen, 1976). In the current study, Subject were selected on the basis of their ICMI scores and participated in a 1-session experiment. As in our first study (Lynn & Rhue, 1986), fantasizers differed from both comparison groups on the measure of absorption and from the nonfantasizers on the measure of hypnotizability. Further, the correlations among fantasy proneness, absorption, and hypnotizability were stable across studies. Fantasy proneness and absorption were not found to be truly discriminable constructs. Unlike our initial study (Lynn & Rhue, 1986), fantasy-prone and medium range Subjects were equally hypnotizable. Methodological differences across studies provide a plausible explanation for the disparate results obtained.

Ronnestad, Michael Helge (1989). Hypnosis and autonomy: A moderator analysis. International Journal of Clinical and Experimental Hypnosis, 37, 154-168.

The study focused on autonomy as a moderator variable in the prediction of subjectively reported hypnotic depth. Ss in the experimental part of the study were 56 undergraduate psychology and education majors classified as either high or low in autonomy. Ss who were equated on capacity for absorption were individually administered 1 of 3 hypnotic inductions: an authoritarian induction, a permissive hetero- induction, or a self-hypnosis induction. The study had a double-blind design. The data suggest that situational manipulation has greater impact on low than on high autonomy Ss. Individual-difference variables such as absorption, have greater impact on hypnotic depth for high than for low autonomy Ss. The data indicate that the hypnotic behavior of high autonomy Ss is more likely to be self-congruent and less likely to be demand-congruent. A factor-analytic inquiry of absorption confirmed the importance of affective/regressive capacity for hypnotic functioning for high autonomy Ss. The study supported the alternate-path perspective of hypnosis.

NOTES

1:

There is very little research on autonomy and hypnosis. The authors cite studies showing only a modest relationship between hypnotizability and locus of control.

In this study, 176 students were assigned to the high autonomy group if they were in the upper 1/3 of two of 3 autonomy scales (Rotter's Locus of Control Scale, the Inner- Directedness Subscale of the Shostrom Personal Orientation Inventory, and the Autonomy subscale of Jackson's Personality Research Form) and not in the lower 1/3 of the third scale. Ss were designated as low autonomy if the obverse obtained. This procedure yielded 27 high and 29 low autonomy Ss.

Ss were hypnotized with one of three inductions: authoritarian with many motor items (Barber Suggestibility Scale), permissive with mostly imagery (Barber & Wilson's Creative Imagination Scale), or guided self-hypnosis with mostly imagery (taken from Fromm et al, 1981). After hypnosis, Ss rated their own hypnotic depth on a 1-10 scale, and their perception of E or the procedure as authoritarian and directive. Ss' attitude, expectations, motivation, and experienced effortlessness were measured. E rated Ss for pre-hypnosis rapport and post-hypnosis rapport.

The results indicated that there was no difference in hypnotizability level between high and low autonomy Ss. The correlation between effortlessness of experience and hypnotic depth was high for low autonomy Ss (.51) but not significant for high autonomy Ss (.12). In general the two groups were very similar in terms of mean scores on most variables. The differences appeared in the correlations between self-reported hypnotic depth and the other variables. For low autonomy Ss correlations were not significant between depth and pre-hypnotic variables (rapport-pre, absorption, expectation) but for highs the same correlations were significant (rapport-pre .47, absorption .54, expectation .48).

But for post-hypnosis variables, low autonomy Ss had significant correlations between depth and the two variables measured from post-hypnosis interviews (perceived authoritarian/directiveness .40, effortlessness .51) and the highs did not have significant correlations. The multiple correlation between these variables and depth was  $R = .28$  for low autonomy Ss (with no contribution from rapport-pre) and  $R = .72$  for high autonomy Ss, with absorption contributing most. The more they perceived the induction as authoritarian or directive, the greater depth reported by low autonomy Ss. Although low and high absorption Ss did not differ on the Absorption Scale, absorption predicted hypnotic depth better for the highs.

The author divided the Absorption Scale into four rational factors: Affective/Regressive, Perceptual/Cognitive, Dissociative, and Mystical. Low and high autonomy Ss scored at approximately the same level on these categories, but correlations between these categories and depth for low and high autonomy Ss were somewhat different. (See Table.)

Correlations between Categories of Absorption and Hypnotic Depth for Low and High Autonomy Ss

Absorption	Low Autonomy	High Autonomy	All Ss	Category	r	r
Affective/Regressive	.14	.56**	.33**	Perceptual/Cognitive	.25	.33*
	.32*	.57**	.47**	"Mystical"	.07	.16
				Dissociative	.29*	

In their discussion, the authors note that one might assume that high autonomy Ss would be less affected by variations in hypnosis procedures than low autonomy Ss.

The differences found in depth scores for these two groups were supportive of this expectation. "Fluctuations in subjectively reported depth scores for low autonomy Ss only, clearly suggest autonomy to be a moderator variable" (p. 163).

Moreover, the results indicate "that high autonomy Ss in comparison to low autonomy Ss are more likely to express their inner dispositions, such as absorption and expectation, in the hypnotic setting. High autonomy Ss may be more reflective of and attuned to individual predisposing characteristics and less influenced by situational demands. ... the hypnotic behavior of high autonomy Ss is more likely to be self-congruent and less likely to be demand-congruent. Low autonomy Ss, however, are more likely to be demand congruent and less likely to be self-congruent. The latter finding was suggested both by the significant F ratio for low autonomy Ss across treatments, and also by the stronger relationship found for this group between depth and how authoritarian/directive they perceived the procedure to be" (p. 163).

[Paradoxically, among low autonomy Ss an authoritarian approach yields less depth but greater suggestibility (higher hypnotizability scores).] "The tendency for low autonomy Ss to have a higher behavioral score on the authoritarian procedure is consistent with Tellegen's (1979) assumption that there are two pervasive dimensions in current hypnotizability measures--a compliance dimension and a true hypnotic responsiveness dimension. According to Tellegen, motor items may be more saturated with compliance, while cognitive items may be more saturated with true hypnotic responsiveness. The BSS has a motor emphasis, and the higher behavioral scores for the low autonomy group of Ss may be interpreted as an expression of compliance.

"In addition to the inner-directedness and self-congruence hypothesis of why autonomy may be a moderator variable, another possible explanation is related to accuracy of self-perception. The intercorrelational and multiple regression data showed repeatedly that a stronger relationship existed between prehypnotic variables and hypnotic depth for high autonomy than for low autonomy Ss. The relational capacity, as tapped by the rapport-pre variable, absorption, which may be conceptualized as a personality trait; and expectation, a cognitive variable, were all related to depth for high autonomy Ss. For low autonomy Ss, none of these variables were individually related to depth. Differences in Ss' accuracy of self-reporting may explain this. According to ego-psychology theory, highly individuated Ss, with clear self-other differentiation and congruence in self-perception, are better able to make accurate statements about themselves. The self-assessments of Ss with low differentiation capability may be less accurate and possibly more affected by demand characteristics and response set. In other words, their self-assessments have more error. The generally lower correlations for the low autonomy Ss may reflect this" (p. 164).

"A report of subjectively reported hypnotic depth following CIS and the self-hypnosis scales may reflect clarity of imagery, while a report of depth following BSS may reflect experiences of kinesthetic/bodily changes" (p. 165).

**Snodgrass, M.; Lynn, Steven Jay (1989). Music absorption and hypnotizability. International Journal of Clinical and Experimental Hypnosis, 37, 41-54.**

The present study investigated differences between high (N = 15), medium (N = 20), and low (N = 16) hypnotizable Ss' involvement in imaginative versus nonimaginative music. Ss were first screened for hypnotizability with the Harvard Group Scale of Hypnotic Susceptibility, Form A (Shor & E. Orne, 1962). In a second session presented as a study of music appreciation, Ss listened to classical music of high- and low-rated music imaginativeness. Ss' involvement was indexed by absorption, imagery elaboration reported in open-ended essays, and reaction time to a pure tone. High hypnotizable Ss reported more absorption than low hypnotizable Ss, regardless of the imaginativeness level of the music. Ss reported more imagery elaboration in the imaginative than in the low-imaginative passages. High hypnotizable Ss tended to differ in their imagery elaboration in response to the imaginative passages but not in response to the nonimaginative passages. Reaction time results were nonsignificant. No sex differences were found. Medium hypnotizable Ss were indistinguishable from both high- and low-hypnotizable Ss. The findings are generally compatible with J. R. Hilgard's (1970, 1974) construct of imaginative involvement.

Spanos, Nicholas P.; Flynn, Deborah M. (1989). Compliance, imaginal correlates and skill training. [Comment/Discussion] .

#### NOTES

1:

The authors defend the Carlton skill training program against accusation that the trained Ss are simply complying in the context of social pressure. They also discuss characteristics of high hypnotizables (absorption and imagery), noting that the majority of lows do not have low absorption/imagery scores (citing de Groh, 1988, and noting the research on context dependency for absorption).

"Despite all of this, it is worth noting that the results of our modification studies are not inconsistent with the hypothesis that high hypnotizability requires imaginative skills that some subjects do not possess in sufficient degrees. For example, two recent studies (Spanos et al., 1987; Cross and Spanos, 1988) found that the extent to which low hypnotizables showed gains following administration of the CSTP was predicted by their pre-tested levels of imagery vividness. Lows with good imagery benefitted substantially more from the CSTP than did lows with poor imagery ability. When it is kept in mind that most low hypnotizables do not score low on measures of imagery/absorption (de Groh, 1988), then the findings that substantial numbers of low hypnotizables can be taught to attain high hypnotizability is not at all inconsistent with the notion that high hypnotizability requires at least moderate levels of imagery/absorption ability" (p. 14).

Zamore, Neal; Barrett, Deirdre (1989). Hypnotic susceptibility and dream characteristics. Psychiatry Journal of the University of Ottawa, 14 (4).

This study examined the relationship of hypnotic susceptibility to a variety of dream characteristics and types of dream content. A Dream Questionnaire was constructed synthesizing Gibson's dream inventory and Hilgard's theoretical conceptions of

hypnosis. Several dream dimensions correlated significantly with hypnotizability as measured by the Harvard Group Scale of Hypnotic Susceptibility and the Field Inventory. For Ss as a whole, the strongest correlates were the frequency of dreams which they believed to be precognitive and out-of-body dreams. Ability to dream on a chosen topic also correlated significantly with hypnotic susceptibility for both genders. For females only, there was a negative correlation of hypnotizability to flying dreams. Absorption correlated positively with dream recall, ability to dream on a chosen topic, reports of conflict resolution in dreams, creative ideas occurring in dreams, amount of color in dreams, pleasantness of dreams, bizarreness of dreams, flying dreams, and precognitive dreams.

de Groh, Margaret (1989). Correlates of hypnotic susceptibility. In Spanos, Nicholas P.; Chaves, John F. (Ed.), Hypnosis: The cognitive-behavioral perspective (pp. 32-63). Buffalo, NY: Prometheus Books.

#### NOTES

1:

The author describes a non-linear relationship between imagery and hypnotizability and between absorption and hypnotizability. People good at imagery may be high or low on hypnotizability scales; the same is true for people high on absorption trait. However, people low on those traits generally are low on measured hypnotizability.

#### 1988

Houle, M.; McGrath, Patricia Anne; Moran, Greg; Garrett, Owen J. (1988). The efficacy of hypnosis- and relaxation-induced analgesia on two dimensions of pain for cold pressor and electrical tooth pulp stimulation. Pain, 33 (2), 241-251.

This study evaluated hypnosis- and relaxation-induced suggestions for analgesia for reducing strength and unpleasantness of pain (noxious tooth pulp stimulation; cold pressor stimulation). The Tellegen Absorption Questionnaire was used to assess hypnotic susceptibility for 28 subjects in order to match treatment groups according to sex and susceptibility scores. Tooth pulp stimulation consisted of a 1 sec train of 1 msec pulses at a frequency of 100 Hz, applied at 20 sec intervals to the central incisor. Six stimuli, selected between S's pain and tolerance thresholds, were presented 3 times each in random order. Cold pressor stimulation consisted of forearm immersion in a circulating water bath maintained at 0-1 degrees C. Subjects made threshold determinations of pain and tolerance and used Visual Analogue Scales to rate the strength and the unpleasantness of both noxious stimuli before and after receiving either hypnosis- or relaxation-induced analgesia.

There were no significant differences between hypnosis- and relaxation-induced interventions. However the percent reduction in both strength and unpleasantness varied as a function of type of pain. Both hypnosis and relaxation significantly reduced the strength and unpleasantness of tooth pulp stimulation, but only the unpleasantness of cold pressor pain. The pain reductions were not correlated with subjects' hypnotic susceptibility levels.

The results indicate that the extent and the quality of the analgesia produced by these cognitive-based therapies vary not only according to subjects' characteristics and the efficacy of the intervention, but also according to the nature of the noxious

stimuli. Tooth pulp and cold pressor stimulation represent qualitatively different stimuli with respect to both the type of nerves activated and the mode of stimulus application. Discrete, randomly presented levels of noxious electrical stimulation to the teeth activate predominantly small fibers and produce brief pain sensations that vary unpredictably in intensity. In contrast, continuous cold stimulation to the forearm activates a variety of nociceptive and non-nociceptive fibers and produces progressive cold and pain sensations with a predictable increase in intensity from cold sensations to paresthesia and severe pain.

#### NOTES

1:

In this investigation, when the authors conclude that "pain reductions were not correlated with subjects' hypnotic susceptibility levels" (p. 241), it must be noted that hypnotizability was estimated from scores on the Tellegen Absorption scale, which is not actually a measure of hypnotic susceptibility level.

**Kumar, V. K.; Pekala, Ronald J. (1988). Hypnotizability, absorption, and individual differences in phenomenological experience. International Journal of Clinical and Experimental Hypnosis, 36, 80-88.**

The phenomenological effects associated with a baseline condition of eyes- closed and a hypnotic induction condition were compared across individuals of differing absorption capacity and hypnotizability. The results indicated that individuals of differing absorption capacity and hypnotizability reported different intensities of phenomenological experience during the baseline eyes-closed condition. The induction further augmented intensity differences for low, medium, and high absorption and hypnotizable Ss, but more so for high (and medium) than low hypnotizable Ss. The results support both a trait and state interpretation of hypnotizability, and highlight the importance of the interaction between these factors on the resulting hypnotic experience of S.

#### NOTES

1:

Based on a review of relevant literature, the authors predicted that (1) during hypnosis and a baseline condition (eyes-closed), high absorption and high hypnotizable Ss will report the phenomenological effects at greater intensity relative to low absorption and low hypnotizable Ss, respectively; (2) hypnotic induction will be associated with increased absorption; greater alterations in awareness and experience; and decreased volitional control, rationality, and memory; (3) phenomenological intensity differences (hypnosis compared to eyes-closed) will be significantly greater for high than for low hypnotizable Ss.

They used the Phenomenology of Consciousness Inventory (PCI) developed by Pekala (1982), which is a 53 item self-report instrument that is completed retrospectively in reference to a preceding stimulus condition. The PCI measures the following dimensions and subdimensions: internal dialogue; self-awareness; state of awareness; imagery (amount, vividness); positive affect (joy, sexual excitement, love); negative affect (anger, fear, sadness); altered experience (time

sense, body image, perception, unusual meanings); attention (absorption, direction); memory; rationality; volitional control; and arousal.

The 217 Ss were administered the Tellegen Absorption Scale, then sat quietly with eyes closed for four minutes, then completed the PCI, Form 1, relative to that 4-minute period. They were administered a slightly shortened version of the Harvard Group Scale of Hypnotic Susceptibility, Form A (HGSHS:A); before the posthypnotic suggestion and amnesia suggestion they experienced another 4-minute silent period during which they were told to 'continue to experience the state you are in right now.' After the HGSHS:A they completed PCI, Form 2, in reference to the silent period during the HGSHS:A, before they completed the 11-point questionnaire on the HGSHS:

A. Subjects who did not have reliable PCI response forms were removed from the sample, leaving 173 Ss who were divided into high, medium, and low Absorption groups, and high, medium, and low hypnotizability groups. The statistical analysis employed MANOVA on intensity scores for first the major PCI dimensions and then the 14 subdimensions using Conditions (eyes closed, hypnosis) and Groups. There were significant main and interaction effects. Subsequent ANOVAs for each (sub)dimension, Conditions by Hypnotizability Groups (2 x 3) were then performed. Hypnosis "was associated with significantly less positive affect (joy, sexual excitement, love); negative affect (anger, sadness); visual imagery (amount, vividness); self-awareness, internal dialogue, rationality, volitional control, and memory; and significantly more altered experience (time sense, perception) and altered state of awareness.

"Significant main effects for Hypnotizability Groups were found for positive affect (joy, love); altered experience (body image, time sense, perception, meaning); attention (direction, absorption); self-awareness; altered state of awareness; rationality; volitional control; and memory.

"Post-hoc comparisons for the eyes-closed condition revealed that high relative to low, hypnotizables reported significantly greater alterations in body image, time sense, meaning, and altered state of awareness. Medium hypnotizable Ss, compared to low hypnotizables, reported significantly increased alterations in body image and state of awareness.

"Post-hoc comparisons for the hypnotic induction condition revealed that high, viz-a-viz low, hypnotizables reported significantly increased absorbed attention; greater altered experience (body image, time sense, perception, meaning); and increased alterations in state of awareness. High hypnotizables also reported significantly less imagery vividness, self-awareness, rationality, volitional control, and memory. Medium hypnotizable Ss, vis-a-vis low hypnotizables, reported significantly more altered experience (body image, time sense, perception, meaning); absorbed attention; and altered state of awareness; and significantly less imagery vividness, self-awareness, rationality, volitional control, and memory. High hypnotizable Ss, relative to medium hypnotizables, reported significantly more altered experience (perception, meaning) and absorption, and significantly less rationality, volitional control, and memory.

"Concerning the significant interactions ( $\alpha = .01$ ), graphs of the means indicated significant ordinal interactions between Conditions and Hypnotizability

Groups for altered experience (perception), imagery (vividness), self-awareness, altered state of awareness, rationality, volitional control, and memory. For all of the PCI (sub)dimensions, the hypnotic induction condition (compared to eyes-closed) was associated with a significantly greater increase in altered experience (perception), and altered state of awareness; and a significantly greater decrease in imagery (vividness), rationality, volitional control, and memory for the high (and medium) hypnotizable groups relative to the low hypnotizable group.

"Significant disordinal interactions were found for absorption and unusual meanings. Whereas high hypnotizable Ss reported a more absorbed attentional focus and more unusual meaning during hypnosis, low hypnotizable Ss reported being less absorbed (or more distracted) during the induction than eyes-closed. Low hypnotizables reported more unusual meanings in reference to eyes closed" (pp. 84-85).

Correlations among the major PCI dimensions, absorption, and hypnotizability differ between the two conditions. In hypnosis, the hypnotizability correlations that reached the .001 level were: --Self Awareness -.55 --State of Awareness .60 --Altered Experience .56 --Inward Absorbed Attention .44 --Rationality -.41 --Volitional control -.65 --Memory -.41 --Arousal -.28

In the eyes closed condition, the only PCI variables that Hypnotizability correlated with, at the .001 level, were: --Positive Affect .26 --Altered Experience .32

MANOVAs and ANOVAs were computed for Absorption groups in a similar fashion. Main effects but not interaction effects were significant. Results are not abstracted here.

In their Discussion, the authors note that "The three hypotheses were supported by the results. Several of the absorption group comparisons obtained in previous research (Pekala et al., 1985) involving alterations in subjective experience (body image, perception, meaning); state of awareness; and volitional control were replicated in the present research" (p. 85).

Lynn, Steven Jay; Weekes, John R.; Matyi, Cindy L.; Neufeld, Victor (1988). Direct versus indirect suggestions, archaic involvement, and hypnotic experience. Journal of Abnormal Psychology, 97 (3), 296-301.

This study examined the effects of direct (Harvard Group Scale of Hypnotic Susceptibility; Shore & Orne, 1962) versus indirect (Alman-Wexler Indirect Hypnotic Susceptibility Scales; Pratt, Wood, & Alman, 1984) suggestions on archaic involvement (Nash & Spinler, in press) with the hypnotists, objective responding, and subjective involvement and involuntariness ratings, when the scales were administered in all possible combinations (direct/indirect, N = 61; indirect/direct, N = 61, direct/direct, N = 57; indirect/direct, N = 95), across two sessions. At the initial testing, subjects who received indirect suggestions reported a greater emotional bond with the hypnotist and increased fear of negative appraisal than subjects who received direct suggestions. Repeated testing resulted in response decrements on measures of objective responding, subjective involvement, and involuntariness that were paralleled by diminished involvement with the hypnotist. The most stable relation between scales was evident when scales were defined as direct hypnosis

across both sessions. Although direct and indirect suggestions produced comparable effects in the first session, in the second session, direct suggestions fostered greater subjective involvement and feelings of involuntariness.

1987

Chaves, John; Brown, Jude (1987). Spontaneous cognitive strategies for the control of clinical pain and stress. Journal of Behavioral Medicine, 10 (3), 263-276.

The spontaneous cognitive strategies employed by 75 patients undergoing dental extractions or mandibular block injections were elicited using a structured interview. Interest focused on the relationship between these strategies and several personality variables, including state and trait anxiety, locus of control, and absorption. In addition, the effect of strategy utilization on perceived pain and stress was assessed. Forty-four percent of the patients employed cognitive strategies designed to minimize pain and stress, while 37% catastrophized, engaging in cognitive activity which exaggerated the fearful aspects of their experience. Only 19% of the patients denied any cognitive activity during the clinical procedure, and many of these used noncognitive coping strategies. Discriminant analysis revealed that situational anxiety was associated with the use of cognitive coping strategies. Catastrophizing was associated with increasing age, past dental stress, and higher levels of stress vulnerability (high trait anxiety and external locus of control). Copers reported less stress than catastrophizers but not less pain.

Nadon, Robert; Laurence, Jean-Roch; Perry, Campbell (1987). Multiple predictors of hypnotic susceptibility. Journal of Personality and Social Psychology, 53, 948-960. Report two experiments in which various measures thought to be related to hypnotizability were analyzed by stepwise discriminant analysis. Absorption and preference for an imagic style of thinking predicted hypnotizability. Addition of 2 other variables in Experiment 2--a Sleep-Dream score derived from Evans's Cognitive Control of Sleep Mentation subscale and Gibson's Dream Questionnaire, and the Belief in the Supernatural subscale of the Taft Experience Questionnaire--increased the correct classification of the medium-hypnotizable subjects from chance levels to 74%. Argue for a confirmatory and hierarchical approach in future studies to explore correlates of hypnotizability more fully.

#### NOTES

1:

The following notes were made at an SCEH presentation: [Robert Nadon, Hypnotizability: A Correlational Study Involving Experiential, Imagery, and Selective Attention Variables.]

Author used a number of variables that have related to hypnotizability in single measure studies to predict with a multiple  $r$ . 30 male and 30 female Ss, given Harvard (?) then screened on Form A, and finally on Form C. Classed as Low (0-2), Medium (5-10 without amnesia), and High (11-12 with amnesia).

Belicki, Kathryn; Belicki, Denis (1986). Predisposition for nightmares: A study of hypnotic ability, vividness of imagery, and absorption. Journal of Clinical Psychology, 42 (5), 714-718.

The relationships of nightmare frequency to hypnotic ability, vividness of visual imagery, and the tendency to become absorbed in fantasy-like experiences were examined. Subjects were 841 undergraduate university students who participated in group tests of hypnotic ability, after which they estimated the number of nightmares that they had experienced in the prior year. In addition, 406 of the subjects completed Marks' Vividness of Visual Imagery Questionnaire, and Rotenberg and Bowers' Absorption scale. Of the subjects, 76% reported experiencing at least one nightmare in the prior year; 8.3% indicated one or more per month. Individuals with frequent nightmares scored higher on hypnotizability, vividness of visual imagery, and absorption.

NOTES

1:  
620, Belicki & Bowers, 1982 ABSTRACT: Investigated the role of demand characteristics in dream change by comparing dream report change following pre- and postsleep administrations of instructions to pay attention to specific dream content. This design was based on the assumption that if presleep instructions merely distort dream reports rather than influence actual dreams, report change should be observable following a postsleep instruction. 42 undergraduates were prescreened with the Harvard Group Scale of Hypnotic Susceptibility (Form A), which allowed experimenters to examine the role of hypnotizability in dream change. Significant differences were observed only following the presleep instructions. It is concluded that report distortion as a result of paying attention to a dimension of dream content was insufficient to account for dream report change following presleep instructions. Hypnotic ability correlated significantly with the amount of dream change.

Council, James R.; Kirsch, Irving; Hafner, L. P. (1986). Expectancy versus absorption in the prediction of hypnotic responding. Journal of Personality and Social Psychology, 50, 182-189.

The Absorption Scale was administered to subjects in the context of a hypnosis experiment and in a context unrelated to hypnosis. Expectancies of responding to hypnotic suggestions were assessed both before and after trance induction, but before administration of suggestions. Hypnotic depth was assessed by different methods before suggestions were given, and after hypnosis. Absorption was correlated with hypnotic responsivity and expectancy, but only when assessed in a

hypnotic context. Completing the Absorption Scale in a hypnotic context appeared to affect responsiveness by altering expectancies. Only postinduction expectancies were predictive of response to suggestions. Results of path analysis suggest that trance inductions alter expectancies for responding to hypnotic suggestions and that these altered expectancies determine subsequent hypnotic behavior.

Lynn, Steven Jay; Rhue, Judith W. (1986). The fantasy-prone person: Hypnosis, imagination, and creativity. Journal of Personality and Social Psychology, 51, 404-408.

Experimenters selected subjects who ranged along the continuum of fantasy proneness and assessed hypnotizability, absorption, vividness of mental imagery (QMI; Sheehan, 1967), response to waking suggestion (Creative Imagination Scale), creativity, and social desirability (Crowne & Marlowe). Fantasy-proneness was evaluated with the Inventory of Childhood Memories and Imaginings (Wilson & Barber, 1981). Strong support was secured for J. R. Hilgard's construct of imaginative involvement and Wilson and Barber's contention that fantasy prone persons can be distinguished from others in terms of fantasy and related cognitive processes. Fantasizers were found to outscore subjects in both comparison groups on all of the measures of fantasy, imagination, and creativity, with social desirability used as a covariate. Low fantasy-prone subjects were no less creative or less responsive to hypnosis than their medium fantasy-prone counterparts.

Mitchell, George P.; Lundy, Richard M. (1986). The effects of relaxation and imagery inductions on responses to suggestions. International Journal of Clinical and Experimental Hypnosis, 34, 98-109.

Theoretical attempts to understand the meaning and importance of induction procedures in producing hypnotic phenomena suggest that 2 critical components, relaxation and imagery, should be isolated and their relative effect on hypnotic responding studied. Objectively and subjectively scored responses to 12 hypnotic suggestions, which had followed relaxation, imaginal, or combined inductions, were obtained from 59 Ss, divided into 3 levels of hypnotizability. Regardless of hypnotizability level, the combined induction led to a greater subjective report of hypnotic response than did either the relaxation or the imagery inductions; and the relaxation led to a greater subjective report than the imagery induction. It may follow that the subjective experience of hypnosis is facilitated by inductions which include relaxation. The inductions were equally effective in producing objectively measured behavioral responses. There were no significant interactions found between induction type and hypnotizability level.

#### NOTES

1:  
As suggested by Sacerdote (1970), the combination procedure was the most generally effective in producing hypnotic responses. The difference between combined and imagery inductions reached statistical significance on four dependent variables, and the difference between combined and relaxation reached significance

on three. It may also be of interest that Ss receiving the combined procedure scored consistently higher on all nine dependent variables.

A somewhat unexpected finding was that the relaxation induction produced scores on four of the dependent variables that were statistically higher than the imagery induction scores. Considering the difficulty of isolating relaxation and imagery components, it is quite noteworthy that these differences between inductions were found.

The four variables in which the combination and relaxation conditions produced significantly higher scores than the imagery condition were subjective reports--subjective score, degree hypnotized, response volition, and Field Inventory. In contrast to Ss in the imagery induction, Ss in the other two induction conditions believed that they were responding more, felt that their responses were more nonvolitional, and felt that they were more deeply hypnotized.

The fact that relaxation instructions were present in both conditions that were superior to the imagery condition would appear to support Edmonston's (1981) position which posits relaxation as essential for the production of the state of neutral hypnosis. For Edmonston the condition of neutral hypnosis is defined as the relaxed state and precedes other phenomena, such as dissociation and increased suggestibility, which other theoreticians may include in the definition of hypnosis.

However, the statistically significant superior effect of the combined over the relaxation induction on three measures casts doubt on Edmonston's position. The S believes that he or she is more deeply hypnotized and is responding less volitionally when an imagery component is combined with relaxation. The Ss also responded more to the Field Inventory when the combined induction was used.

Another explanation for imagery's relatively poor showing may lie in Ss' differential expectations. The Ss, especially those with previous experience with a traditional hypnotic induction, as was the case in the present study, may not expect to be hypnotized when presented with an imagery alone induction. Such expectations, of course, might reduce responses. On the other hand, there is no reason to believe that the reduced expectation in the imagery condition would not affect the behavioral responses as well, and such was not the case.

Thus, we may be left with the explanation that relaxation adds to the subjective experience of hypnosis. This is in keeping with Edmonston's (1981) position as well as with previous research, such as that by Hilgard and Tart (1966), which finds traditional inductions, with their relaxation components, superior to nontraditional inductions, such as fantasy or task-motivational. If future research should find that bodily involvements such as the physical exertion or repetitive motor behavior (Banyai and Hilgard, 1976) lead to the same level of subjective experience as relaxation did, then we may need to broaden the concept of the somatic component beyond relaxation alone.

In terms of the behavioral compliance of Ss, the results of the present study are in accord with some previous studies in finding all procedures equally effective. Neither imagery, relaxation, nor the combined procedure was superior for the behavioral measure.

Personality factors (social desirability, internality/externality, and absorption) did not affect the basic findings. To the degree that the Tellegen scales measure the

ability to engage in imagery there seems to be little basis for believing that imagery ability is related to the general findings.

Sarbin (1983) would call the inductions studied here 'entrance rituals,' and he has recently asked in his review of Edmonston's book, "Which ritual is more suitable... [p. 58]' for preparing S to respond in various hypnotic ways? One answer from the present results is that an entrance ritual should include muscular relaxation if one wants a better subjective response from S. From Sarbin's point of view, the relaxation component may be more ego-involving, producing more subjective experience and meaning for S.

If one wants to produce only a behavioral response, either a relaxation or imagery ritual will serve.

**Register, Patricia A.; Kihlstrom, John F. (1986). Finding the hypnotic virtuoso. International Journal of Clinical and Experimental Hypnosis, 34, 84-97.**

Measures of hypnotizability based on the Harvard Group Scale of Hypnotic Susceptibility, Form A (HGSHS:A) correlate only moderately with those based on the Stanford Hypnotic Susceptibility Scale, Form C (SHSS:C). Ss (N = 148) scoring in the high range (10-12) on HGSHS:A were classified according to whether they scored in the "virtuoso" range (11-12) or not on a subsequent administration of SHSS:C. Significant group differences were found on items comprising the cognitive distortion subscale of HGSHS:A, whether assessed in terms of overt behavior or subjective impressions of success. The 2 groups also differed on global self-ratings of hypnotic depth and on those subscales of Field's Inventory Scale of Hypnotic Depth concerned with subjective feelings of loss of control, automaticity, transcendence of normal functioning, and fluctuating depth. Assessments of hypnotizability are enhanced when investigators consider subjective involvement as well as behavioral measures of hypnotic response. This is particularly important when the more dissociative aspects of hypnosis are under scrutiny.

#### NOTES

1:

The correlation between Harvard Group and Stanford Scale scores is usually about  $r = .60$  (Bentler & Roberts, 1963; Coe, 1964; Evans & Schmeidler, 1966). This is much lower than one would expect ( $r = .82$ ), based on the tests' individual reliabilities (Evans & Schmeidler, 1966).

The authors developed a Table to show the cross-classification of Ss in terms of Harvard and SHSS:C. Only a minority (33%) of Ss scoring in the highest range of HGSHS:A also scored in the highest range on the SHSS:C (or 50% if cutting points are different).

The Absorption scale correlated  $r = .38$  ( $p < .001$ ) with the Harvard Scale, which fell to  $r = .31$  ( $p < .01$ ) when corrected for expansion of range. The correlation between Absorption and SHSS:C was  $.35$  ( $p < .001$ ).

The issue of predicting Stanford 'virtuosos' from Harvard 'virtuosos' was addressed. HGSHS:A predictor variables were used to determine which items determined whether or not one of the HGSHS:A 'virtuosos' (the 20% who scored 11-12) would also be a SHSS:C 'virtuoso.' It was found that 70% of the SHSS:C

virtuosos, but only 53% of the nonvirtuosos, had reversible posthypnotic amnesia on the HGSHS:A. None of the ideomotor or challenge subscale items demonstrated this ability to predict group association. Although the 'virtuosos' differed from the 'nonvirtuosos' in self reported depth, none of the coding categories associated with the depth variable differentiated the groups; also, judges could not predict who would be a Stanford 'virtuoso' based on subjects' descriptions of depth following the Harvard scale administration.

The Experimenters also could not predict who among the Harvard 'virtuosos' would be classified as a Stanford 'virtuoso' based on either their Absorption Scale score or previous experience with hypnosis.

It was found that subjects' subjective experience of the suggestions for hallucinations, amnesia, and posthypnotic behavior (all considered to be cognitive alterations) were the most highly correlated with the subsequent total SHSS:C score. On the Field scale, which measures subjective experience, the most predictive items had to do with feelings of automaticity and loss of control (referred to as nonvoluntary behavior in other literature). Predicting SHSS:C score by 5 items (Harvard behavioral score, Harvard subjective score, Field total score, Tellegen Absorption total score, and self reported depth rating),  $r = .44$ . "The 5-element regression, employing only total scores, explained 17% ... of the variance of SHSS:C; thus, the feelings of subjective success accounted for the vast proportion (79%) of the explainable variance. For the 16 element regression, employing subscales derived from factor analysis of HGSHS:A and Inventory Scale of Hypnotic Depth, the cognitive subscale was dominant, accounting for 65.5% of explainable variance" (p. 92).

A discriminant function analysis employing the same five total score variables correctly classified 63.3% of the virtuosos.

In their Discussion, the authors suggest that investigators use subjective response as well as behavioral response when identifying hypnotic talent (virtuosos) for research. Particularly, the subjective experience of success seems to be important. Little is known, to date, about the determinants of that sense of success with hypnotic suggestions. "In part, they may relate to the 'classic suggestion effect' (K. S. Bowers, 1981; P. G. Bowers, 1982; Weitzenhoffer, 1974): the quasi-automatic, compulsory, involuntary quality which distinguishes hypnotic response from compliance with simple social requests. If so, then a direct assessment of perceived involuntariness might enhance the predictive validity of HGSHS:A even more. This is especially true for the perceptual-cognitive alterations which relate to Ss' capacity for dissociation" (p. 94).

The authors further recommend, "In those situations where HGSHS:A must stand alone for economic reasons, however, and especially where HGSHS:A is employed as a convenient preliminary screening device in the search for hypnotic virtuosos, it would seem that some assessment of the subjective experience of hypnosis would provide useful supplementary information at very little cost" (p. 94).

Sweeney, Carol A.; Lynn, Steven Jay; Bellezza, Francis S. (1986). Hypnosis, hypnotizability, and imagery-mediated learning. International Journal of Clinical and Experimental Hypnosis, 34, 29-40.

The relationship between hypnotizability, imagery utilization ability, and hypnosis was examined in a study described to Ss (N = 157) as an 'imagery experiment.' In Session 1, the Tellegen Absorption Scale (Tellegen, 1976) was completed and the imagery-mediated paired-associate learning task was administered as a baseline measure. In Session 2, either hypnosis, task motivation, or no treatment instructions were administered and the learning task was repeated with a different word list (each 15 high, 15 low imagery pairs). In Session 3, the Harvard Group Scale of Hypnotic Susceptibility, Form A (Shor & E. C. Orne, 1962) was administered. Overall, recall was superior for high imagery words. Hypnotizability was not associated with imagery-mediated recall. Recall performance, however, was correlated with Tellegen Absorption Scale scores. Interestingly, learning and recall performance decreased between Sessions 1 and 2 for hypnotized Ss but remained the same for task motivated and control Ss. The decrease in performance was mediated by less concern for performance and diminished anxiety. Self-reports of imagery utilization did not differ among groups of Ss.

#### NOTES

1:

The authors review literature on the relationship between hypnotizability, hypnosis, and imagery abilities, noting that results are conflicting. One reason for differing results may be that imagery scales are self-report measures, subject to reporting bias of varying types. The imagery-mediated paired-associate learning paradigm, using high and low imagery paired associates, may address that reporting bias issue. This investigation used 157 Ss grouped into high (9-12), medium (5-8), and low (0-4) hypnotizability levels on the basis of the Harvard Scale. Given the fact that high imagery words are usually recalled more easily than low imagery words (Paivio, 1971), a relationship observed between hypnotizability and imagery-mediated recall would elucidate the role of imagery utilization for memory functions.

The experimental conditions included hypnosis, task motivation, and a no treatment control condition, in order to evaluate the possible enhancement effects of hypnosis on imagery utilization for memory functions. The task motivation group was included to control for motivational factors, and the no treatment control condition to control for the practice effects of repeated testing.

The word pair stimuli were from Paivio et al (1968): 30 pairs consisting of 15 high and 15 low imagery noun pairs. Each Subject participated in three experimental sessions.

Session 1. Ss were told that they were in an experiment on imagery to remember pairs of words. They completed the Tellegen Absorption Scale, then were given instructions for using imagery for recalling words, and for rating vividness and clarity of each image immediately after it was formed. Finally they performed the learning task.

Session 2. Ss received either hypnosis, task motivation instructions ("try to form good interacting images of the word pairs" with exhortation to score as high as possible), or control (Like Session 1). No one in hypnosis group refused the

induction (despite the fact that they were not forewarned in Session 1 that the experiment might involve hypnosis). Ss completed a questionnaire on the percentage of word pairs they used images to remember, how easy it was to block out or ignore distractions, how vivid and clear were images of words during recall, how concerned they were about their performance, and how much anxiety, if any, they experienced during the experiment.

Session 3. The Harvard Scale was administered. Three Ss declined to participate in the Harvard Scale administration.

The results were analyzed with a 3 x 2 x 2 x 2 repeated-measures ANOVA: hypnotizability, instruction (hypnotic induction, task motivation, no treatment), session (1 and 2), and pair imagery (high and low). The expected enhanced memory performance of high hypnotizables with high imagery words in the hypnosis condition did not emerge in the results. However, the expected stimulus-imagery effect was observed (a higher proportion of high imagery words than low imagery words recalled). The expected higher imagery ratings for hypnotized high hypnotizable Ss also was not found. Furthermore, there was a significant interaction effect for recall session by hypnotizability: low hypnotizable Ss rated imagery less vivid in Session 2 than in Session 1, while highs rated it more vivid in Session 2 than in Session 1. Thus, low hypnotizable Ss' imagery ratings actually decreased between Recall Session 1 and 2, while high hypnotizable Ss' imagery ratings increased between Recall Session 1 and 2.

While the Absorption Scale correlated with the Harvard (.28,  $p < .001$ ) and with various measures of recall, hypnotizability did not correlate with any of the recall measures. The questionnaires administered during Session 2 suggested that hypnotized Ss were less concerned and anxious than the no treatment control Ss, and less concerned than the Ss receiving task motivation instructions.

In their Discussion, the authors speculate that the strong stimulus-imagery effects might have made it unlikely for them to find differences between high, medium, and low hypnotizable Ss in imagery-based paired associate learning. They suggest including word pairs that range across the continuum of imagery ratings in future research. They also speculate that differences between hypnotizability levels might be found (as 'T Hoen reported in 1978 publication) if Ss were required to respond in a shorter time interval, or if hypnotizability were measured by a scale with more cognitive items than the Harvard Scale--both conditions in 'T Hoen's research protocol.

"The most striking finding of the present research is that instead of facilitating performance in an imagery-mediated recall task, hypnosis resulted in a decrement in recall relative to control conditions. In the hypnotic condition, the amount of learning actually decreased from one session to the next (waking-hypnosis) but remained equivalent in the task motivation (waking-task motivation) and no treatment groups (waking-waking)" (p. 37). The authors note that it is not possible to determine from their research design whether hypnosis interfered with the learning task, the retrieval task, or both.

"The findings suggest that hypnotizability may be related to reported vividness and clarity of imagery but unrelated to the actual ability to utilize imagery in an

imagery- mediated paired-associate learning task. ... Although high hypnotizables' self-report ratings of imagery and vividness increased, their recall performance was not accordingly enhanced. The disparity between subjective and objective measures underscores the importance of including both types of measures in studies of imagery abilities" (pp. 37- 38).

To a considerable degree, this study controlled for Ss' expectancies regarding hypnosis better than some earlier studies. This study differs from earlier research in that (1) Experimenters didn't test hypnotizability prior to the imagery-mediation task; and (2) the study was defined as an experiment on imagery, and hypnosis was not mentioned until just before the induction in Session 2.

"In conclusion, the present results indicate that, under certain conditions, hypnosis may decrease Ss' motivation and performance. No support was provided for the ability of hypnosis to facilitate imagery utilization and performance on an imagery-mediated task. The results are compatible with the views proffered [sic] by theoreticians who have emphasized the importance of expectancies and the experimental context (e.g., Barber, 1979; Coe & Sarbin, 1977; M. T. Orne, 1951, 1959; Spanos, 1982)" (p. 38).

Zamansky, Harold S.; Clark, Lorene E. (1986). Cognitive competition and hypnotic behavior: Whither absorption?. International Journal of Clinical and Experimental Hypnosis, 34, 205-214.

According to the widely held absorption notion, the successful response to hypnotic suggestions requires S to focus attention on the content of these suggestions and to avoid incompatible and contradictory cognitive activities. This assumption was tested by exposing high, middle, and low hypnotizability Ss continuously to incompatible suggestions and images as they attempted to respond to the direct suggestions of the hypnotist. Performance under these circumstances was substantially as effective as in baseline sessions (without incompatible suggestions) for the high and medium hypnotizable Ss. On the other hand, fewer than half of the low hypnotizability Ss responded successfully. The results are viewed as compatible with both a social enactment and a neodissociation interpretation of hypnosis.

#### NOTES

1:

Subjects were 58 volunteer students divided into 12 high (8-12), 26 medium (5- 7) and 20 low (<5) hypnotizables on the basis of the Stanford Hypnotic Susceptibility Scale, Form A (SHSS:A). Depending on the number of suggestions passed during the SHSS:A, 2-4 'target suggestions' were selected from among those each S passed. All Ss had passed at least one of the target suggestions.

The target suggestions that had been successfully passed were readministered with incompatible suggestions and imagery being given to the S. For example, the S might be asked to practice the opposite response, to note and remember the movements and muscles used to produce the response, to think that they should be able to resist the suggestion, to picture themselves performing the opposite response by recalling the earlier practice experience. For example, while giving a suggestion for arm rigidity, the Experimenter might say "Picture yourself bending your arm"

or "Imagine what it would be like to bend your arm." The S was even encouraged to perform another competing response, e.g. to bend the other arm, and to try to use that experience in resisting the target suggestion. The S was requested to verbalize the incompatible thoughts out loud while performing the target suggestion. Nevertheless, the direct suggestion also was interspersed, as, "You will find, nevertheless, that your right arm won't bend."

**RESULTS.** All 12 highs passed at least one target item and 10 passed all of the target items. 23 of 26 medium suggestible Ss passed at least one item and 17 passed all of them. Only 8 of 20 low hypnotizable Ss passed at least one target suggestion; 7 passed all of them however. Usually the low hypnotizables had only one or two target items, since they passed few items on the original SHSS:A test.

In their Discussion, the authors state, "Despite popular opinion, therefore, it appears that it is not necessary for the good hypnotic S to be fully 'absorbed' or to be 'imaginatively involved' (J. R. Hilgard, 1979) in the direct suggestions of the hypnotist to perform these suggestions successfully. ... It is the responses of the lows that were quite clearly degraded by the presence of conflicting thoughts and images" (p. 209).

As a control study, the authors tested 11 other Ss who had low hypnotic susceptibility, to determine whether the effect found with lows (that they could resist) was actually a function of test-retest unreliability. They administered 1-2 target suggestions without contradictory suggestions two or more times. The results were that, once a S had passed a suggestion once, they continued to pass it (even when it was administered 3-4 times). "If anything, the suggestions sometimes appeared to gain in effectiveness with repetition" (p. 210).

The authors did another control study with 17 highs, 9 medium Ss, and 8 lows, in which the conflicting suggestion was given by a hypnotist who did not know the hypnotizability of the S: after S was hypnotized, hypnotist A wrote the "target" on a slip of paper, left the room, and hypnotist B entered and gave the conflicting suggestions for that target. All 17 highs and 7 of the 9 medium hypnotizable Ss passed, but only 2 of 8 lows were able to do so.

The authors conclude, "It may well be that processes such as absorption and imaginative involvement may facilitate the successful response to hypnotic suggestions, but, clearly, the utilization of such processes is not essential for the successful hypnotic performance of high and medium hypnotizability Ss" (p. 212).

**1985**

Ashton, M.A.; McDonald, R.D. (1985). Effects of hypnosis on verbal and non-verbal creativity. International Journal of Clinical and Experimental Hypnosis, 33 (1), 15-26.

60 female volunteers, 30 hypnotizable and 30 un hypnotizable, screened on 2 measures of hypnotizability, were assigned to a hypnosis, simulation, or waking motivated treatment condition to assess whether hypnosis has a differentially enhancing effect upon verbal and non-verbal creativity test performance. Verbal

and figural components of the Torrance Tests of Creative Thinking (Torrance, 1974) and the Sounds and Images Test (Cunnington & Torrance, 1965) were the principal dependent variables. Postexperimental measures of absorption and effortless experiencing were also obtained. A 2 x 3 independent groups ANOVA did not sustain the prediction of an interaction effect between S hypnotizability and the presence of hypnosis on 3 composite measures of verbal and nonverbal creativity. Although there was an absence of treatment effects, hypnotizable Ss consistently achieved higher scores on the Torrance scoring categories, and their performance was statistically superior on a composite index of overall creativity. Absorption and effortless experiencing measures were also significantly higher for hypnotizable Ss than for un hypnotizable Ss.

1984

Barabasz, Arreed F. (1984). Antarctic isolation and imaginative involvement - preliminary findings: A brief communication. International Journal of Clinical and Experimental Hypnosis, 32 (3), 296-300.

Group 1 Ss (N = 9) were interviewed in Antarctica prior to and following 1 year of Antarctic isolation. Group 2 Ss (N = 7) were exposed to 3 weeks of Antarctic field-site isolation and were interviewed upon return to the United States. A control group of 10 Ss was also interviewed on 2 occasions, paralleling Group 1. Group 1 showed a significant increase in imaginative involvement from pre- to post-Antarctic isolation. Group 2 showed a significantly greater level of imaginative involvement than the control Ss. The possibility that Antarctic living may have revived the mental processes available to these Ss as children is considered within both regression and learning explanations.

Crouse, Eric; Kurtz, Richard (1984). Enhancing hypnotic susceptibility: The efficacy of four training procedures. American Journal of Clinical Hypnosis, 27, 122-136.

In this study, we have compared the effects on hypnotic susceptibility of several components of training procedures based on a social learning model, which have been reported to be successful in enhancing hypnotic susceptibility. These included: 1) attitude-conception of hypnosis information, 2) involvement instructions, 3) goal-directed fantasy instructions, and 4) practice vs. no practice in responding to hypnotic suggestions. A 3 x 2 x 2 repeated measures factorial design was used for the experiment with 60 female volunteers serving as subjects in the study. Contrary to expectations, no differential treatment effects were obtained on either objective or subjective measures of hypnotizability. Furthermore, it was questionable whether or not any of the three information-based components even produced gains in hypnotic susceptibility. None produced clinically significant gains. They also were not found to alter either the subjects' attitudes or their use of hypnosis-related skills. Similarly, practice was found to be ineffective in enhancing responsiveness to suggestions. Taken as a whole, the results of this study suggest that the gains in

hypnotic susceptibility reported for social learning-type training procedures may be due to causes other than those posited by social learning theory.

## NOTES

1:

Diamond (1977) posited 3 core components to modification procedures: attitudinal and set factors, cognitive strategy factors, and optimal learning factors (specific ways subjects are taught the internal responses).

"The present study was undertaken to more fully clarify the extent to which each of the critical components hypothesized by Diamond contributes to increasing susceptibility. It was predicted that subjects receiving attitude-conception of hypnosis information and subjects receiving involvement instructions would show a significantly greater gain in hypnotizability than Ss receiving goal-directed fantasy instructions. Secondly, it was predicted that a significantly greater gain in subjects' hypnotizability would result from an opportunity to practice responding to hypnotic suggestions when coupled with involvement instructions than when accompanied by goal-directed fantasy instructions or attitude-conception of hypnosis information" (p. 125).

A revised SHSS:C was used; it deleted words that explicitly suggested goal directed fantasies (GDF's) on several items: hand lowering, moving hands apart, taste hallucinations, arm rigidity, arm immobilization. Experimenters used audiotaped presentation. Subjects in 3 of 6 experimental groups were also given opportunity to practice 30 minutes on 3 occasions spaced no more than one week apart. They were given 2 practice trials on each of 5 hypnotic suggestions taken from several different scales.

"While differential treatment effects were not found, there was a general facilitation of hypnotic responsiveness for all Ss across treatment conditions on both objective and subjective hypnotizability measures. The mean change in the objective hypnotizability score for all subjects was +.68, ... $p < .001$ ; the corresponding mean change in the subjective hypnotizability scores was +3.11 ...  $p < .001$ . Although statistically significant, neither of the shifts appear to indicate clinically significant shifts in hypnotic responsiveness" (p. 129).

The changes in the positive direction in hypnotizability were not correlated with hypnotizability. Subjects appear to change in their conceptualization of hypnosis, in the direction of it being more a self-induced phenomenon ( $p < .001$ ).

In their Discussion, the authors write, "Taken as a whole, results of this study challenge assumptions which have been made about how training procedures based on a social learning model affect gains in hypnotic susceptibility" (p. 131). Each experimental manipulation was intended to influence a mediating variable, and that apparently did not happen. Teaching subjects to use GDFs on a few items did not generalize so that subjects would generate GDFs on novel items. The results suggest "caution against assuming that social learning base training procedures are effective in altering subjects' attitudes and/or their use of skills thought to mediate hypnotic responsiveness" (p. 133). Nevertheless, the correlational data support previous studies that relate hypnotizability to the mediating factors under investigation.

Continuing their Discussion, the authors write, "Clearly, more attention should be paid in future studies to assessing changes in mediating variables produced by such

training procedures. This is particularly important in terms of subjects' use of GDF's and their use of cognitive strategies to increase the extent of their involvement in the hypnotic experience. It is significant that in this study neither involvement instructions nor GDF instructions were found to alter subjects' use of cognitive strategies. Changes in these skill-related factors need to be demonstrated if social learning based training procedures are to be proven effective in altering subjects' hypnotic abilities rather than simply in raising subjects to their optimal level of responsiveness.

"One explanation which has been offered for the reported success of such training procedures is that they work by changing subjects' attitudes, motivation and/or expectations of hypnosis while leaving any aptitudinal component to hypnosis unaltered (Perry, 1977). From this point of view the gains in susceptibility reported for such procedures result from subjects moving closer to their optimal or 'plateau' level of responsiveness rather than from real changes in subjects' hypnotic abilities" (p. 134).

Alternatively, it is possible that the increases observed following training programs have something to do with the hypnotist-subject relationship. For example, increases in hypnotizability are more modest when the training is given in written instructions than when it is given in person by a hypnotist.

Kearns, John S.; Zamansky, Harold S. (1984). Synthetic versus analytic imaging ability as correlates of hypnotizability. International Journal of Clinical and Experimental Hypnosis, 32, 41-50.

It was hypothesized that synthetic imaging ability, but not analytic imaging ability, is positively related to hypnotizability. The correlation of scores on a paired-associates task, used as a measure of synthetic imaging ability, with scores on the Stanford Hypnotic Susceptibility Scale, Form C (SHSS:C) of Weitzenhoffer and Hilgard (1962), indicated a statistically nonsignificant trend in the predicted direction. 2 measures of analytic imaging ability, as well as Sheehan's (1967) revision of the Betts (1909) Questionnaire Upon Mental Imagery, a measure of vividness of imagery, did not correlate significantly with SHSS:C. The results are discussed in terms of their relation to studies of creativity and goal-directed fantasy.

#### NOTES

1:  
The authors review the literature on imagery and hypnotizability and propose that an important variable in hypnosis is an ability to expand imaginatively upon a given verbal input (synthetic imaging ability), akin to Spanos' (1971) concept of goal-directed fantasy. They cite studies relating creativity ("essentially a synthetic process") to hypnotizability, and predict that skill in solving spatial relations problems (analytic imaging ability) is not correlated with hypnotizability because it involves "accurately scanning visual images and converging on solutions to specific problems," (p. 42) rather than creative fantasy characteristic of hypnotic behavior. Forty Subjects had two sessions each: imagery tests in #1 and SHSS:C in #2. Imagery tests included, in this order: 1. Paired Associates (Paivio, 1972; a test of synthetic imaging), in which paired words are learned and later recalled;

Experimental Ss were to learn them by combining them into an image, while Control Ss were to simply try to learn them. The nouns differed in imagery strength (potential for stimulating images). 2. Nonsense Forms (a test of analytic imaging), in which Subjects trace with their fingers an irregularly shaped Masonite form, blindfolded, and then choose one of 5 drawings that best matches the form. 3. Cube Visualization (a test of analytic imaging), in which Ss imagine a 2" wooden cube painted red on all faces, that had been sawed into 1" cubes; they are to say how many of the smaller cubes would be red on 3 faces, 2 faces, one face, and none of the faces. 4. Betts QMI.

The Paired Associates (PA) scores were a ratio of high imagery words recalled to low imagery words recalled, intended to reflect the impact of imagery availability on memory. There was a trend for hypnotizability to correlate with PA ratio scores, regardless of whether intermediate or low imagery nouns were used as baseline ( $\rho = .37$  and  $.34$ ,  $p < .10$ ) in the experimental group ("Use imagery to learn."), a trend that was not found in the control group (no imagery instructions). Neither measure of analytic imaging ability (Nonsense Forms, Cube test) correlated with hypnotizability.

In their Discussion, the authors write, "The common factor in successful performance of both imagery-mediated paired associates learning tasks and hypnotic suggestions appears to be the ability to expand imaginatively upon a given verbal input" (p. 47). They cite the literature relating hypnotizable and creative performance (p. 47). "The present findings with the Nonsense Forms Test and the Cube Visualization Test, both of which failed to correlate significantly with SHSS:C, support the hypothesis that hypnotizability is not related to analytic, spatial-imagining skills" (p. 47). "The nonsignificant correlation between Betts QMI and SHSS:C adds to the growing body of inconsistent findings observed with Betts QMI" (p. 47).

"Given the complex nature of hypnotic susceptibility and of imagery (Monteiro et al., 1980), it is perhaps not surprising that studies attempting to relate the two variables directly frequently yield only modest relationships. Very likely, the inclusion of appropriate mediating variables would serve to clarify and, in particular instances, augment the relationships observed between hypnotic responsiveness and imaging ability. One such variable may be the capacity to become fully involved in everyday nonhypnotic experiences, commonly called absorption. This variable has been shown in numerous studies to be related to hypnotizability (e.g. Tellegen & Atkinson, 1974), as well as to creativity and vividness of imagery (P. Bowers, 1978, 1979; Monteiro et al., 1980). Even more relevant to the present study is the possible interaction between level of hypnotic susceptibility and the relationship between synthetic imaging ability and SHSS:C scores. It may be, for example, that the contribution of synthetic imaging ability becomes more critical in eliciting hypnotic behavior from Ss who are only moderately susceptible to hypnosis. Such an analysis was not possible in the present experiment, since the number of high, medium, and low susceptible Ss was approximately equal, and, therefore, the number of Ss at each level was insufficient for an adequate subgroup analysis. Clearly, however, future studies of the role of

imaginal skills in hypnotic responsivity must move in directions such as these" (p. 48).

Magnavito, F.; Gaupp, L. (1984, October). Absorption, hypnotic susceptibility, and automatization of visual attention. [Paper] Presented at the annual meeting of the Society for Clinical and Experimental Hypnosis, San Antonio, TX.

#### NOTES

1:

Absorption (Tellegen Scale) correlated .62 with SHCS and -.45 with a measure of visual automatization. They conclude that highly absorption-prone individuals attend more to sensory information, processing their environment in a childlike, less automatized manner. The measure of visual automatization, H, was obtained by camera recorded eye movements and fixations as Ss viewed slides in any way they desired.

Pekala, Ronald J.; Kumar, V. K. (1984). Predicting hypnotic susceptibility by a self-report phenomenological state instrument. American Journal of Clinical Hypnosis, 114-121.

In an attempt to predict hypnotic susceptibility (as measured by the Harvard Group Scale of Hypnotic Susceptibility, HGSHS) the phenomenological experiences of an hypnotic induction (HI) procedure and a baseline comparison condition (eyes closed, EC, sitting quietly) were assessed. After each experience the subjects (n=217) completed the Phenomenology of Consciousness Inventory (PCI), a self-report phenomenological state instrument, dealing with that condition. Step-wise multiple regression and discriminant analyses were then performed on data using the subject's HGSHS score as the dependent variable and the PCI (sub)dimensions as the independent variables. Regression analyses that held up under cross-validation during HI suggest that the PCI may be an appropriate instrument for predicting susceptibility. The possible clinical usefulness of this approach is discussed.

#### 1983

Council, James R.; Kirsch, Irving; Vickery, Anne R.; Carlson, Dawn (1983). 'Trance' versus 'skill' hypnotic inductions: The effects of credibility, expectancy, and experimenter modeling. Journal of Consulting and Clinical Psychology, 31 (3), 432-440.

A hypnotic induction procedure based on social learning principles (skill induction) was compared with a traditional eye-fixation/relaxation trance induction, a highly credible placebo induction, and a no-induction base-rate control. The trance induction surpassed the skill induction only on the Field Inventory, a measure of hypnotic depth that contains items corresponding to suggestions contained in the trance induction. Experimenter modeling was not found to enhance the effectiveness of the skill induction. Skill and trance inductions elicited slightly higher behavioral scores on the Stanford Hypnotic Susceptibility Scale: Form C than did the placebo

induction. However, this difference was not obtained on other measures of hypnotic responsibility and depth. Significant correlations were found between expectancy, absorption, and responsiveness on all dependent measures. Multiple regression analyses indicated that the relationship between absorption and responsivity was mediated by expectancy. The results are interpreted as supporting the hypotheses that hypnotic responses are elicited by the expectancy for their occurrence and that induction procedures are a means of increasing subjects' expectancies for hypnotic responses.

## NOTES

1:

Trance induction resulted in a higher score on subjective experiences (cognitive & perceptual distortions) but not higher suggestibility scores than cognitive-behavioral skill induction. 2) Trance and cognitive-behavioral inductions got slightly higher scores in suggestibility than placebo biofeedback induction. 3) All inductions did better than a "no induction" control group on subjective and behavioral indices of hypnosis.

One of the goals of this research was to examine the contribution of experimenter modeling to the behavioral skill induction that "trains the subject in hypnosis skills and requires the subject's conscious cooperation in learning cognitive strategies that will enhance hypnotic responsivity" (p. 432). Another goal was to assess the contribution of "a subject's expectancies for the occurrence of behaviors perceived as being involuntary" (p. 433). A third goal was to determine whether congruence between a subject's beliefs about hypnosis and the rationale for a particular induction would increase expectancy. Two different skill inductions were employed (one with, one without a model). Subjects were asked to predict their performance, based on a description of the induction that they would receive. The contributions of credibility and expectancy were assessed using a highly credible placebo (pseudo biofeedback of EEG theta rhythm).

The investigation used only subjects who had never experienced hypnosis. Independent variables included Rotter's (1966) Internal-External Locus of Control Scale, Rotter's (1967) Interpersonal Trust Scale, and Tellegen's Absorption Scale (Tellegen & Atkinson, 1974). Mediating variables included a measure of induction credibility based on Borkovec and Nau (1972), and a 20-item inventory measuring expectancies for hypnotic performance. Dependent variables included 20 standard hypnotic suggestions taken from the Stanford Hypnotic Susceptibility Scale, Form C; the Creative Imagination Scale; ratings of the 'realness' or experienced intensity of each suggestion; and the Field Inventory of Hypnotic Depth (Field, 1965).

The authors conclusion reads as follows: "The results of this study may be summarized as follows: (a) Traditional trance hypnotic inductions and cognitive-behavioral skill inductions were shown to be equally effective in eliciting experiential and behavioral responses to hypnotic suggestions, although trance subjects reported a somewhat greater alteration in conscious experience. (b) Experimenter modeling was not found to be an effective component of the skill induction package. (c) Subjects' expectancies for hypnotic responses, reported prior to hypnotic induction, bore a very strong relationship to hypnotic responsivity. (d) A highly credible placebo induction resulted in levels of expectancy and hypnotic

responsivity generally comparable to those produced by trance and skill hypnotic inductions. (e) Absorption was significantly correlated with expectancy, but was not found to be significantly related to responsiveness once variance due to expectancy was taken into account. Thus the relationship between absorption and hypnotic responsiveness appears to be mediated by expectancies.

"In sum, these results suggest that various hypnotic inductions elicit expectancies for responding to hypnotic suggestions and that these expectancies are sufficient to elicit hypnotic responses. Further studies are needed to determine the nature of the relationship between absorption and hypnotic response expectancies" (p. 439).

Saavedra, Ramon Luis; Miller, R.J. (1983). The influence of experimentally induced expectations on responses to the Harvard Group Scale of Hypnotic Susceptibility, Form A. International Journal of Clinical and Experimental Hypnosis, 31, 37-46.

A sample of 75 female and 63 male undergraduates were told that their hypnotizability was predictable through the application of a battery of questionnaires and physiological measures. Three levels of hypnotizability expectations were created, with 3 groups of Ss informed that they were highly hypnotizable, moderately hypnotizable, or low in hypnotizability, respectively. A control group received no such expectations. All Ss were then administered the Harvard. Results indicated a significant main effect due to the assigned hypnotizability expectations. Only Ss in the low expectation group, however, scored significant differently from the other groups on the Harvard. Four other variables were examined as covariates: locus of control, attitude toward hypnosis, absorption, and self-predictions of hypnotizability. All but locus of control correlated significantly with the Harvard. It also was shown that the degree to which assigned expectations influenced Harvard scores was a function of the confidence Ss had in those expectations.

#### NOTES

1:

The authors state that research has shown that it is easier to lower hypnotizability scores by providing negative expectancies than to increase hypnotizability scores through provision of positive expectancies. In this study, very little of the variance of hypnotizability scores was accounted for by the expectancy manipulation.

#### 1982

Crawford, Helen J. (1982). Hypnotizability, daydreaming styles, imagery vividness, and absorption: A multidimensional study. Journal of Personality and Social Psychology, 42 (5), 915-926.

In 25 male and 31 female university student and staff volunteers, the interrelationships between the following measures were studied: hypnotic susceptibility (SHSS:A and C), imagery vividness (VVIQ), involvement in everyday activities (TAS), and daydreaming styles (28 scales of Singer & Antrobus's Imaginal Processes Inventory). Factor analysis produced a factor characterized as a positively vivid and absorptive imagination style. Hypnotic susceptibility, VVIQ, TAS, and

positive-affect daydreaming styles all loaded on this factor. Two other factors were a dysphoric daydreaming style and a lack-of-attentional-control style. Stepwise multiple regressions suggested that males and females, at least within this sample, exhibit different relationships between hypnotic susceptibility and predictor variables. Similar differences were found for the VVIQ and the TAS and their daydreaming-scale predictor variables.

St. Jean, Richard; MacLeod, Carrie; Coe, W. C.; Howard, M. L. (1982). Amnesia and hypnotic time estimation. International Journal of Clinical and Experimental Hypnosis, 30, 127-137.

Previous research has shown that hypnotic Ss tend to underestimate the duration of the hypnotic interval (Bowers, 1979; Bowers & Brennehan, 1979). Based on Ornstein's (1970) work, the present investigation tested the hypothesis that such underestimation occurs to the extent that Ss are amnesic for the events of the hypnotic session. Two separate studies, in which time estimates were collected in conjunction with administrations of the Harvard, failed to find a relationship between responses to the amnesia suggestion and time estimation. Ss in both studies substantially underestimated the duration of the hypnotic interval, but the degree of such underestimation was not related to hypnotic responsiveness. Thus, Ornstein's hypothesis that underestimation occurs to the extent that Ss are amnesic for the events of the hypnotic session was strongly disconfirmed.

1981

Baum, D.; Lynn, Steven J. (1981). Hypnotic susceptibility level and reading involvement. International Journal of Clinical and Experimental Hypnosis, 29 (4), 366-374.

The study investigated differences between high and low hypnotizable Ss in their involvement in imaginative versus nonimaginative reading material. 10 high and 8 low susceptible Ss read passages of high and low rated imaginativeness. Ss' involvement in the passages was measured by self-report and reaction time. High and low hypnotizable Ss differed only in their involvement in imaginative material, with good Ss expressing greater involvement. High susceptible Ss tended to report more involvement in high than in low imaginative material, confirming J. R. Hilgard's (1965, 1970) observations. The reaction-time measure failed to parallel self-report, yielding non-significant results.

Fromm, Erika; Brown, Daniel P.; Hurt, Stephen W.; Oberlander, Joab Z; Boxer, Andrew M.; Pfeifer, Gary (1981). The phenomena and characteristics of self-hypnosis. International Journal of Clinical and Experimental Hypnosis, 29 (3), 189-247.

Self-hypnosis and hetero-hypnosis were compared, and self-hypnosis was studied longitudinally. Results indicated that absorption and the fading of the general

reality orientation are characteristics of both hetero-hypnosis and self-hypnosis. The differentiating characteristics lie in the areas of attention and ego receptivity. Expansive, free-floating attention and ego receptivity to stimuli coming from within are state-specific for self-hypnosis, while concentrative attention and receptivity to stimuli coming from one outside source--the hypnotist on whom the subject concentrates his attention--are state-specific for laboratory defined hetero-hypnosis. Attempts to produce age regression and positive or negative hallucinations are markedly more successful in hetero-hypnosis. Imagery is much richer in self-hypnosis than in hetero-hypnosis. Self-hypnosis requires adaptation to the state: in the beginning of self-hypnosis there is a good deal of anxiety and self-doubt. As the subject feels more comfortable in the self-hypnotic state, he spends less time worrying about failures in self-suggestion, his ability to enter trance quickly and easily increases, as does the fading of the general reality orientation, trance depth, and absorption. An attempt was also made in the present study to find personality characteristics related to the ability to experience self-hypnosis.

Tellegen, Auke (1981). Practicing the two disciplines for relaxation and enlightenment: Comment on 'Role of the feedback signal in electromyograph biofeedback: the relevance of attention' by Qualls and Sheehan. Journal of Experimental Psychology: General, 110, 217-226.

High and Low Absorption Ss differ in set rather than in capability for attending to external or internal stimuli, as Qualls and Sheehan suggest. Trait x Treatment interaction for Absorption illustrates concept of personality dispositions being inherently interactive functional units. Provides a content analysis of Absorption scale (subscales) and relates absorption to other constructs in psychology. "It is not the internal versus external focus per se that play a decisive role but the subject's experiential versus instrumental set. For example, with two treatment levels, one would expect to obtain an Absorption x Treatment interaction even if both treatment conditions required an external attentional focus, as long as they contrasted an experiential and an instrumental set" (pp 223-224).

Yanchar, R. J.; Johnson, H. J. (1981). Absorption and attitude toward hypnosis: A moderator analysis. International Journal of Clinical and Experimental Hypnosis, 29 (4), 375-382.

2 factors which have been found to correlate to a small degree with susceptibility are (a) an individual's attitude toward being hypnotized and (b) an individual's capacity for subjective involvement in an experience (absorption). The present study was an attempt to replicate previous findings by Spanos and McPeake (1975) and to extend these findings to determine if there was a significant interaction between these 2 factors in their relationship to susceptibility. 99 Ss (65 females and 34 males) completed the absorption questionnaire of Tellegen (1979) and the attitude questionnaire of Barber and Calverley (1966). Their hypnotic susceptibility was assessed with the Harvard Group Scale of Hypnotic Susceptibility, Form A (Shor & E. Orne, 1962). Attitude and absorption were found to have small positive

correlations with susceptibility, results which corroborate previous research. The multiple regression analyses indicated that there were no significant interactions between the factors of attitude, absorption, and sex.

NOTES

1:

Bowers found that there was a negative correlation between amount of time underestimation and hypnotizability, measured by the Stanford Scale, Form C:  $r = -.41$  to  $-.53$ .

I. Group Stanford C condition.  $N=151$  Time estimate taken before amnesia suggestion. Ss rated their absorption on each item using Tellegen Scale. 126 underestimates  $r = -.23$  25 overestimates  $r = -.52$  Combined with deviation score,  $r = .26$ . (May be lower than the correlations found by Ken Bowers because individual form C used by Bowers has more cognitive items.) These results lend support for Bowers' absorption theory of time distortion. Tellegen Scale did not correlate with time distortion.

II. Non-hypnotized condition Retested 48 underestimators of time elapsed: a. 24 in absorption condition (listening to Poe's Pit and Pendulum) b. 24 in non absorption condition (listening against white noise background, so it was hard to hear words and they could not "get absorbed")

Percent of actual elapsed time (which was 35 minutes) was used as the measure. (Hypnosis session in Study I was 38-4 minutes.) Using ANOVA they found a significant difference between trance and non-trance conditions, but no difference for the story condition.

The authors suggested that perhaps absorption is not important in the non-trance condition or maybe button pressing for distraction interfered. Underestimation was greater in trance than non-trance conditions. Interaction was significant. Highs did not underestimate as much in the story condition as in the hypnosis condition.

CONCLUSION: This study replicates and extends earlier studies and supports the absorption explanation.

O'Grady, K. E. (1980). The Absorption Scale: A factor-analytic assessment. International Journal of Clinical and Experimental Hypnosis, 28 (3), 281-288.

95 female and 53 male introductory psychology students were administered the Tellegen Absorption Scale (Tellegen & Atkinson, 1974); the Repression-Sensitization Scale (Byrne, Barry, & Nelson, 1963); the F Scale (Adorno, Frenkel-Brunswick, Levison, & Sanford, 1950); the State-Trait Anxiety Inventory (Spielberger, Gorsuch, & Lushene, 1970); the Nowicki-Strickland Locus of Control Scale (Nowicki & Duke, 1974); and the Marlowe-Crowne Social Desirability Scale (Crowne & marlowe, 1964). A principal axis analysis of the inter-correlations

indicated that 3 major factors could account for the bulk of variance among the 6 inventories. Inspection of the correlation matrix and the factor loadings showed that the Absorption Scale shared a quite modest amount of variance with the remaining scales, and that it appeared to represent a dimension entirely different than those found in the other measures. These results offer strong support to the notion that the Absorption Scale is tapping a relatively new personality dimension.

St. Jean, Richard (1980). Hypnotic time distortion and learning: Another look. Journal of Abnormal Psychology, 89 (1), 24.

Conducted 2 studies employing different methodologies with a total of 75 undergraduates to test the hypothesis that hypnotic time distortion facilitates verbal learning. All of the Ss in Exp 1 and most of those in Exp II were given a modified version of the Stanford Hypnotic Susceptibility Scale-Form C. All Exp II Ss were also given the Harvard Group Scale of Hypnotic Susceptibility. Analysis of previous research indicated that hypnotic susceptibility and the form of time-distortion suggestions might be important moderator variables in the relationship. The separate and combined effects of these variables were observed in both studies. No combination of hypnotic susceptibility and time-distortion suggestions in either study raised performance level beyond that of the waking- and/or hypnotic-control conditions. Responses to a postexperimental questionnaire in Exp II indicated that high-susceptible Ss reported subjectively convincing changes in experienced time flow following time-distortion suggestions (12 ref)

1979

Bowers, Kenneth S.; Breneman, H. A. (1979). Hypnosis and the perception of time. International Journal of Clinical and Experimental Hypnosis, 27, 29-41.

Ss who were administered the Harvard Group Scale of Hypnotic Susceptibility, Form A of Shor and E. Orne (1962) underestimated the duration of the 'hypnotic interval' by 41%. The same Ss underestimated a nonhypnotic interval of the same length by only 14%. This temporal foreshortening of the hypnotic interval, replicated on several different samples (combined, N = 435) confirms informal observation that people underestimate the length of time they have been hypnotized. Contrary to prediction, however, there was no relation between the amount of underestimation and hypnotic responsiveness. Discussion focused on possible reasons why significant underestimation of the interval was not accompanied by the expected (negative) correlation of hypnotic responsiveness and temporal foreshortening.

Bowers, Kenneth S. (1979). Time distortion and hypnotic ability: Underestimating the duration of hypnosis. Journal of Abnormal Psychology, 88, 435-439.

In a replication of previous research, 3 different samples of Ss (109 Ss) underestimated the length of time they were hypnotized. However, as in a previous investigation, there was no significant relation between Ss' hypnotizability and the

amount of temporal foreshortening of the hypnotic interval. A small subset of Ss (13-23%) in each of 3 separate samples overestimated instead of underestimated the length of time they had been hypnotized. When this small group of overestimators is set aside, the correlations between hypnotic ability and temporal estimates become significant for each of the 3 (sub) samples of underestimators - ranging from -.41 to -.53. It is demonstrated that these correlations could not be accounted for by R. F. Ornstein's (1976) storage-size hypothesis, but were probably due to Ss of varying hypnotizability becoming differentially absorbed in the hypnotic proceedings. This understanding is consistent with work in time perception showing that imaginative absorption leads to a foreshortening of time. (12 ref).

Quall, Penelope J.; Sheehan, Peter W. (1979). Capacity for absorption and relaxation during electromyograph biofeedback and no-feedback conditions. Journal of Abnormal Psychology, 88 (6), 652-662.

The present research examined the relation between absorption capacity and relaxation during electromyograph biofeedback and no-feedback (instructions only) conditions. Sixteen high absorption and 16 low absorption female subjects underwent a biofeedback and no-feedback session with the order of conditions counterbalanced. For high absorption subjects in the first session, EMG reductions were greater during no- feedback than during biofeedback, although the performance of biofeedback subjects improved in the second session. For low absorption subjects, no differences in EMG reductions were apparent across experimental conditions. Postexperimental self-report data demonstrated differences between absorption groups in subjects' state of arousal and quality of consciousness. It was concluded that for subjects with high capacity for absorbed attention, experimental conditions that allow for a withdrawal from the external environment are most conducive to relaxation, whereas for subjects with limited capacity for absorbed attention, conditions such as biofeedback that place an attentional demand on subjects may be preferable.

Spanos, Nicholas P.; Steggle, Shawn; Radtke-Bodorik, H. Lorraine; Rivers, Stephen M. (1979). Nonanalytic attending, hypnotic susceptibility, and psychological well-being in trained meditators and nonmeditators. Journal of Abnormal Psychology, 88 (1), 85-87.

Four groups of trained meditators differing in amount of meditation practice and a group of nonmeditators attended nonanalytically to a mantra in two meditation sessions. Subjects signaled intrusions into their attending, and were also assessed on several person variables. The four trained meditator groups differed from one another only in terms of self-esteem. When combined into a single group, meditators signaled fewer intrusions and reported "deeper" levels of meditating than nonmeditators. However, meditators and nonmeditators did not differ on hypnotic susceptibility, absorption, or indices of psychopathology.

Bowers, Patricia G. (1978). Hypnotizability, creativity and the role of effortless experiencing. International Journal of Clinical and Experimental Hypnosis, 26, 184-202.

Creative people and highly hypnotizable people describe their experience of finding creative solutions or responding to hypnotic suggestions as "effortless." It is suggested that receptiveness to subconscious work accounts for the experience of effortlessness in both tasks. An experiment using 32 high and low hypnotizable men and women was designed to explore the hypothesis that the aptitude for such effortless experiencing accounts for the relationship found between creativity and hypnotizability.

Analyses of variance indicate highly significant effects of level of hypnotizability on composite scores reflecting effortless experiencing of several tasks and creativity. Intercorrelations of these indices are about .60. As predicted, effortless experiencing accounts for much of the relationship between high versus low hypnotizability and composite creativity. The role of imagery vividness and of absorption in both hypnotizability and creativity were also explored.

Finke, R. A.; Macdonald, H. (1978). Two personality measures relating hypnotic susceptibility to absorption. International Journal of Clinical and Experimental Hypnosis, 26 (3), 178-183.

2 scales of involvement in absorbing experiences, developed independently by Tellegen (1976) and Swanson (1978), were compared with each other and with a group version of the Stanford Hypnotic Susceptibility Scale, Form C (Weitzenhoffer & Hilgard, 1962). Significantly positive correlations were obtained for all three comparisons. The results further confirm the relationship between hypnotic susceptibility and absorption, providing new evidence for the existence of stable individual differences in hypnotizability.

Schwartz, W. (1978). Time and context during hypnotic involvement. International Journal of Clinical and Experimental Hypnosis, 26 (4), 307-316.

A recent conceptualization of hypnosis suggests that hypnotized Ss should show a disruption in episodic memory which would reflect a diminished awareness of duration and sequence. Specifically, the predictions were that hypnotized Ss would exhibit less accurate estimates of duration, and less sequence in their recall of activities, than would nonhypnotized Ss. The empirical task consisted of giving Ss the Stanford Hypnotic Susceptibility Scale, Form C (Weitzenhoffer & Hilgard, 1962), either with the induction (hypnosis condition), or without the induction (control condition). Prior to the termination of the scale, Ss were asked to recall the activities they had performed and the time that had elapsed since they began the scale. Hypnotized Ss (N = 10) were significantly less sequential in their recall of activities, and less accurate in their estimations of the passage of time, than were nonhypnotized Ss (N = 10). These results suggest that persons who respond to hypnosis are less concerned with the context which the world provides for their actions than are nonhypnotized controls.

NOTES

1:

This paper presents a therapeutic procedure that involves experiential focusing, described as a bodily method. The paper provides a step by step procedure that has been used in research. "First of all, the method involves a sharp and complete shift in direction. One must cease talking at oneself inside; one must ask: 'What's wrong?' and then keep quiet, and refrain from answering oneself. It is understood that everyone knows a great deal about what is wrong..." (P. 4).

"Whenever the patient is unsure about what he has found (explaining or doubting) the way to deal with it is always again with a fresh start. One needn't decide the verbal issues that arise. 'Focus freshly on it instead, let it come freshly again' - this is almost always the answer to whatever the issue now seems to be" (p. 6).

"In this experiential therapy, it is important that the therapist respond to what is directly felt even while it isn't yet conceptually clear. What patients sense in focusing is often conceptually vague. The patient feels the felt meaning distinctly enough, but if he talks, he often begins by complaining that it isn't possible to think about it clearly. 'There's something funny there, about the way I pull out of relationships ... (He has talked about the problem before, but not about what is 'funny' here, he just focused and encountered that) ... but I can't describe it. It's ... ah ... funny, there.' The therapist must be able to talk to that, even without knowing what it is: 'You got something there, but you don't know what it is, yet. It's a funny something that you find, right there in how you pull out'" (pp. 6-7).

The theory postulates 'felt meaning' as a body sense of the many complexities of a problem, and experiential effect as a kind of body resolution of a problem. Focusing is viewed as "one essential of psychotherapy, desensitization, Jungian imagery, hypnotherapy, free association, and other methods" (p. 9). "Experiential focusing makes specific and synthesizes the steps of those therapeutic methods which systematically seek to engender body change process" (p. 10).

1968

Gendlin, Eugene T. (1968). The experiential response. In Hammer, E. F. (Ed.), Use of interpretation in treatment: Technique and art (pp. 208-227). New York: Grune & Stratton.

NOTES

1:

The author poses the question, "How can a therapist's response have a concrete experiential effect in the individual?" He notes that therapists do not deal with clear emotions but with more complex experiencing. "What we feel is not an internal object (an 'affective state' as something only inside us), but a felt sense of a whole situation - how we are in that situation, what we bring about, perceive, and feel we are up against" (p. 209). "Therefore, such a felt sense isn't something only felt, but is also intellectual" (p. 209). The therapist should draw the patient's attention to the complexity of experiencing. "Only as the client 'focuses' on his felt meaning, can it

shift, and only from it can further facets emerge. Some individuals come into psychotherapy with a great ability to engage in this experiential 'focusing'(Gendlin, 1968), while with others the therapist must struggle to draw their attention again and again to the felt sense they concretely have. Sometimes the client acts as though he had no idea that he has access to anything but his words" (p. 211). The therapy must remain experiential. "A therapeutic response always aims at the client's own directly-felt sense of what he is talking about" (p. 213).

**Field, Peter B. (1965). An inventory scale of hypnotic depth. International Journal of Clinical and Experimental Hypnosis, 13, 238-249. (Abstracted in American Journal of Clinical Hypnosis, 1966, 1, 86)**

An inventory of 300 items describing subjective experiences during hypnosis was administered to 102 students after they had wakened from hypnosis. The 38 items that correlated best with a standard measure of hypnotic susceptibility are proposed as an inventory measure of hypnotic depth. Items dealing with absorption and unawareness, automaticity and compulsion, and discontinuity from normal experience correlated best with the criterion, while items dealing with conscious motivation to enter hypnosis, feelings of surface compliance with suggestions, and unusual bodily sensations showed generally weaker relationships to the hypnotizability criterion. **1959**

**Bowers, Margaretta K. (1959). Friend or traitor? Hypnosis in the service of religion. International Journal of Clinical and Experimental Hypnosis, 7 (4), 205-215.**

**NOTES**

**1:**

Hypnosis may potentiate religious experiences like prayer and worship, where hypnosis meets the world of inner reality. In the first to fourth centuries, Jewish mystics alluded to depth of mind in religious experience, but the idea of oneness with God "cannot be accepted as a healthy psychological concept" (p. 207).

"We have the possibility of understanding prayer and worship as an intrapsychic phenomenon, as a communication with one's total being. Once the premise of the indwellingness of God can be accepted as a psychological [sic] entity, then we can understand prayer as being a total response of the psychic life of the individual in order that he can understand the feelings of wholeness, self-confidence, and self-esteem in himself, and further, how this can be aided by hypnotic techniques" (p. 207).

The author interprets the 13th Century mystic's words, 'the divine will, dresses or cloaks itself in the will of the devout,' as similar to hypnosis, in which a state "may occur where the patient loses his awareness of the separateness of himself and the hypnotist so that the hypnotist's voice may be felt as his own voice" (p. 208). This is

all right as long as awareness of separateness is re-established when the person comes out of the hypnotic or religious experience.

The religious mystic also may use autohypnosis "to achieve a greater experiencing of God and a heightened religious experience. Such a state likewise produces an ecstasy. Such ecstasy is sometimes present in religious conversion experiences as well. This ecstasy is healthy if the separateness and integrity of God and Man are kept separate" (p. 209). The author describes a phenomenon in which a priest who leads a deeply devotional religious service may feel a loss of a sense of self afterward, complaining of great fatigue and inability or unwillingness to relate to people. The same post-devotional emptiness and depression sometimes occurs among parishioners.

A psychoanalytically oriented case study of misdirected religious belief, amplified by religious service induced trance, is presented.

Ewer TC, Stewart DE Improvement in bronchial hyper-responsiveness in patients with moderate asthma after treatment with a hypnotic technique: a randomised controlled trial *BMJ Clinical Research Edition*. 1986;293(6555):1129-32 A prospective, randomised, single blind, and controlled trial of a hypnotic technique was undertaken in 39 adults with mild to moderate asthma graded for low and high susceptibility to hypnosis. After a six week course of hypnotherapy 12 patients with a high susceptibility score showed a 74.9% improvement (p less than 0.01) in the degree of bronchial hyper-responsiveness to a standardised methacholine challenge test. Daily home recordings of symptoms improved by 41% (p less than 0.01), peak expiratory flow rates improved by 5.5% (p less than 0.01), and use of bronchodilators decreased by 26.2% (p less than 0.05). The improvement in bronchial hyper-reactivity occurred without a change in subjective appreciation of the degree of bronchoconstriction. A control group of 17 patients and 10 patients undergoing treatment with low susceptibility to hypnosis had no change in either bronchial hyper-responsiveness or any of the symptoms recorded at home. This study shows the efficacy of a hypnotic technique in adult asthmatics who are moderately to highly susceptible to hypnosis.

Kohen DP Relaxation-mental imagery (self-hypnosis) for childhood asthma: behavioral outcomes in a prospective, controlled study *Hypnos* 1995 Sep;22(3):132-44 Twenty-eight (28) 7-12 yr old children entered a controlled study of the effects of self-hypnosis on asthma. Asthma belief and behavioural inventories were collected before, and at one and two yrs after intervention. Asthma diaries were kept daily and mailed monthly. Subjects were randomly assigned to (1) Experimental (self-hypnosis), (2) Waking suggestion (no Hypnosis), (3) attention placebo (no hypnosis or asthma discussion), or (4) traditional control groups. Twenty four (24) completed 1 month follow-up, 16 completed 6 months, and 13 completed 2 yrs. Results included fewer Emergency Room visits in the experimental group (p greater than 0.05); (2) less school missed in the experimental group compared to the traditional controlled group (p greater than 0.001) and to the waking suggestion group (p greater than 0.005); (3) no differences in psychological evaluations between groups,

and (4) surprising findings regarding hypnotic and hypnotic-like experiences among subjects.

**Anbar, Ron** (2002, Dec 3). Hypnosis in pediatrics: applications at a pediatric pulmonary center.. *BMC Pediatrics*, 2 (1), 11-18.

**BACKGROUND:** This report describes the utility of hypnosis for patients who presented to a Pediatric Pulmonary Center over a 30 month period.

**METHODS:** Hypnotherapy was offered to 303 patients from May 1, 1998 - October 31, 2000. Patients offered hypnotherapy included those thought to have pulmonary symptoms due to psychological issues, discomfort due to medications, or fear of procedures. Improvement in symptoms following hypnosis was observed by the pulmonologist for most patients with habit cough and conversion reaction. Improvement of other conditions for which hypnosis was used was gauged based on patients' subjective evaluations.

**RESULTS:** Hypnotherapy was associated with improvement in 80% of patients with persistent asthma, chest pain/pressure, habit cough, hyperventilation, shortness of breath, sighing, and vocal cord dysfunction. When improvement was reported, in some cases symptoms resolved immediately after hypnotherapy was first employed. For the others improvement was achieved after hypnosis was used for a few weeks. No patients' symptoms worsened and no new symptoms emerged following hypnotherapy.

**CONCLUSIONS:** Patients described in this report were unlikely to have achieved rapid improvement in their symptoms without the use of hypnotherapy. Therefore, hypnotherapy can be an important complementary therapy for patients in a pediatric practice.

Isenberg, S. A.; Lehrer, P. M.; Hochran, S. (1992). The effects of suggestions and emotional arousal on pulmonary functions in asthma: A review and a hypothesis regarding verbal mediation. Psychosomatic Medicine, 54, 192-216.

This paper reviews the empirical literature on the relation between asthma, suggestion, and emotion, and proposes the hypothesis that these effects are mediated parasympathetically. The literature indicates that, among asthmatics, suggestion can produce both bronchoconstriction and bronchodilation, and that stress can produce bronchoconstriction. The proportion of asthmatic subjects showing bronchoconstriction to both suggestion and stress averages 35%-40% across studies, but, because of methodological considerations, might be conservatively estimated as closer to 20%. The effect is smaller for suggestion of bronchodilation, and is very short-lived among nonasthmatics. No clear connection has been found between these responses and such subject variables as age, gender, asthma severity, atopy, or method of pulmonary assessment, although some nonsignificant tendencies appear. Most studies in this literature used small n's and did not systematically examine various somatic, environmental, and demographic factors that could influence results. A hypothesis is presented regarding vagal mediation of psychological effects on the airways, as well as possible alternative mechanisms, and recommendations for future research to evaluate these hypotheses.

Isenberg, S. A.; Lehrer, P. M.; Hochron, S. (1992). The effects of suggestion on airways of asthmatic subjects breathing room air as a suggested bronchoconstrictor and bronchodilator. Journal of Psychosomatic Research, 36, 769-776.

The Thirty-three asthmatic subjects were told they were receiving, alternately, an inhaled bronchoconstrictor and inhaled bronchodilator, although they actually were only breathing room air. No subjects showed suggestion-produced effects on FEV1, although two (of the 19 on whom FEF50 was measured) showed effects of greater than 20% on measures of maximal midexpiratory flow. The incidence of the effect is smaller than reported previously, possibly because some subjects in previous studies inhaled saline, a mild bronchoconstrictor, and reversal of effect was not required for classification as a reactor. Higher percentages of subjects in this study showed decreased MMEF in response to the "bronchoconstrictor", but this appeared to reflect fatigue rather than suggestion effects. However, the fact that the effect occurred in a relatively non-effort-dependent measure suggests that real changes occurred in bronchial caliber, not just in test effort. Suggestion had a significant effect on perception of bronchial changes, but the correlation between actual and perceived changes was minimal. There was an increase in FVC prior to

administration of the "bronchoconstrictor", possibly reflecting a preparatory response to the expected drug. Correlations among self-report variables suggested the existence of three personality dimensions among our population related to suggestion and asthma: cognitive susceptibility to suggestion of bronchial change; feeling of physical vulnerability; and anxiety. However, there was no significant relationship between airway response to suggested changes and hypnotic susceptibility, as measured by the Harvard Group Scale of Hypnotic Susceptibility.

Madrid AD, Barnes SH. (1991, Oct). A hypnotic protocol for eliciting physical changes through suggestions [Abstract]. American Journal of Clinical Hypnosis, 34 (2), 122-128.

We employed brief hypnotherapy to effect physical changes in patients suffering from medical disorders including allergies, rectal bleeding, systemic lupus, hyperemesis, headache, asthma, and chronic pain. We present, in language appropriate to the individual patient, considerations and suggestions to effect the release of healing biochemicals. Ideomotor signals indicated the patient's awareness of the healing. We hypothesize that the technique triggered novel state-dependent memory, learning and behavior.

Madrid, Antonio D.; Barnes, Susan v.d.H. (1991). A hypnotic protocol for eliciting physical changes through suggestions of biochemical responses. American Journal of Clinical Hypnosis, 122-128.

We employed brief hypnotherapy to effect physical changes in patients suffering from medical disorders including allergies, rectal bleeding, systemic lupus, hyperemesis, headache, asthma, and chronic pain. We present, in language appropriate to the individual patient, considerations and suggestions to effect the release of healing biochemicals. Ideomotor signals indicated the patient's awareness of the healing. We hypothesize that the technique triggered novel state-dependent memory, learning, and behavior.

**NOTES**

**1:**

They hypothesize that the technique they use triggers novel state-dependent memory, learning, and behavior (See for example Rossi, 1987, and Rossi & Cheek, 1988).

Hypnotic Protocol: "1. Tell the patient that he can heal himself by allowing his body to supply its own biochemicals needed to make him well. If a specific biochemical is known, such as cortisone or endorphins, name it. "2. Hypnotize the patient. Resistant or hard to hypnotize patients need not be deeply hypnotized because the patients, using this protocol, will automatically go into trance while accomplishing the next task of accessing and using ideomotor signals (Erickson, 1980; Rossi & Cheek, 1988). "3. Tell the patient that his index finger will automatically and involuntarily twitch and float when his body releases the biochemicals he needs. This ideomotor response (Rossi & Cheek, 1988) is the sole physical response

required of the patient. Rossi hypothesizes that the ideomotor response correlates with biochemical changes (Rossi & Cheek, 1988). "4. Next, ask the patient to consider some things (as described below). Present the considerations one after another until one of them triggers the ideomotor response. "5. In some instances, ask the patient to practice on his own. Many patients who have dramatic emotional reactions during or at the completion of the task may not need to practice on their own" (p. 123).

They present several 'considerations' to the patient, one after the other, tailored to the patient's specific case, until his finger twitches or floats, indicating a biochemical response. For example, the following 'considerations' have been used: "1. Psychodynamic: 'Consider that you are not blamed for anything; that you are in fact perfect just the way you are; that you are loved by those you care about.' 'Consider that you can forgive whoever needs forgiving for hurting you.' 'Consider that there are no longer any threats; everything is better; everything is as it used to be.' "2. Autosuggestion: 'Tell your body to heal. It knows what to do; so ask it to do it.' 'Tell your adrenal glands to produce the steroids that your body needs.' 'Allow a glowing light to permeate that injured back, filling it with healing energy.' "3. Incompatible responses: 'Cover yourself with a cool breeze, cooling the injured leg.' 'Imagine your back getting slack and limp and relaxed.' 'Imagine your stomach lining becoming smooth and moving with easy, ocean-like waves.' "4. Emotion calling: 'Consider yourself feeling very happy with everything, for no reason at all.' 'Consider yourself getting angry at someone--your mother, your wife (husband), your boss, your lawyer.' "5. Bargaining: 'Tell yourself that you will heal if you agree to stay away from that job.' 'Tell yourself you will heal by allowing your right arm to begin to hurt when you are over- exerting yourself.' 'Tell yourself that you will heal in exchange for something else, not so serious, to replace this disease and to serve the same function'" (pp. 123-124).

They present seven cases involving, respectively, allergies, rectal bleeding, systemic lupus, hyperemesis of pregnancy, adult onset asthma, chronic pain, and cluster headaches. Two cases were particularly interesting because they represented patients who did not respond initially.

Their procedure involves reframing the state or emotion originally associated with the onset of disease using considerations, and then giving a suggestion that it is within the power of the person, rather than factors outside, to heal the body. First they instruct the patient that the body can heal itself; then they give the list of suggestions for the patient to consider, persisting with different considerations until they get an ideomotor response. Incorporation of the patient's psychodynamic issues appears to be very important.

The authors regard it as unimportant if the patient cannot be hypnotized; "As Cheek (Cheek & LeCron, 1968; Rossi & Cheek, 1988) points out, the patient's inability to be hypnotized may be synonymous with his disease. It is actually beneficial if the patient cannot achieve ideomotor responses at first because both he and the therapist then trust the validity of the response when it does occur after the appropriate consideration" (p. 127).

Murphy, A. I.; Lehrer, P. M.; Karlin, R.; Swartzman, L.; Hochron, S.; McCann, B. (1989). Hypnotic susceptibility and its relationship to outcome in the behavioral treatment of asthma: Some preliminary data. Psychological Reports, 65, 691-698.

## NOTES

1:

Twelve subjects from an experiment on relaxation therapy for asthma were given the Harvard. Hypnotizability was positively correlated, at a borderline significance, with improvement in the methacholine challenge test, a measure of asthma severity. Performance on the amnesia item of the Harvard was correlated with improvement in self-reported symptoms of asthma.

## 1987

Pastorello, E. A. (1987). The role of suggestion in asthma. I. Effects of inactive solution on bronchial reactivity under bronchoconstrictor or bronchodilator suggestion. Annals of Allergy, 59, 336-338.

Twenty-eight Ss affected by perennial asthma were selected in order to investigate the possibility of inducing or relieving an asthmatic attack by means of suggestion. 25 were positive to a methacholine challenge test, and among them, 11 reacted to an ultrasonic nebulized distilled water test. The effect of suggestion on airway response was assessed by 8 inhalations of normal saline at 32 degrees Centigrade alternately presented as a bronchoconstrictor or as a bronchodilator drug. 8 inhalations of the same diluent without any psychic stimulus were used as a control test. 7 patients reacted with bronchoconstriction to both positive and negative suggestion and to the control test. Further, this group of patients showed a lower methacholine PD10 when compared with the other Ss. In this study, the effects of suggestion on bronchial reactivity were not observed and bronchoconstriction belonged to an individual hyperactivity of the airways.

## 1979

Di Piano, Frank A.; Salzberg, H. C. (1979). Clinical applications of hypnosis to three psychosomatic disorders. Psychological Bulletin, 86, 1223-1235.

Studies of hypnosis in the treatment of skin disorders, headaches, and asthma were reviewed in terms of outcomes and methodological soundness. Some studies focused on changing physiological functions, others on increasing insight in their patients, and still others on altering patients' perceptions of their symptoms. Methodological weaknesses included lack of control groups, nonrandom assignment of patients to treatment conditions, and confounding of treatment effects or lack of control for placebo effects. Additional weaknesses centered around the use of single outcome measures and the failure to assess the specific roles of mediating variables. Most of the studies reviewed showed positive treatment effects. However, there is equivocal evidence that hypnosis can directly influence autonomic functioning. Hypnosis may be valuable in facilitating one's capacity to gain insight into how one's symptoms developed and are maintained. In addition, hypnotic procedures have resulted in some success when used to indirectly alleviate symptoms by altering how individuals perceive their disorders and how these disorders affect their lives.

**1978**

15 asthmatic and 19 non-asthmatic Ss were administered the Harvard Group Scale of Hypnotic Susceptibility, Form A (Shor & E. Orne, 1962) and accordingly assigned to one of three susceptibility groups -- low, medium, or high. Subsequently, all Ss were exposed to a hypnotically suggested asthma experience. Subjective and physiological measures of respiratory efficiency were administered before, during, and after the hypnotically suggested asthma experience. Ss did respond significantly differently in these three conditions, but the physiological measures did not reveal typical asthma physiological patterns. High and medium susceptible Ss were ostensibly convinced that they "experienced" asthma, but the low susceptible Ss were uniformly unimpressed. One of the most noteworthy findings was that Ss' ability to respond differentially (according to the asthma suggestions) was enhanced by greater susceptibility to hypnosis yet not "enhanced" by their history of previous asthma.

**1975**

Retrospective analysis of 121 asthmatic patients who were treated by hypnotherapy. Subjects were first broken down into one of three possible groups: "light," "medium," or "deep," according to the depth of trance typically achieved. Hypnoidal states were included in the light trance group and somnambulistic state in the deep trance. All sessions concentrated on suggesting physical and mental relaxation since we know this is one of the causes of the appearance of the "asthma attack." The actual wording varied however, and this involved discussion under hypnosis, of the main personalities of the environment, fears, failures, aims, hopes and frustrations. Post-hypnotic suggestions of continued relaxation and ability to cope with the various situations of life were given in all the cases. Auto-hypnosis was taught to enable the patient to reinforce the above suggestions and to remain in or selectively achieve a relaxed state. Results were classified into four different categories: "excellent," "good," "poor," and "nil." It was found that those patients who experienced a "high" trance depth were more likely to show excellent improvement than those who were measured as "medium" or "low" trance subjects

Alexander, A. Barney; Miklich, Donald; & Hershkoff, Helen (1972, September-October). The immediate effects of systematic relaxation training on peak expiratory flow rates in asthmatic children . Psychosomatic Medicine, 34 (5), 388-393.

Clinical experience has often suggested that having asthmatic patients sit quietly and/or relax during asthma attacks is helpful. The present study was an attempt to provide a controlled experimental demonstration of the effect of systematic relaxation on peak expiratory flow rate in asthmatic children. Eighteen male and 18 female asthmatic children were divided into two groups matched for mean age, sex composition and asthma severity. One group of subjects underwent three sessions of

modified jacobsonian systematic relaxation training, while the second group sat quietly for three sessions. Peak expiratory flow rate measures were obtained prior to and following each session. It was found that relaxation "subjects manifested a significant mean increase in peak expiratory flow rate over sessions compared to a nonsignificant mean peak expiratory flow decrease for control subjects. It was suggested that these results have important implications both for the clinical treatment and the understanding of bronchial asthma.

1971

Moorefield, C. W. (1971). The use of hypnosis and behavior therapy in asthma. American Journal of Clinical Hypnosis, 13, 162-163.

Nine patients with asthma were treated with hypnosis and behavior therapy. All of these patients showed subjective improvement to a rather marked degree, except for one patient who has had three slight attacks of asthma since the onset of her treatment. These patients have been followed from eight to approximately 24 months. The results so far have been rather encouraging and the author believes this form of treatment will prove to be of benefit in the treatment of asthma and possibly many other related conditions.

Luparello, Thomas; Leist, Nancy ; Laurie, Cary; Sweet, Pauline (1970, September-October). The interaction of psychologic stimuli and pharmacologic agents on airway reactivity in asthmatic subjects. Psychosomatic Medicine, 32 (5), 509-513.

Two bronchoactive substances, isoproterenol and carbachol were presented by inhalation to 20 asthmatic subjects in a double blind study. Each drug was given under two conditions: in one case, the subject was told the drug was a bronchodilator; in the other, he was told it was a bronchoconstrictor. The bronchodilator effect of isoproterenol was greater when the subject was told it was a bronchodilator than when told it was a bronchoconstrictor. Similarly, the bronchoconstricting effect of carbachol was greater when the subject was told it was a bronchoconstrictor than when told it was a bronchodilator.

Maher-Loughnan, G. P. (1970). Hypnosis and auto-hypnosis for the treatment of asthma. International Journal of Clinical and Experimental Hypnosis, 18 (1), 1-14.

Conducted 2 controlled studies into the use of hypnosis in 252 asthma patients. Several different control procedures were used. Methods and results were summarized, and the same conclusion was reached: That hypnosis supplemented by autohypnosis was significantly more effective than control procedures. An outline is given of details of treatment methods. A current analysis of Ss involving up to 6 yr. of follow-up, is presented to provide a working guide to the regime in regular practice. To be fully effective hypnosis should be employed before steroids are started. Steroid-dependent asthma is rarely totally relieved by hypnotherapy. Chong, Tong Mun (1969, September). The value of hypnotherapy as an adjunct in the treatment of bronchial asthma. Singapore Medical Journal, 10 (3), 182-186

[Introductory paragraphs] Bronchial asthma is a disorder characterised by recurrent spontaneous attacks of dyspnea and wheezing, and remissions either spontaneously or as a result of treatment. Two problems clearly exist in the treatment of bronchial asthma, (1) Treatment of acute attacks and (2) Prevention of future attacks.

Hypnotism has been used in the treatment of diseases for hundreds if not thousands of years. Success was claimed for the hypnotic treatment of asthma about 60 years ago by Gerrish (1909). Varying reports have appeared in literature about the efficacy of hypnotherapy. Marchesi (1949), Magonet (1955), Asher (1956), Stewart (1957), Fry (1957), Ambrose and Newbold (1958), Diamond (1959), Meares (1960), Edwards (1960), Sinclair-Gieben (1960), Maher-Loughnan et al (1962), Chong (1964, 1965, 1966, 1968), Maher-Loughnan (1965), McLean (1965), Houghton (1967), British Tuberculous Association (1968). Most authors used various degrees of psychotherapy, and believed that psychotherapy is an essential part of the treatment. However, Maher-Loughnan et al in a controlled study, using only symptom-removal suggestions, found that hypnosis is of value in the symptomatic treatment of asthma. Sinclair-Gieben (1960) reported a case of Status Asthmaticus resistant to all physical therapy and as a final resort, hypnosis was tried and found to cut short the attack instantaneously. Here also only symptom-removal suggestion had been used.

#### CONCLUSION:

Hypnotherapy is of value as an adjunct in the prevention of future attacks of asthma. It has also been shown to be a useful adjunct in other branches of medicine by the author elsewhere.

#### **CONCLUSION**

Hypnotherapy is of value as an adjunct in the prevention of future attacks of asthma. It has also been shown to be a useful adjunct in other branches of medicine by the author elsewhere.

**1968**

**British Tuberculosis Association (1968). Hypnosis for asthma: A controlled trial: A report to the research committee of the British Tuberculosis Association. British Medical Journal, 71-76.**

An investigation of hypnosis in asthma was made among patients aged 10 to 60 years with paroxysmal attacks of wheezing or tight chest capable of relief by bronchodilators. One group of patients was given hypnosis monthly and used autohypnosis daily for one year. Comparisons were made with a control group prescribed a specially devised set of breathing exercises aimed at progressive relaxation. Treatment was randomly allocated and patients were treated by physicians in nine centres. Results were assessed by daily diary recordings of wheezing and the use of bronchodilators, and by monthly recordings of F.E.V. and vital capacity. At the end of the year independent clinical assessments were made by physicians unaware of the patients' treatment.

There were 252 patients (127 hypnosis and 125 controls) accepted for analysis, but a number of them did not continue the prescribed treatment for the whole year: 28 hypnosis and 22 control patients failed to cooperate, left the district, or had family problems; one hypnosis and one control patient died. Seven hypnosis and 17 control patients were withdrawn as treatment failures, the difference between the two groups being statistically significant.

As judged by analyses based on the daily "score" of wheezing recorded in patients' diaries, by the number of times bronchodilators were used, and by independent clinical assessors, both treatment groups showed some improvement. Among men the assessments of wheezing score and use of bronchodilators showed similar improvement in the two treatment groups; among women, however, those treated by hypnosis showed improvement similar to that observed in the men, but those given breathing exercises made much less progress, the difference between the two treatment groups reaching statistical significance. Changes in F.E.V. and V.C. between the control and hypnosis groups were closely similar.

Independent clinical assessors considered the asthma to be "much better" in 59% of the hypnosis group and in 43% of the control group, the difference being significant. There was little difference between the sexes. Physicians with previous

experience of hypnosis obtained significantly better results than did those without such experience.

**NOTES**

**1:**

This paper was originally presented by the physician, an instructor at George Washington University Medical School, at the First Annual Meeting of the American Society of Clinical Hypnosis in 1958. He treated 55 cases, beginning in 1954, with 40 having complete remission. He gives 3 case histories where early childhood experiences gave rise to the asthma, and the symptoms were quickly relieved when the repressed material was reviewed by the patient.

**2002**

**Sapp, Marty (2002). Implications of Barber's Three Dimensional Theory of Hypnosis [Abstract]. Sleep and Hypnosis, 4 (2), 70-76.**

Recently, Barber has presented a three dimensional paradigm of hypnosis. He proposed that there are three types of hypnosis clients- the fantasy-prone, amnesic-prone, and positively-set. This paper discusses the major theoretical implications of this new paradigm, and, if Barber is correct, his new theory should bridge a gap between the special process (state) and nonstate theorists. Finally, only research will determine if Barber's new theory will actually unify the previous disagreements between the state and nonstate theorists.

**2000**

**Eimer, Bruce. N. (2000). Clinical applications of hypnosis for brief and efficient pain management psychotherapy. American Journal of Clinical Hypnosis, 43 (1), 17-40. (July)**

This paper describes four specific clinical applications of hypnosis that can make psychotherapy for pain management briefer, more goal-oriented, and more efficient: (1) the assessment of hypnotizability; (2) the induction of hypnotic analgesia and development of individualized pain coping strategies;

(3) direct suggestion, cognitive reframing, hypnotic metaphors, and pain relief imagery; and (4) brief psychodynamic reprocessing during the trance state of emotional factors in the patient's experience of chronic pain. Important theoretical and clinical issues regarding the relationship between hypnotizability to the induction of hypnotic analgesia are presented, and attempts to individualize pain treatment strategies on the basis of assessed differences in hypnotizability and

patients'' preferred coping strategies are described. Some ways are also presented of integrating direct hypnotic suggestion, COGNITIVE-EVALUATIVE reframing, hypnotic metaphors, and imagery for alleviating the SENSORY and AFFECTIVE-MOTIVATIONAL components of pain, with an exploratory, insight-oriented, and brief psychodynamic reprocessing approach during trance for resolving unconscious sources of resistance to treatment, and reducing the emotional overlay associated with chronic pain. Some basic assumptions underlying the use of this approach are discussed, and a brief step-by-step protocol is outlined.

**Wickramasekera, Ian (1999).** How does biofeedback reduce clinical symptoms and do memories and beliefs have biological consequences? Toward a model of mind-body healing. Applied Psychophysiology and Biofeedback, 24 (2), 91-105.

Changes in the magnitude and direction of physiological measures (EMG, EEG, temperature, etc.) are not strongly related to the reduction of clinical symptoms in biofeedback therapy. Previously, nonspecified perceptual, cognitive, and emotional factors related to threat perception (Wickramasekera, 1979, 1988, 1998) may account for the bulk of the variance in the reduction of clinical symptoms. The mean magnitude of these previously nonspecified or placebo factors is closer to 70% when both the therapist and patient believe in the efficacy of the therapy. This powerful placebo effect is hypothesized to be an elicited conditioned response (Wickramasekera, 1977a, 1977c, 1980, 1985) based on the memory of prior healing. These memories of healing are more resistant to extinction if originally acquired on a partial rather than continuous reinforcement schedule. High and low hypnotic ability in interaction with threat perception (negative affect) is hypothesized to contribute to both the production and reduction of clinical symptoms. High and low hypnotic ability respectively are hypothesized to be related to dysregulation of the sympathetic and parasympathetic arms of the autonomic nervous system. Biofeedback is hypothesized to be the most effective for reducing clinical symptoms in people of low to moderate hypnotic ability. For people high in trait hypnotic ability, training in self-hypnosis or other instructional procedures (e.g., autogenic training, progressive muscle relaxation, meditation, CBT, etc.) will produce the most rapid reduction in clinical symptoms.

**Lynn, Steven Jay (1997).** Automaticity and hypnosis: A sociocognitive account. International Journal of Clinical and Experimental Hypnosis, 45 (3), 239-250.

This article provides an overview of a new theory of suggested involuntariness in hypnosis, developed in conjunction with Irving Kirsch. The theory is based on the following ideas. First, high hypnotizable participants enter hypnosis with a conscious intention to feel and behave in line with suggested experiences and movements. Second, people who are easily hypnotized hold firm expectations that they will succeed in following the suggestions of the hypnotist. Third, the intention and expectation in turn function as response sets in the sense that they trigger the

hypnotic response automatically. Fourth, given the intention to feel and behave in line with the hypnotist's suggestions, hypnotized individuals show no hesitation to experience the suggested movements as involuntary because (a) these movements are actually triggered automatically, and (b) the intention to cooperate with the hypnotist as well as the expectation to be able to do so create a heightened readiness to experience these actions as involuntary. - Journal Abstract

**1996**

**Walling, David P.; Baker, Jeffrey M.; Dott, Sharon G. (1996). A national survey of hypnosis training -- its status in psychiatric residency programs: A brief communication. International Journal of Clinical and Experimental Hypnosis, 44 (3), 184-188.**

Hypnosis training in psychiatric residency programs has not previously been well documented in the literature. This article examines the extent of such training in residency programs and the attitudes of residency directors to training and the use of hypnosis. A brief survey requesting information on hypnosis training was sent to all psychiatric residency directors in the United States. Sixty-three percent of responding program directors (n = 154) report offering either required or elective coursework in hypnosis. Of programs offering hypnosis training, the mean number of hours was 8, suggesting that many psychiatrists have only limited exposure to hypnosis during residency. The authors conclude that hypnosis training is widely variable within psychiatric residency programs and is dependent on the faculty and training director interests within individual programs.

**Zachariae, Robert; Sommerlund, Bo; Molay, Francine (1996). Danish norms for the Harvard Group Scale of Hypnotic Susceptibility, Form A. International Journal of Clinical and Experimental Hypnosis, 44 (2), 140-152.**

Norms for a Danish adaptation of the Harvard Group Scale of Hypnotic Susceptibility, Form A (HGSHS:A) are presented. Four samples tested from 1988 to 1991 (n = 166, n = 54, n = 95, and n = 61) were pooled, resulting in an aggregate sample of 376 participants. The normative data were generally congruent with earlier normative studies with regard to score distribution, item difficulty levels, and reliability. Studies using the Danish adaptation of the HGSHS:A as a screening instrument have shown the predictive value of the instrument in a Danish context. Data for a comparable American sample of volunteers (n = 170) tested by the same hypnotist were included in the analysis. A comparison revealed a marked difference for the posthypnotic suggestion item, hinting that cultural differences between the Danish and American samples with regard to expectancies and attitudes toward hypnosis may play a role. Further studies comparing attitudes toward hypnosis across different cultural contexts are needed to clarify this issue. - Journal Abstract

Repka, Renee J.; Nash, Michael R. (1995). Hypnotic responsivity of the deaf: The development of the University of Tennessee Hypnotic Susceptibility Scale for the Deaf. International Journal of Clinical and Experimental Hypnosis, 43 (3), 316-331.

The purpose of these two studies was to develop and test a measure that assesses the hypnotic responsivity of deaf individuals. The University of Tennessee Hypnotic Susceptibility Scale for the Deaf (UTHSS:D) is a signed, videotaped version of a standard hypnotic induction with 12 standard suggestions. Experiment 1 compared the behavioral and subjective hypnotic responsivity of deaf and hearing individuals using the UTHSS:D and the Field Depth Inventory (FDI), respectively. As compared to hearing subjects, deaf participants were found to be less responsive to hypnosis when assessed behaviorally (UTHSS:D) and equally responsive to hypnosis when assessed subjectively (FDI). Experiment 2 undertook a more comprehensive examination of the hypnotic responsivity of deaf individuals, using hearing individuals as controls. Three dimensions of hypnosis responsivity were assessed: behavioral (UTHSS:D), subjective (FDI), and interpersonal (Archaic Involvement Measure). Additionally, correlates of hypnotic responsivity (absorption, attitudes, expectations) were examined for the two groups. In Experiment 2, no significant differences were found between the deaf and hearing participant groups on any measures of hypnotic responsivity or on any measure of the correlates of hypnotic responsivity.

Lynn, Steven Jay; Myers, B.; Sivec, H. (1994). Psychotherapists' beliefs, repressed memories of abuse, and hypnosis: What have we really learned?. [Comment/Discussion] .

NOTES

1:

The authors are responding to an article by Michael D. Yapko in the same issue of AJCH, "Suggestibility and repressed memories of abuse: A survey of psychotherapists' beliefs." They are of the opinion that "Yapko's research and data analysis do not justify the conclusion that many, if not virtually all, therapists are naive, credulous, and out of touch with the scientific literature, although it is evident that certain therapists can be so described" (p. 184). They state that "Yapko's research is important insofar as it suggests that unfounded stereotypes of hypnosis persist even among Ph.D.- and M.D.-level clinicians" (p. 184).

Singh, Asha (1994, August). Positive and negative effects in hypnosis: Some contributing variables. [Paper] Presented at the annual meeting of the American Psychological Association, Los Angeles.

Subjects (N = 155) were randomly assigned to hypnosis with the Harvard hypnotizability scale, hypnosis with neutral imagery instead of the test items in the Harvard scale, and a control condition of a taped chapter read from an Introductory Psychology text. All procedures were taped. Subjects' attitudes toward hypnosis and psychiatric symptoms were first measured. Using self-report

measures, positive and negative effects were assessed at three time periods: (a) retrospective assessment of the experience during the intervention; (b) pre-post testing for assessing state immediately after the intervention; and (c) assessment 2 to 4 days later. Results showed a consistent trend at all three time periods. Hypnosis with imagery was more positive and less negative than the control condition. It was also more positive than the Harvard scale. Hypnosis with the Harvard scale was slightly less negative and slightly more positive than the control condition. Hypnotizability was not correlated with hypnosis effects; however, the intensity of hypnosis, or 'hypnoidal state', predicted positive effects (but not negative effects) at every time period in all three groups. Initial attitude was only slightly associated with effect; a positive attitude predicted an overall positive reaction to the experience for all groups, and negative attitude predicted reduced state anxiety 2 to 4 days later. Psychiatric symptomatology predicted a more negative experience during all conditions, but was associated with less negative feelings, more positive feelings, and reduced state anxiety afterward. In conclusion, hypnosis with a self-selected student population in an experimental setting is no more harmful than a control condition; in fact it is more enjoyable and more positive in its effects than the latter. Hypnosis has more positive and less negative effects when the Harvard test items are replaced by neutral imagery. Subject attributes play a more complex role than hypothesized in determining hypnosis effects. The implications of these findings are discussed. (ABSTRACT from Bulletin of Division 30, Psychological Hypnosis, Fall 1994, Vol. 3, No. 3.)

Wagstaff, Graham F.; Royce, C. (1994). Hypnosis and the treatment of nail biting: A preliminary trial. Contemporary Hypnosis, 11, 9-13.

A clinical trial was conducted examining the relative efficacy of therapeutic suggestions preceded by and without a hypnotic induction in the treatment of nail biting in 17 students. Outcomes showed a hypnotic induction added significantly to therapeutic benefits and was the only condition that resulted in symptom improvement. Results from only one session showed that 7 of 11 hypnosis subjects stopped nail biting compared to only 1 of 6 control subjects. Reports of "believed in efficacy" predicted treatment success better than ratings of motivation, hypnotic induction per se, or scores on the Creative Imagination Scale. However, within the group receiving hypnotic induction, hypnotic- depth scores significantly correlated with treatment success, suggesting that state factors such as dissociation might be involved.

#### NOTES

1:

The hypnotized Ss were given the T. X. Barber (1969) induction, a request for their depth estimate on a scale of 0-10, and then a set of suggestions to discourage nail biting. The suggestions were of four types: (1) to have a positive attitude, that nail biting is a habit that can be broken and that stopping will enhance attractiveness and self esteem; e.g., 'With just a little self control you will stop biting your nails and feel better about yourself.' (2) to stop the habit; e.g. to say to themselves, 'I will not bite my nails today/tomorrow,' five times each morning and at night, and whenever

the temptation arose. (3) to improve feelings of self-efficacy; e.g., 'If you ever feel the urge to bite your nails tell yourself that you want to break the habit and that you are perfectly capable of doing so. You are not weak.' (4) that the results would be outstanding; e.g. 'After only ten days or so ... you will have no desire to bite your nails, indeed the very thought of doing so will repulse you.'

Control subjects received the same instructions, without a hypnotic induction; the procedure was labeled a 'positive attitude for self discipline' technique.

Judges rated improvement without being aware of the Ss' self-report on whether they had stopped biting their nails. Judges' ratings correlated  $r = .94$  with Ss' statements about whether they had stopped the habit. Improvement scores also correlated significantly with belief the treatment would be effective ( $r = .60$ ) and Creative Imagination Scale scores ( $r = .53$ ), but not with motivation. The hypnosis group had significantly higher belief scores than the control group. Within the hypnosis group itself, hypnotic depth was the only variable to correlate significantly with improvement.

The Discussion stated, "However, taken together, the findings indicate that hypnotic induction added significantly to the therapeutic benefits of suggestions for the cessation of nail biting, and that Johnson and Barber's (1978) concept of 'believed-in efficacy' was more important in accounting for therapeutic success than motivation (at least as measured here), hypnotic induction per se, or the subject's proclivity for imaginative involvement. Nevertheless, belief still accounted for less than 40% of the variance in improvement. This may have been due to measurement error or insensitivity in the measures. Alternatively, or additionally, other factors may have been influential. For example, if CIS scores are considered to be indirect measures of hypnotic susceptibility, then belief was more influential than hypnotic susceptibility; however, from a hypnotic state theory perspective, the significant correlation between hypnotic depth (LSS scores) and improvement within the hypnosis group might suggest that some further feature of the 'hypnotic state' could still have been at work, such as a dissociative process (Hilgard, 1986). On the other hand, from a non-state perspective, perhaps subjects receiving hypnotic induction and reporting high depth scores might have felt more obliged to respond to the demand characteristics of the study, and tried harder to please the experimenter (Wagstaff, 1981); the general motivation questions used here could have been insensitive to such an effect" (p. 12).

Pekala, R. J.; Kumar, V. K.; Cummings, J. (1992). Types of high hypnotically susceptible individuals and reported attitudes and experiences of the paranormal and the anomalous. Journal of the American Society for Psychical Research, 86, 135-150.

A total of 575 subjects were given the Harvard Group Scale of Hypnotic Susceptibility and completed two self-report questionnaires that assessed the frequency of paranormal and unusual experiences and attitudes and beliefs towards such experiences. Subjects highly susceptible to hypnosis endorsed a significantly

greater number of the psi- related items and anomalous and unusual beliefs and experiences than did subjects who were not highly susceptible to hypnosis. Subsequent cluster analyses of the responses of the highly-susceptible subjects suggested that about 10% of the high susceptibles (about 1% of the total subject population) were especially likely to report psi-related and unusual experiences. The implications of using such individuals in parapsychological research to increase the effect size associated with paranormal events are discussed.

**Spanos, Nicholas P.; Burgess, C. A.; Cross, P. A.; MacLeod, G. (1992). Hypnosis, reporting bias, and suggested negative hallucinations. Journal of Abnormal Psychology, 101, 192-199.**

Examined the role of reporting bias in hypnotic negative hallucinations by using a paradigm in which reporting bias was assessed independently of perceptual change. In Experiment 1, highly hypnotizable subjects reported significant loudness reductions when tested for hypnotic deafness. Later, however, these subjects biased their reported loudness reductions in the absence of perceptual change, and their reporting bias scores were almost as large as their hypnotic deafness reports. Subjects also biased their ratings of strategy use. In Experiment 2, ratings of blindness given in response to a hypnotic negative visual hallucination suggestion were significantly correlated with reporting bias scores obtained in this paradigm. Although hypnotic blindness and hypnotic deafness correlated significantly, the partial correlation between these variables was nonsignificant when reporting bias scores were statistically controlled. Results are used to support a skeptical view of hypnotic response as being based on compliance.

**1991**

**Court, John (1991). Lord of the trance. Journal of Psychology and Christianity, 10 (3), 261-265.**

A verbatim account of hypnotically-based therapy utilizing Christian imagery serves as the basis for illustrating some of the benefits of this approach where therapist and client share the same value system. The interactions challenge some of the familiar objections to Christian involvement with hypnosis.

**Daglish, Mark R. C.; Wright, Peter (1991). Opinions about hypnosis among medical and psychology students. Contemporary Hypnosis, 8, 51-55.**

A survey was undertaken of opinions about hypnosis among first year medical and psychology students at the University of Edinburgh. Data are presented on the effects of self-estimated hypnotizability and sex, on opinions about hypnosis. The results are compared with those from similar studies conducted in Australia and the USA. Overall, the surveyed population showed a similar level of knowledge about hypnosis to that found among the general public.

Spanos, Nicholas P.; DuBreuil, Susan C.; Gabora, Natalie J. (1991). Four-month follow-up of skill-training-induced enhancements in hypnotizability. Contemporary Hypnosis, 8, 25-32.

Low hypnotizability subjects were exposed to skill training aimed at enhancing hypnotizability, and post-tested 2 weeks later. Those in a short delay condition were administered a second hypnotizability post-test within 2 weeks of the first, whilst those in a long delay condition were administered the second post-test 16-18 weeks after the first post-test. Skill-trained subjects in the two delay conditions did not differ on the first post-test. Skill-trained subjects in the two delay conditions did not differ significantly on behavioural or subjective indices of hypnotizability at either post-test. However, skill-trained subjects attained significantly higher hypnosis scores on both post-tests than did no-treatment control subjects. Attitudes towards hypnosis were also significantly enhanced by skill training, and these enhancements were maintained across the post-test intervals. Among the skill-trained subjects, post-tested hypnotizability was predicted by subjects' attitudes and by the trainer's ratings of subjects' receptivity and resistance towards the training.

#### NOTES

1:

"Immediately before each hypnotizability test, subjects' attitudes towards hypnosis were assessed with a 14-item questionnaire taken from Spanos, Cross et al. (1987). On this instrument higher scores indicate more positive attitudes" (p. 27).

"Immediately following each skill-training session, the trainer evaluated the subject's receptivity to the training using a nine-item checklist. The items described aspects of the training which experienced trainers in our laboratory have judged to be indicators of successful modification. The items (e.g. 'Does the subject volunteer that they found the ideas presented interesting/fun?') were scored dichotomously (yes/no), and summed to yield a receptivity to training score for each subject. The trainer also rated the degree to which each subject displayed resistance to the training on a global three-point scale" (p. 27)

The correlation between receptivity towards the skill training procedure and baseline attitudes toward hypnosis was .50.

"Some evidence indicates that untrained subjects (high hypnotizables included) exhibit substantial decrements in responsiveness to suggestions when they are exposed between testings to negative information about hypnosis (Barber & Calverley, 1964; Spanos & McPeake, 1975) or to information that alters their expectations about their responsiveness (Spanos, Gabora, Jarrett & Gwynn, 1989)" (p. 30)

"These findings suggest that the subjects who initially hold the most negative attitudes towards hypnosis are the least receptive to skill-training procedures. After training, these subjects continue to hold relatively negative attitudes towards hypnosis which limit the extent of their hypnotizability gain" (p. 30).

Spanos, Nicholas P.; DuBreuil, Susan C.; Gwynn, Maxwell I. (1991). The effects of expert testimony concerning rape on the verdicts and beliefs of mock jurors. Imagination, Cognition and Personality, 11, 37-51.

Mock jurors heard one of 4 versions of a 'date rape' case and deliberated in small groups, to a verdict. Exposure to the direct examination of an expert who testified about rape myths undermined belief in the defendant's testimony that sex with the complainant had been consensual, and increased the frequency of guilty votes. However, exposure to the expert's cross-examination reversed the effects of the direct examination on the frequency of guilty votes. Women jurors disbelieved the defendant and voted him guilty to a greater extent than male jurors, while in both sexes profeminist attitudes correlated with disbelief in the defendant's testimony but failed to correlate significantly with final verdicts. Implications are discussed.

Spanos, Nicholas P.; Gabora, Natalie J.; Hyndford, Christine (1991). Expectations and interpretations in hypnotic responding. Australian Journal of Clinical and Experimental Hypnosis, 19, 87-96.

A total of 304 subjects rated the extent to which they expected to respond to hypnotic suggestions immediately before being administered an hypnotic induction procedure. After the induction procedure, but before administration of the test suggestions, subjects again rated their expectations, and also rated the extent to which they planned to adopt each of three interpretations of suggestions: (a) resisting suggestions, (b) actively generating suggested effects, and (c) passive waiting. Subjects were then assessed on behavioural and subjective indexes of hypnotizability. Post- induction expectancies correlated with hypnotizability more highly than did pre-induction expectancies. The extent to which subjects adopted an active set towards suggestions also correlated with hypnotizability and, contrary to the response expectancy hypothesis, active interpretation scores predicted hypnotizability above and beyond the effects of post- induction expectancies. Theoretical implications are discussed.

#### NOTES

1:

"The most important findings of the study indicate that the extent to which subjects held active pre-suggestion interpretations predicted hypnotizability above and beyond the effects of post-induction expectancies. Relatedly, subjects with uniformly high expectancies continued to exhibit variability on both behavioural and subjective indexes of hypnotizability, and this residual variability correlated significantly with the degree to which subjects planned to adopt an active interpretation of suggestions. ....

"The present findings, along with those of Spanos, Gwynn, Gabora, and Jarrett, (1990), are inconsistent with the hypothesis that response expectancies are the direct determinant of responsiveness to suggestion. A number of other recent studies have also obtained results than [sic] run counter to the predictions of the response expectancy hypothesis. For example, two recent studies found that suggestion-induced wart regression was unrelated to subjects' post-suggestion expectations of treatment success (Spanos, Stenstrom, & Johnston, 1988; Spanos, Williams, & Gwynn, 1990). Relatedly, Spanos, Perlini, and Robertson (1989) found that suggestions produced significantly greater reductions in reported pain than did a

placebo, even though subjects in the suggestion and placebo treatments reported equivalent post-treatment expectations. Finally, Johnston, Chajkowski, DuBreuil, and Spanos (1989) found that false feedback substantially raised subjects' hypnotic response expectancies but failed to influence their level of subjective responding on tests of hypnotizability" (p. 93).

[Although ] "the extent to which subjects endorsed passive interpretations correlated in a negative direction to a slight but significant degree with hypnotizability ... at least some of the subjects who reported passive interpretations attained relatively high hypnotizability scores" (pp. 93-94). [The authors go on to give possible reasons why, on p. 94.]

Terr, Lenore C. (1991). Childhood traumas: An outline and overview. American Journal of Psychiatry, 148, 10-20.

Suggests 4 characteristics common to most cases of childhood trauma: visualized or otherwise repeatedly perceived memories of the traumatic event; repetitive behaviors; trauma-specific fears; and changed attitudes about people, life, and the future. Childhood trauma is divided into 2 basic types. Type I trauma includes full, detailed memories, "omens," and misperceptions while Type II trauma includes denial and numbing, self-hypnosis and dissociation, and rage. Characteristics of both types of childhood trauma can exist side by side. Such crossover Type I - Type II traumatic conditions of childhood are characterized by perceptual mourning and depression and childhood disfigurement, disability, and pain. Case examples are provided.

Appel, Philip R. (1990). Clinical applications of hypnosis in the physical medicine and rehabilitation setting: Three case reports. American Journal of Clinical Hypnosis, 33 (2), 85-93.

Hypnosis is useful in the rehabilitation setting to help patients master skills, to increase their sense of self-efficacy and self-esteem and, in general, to facilitate and accelerate their rehabilitation program. I used hypnosis with three patients where patient behaviors and beliefs were interfering with the rehabilitation treatment goals set by the patient and the health care team. Collectively, these cases demonstrate the use of hypnotic techniques in diagnosing and treating problems with patient compliance and assisting patients to gain greater benefit from their rehabilitation regimen. - Journal Abstract

Baker, Elgan L.; Hulsey, Timothy L.; Glenn, Michael B. (1990). Attitudes and practices regarding clinical hypnosis with psychotic patients--a survey: A brief communication. International Journal of Clinical and Experimental Hypnosis, 38 (3), 162-167.

Attitudes toward and actual use of hypnotherapeutic techniques with psychotic patients were assessed. Results are discussed in light of historical and current attitudes toward the use of hypnosis with psychotics. Respondents were selected

from the 1980 membership directory of the Society for Clinical and Experimental Hypnosis (SCEH). 80 respondents completed and returned the survey. Results indicate that the perceived usefulness of hypnosis with psychotics is currently quite high and negative attitudes toward its use quite low. The growth of the use of hypnotherapeutic techniques and the need for further research are discussed.

Labelle, L.; Lamarche, M. C.; Laurence, Jean-Roch (1990). Potential jurors' opinions on the effects of hypnosis on eyewitness identification: A brief communication. International Journal of Clinical and Experimental Hypnosis, 38 (4), 315-319.

The present study examined a selected group of potential jurors' opinions on the effects of hypnosis on eyewitness identification and testimony. A group of 78 undergraduate psychology and optometry students completed a 2-part multiple choice questionnaire. The first part assessed Ss' knowledge of several issues concerning eyewitness testimony. The second part of the questionnaire contained 11 items which assessed Ss' beliefs and expectations concerning the effects of hypnosis on eyewitness identification and testimony. It was found that Ss' opinions on the effects of hypnosis on eyewitness testimony and identification were at odds with current empirical findings. These results, in accord with the previous literature, suggest that it is imperative that the courts be informed of the use of hypnosis during police work and that adequate precautions be taken to avoid a potential source of miscarriage of justice.

Ross, Colin A. (1990). Twelve cognitive errors about multiple personality disorder. American Journal of Psychotherapy, 44 (3), 348-356

Presents 12 cognitive errors made by mental health professionals regarding multiple personality disorder. The errors include the mistaken idea that (1) multiple personality patients actually harbor more than one personality, (2) these patients can evade responsibility for their behavior because of their diagnosis, and (3) the disorder will disappear if treated with benign neglect. The errors are corrected by argument and by reference to research findings.

1989

Van Denberg, Eric J.; Kurtz, Richard M. (1989). Changes in body attitude as a function of posthypnotic suggestions. International Journal of Clinical and Experimental Hypnosis, 37, 15-30.

Hypothesized that highly hypnotizable subjects who remained amnesic for posthypnotic suggestions to improve body attitude would show greater changes than subjects who were not amnesic. Subjects given simulating instructions were used as a comparison group to assess experimental demands. 48 females were screened with the Harvard and assigned to one of 4 conditions: (a) high hypnotizable with amnesia suggestions, (b) high hypnotizable without suggested amnesia, (c) low hypnotizable simulator with amnesia, and (d) low hypnotizable simulator without suggested

amnesia. A fifth group was formed of those high hypnotizable subjects who remembered the suggestion despite instructions to the contrary. The Body Attitude Scale (Kurtz, 1966) was administered prior to and 3 days after the experimental suggestions. Results generally demonstrated that high hypnotizable amnesic subjects manifested the greatest attitudinal and phenomenological changes as a result of the posthypnotic suggestion, although conclusions were tempered by performance of simulating subjects. The implications for hypnosis research and clinical practice are discussed.

#### NOTES

1:

"The hypothesis that hypnotized subjects would report greater positive changes in affect, self-esteem, and social functioning than simulators was tested using a brief structured questionnaire. An analysis of Subjects responses to the questionnaire while with the 'blind' research assistant (simulators in role) revealed number significant differences between groups (N = 48) on six of the seven questions. ... An analysis of Subjects' responses to the questionnaire while being debriefed by the primary investigator (simulators out of role) revealed significant differences among groups (N = 48) on three of the seven questions. ... High hypnotizable subjects with maintained amnesia demonstrated a strong tendency to be the most responsive of all groups of subjects on the first and second assessment. In contrast, the high hypnotizable Ss for whom amnesia 'broke down' reported the fewest phenomenological changes of any of the five groups during the first assessment, and comparatively few during the second assessment. Also of note is that once out of their role, simulators in both conditions dramatically reduced their reporting of positive change" (pp. 23-24).

"Moreover, a closer examination of the data demonstrated that phenomenological and behavioral differences in the groups did appear at several points during the experiment. For example, the 10 high hypnotizable subjects told to explicitly remember the suggestion did so, while 3 of the 10 simulators in this condition claimed to have forgotten it. On debriefing, these Subjects reported they did this because they believed 'really hypnotized subjects wouldn't be able to remember anything, even if they were told they could.' Further, no simulator in the amnesia condition reported they could recall the suggestion, in contrast to the high hypnotizable subjects, 44% of whom said they did remember it. With regard to phenomenological differences, simulators stated during debriefing with the primary investigator that they intentionally faked changes on BAS, and that they experienced no true effects from the suggestion for positive body attitude change. In contrast, high hypnotizability amnesic subjects reported global, pervasive changes in their mood and self-esteem that went beyond specific alterations in attitudes toward their appearance. By comparison, high hypnotizable subjects told to remember the suggestion reported greatly increased self-absorption and acute awareness of the suggestion, 'sort of like a broken record in my head'" (pp. 25-26).

"As shown by the present study, amnesia maintenance can be quite problematic. Of 18 high hypnotizable subjects for whom amnesia was suggested, only 10 remained fully amnesic for the suggestion after 3 days. In addition, those 8 subjects for whom amnesia 'broke down' showed minimal shifts on BAS, or in reports of

phenomenological changes. Such frequent amnesia failure has been reported by other researchers, although the effectiveness of the suggestion is not always so compromised" (p. 26).

e Groh, Margaret (1989). Correlates of hypnotic susceptibility. In Spanos, Nicholas P.; Chaves, John F. (Ed.), Hypnosis: The cognitive-behavioral perspective (pp. 32-63). Buffalo, NY: Prometheus Books.

#### NOTES

1:

The author describes a non-linear relationship between imagery and hypnotizability and between absorption and hypnotizability. People good at imagery may be high or low on hypnotizability scales; the same is true for people high on absorption trait. However, people low on those traits generally are low on measured hypnotizability.

Donovan, David (1988). Factor analytic structure of attitudes towards hypnosis, guided imagery, and relaxation. [Unpublished manuscript] (Paper written for Comrey's Factor Analysis Course, UCLA)

#### NOTES

1:

Factor analysis of semantic differential responses of 212 adults regarding 3 terms (hypnosis, imagery, relaxation) placed imagery in an intermediate position between the extremes of hypnosis and relaxation. Both common and unique factors extracted are discussed.

Tobacyk, Jerome; Milford, Gary; Springer, Thomas; Tobacyk, Zofia (1988). Paranormal beliefs and the Barnum effect. Journal of Personality Assessment, 52 (4), 737-739.

Examined in 128 college students the hypothesis that paranormal beliefs emphasizing divinatory procedures that produce personalized feedback are associated with greater susceptibility to the Barnum effect, which is acceptance of bogus personality feedback consisting of relatively trivial statements with a high base rate. 76% of the Ss rated the accuracy of their personality descriptions favorably, showing a robust Barnum effect

1987

Spanos, Nicholas P.; de Groh, Margaret; de Groot Hans (1987). Skill training for enhancing hypnotic susceptibility and word list amnesia. British Journal of Experimental and Clinical Hypnosis, 4 (1), 15-23.

Subjects who pretested as low on hypnotic susceptibility received either cognitive skills training aimed at inculcating positive attitudes and interpretations concerning hypnotic responding, or no treatment. Trained subjects scored significantly and substantially higher on subjective and behavioral dimensions of susceptibility than controls. A second posttest assessed amnesia for a previously learned word list. Trained subjects showed more word list amnesia than either no treatment controls

or subjects who had been matched to the trained subjects in terms of posttest susceptibility. Theoretical implications for theories of hypnotic susceptibility are discussed.

**1986**

Judd, Fiona K.; Burrows, Graham D.; Dennerstein, Lorraine (1986). Clinicians' perceptions of the adverse effects of hypnosis: A preliminary study. Australian Journal of Clinical and Experimental Hypnosis, 14, 49-60.

Questionnaires were sent to all members of the Australian Society of Hypnosis and responses obtained from 202 members and associate members who used hypnosis clinically. Respondents' experience in the use of hypnosis and the frequency of use of hypnosis as a treatment modality varied. Overall 43.5% of respondents reported adverse effects with one or more patients over the preceding year. Most adverse effects attributed to hypnosis were transient and included development of panic or extreme anxiety, development of excessive dependence and difficulty in terminating hypnosis. Exacerbation or precipitation of significant depression was an infrequent but serious adverse effect attributed to hypnosis. Other infrequent adverse effects included symptom substitution, acting out behaviour, fantasied sexual seduction, precipitation or worsening of psychotic illness or difficulties in the management of organic conditions. The difficulties were acknowledged of differentiating between the effects of hypnosis itself and other components of the therapeutic transaction, but the results of this survey suggested both that hypnosis be employed clinically by properly trained professionals and that further sensitive clinical research is needed in the area.

**1986**

Madigan, R. J.; Bollenbach, A. K. (1986). The effects of induced mood on irrational thoughts and views of the world. Cognitive Therapy and Research, 10 (5), 547-562.

Sixty college students participated in an experiment concerning the influence of somatic mood induction statements on measurements of irrationality as defined by Ellis. Subjects were randomly assigned to depression, elation, and neutral mood induction groups. There were significant differences between groups on mood and irrationality. Results are discussed in terms of the Ellis and Beck cognitive models of depression, the Isen cognitive loop model, and the relationship between irrationality and depression. This study added irrational thinking as defined by Ellis to the growing list of cognitions that have been manipulated by mood, and it supports a body of findings that demonstrate the reciprocal influence of cognition and mood in depression. The study also has implications for the Beck and Ellis hypothesis that cognitions are the dominant causes of depression.

McConkey, Kevin M. (1986). Opinions about hypnosis and self-hypnosis before and after hypnotic testing. International Journal of Clinical and Experimental Hypnosis, 34, 311-319.

Before hypnotic testing, Ss completed a questionnaire on their opinions about hypnosis and self-hypnosis. Approximately 1 week later, they completed a similar questionnaire that included questions about their experiences of hypnotic testing. Data are presented concerning Ss' agreement with statements about hypnosis and self-hypnosis. Findings are discussed in terms of their generality and in terms of whether Ss' opinions are consistent with scientific evidence.

Spanos, Nicholas P.; Robertson, Lynda A.; Menary, Evelyn P.; Brett, Pamela J. (1986). Component analysis of cognitive skill training for the enhancement of hypnotic susceptibility. Journal of Abnormal Psychology, 95, 350-357.

Four treatments to enhance the hypnotic responsiveness of subjects who pretested as low in hypnotic susceptibility were compared. Complete skill training included information aimed at encouraging (a) positive attitudes, (b) the use of imagery strategies, and (c) an interpretation of hypnotic behavior as active responding. Partial training included only components (a) and (b). Both training packages enhanced attitudes toward hypnosis to an equivalent degree. However, complete training was much more effective than either partial training or no treatment at enhancing behavioral and subjective responding on two different posttest scales of hypnotic susceptibility. More than half of the subjects who received complete training, but none of the partial training or control subjects, scored in the high-susceptibility range on both posttests. Subjects explicitly instructed to fake hypnosis and those in the complete skill-training treatment exhibited significantly different patterns of posttest responding. Findings support social psychological perspectives that emphasize the importance of contextual factors in hypnotic responding.

1986-87

Spanos, Nicholas P.; Voorneveld, Peggy W.; Gwynn, Maxwell I. (1986-87). The mediating effects of expectation on hypnotic and nonhypnotic pain reduction. Imagination, Cognition and Personality, 6, 231-245.

High and low hypnotically susceptible subjects were assigned to three treatments and administered a baseline trial and two posttest trials of finger pressure pain. Subjects in one treatment received hypnotic analgesia on both posttest trials while those in a second treatment received hypnotic analgesia before their first posttest trial and waking instructions to "do whatever you can to reduce pain" before their second posttest trial. Controls received their two posttest trials without intervening treatment instructions. During hypnotic analgesia high susceptibles reduced reported pain, increased pain tolerance and rated themselves as more deeply hypnotized than low susceptibles. Low susceptibles reduced pain to a significantly greater degree under waking instruction than under hypnotic analgesia. Importantly, lows given waking instruction reduced pain to the same degree as highs given hypnotic analgesia. These findings underscore the importance of attitudes and expectations in hypnotic pain reduction. However, they are inconsistent with the view that high susceptibles are intrinsically more able than low susceptibles to cognitively control pain.

## NOTES

1:

"Social psychological accounts of suggested analgesia emphasize the role of subjects' attitudes and expectancies in the cognitive control of pain. According to this perspective high susceptible subjects usually hold positive attitudes and expectancies toward hypnosis and are strongly invested in validating their role as 'good' hypnotic subjects. ... [while Lows] often hold negative attitudes about hypnosis and negative expectations about their responsiveness to hypnosis even before they are tested [and their poor performance] only confirms their already negative attitudes and expectancies. Standard analgesia suggestions and the suggestions employed on scales hypnotic susceptibility are often similarly constructed. In both cases these suggestions are typically worded in the passive voice to imply that things are happening to rather initiated by subjects (e.g., 'Your hand is becoming numb dull and insensitive,' 'Your arm is stiff and rigid.'). Furthermore, both types suggestions usually invite subjects to imagine specific events (e.g. 'Imagine Novocain being injected into your hand,' 'Imagine your arm is held tightly by a cast.'). Thus the usual superiority of high susceptibles at suggested analgesia may occur because expectations from the hypnotic susceptibility test situation are carried over to the pain testing situation" (p. 232).

"Low susceptibles subjects may fail to exhibit hypnotic responding for at least two different reasons. Some lows may be quite willing to cooperate with the proceedings, but hold negative or inaccurate expectations that interfere with appropriate responding. Other low susceptibles, however, may be purposefully uncooperative. They may become actively invested in presenting themselves as unresponsive to hypnotic procedures because they wish to be seen as independent-minded and nongullible. ...

"Alternatively we anticipated that the low susceptibles would attempt to validate their status as independent-minded and nonsuggestible. To this end they would show little pain reduction under a hypnotic condition but large pain reductions when the situation was divorced from hypnosis and pain reduction was defined in terms of independent self- control. Unlike the high susceptibles, we expected the low susceptibles to rate themselves as un hypnotized under both the hypnotic and nonhypnotic situations" (pp. 233-34).

"Our major finding, however, was that the low susceptible subjects instructed to try and reduce pain in a context that was divorced from hypnosis and defined in terms of self control exhibited just as much pain reduction as high susceptible subjects. In sum, hypnotic susceptibility correlated either positively with degree of pain reduction (under hypnosis) or negatively with degree of pain reduction (under instruction), depending upon the expectations conveyed to subjects by their experimental instructions" (p. 241).

"The present findings clearly contradict the hypothesis that low susceptibles lack the cognitive capacities required to reduce pain to the same degree as high susceptibles. ... In short, low susceptibles usually exhibit less hypnotic analgesia than high susceptibles not because of intrinsic deficiencies in the pain-reducing capacities of low susceptibles, but instead, because low susceptibles hold negative attitudes and

expectations about hypnosis that interfere with the use of their pain reduction abilities" (p. 242).

Wilson, L.; Greene, E.; Loftus, Elizabeth F. (1986). Beliefs about forensic hypnosis. International Journal of Clinical and Experimental Hypnosis, 34 (2), 110-121.

The beliefs people hold about hypnosis have an impact on the behavior of a witness who is hypnotized and on juries who hear these witnesses and weigh hypnotically influenced testimony. Students in Experiment 1 and registered voters from the community in Experiment 2 responded to questions about forensic hypnosis. Over 70% of the students as compared to about 50% of the community members were favorable toward the use of hypnosis by police for memory enhancement. In both groups, however, twice as many people reported that they would put less faith rather than more faith in the testimony of someone who had been hypnotized. A substantial portion of the students affirmed common myths about the effects of hypnosis on memory and behavior.

Gottschalk, Louis A. (1985). Hope and other deterrents to illness. American Journal of Psychotherapy, 39, 515-524.

Reviews animal and human research demonstrating that events during early development influence vulnerability to physical and mental illness. In addition, effectiveness of coping methods used to deal with problems of living can affect susceptibility to illness. The intervening mechanisms between stressful life experiences and illness appear to involve physiological homeostasis and immune competence.

**1984**

372 preclinical medical students from the University of Sydney, Australia were surveyed concerning their beliefs about hypnosis and its medical use. Several "myths" concerning hypnosis emerged (e.g., hypnosis is a passive state, there are sex differences in hypnotizability, posthypnotic amnesia is inevitable, and there is automatic obedience to the hypnotist). Sex differences in expectations of hypnotizability were found. Relatively few physical problems were perceived as being amenable to treatment by hypnosis and the proportion of medical practitioners in the national professional hypnosis society was grossly underestimated.

Spanos, Nicholas P.; Kennedy, Sharon; Gwynn, Maxwell I. (1984). The moderating effects of contextual variables on the relationship between hypnotic susceptibility and suggested analgesia. Journal of Abnormal Psychology, 93 (3), 285-294.

Assessed 75 undergraduates high, medium, or low on hypnotic susceptibility (the Carleton University Responsiveness to Suggestion Scale) on the cold pressor task before and after 1 of 3 instructional treatments. The treatments were (a) brief instructions to try to reduce pain, (b) the same analgesia instructions preceded by a hypnotic induction procedure, and (c) no hypnotic induction or instructions. In the hypnotic treatment, susceptibility correlated significantly with reductions in reported pain, and high-susceptible Ss reported significantly larger pain reductions than did control ss. In the instruction-alone treatment, there was no significant relationship between susceptibility and pain reduction, and Ss at all 3 susceptibility levels reduced reported pain significantly more than did controls and as much as did high-susceptible hypnotic Ss. Findings suggest that the correlation between hypnotic susceptibility and hypnotic analgesia is moderated by Ss attitudes and expectancies concerning their own performance in situations defined as related to hypnosis

**1983**

McIntosh, I. B.; Hawney, M. (1983). Patient attitudes to hypnotherapy in a general medical practice: A brief communication. International Journal of Clinical and Experimental Hypnosis, 31 (4), 219-223.

A study to investigate public awareness of hypnotherapy planned to identify sources of information and compare their impact on patient acceptance of hypnosis in medical treatment. A structured questionnaire was presented to a random sample of

patients coming to a medical center; the sample was representative of 10% of the total medical center population. 910 people participated and 884 questionnaires were analyzed. 80% of the sample had previously heard of the use of hypnosis in medicine, 36.6% would accept hypnotherapy if recommended by their doctor, 5.5% would refuse treatment by hypnosis, and almost all of the remainder of the sample would request further information before making a decision. There was a significant association between preknowledge of medical hypnosis and acceptance of hypnotherapy as was there between source of information and attitude to treatment. 41% of the sample were unaware of any medical indications for hypnosis.

#### NOTES

1:

An apparent discrepancy in the abstract between "80% of patients had previously heard of the use of hypnosis in medicine" and "41% of the sample were unaware of any medical indications for hypnosis" may be understood from the following statement: "Of the total sample, 41% were unable to name any medical condition appropriate for hypnotherapy and 26% of those previously aware of medical hypnosis were unable to name a disorder suited to such treatment" (p. 221).

Saavedra, Ramon Luis; Miller, R.J. (1983). The influence of experimentally induced expectations on responses to the Harvard Group Scale of Hypnotic Susceptibility, Form A. International Journal of Clinical and Experimental Hypnosis, 31, 37-46.

: A sample of 75 female and 63 male undergraduates were told that their hypnotizability was predictable through the application of a battery of questionnaires and physiological measures. Three levels of hypnotizability expectations were created, with 3 groups of Ss informed that they were highly hypnotizable, moderately hypnotizable, or low in hypnotizability, respectively. A control group received no such expectations. All Ss were then administered the Harvard. Results indicated a significant main effect due to the assigned hypnotizability expectations. Only Ss in the low expectation group, however, scored significantly differently from the other groups on the Harvard. Four other variables were examined as covariates: locus of control, attitude toward hypnosis, absorption, and self-predictions of hypnotizability. All but locus of control correlated significantly with the Harvard. It also was shown that the degree to which assigned expectations influenced Harvard scores was a function of the confidence Ss had in those expectations.

#### NOTES

1:

The authors state that research has shown that it is easier to lower hypnotizability scores by providing negative expectancies than to increase hypnotizability scores through provision of positive expectancies. In this study, very little of the variance of hypnotizability scores was accounted for by the expectancy manipulation.

1981

Yanchar, R. J.; Johnson, H. J. (1981). Absorption and attitude toward hypnosis: A moderator analysis. International Journal of Clinical and Experimental Hypnosis, 29 (4), 375-382.

2 factors which have been found to correlate to a small degree with susceptibility are (a) an individual's attitude toward being hypnotized and (b) an individual's capacity for subjective involvement in an experience (absorption). The present study was an attempt to replicate previous findings by Spanos and McPeake (1975) and to extend these findings to determine if there was a significant interaction between these 2 factors in their relationship to susceptibility. 99 Ss (65 females and 34 males) completed the absorption questionnaire of Tellegen (1979) and the attitude questionnaire of Barber and Calverley (1966). Their hypnotic susceptibility was assessed with the Harvard Group Scale of Hypnotic Susceptibility, Form A (Shor & E. Orne, 1962). Attitude and absorption were found to have small positive correlations with susceptibility, results which corroborate previous research. The multiple regression analyses indicated that there were no significant interactions between the factors of attitude, absorption, and sex.

1980

Fromm, Erika (1980). Values in hypnotherapy. Psychotherapy: Theory, Research and Practice, 17 (4), 425-430.

Hypnosis is an altered state of consciousness characterized by a regression in the service of the ego along with increased access to the unconscious. This makes it possible to achieve lasting therapeutic results faster in hypnosis than in the waking state. Hypnosis is also a state of decreased vigilance, a vulnerability that involves dangers if a patient is in the hands of a poorly trained, incompetent, or unscrupulous therapist. In general, the same human and moral values that guide responsible therapists with patients in the ordinary waking state must guide them with patients in hypnosis, only more so. Contemporary permissive hypnotherapists do not superimpose their own wills or personalities onto patients but provide support, help patients face the frightening parts of the unconscious, and thus aid them in coping with conflicts and gaining full autonomy and freedom from fear. (11 ref).

1978

Hiscock, Merrill (1978). Imagery assessment through self-report: What do imagery questionnaires measure?. Journal of Consulting and Clinical Psychology, 46, 223-229.

Four studies examined imagery questionnaires and addressed issues of reliability, agreement among different questionnaires, social desirability, and construct validity. The Betts, Paivio, and Gordon scales were examined. In two studies the Betts and Paivio correlated .45-.50, but correlations involving the Gordon were inconsistent from one study to the next. Imagery measures generally were not influenced by social desirability. Factor analysis indicated that subjective and

objective measures of visualization are independent. Concludes that imagery is not a unitary construct and that criteria other than visuospatial tests may be appropriate for validating imagery questionnaires.

Spanos, Nicholas P.; Rivers, Stephen M.; Gottlieb, Jack (1978). Hypnotic responsivity, meditation, and laterality of eye movements. Journal of Abnormal Psychology, 87 (5), 566-569.

Right-handed male subjects were pretested on a number of person variables; they then meditated for eight sessions. Measures of hypnotic responsivity, meditating skill, imaginal abilities, and attitudes toward hypnosis loaded on a common factor that was labeled sustained nonanalytic attending. However, laterality of eye movement (left moving) failed to load on this factor. The implications of these findings for current theorizing concerning hypnosis and meditation are discussed.

1976

Gardner, G. Gail (1976). Attitudes of child health professionals toward hypnosis: Implications for training. International Journal of Clinical and Experimental Hypnosis, 24, 63-73.

A survey of child health professionals -- pediatricians, pediatric nurses, child psychologists, and child psychiatrists -- revealed that they have generally positive attitudes toward hypnosis but little knowledge of its specific advantages or applications. Recommendations are made for designing training opportunities in hypnosis which might enhance the probability that the professional will actually use hypnosis or refer a child else where for hypnotherapy.

King, Dennis R.; McDonald, Roy D. (1976). Hypnotic susceptibility and verbal conditioning. International Journal of Clinical and Experimental Hypnosis, 24, 29-37.

18 Subjects highly susceptible to hypnosis and 18 Subjects refractory to hypnosis were studied in a verbal conditioning task modeled after the one used by Taffel (1955). Results indicated that the highly susceptible group showed significantly greater conditioning than the low group. Awareness of the reinforcement contingency by S was not related to the learning task nor to hypnotic susceptibility. A measure of S's attitude toward the reinforcement cue during learning showed that the highly susceptible group had a more positive set toward the cue, whereas the low group tended to respond to it in a neutral or negative manner. Results were interpreted in terms of the theoretical nature of hypnotic susceptibility.

NOTES

hey review literature on attempts to correlate hypnotizability with verbal conditioning ability. 1:

Volunteer students participated; screened by HGSHS:A: highs 10-12, lows 0-4.

**Verbal conditioning procedure:** S viewed 100 3x5 cards on which were a two-syllable, past tense verb, below which typed in upper case letters on one line were the pronouns I, WE, HE, SHE, THEY, and YOU (randomly assigned to different orders). E was blind to hypnotizability. E instructed S to make up a sentence using the verb and a pronoun; gave no response for first 20 trials; said "good" to usage of I or WE during conditioning.

Afterwards, S filled in an Awareness Questionnaire (What was purpose? If E gave cues, what were they? If you noticed cues, what do you think they indicated?) and attitude toward the reinforcement cue (Did you notice that I did anything special? What? Did I say "good" for a special reason? What was the reason for my saying "good"? How did hearing the word "good" affect you during the experiment? IN a positive, negative, or neutral way?)

**Results.** Groups did not differ at baseline but did differ at Blocks 2 (highs 9.7 vs lows 6.3;  $p < .05$ ) and 3 (highs 10.4 vs lows 6.3;  $p < .05$ ). Although the High group continued to maintain a somewhat higher level of responding than the Low group during extinction (9.8 vs 7.6), this difference did not reach statistical significance. (The graph shows an increase for Lows during extinction!)

Using a liberal definition of awareness and a learning index computed for each S by subtracting his operant level of response from the mean number of correct responses shown during the 3 blocks of acquisition trials, Subjects were ordered and a median test applied; contingency coefficient of .28 not significant ( $p < .10$ ).

Attitude significantly differentiated High and Low hypnotizability groups (see Table 2) with Highs more often responding in positive manner to reinforcement cue and Lows giving a neutral rating. Awareness of reinforcement contingency was equally represented in High and Low groups. The Aware High Positive groups learning index differed significantly from Aware Low Neutral group ( $p < .01$ ); the Unaware Low Positive group ( $p < .05$ ); and the Unaware Low Neutral group ( $p < .001$ ).

Thus, the Aware High Positive group's learning index score was significantly higher than that of the 3 Low groups. Also, the Unaware High Positive group differed significantly from the Unaware Low Neutral group ( $p < .05$ ). No other High groups differed from the Low groups and none of the High groups differed among themselves.

Among the Low groups, only the Unaware Low Positive group differed significantly from the Unaware Low Neutral group ( $p < .05$ ).

**Discussion.** Data show that hypnotizability is important in response to verbal conditioning, extending findings of Das (1958) by showing that primary suggestibility is associated with operant as well as classical conditioning but also those of Weiss et al. (1960) in illustrating that higher hypnotic susceptibility leads to enhanced verbal conditioning, using an improved measure of hypnotic susceptibility.

Awareness of reinforcement contingencies is not sufficient to account for subject differences in verbal conditioning; the characteristics tapped by HGSHS:A produce conditioning which cannot be accounted for by awareness alone.

The fact that high susceptible Subjects here rated E's cue more positively than low susceptible Subjects is further consistent with some of the personological descriptions associated with hypnotic susceptibility which have been offered by

Hilgard (1968). In addition, Cairns and Lewis (1962) and Spielberger et al. (1962) found that persons who assigned more positive value to the kind of reinforcement present in verbal conditioning experiments produced greater conditioning than Subjects whose attitudes were less favorable or non-committal toward the reinforcement. This relationship is not clear-cut in the present data in that although the High groups had an overall more positive attitude regarding reinforcement, only the Aware High Positive group learned better than all the Low groups, while the only other High group learning better than a Low group was the Unaware High Positive which had a significantly better learning index score than the Unaware Low Neutral group. Moreover, positive attitude did not differentiate learning within the High groups or the Low groups. Thus, the present data are unclear regarding the role attitude plays in the acquisition of verbally conditioned responses.

The roles of awareness and attitude could probably be better defined in future research using larger experimental groups. The attitude measure employed here was a gross one and a more sophisticated assessment of the valence characteristics of reinforcement cues could reveal more complex relationships in subsequent research. In addition, a more careful assessment than was done here of the role of cooperation and demand characteristics would contribute substantially to understanding more completely the effect of awareness on these phenomena.

The general indications regarding attitude may in part account for the increased interest in production of conditioned responses in Figure 1 shown by the Low group (graph) during the extinction phase of this experiment. Although highly susceptible Subjects show a decrease in the correct response with nonreinforcement, low susceptible Subjects begin to evidence an increase in the correct response. The attitude measure indicates that Subjects in the Low group did not respond positively to the reinforcement cue, and one of these Subjects reported in the interview that he did not like being told what to do by the E. It can be speculated that these Subjects were aware of the reinforcement contingency but did not "cooperate" until the reinforcement was absent. This follows the interpretation of Farber (1963) who found that aware Subjects who conformed to the demand characteristics of the experimental situation showed greater verbal conditioning than those who were aware and nonconforming. It thus appears that a willingness to go along with E's expectations and a positive, cooperative attitude are common features in individuals who make good hypnotic Subjects and who evidence an enhanced propensity for verbal conditioning.

1975

Mather, Marcia; Degun, Gian S. (1975). A comparative study of hypnosis and relaxation. British Journal of Medical Psychology, 48, 55-63.

NOTES

1:

The results of this research are as follows: Hypothesis 1. Post hypnotic suggestions would be performed better than post-relaxation suggestions ( $p < .05$ )

Hypothesis 2. Learning would be an important variable in the efficacy of post-hypnotic suggestions (n.s.) Hypothesis 3. Suggestions made towards the end of the

experimental session would be more effective than suggestions at the beginning; the assumption being that the trance might deepen with the passage of time (n.s.) Hypothesis 4. There would be a significant difference in heart rate between the waking and hypnotic states (n.s.) Hypothesis 5. There would be a shift in attitudes of the subject in favor of hypnosis from pre- to post-experiment due to an increase in susceptibility following training. (p.<.01)

The study employed 3 groups, 2 subject groups; there were 1 hypnosis and 1 relaxation session per subject, in a randomized AB, BA design. The relaxation condition only asked the subject to lie on a couch and relax; no relaxation instructions were given, therefore it is not really analogous to relaxation training given in clinical settings. A posthypnotic suggestion was given - to dream on a subject related topic, then to awaken, and to carry out an action.

Spear, J. E. (1975). The utilization of non-drug induced altered states of consciousness in borderline recidivists. American Journal of Clinical Hypnosis, 18, 111-126.

Utilizing non-drug induced altered states of consciousness, various modes of interior reflection, behavior modification and reprogramming of conscious attitudes and values were utilized with 49 borderline recidivists. Such offenders were so determined by the Department of Corrections, Probation and Parole Office, District II. No coercion was used to induce such individuals to enter the program and there was no reprisal for stopping therapy at any time. Over a two and one-half year period the recidivist rate among this group was less than 5%. It is suggested that non-drug induced altered states of consciousness combined with indirect as well as symbolic techniques may prove to be the most effective means of criminal rehabilitation.

#### NOTES

1:  
Borderline recidivists were "individuals, who, in the opinion of the P.O. [probation officer] were, in all probability, to be returned to prison within a few months, or less, if there wasn't a major change in attitude and actions" (p. 111). Therapy employed closed circuit TV with bi-directional audio and induction of altered state of consciousness using an ophthalmology-type rotary prism. Therapy involved (s) recall of relaxed state when under stress, (2) exploration of early conditioning events, (3) self evaluation during the ASC, (4) use of symbolic mental exercises and mental practice for similar circumstances in normal waking state, (5) suggestions for setting goals and ideals, (7) a type of logotherapy, (7) 'nudging' the person to examine their relationship with their concept of God. The author noted in the parolees: (1) low levels of self esteem, (2) depression, (3) going into deep levels of altered states once trust was established with the therapist.

1969

Barber, Theodore Xenophon (1969). An empirically-based formulation of hypnosis. American Journal of Clinical Hypnosis, 12 (2), 100-130.

A formulation is presented which does not invoke a special state of consciousness ("hypnosis" or "trance") to account for the behaviors that have been historically associated with the word hypnotism. Instead, so-called hypnotic behaviors - e.g., "analgesia," "hallucination," "age-regression," and "amnesia" - are conceived to be functionally related to denotable antecedent variables which are similar to those that control performance in a variety of interpersonal test-situations. The antecedent variables which determine behavior in a "hypnotic" situation include Ss' attitudes, expectancies, and motivations with respect to the situation, and the wording and tone of instructions- suggestions and of questions used to elicit subjective reports. The formulation is exemplified by several dozen experimental studies, and prospects for further research are delineated.

1968

Goss, Allen; Morosko, Tom (1968). Stanford Hypnotic Susceptibility Scale, Form A: Score distribution of volunteer subjects. International Journal of Clinical and Experimental Hypnosis, 237-242.

Investigates the applicability of the reported norms of the Stanford Hypnotic Susceptibility Scale, Form A to a population which differs from the normative sample. 40 "true volunteer" dental students were found to score well above the 533 "volunteer" normative sample due mainly to the reduced percentages of low hypnotic susceptibility Ss. The effects of schooling, volunteering, and implications concerning the relationship between personality and hypnotic susceptibility in the volunteer sample are discussed. 1965

Moss, C. Scott; Rigger, G.; Coyne, L.; Bishop, W. (1965). Some correlates of the use (or disuse) of hypnosis by experienced psychologist-therapist. International Journal of Clinical and Experimental Hypnosis, 13, 39-50.

147 psychologist-psychotherapists were compared on the basis of their attitude towards the employment of hypnosis as a technique in psychotherapy. 1 finding was the absence of extensive differences between the 2 groups in the use of most other therapy techniques, though the hypnosis-favorable group made somewhat more active use of a wider variety of approaches. Doctrine and experience level per se were not significant determinants of the behavior in question. A major finding was that those favorably disposed were inclined to represent themselves as significantly more objective (rather than clinical or intuitive) in their frame-of-reference. A number of significant biographical correlates were found which led to the advancement by speculation of vignettes of the 2 extreme attitude groups. (PsycINFO Database Record (c) 2002 APA, all rights reserved)

Zamansky, H. S.; Brightbill, R. F. (1965). Attitude differences of volunteers and nonvolunteers and of susceptible and nonsusceptible hypnotic subjects. International Journal of Clinical and Experimental Hypnosis, 13 (4), 279-290.

A form of the Semantic Differential, containing 9 concepts related to hypnosis and research, was administered to 96 hypnotically inexperienced male Ss. The Ss were later asked to volunteer for a hypnotic experiment, and the hypnotic susceptibility of all volunteers ( $N = 51$ ) was then determined. Semantic Differential responses of volunteers and nonvolunteers and of highly susceptible and unhypnotizable Ss were compared. Differences between groups, in both comparisons, were generally not statistically significant, a finding which suggests that there is no simple relationship

between paper-and-pencil measures of attitudes and volunteering for hypnotic experiments or hypnotizability. (PsycINFO Database Record (c) 2002 APA, all rights reserved)

1964

Leckie, F. H. (1964). Hypnotherapy in gynecological disorders. International Journal of Clinical and Experimental Hypnosis, 12 (3), 121-146.

The attitude and position of a gynecologist employing hypnotherapy in clinical practice is emphasized. Particular consideration is given to dysmenorrhea (25 cases), dyspareunia (30 cases), vaginismus (15 cases), frigidity (12 cases), and anxiety states encountered in gynecological practice (26 cases). An indication is given of the general method and of the specific pattern of treatment, which initially is directed to symptom removal by direct suggestion. When this method proves ineffective, special techniques are employed to carry out therapy at a deeper level. Details of clinical data of all cases are presented together with evaluation of the percentage of success achieved. Results have proved encouraging. Several illustrative cases are described.

Levitt, Eugene E.; Brady, J. P. (1964). Expectation and performance in hypnotic phenomena. Journal of Abnormal and Social Psychology, 69, 572-574.

Expectations concerning the occurrence of 7 phenomena through hypnotic suggestion were solicited from 12 female Ss, all of whom scored high on the Stanford Hypnotic Susceptibility Scale. Attempts were then made to induce these phenomena in the Ss. The results indicate that performance and expectation were discordant about as often as they were in accord. There appeared to be an interaction between task and expectation-performance accord. (PsycINFO Database Record (c) 2002 APA, all rights reserved)

NOTES

1:

When Ss were not manipulated into their expectations, the relationship between expectancy and hypnotic behavior was minimal.

Melei, Janet P.; Hilgard, Ernest R. (1964). Attitudes toward hypnosis, self-predictions, and hypnotic susceptibility. International Journal of Clinical and Experimental Hypnosis, 12, 99-108.

Correlation of questionnaire results from a sample of 1326 students with hypnotic susceptibility scores of 340 of these later hypnotized showed (a) that those volunteering for hypnosis were more favorable in attitude than those who did not volunteer; (b) attitudes toward hypnosis were predictive of susceptibility for females, not for males; and (c) self-predictions yielded significant low positive correlations with actual susceptibility for both sexes. Other findings concern differences between those having prior experience with hypnosis and those without such experience.

Rosenhan, D. L.; Tomkins, S. S. (1964). On preference for hypnosis and hypnotizability. International Journal of Clinical and Experimental Hypnosis, 109-114.

44 male and 44 female coerced volunteers, who either preferred or did not prefer to participate in hypnosis experiments, were compared with regard to (a) scores on the EPPS, (b) birth order, and (c) performance on the Harvard Group Scale of Hypnotic Susceptibility. Sex-specific personality differences were obtained between Ss who preferred and did not prefer hypnosis, but these personality differences were not apparently relevant to hypnotizability. However, for females, preference for hypnosis correlated .41 with hypnotizability; for males no relationship was obtained. Some theoretical and methodological implications of these data are discussed. (PsycINFO Database Record (c) 2002 APA, all rights reserved)

Shor, Ronald E. (1964). The accuracy of estimating the relative difficulty of typical hypnotic phenomena. International Journal of Clinical and Experimental Hypnosis, 12 (3), 191-201.

College student Ss with little or no reported prior knowledge about hypnosis were able to estimate with reasonably high objective accuracy the relative difficulty levels (pass percents) of a standardized set of carefully described typical hypnotic items. The correlation between the estimated percentages and the actual test responses as derived from 4 college student reference samples was .73. Subsidiary normative data are presented. (PsycINFO Database Record (c) 2002 APA, all rights reserved)

1963

Brightbill, Roger; Zamansky, Harold S. (1963). The conceptual space of good and poor hypnotic subjects: A preliminary exploration. International Journal of Clinical and Experimental Hypnosis, 11, 112-121.

A form of the Semantic Differential, containing 8 concepts related to hypnosis and research, was administered to 12 deeply hypnotizable and 14 nonsusceptible Ss. The good hypnotic Ss evaluated all the concepts more favorably than did the poor hypnotic Ss, with the greatest differential between the 2 groups occurring on the concept hypnosis. Moreover, the susceptible Ss perceived hypnosis as closer in connotative meaning to such concepts as experiment and professor, than did the nonsusceptible Ss. All differences between the 2 groups of Ss were of small absolute magnitude, however. Therefore, while the results suggest a relationship between hypnotic susceptibility and attitude toward hypnosis, they appear to preclude the use of the Semantic Differential as a practical predictor of hypnotic susceptibility.

Farberow, N. L. (1963). Taboo topics. New York: Atherton Press (Prentice-Hall). (Reviewed in American Journal of Clinical Hypnosis by Leo Wollman, 1964, 6, 373-374)

## NOTES

1:

Includes chapter by J. G. Watkins on hypnosis, along with other socially taboo topics such as sex, suicide, death, etc. Watkins notes the reluctance of scientists to study hypnosis, the magical or mystical meanings people attach to hypnosis, the death fears activated by hypnosis for some people, the negative impressions conveyed by Sigmund Freud and Anna Freud. He also lists research problems to be addressed as: "1. What is 'depth' in hypnosis? 2. What is the extent of the confusion among investigators of hypnotic phenomena with 'simulation' and 'role-playing'? 3. Can hypnotic regression be validated sufficiently to be used as a research method in the study of other psychological problems? 4. What are the essential conditions of hypnotizability, and who is hypnotizable? 5. How do induction techniques compare in relative effectiveness? 6. And can we develop some objective way of determining the appropriate technique for a given subject or patient?" p. 374

Ludwig, Arnold M. (1963). Hypnosis in fiction. International Journal of Clinical and Experimental Hypnosis, 11, 71-80.

Some common conceptions of hypnosis found in selected literary works are presented. Many supranormal powers are attributed to hypnosis. The hypnotist is generally viewed as an evil, demonic agent and the S as a naive, but good, hapless victim. The hypnotist is almost inevitably punished for possessing these extraordinary powers. (PsycINFO Database Record (c) 2002 APA, all rights reserved)

Stachowiak, J. G.; Moss, C. S. (1963). The hypnotic alteration of social attitudes. Journal of Personality and Social Psychology, 2, 77-83.

Measures the effectiveness of influencing S attitudes toward Negroes through the medium of a hypnotically administered communication. Precision was added by conceptualizing the interaction between 2 variables, the concept to be influenced (Negro) and the source of the influence (hypnotist), within the theoretical model provided by Osgood's principle of congruity. Ss who were exposed to a positive communication about Negroes while they were hypnotized showed significantly greater attitude change than did Ss who were exposed to the same communication in the "waking state." Predictions generated by the congruity principle held up well with respect to direction of attitude change, but insufficiencies were evident with regard to predictions of the magnitude of the changes. 1962

Levitt, Eugene E.; Lubin, Bernard; Brady, J. P. (1962). On the use of TAT Card 12M as an indicator of attitude toward hypnosis. International Journal of Clinical and Experimental Hypnosis, 10 (3), 145-150. (Abstracted in Psychological Abstracts, 63: 5233)

This investigation indicates that responses to TAT Card 12M do not predict attitude toward hypnosis in female Ss, though such predictiveness has been reported for male respondents. The basis for this differential predictiveness may be that the latter give a significantly greater proportion of themes involving hypnosis. An explanatory hypothesis, based on perceptual theory and the stimulus properties of the card, is advanced. (PsycINFO Database Record (c) 2002 APA, all rights reserved)

London, Perry; Cooper, Leslie M.; Johnson, Harold J. (1962). Subject characteristics in hypnosis research. International Journal of Clinical and Experimental Hypnosis, 13-21.

**ABSTRACT:** Items of experiences, interests, and attitudes, in London's Survey, tended to cluster among themselves, suggesting a separate factor for each. The items were compared to several objective tests, but correlations were low. The Survey and Shor's Personal Experiences Questionnaire combined, correlated .64 with Stanford Scale A, suggesting the possible development of a paper-and-pencil predictor of hypnotic suggestibility. Orne, Martin T. (1962). On the social psychology of the psychological experiment, with particular reference to demand characteristics and their implications. American Psychologist, 17 (11), 776-783.

#### NOTES

1:

"In summary, we have suggested that the subject must be recognized as an active participant in any experiment, and that it may be fruitful to view the psychological experiment as a very special form of social interaction. We have proposed that the subject's behavior in an experiment is a function of the totality of the situation, which includes the experimental variables being investigated and at least one other set of variables which we have subsumed under the heading, demand characteristics of the experimental situation. The study and control of demand characteristics are not simply matters of good experimental technique; rather, it is an empirical issue to determine under what circumstances demand characteristics significantly affect subjects' experimental behavior. Several empirical techniques have been proposed for this purpose. It has been suggested that control of these variables in particular may lead to greater reproducibility and ecological validity of psychological experiments. With an increasing understanding of these factors intrinsic to the experimental context, the experimental method in psychology may become a more effective tool in predicting behavior in nonexperimental contexts" (p. 783).

Shor, Ronald E.; Orne, Martin T.; O'Connell, D. N. (1962). Validation and cross-validation of a scale of self-reported personal experiences which predicts hypnotizability. Journal of Psychology, 53, 55-75. (Abstracted in Psychological Abstracts, 62: 4 II 55S)

A paper-and-pencil self-report questionnaire was designed to measure the incidence

of "hypnotic-like" experiences which have occurred naturally in the normal course of living. The questionnaire as evolved was found to predict hypnotizability, especially in the deepest region of the hypnotizability, especially in the deepest region of the hypnotizability continuum. Ramifications of the data are presented in terms of theoretical formulations where both ability factors and nonability factors (such as attitudes and motives) are viewed as components of achieved hypnotizability. From Psyc Abstracts 36:04:4II55S. (PsycINFO Database Record (c) 2002 APA, all rights reserved)

1961

Glass, Louis B.; Barber, Theodore X. (1961). A note on hypnotic behavior, the definition of the situation and the placebo effect. Journal of Nervous and Mental Disease, 132, 539-541.

Subjects were tested for responses to hypnotizability tests under three conditions: after 20 minute induction, after being told they would not be hypnotized but would take tests of imagination (with motivating instructions to do well), after taking a placebo pill that "would make them deeply hypnotized." Of 12 Ss who dropped in score between Session 1 and Session 2, 11 attained higher scores following placebo than during the control session; mean scores under placebo and control (5.8 and 3.7) differed significantly,  $p < .01$ . Scores were as high in the third as the first session (5.8 and 6.3 respectively).

1959

Conn, Jacob H. (1959). Cultural and clinical aspects of hypnosis, placebos, and suggestibility. International Journal of Clinical and Experimental Hypnosis, 7 (4), 175-185.

NOTES

1:

The author traces the history of hypnosis, suggestion, and placebo, noting that popularity of hypnosis with professionals waxes and wanes over the years. When practitioners lose faith in a drug, it becomes less effective with their patients. The same holds true for hypnosis. Frequently illness is ameliorated or cured by suggestion without hypnosis.

"Hypnosis is nothing more than the suggestive, placebo effect presented in a specific inter-personal setting. It is not just a state of mind, but the end result of various psychologic processes. (2) A patient may be more suggestible when fully awake. ... Another patient may be more suggestible when asleep. There are those who respond best to suggestions in the light stage of hypnosis, while about 10% of subjects are capable of developing the deeper, somnambulistic phase" (p. 181).

Rosenberg, Milton J. (1959). A disconfirmation of the descriptions of hypnosis as a dissociated state. International Journal of Clinical and Experimental Hypnosis, 7 (4), 187-204.

NOTES

1:

"SUMMARY. An experiment is described in which each of a group of hypnotic

subjects received a posthypnotic suggestion reversing his affective response on an attitude issue of high interest. The consequent changes in the subjects' affect-related beliefs are compared to 'belief-changes' achieved by members of a group of subjects who were required to role-play the occurrence of 'affect reversal'.

"The data are interpreted as disconfirming the description of hypnosis as a dissociated state. Some reasons for the persistence of the dissociation description of hypnosis and some theoretical implications of the demonstration of non-dissociation are briefly discussed" (pp. 202-203).

The 11 hypnotic subjects were capable of achieving posthypnotic amnesia. Direct suggestions were given, in the opposite direction from attitudes detected with a 'cognitive structure test'. "For example one of the subjects, having expressed strong negative affect toward Negroes moving into white neighborhoods, was given exactly the following hypnotic instructions: 'When you awake you will be very much in favor of Negroes moving into white neighborhoods. The mere idea of negroes moving into white neighborhoods will give you a happy, exhilarated feeling. You will have no memory for this suggestion having been made until the signal to remember is given'" (p. 193).

Wagner, Frederik F. (1959). A clinical study of attitudes towards hypnotic induction. International Journal of Clinical and Experimental Hypnosis, 7 (1), 3-8.

## NOTES

1:

### "Summary and Conclusion

"In spite of the supposed interest in hypnosis, less than one fourth out of 53 psychiatric residents volunteered as subjects in a research project on hypnotic induction. The immediate impression of a general attitude of anxious hesitancy was confirmed through the subsequent projective testing, interviews and the hypnotic experiment. The subjects' attitude as revealed through the different sources of information, showed a considerable consistency.

"Hypnosis was frequently fantasied as a controlling powerful instrument and the hypnotic induction as a 'battle between minds'. The underlying conflict: Dominance versus submission or independence versus dependence was easily discernible. This finding supports the results of a review made by LeCron (4) among psychologists and psychiatrists who use hypnosis for therapeutic purposes.

"The subjects' responses to the hypnotic situation varied from strong resistance to consistent co-operation. Mixed responses frequently reflected attempts by the subject to harmonize conflicting motives and fantasies. Some typical examples are described to illustrate the uniqueness of such compromise solutions, characteristic for the individual. The closer the subject's preconceived ideas came to the actual experimental situation, the more 'successful' were his responses. No direct connection between 'maturity' or 'neurotization' and 'susceptibility' could be demonstrated. No common character trait could be found or related to the subjects' ability to follow the suggestions. The responses could, however, be understood in terms of the individual's attempt to gratify, or ward off, needs, and anxiety aroused in the interpersonal relationship as structured by the experimental setting" (p. 8).

Wilcox, Warren; Faw, Volney (1959). Social and environmental perceptions of susceptible and unsusceptible hypnotic subjects. International Journal of Clinical and Experimental Hypnosis, 7 (3), 151-160.

#### NOTES

1:

1. The purpose of this study was to test the hypothesis that hypnotic susceptibility was positively related to the perception of fundamental aspects of the social and environmental milieu and, further, to consider the nature of hypnosis itself.
2. Ss for this study, 44 women and 36 men, were employed from a previous study (Faw and Wilcox, 1958). A mass hypnotic technique was used and susceptibility was operationally defined by the use of rating scales. The susceptible were found to have better personality adjustment than the unsusceptible.
3. New for this study were self-rating scales of the Ss' perception of parents, personal worries and problems, social activities as group or individually oriented, social activities in school, and physical care. The rating scales were administered several months prior to and independently of the hypnotic induction.
4. Interpretation of results support the hypothesis that the susceptible perceived their social and environmental milieu in more positive terms than did the unsusceptible. The susceptible perceived their parents in significantly stronger affectional and supportive relationships than did the unsusceptible. The susceptible were less concerned about adjustment to the opposite sex, not as worried about personal appearance, were more group oriented and more likely to engage in social activities than were the unsusceptible. Susceptible males were less frequently hospitalized than were unsusceptible males while susceptible females were more frequently hospitalized than were unsusceptible females.
5. Hypnosis was defined as a tendency to accept suggestions and to actualize, maintain and affirm them in the form of perceptual experiences activated by the stimulus situation as interpreted by the S and formulated by the hypnotist. The suggestions arouse expectancies or personal hypotheses which become a gauge to test the efficacy of the suggestions. Perceptualization is shaped by motives and past stimulation of the social and environmental milieu" (p. 158).

1957

Martin, R. M.; Marcuse, F. L. (1957). Characteristics of volunteers and non-volunteers for hypnosis. Journal of Clinical and Experimental Hypnosis, 5 (4), 176-180.

#### NOTES

103 introductory psychology students were tested with the Taylor Manifest Anxiety Scale, the Levinson Ethnocentrism Scale (score already on file), and the Bernreuter Personality Inventory. Later a request for volunteers for an experiment dealing with hypnosis was made (with no reward promised). A week later the same experimenter informed the class that due to a redesign of the experiment, it was necessary to go through the request for volunteers again (a reliability check for volunteering).

"Discussion and Conclusion. There were significant differences between volunteers and nonvolunteers on the variables of intelligence, anxiety, ethnocentrism, dominance-submission, and sociability. Volunteers for hypnosis as a group were

found to have a higher mean intelligence score and to be less ethnocentric than nonvolunteers. Male volunteers for hypnosis were more and not, as commonly supposed, less dominant in face-to-face relations and less and not, as commonly supposed, more anxious than nonvolunteers. Female volunteers tend to be more solitary and independent. The very fact that no significant differences were found in any comparison between volunteers and nonvolunteers for hypnosis in self-sufficiency and introversion-extroversion is considered important in that popular belief suggests the contrary.

" ... The data from this study, far from supporting the popular image of the hypnotic subject in terms of inferiority, might be argued to suggest superiority" (p. 178).

Wagner, Frederik F. (1956). The Interpersonal Relationship Test, (IRT): A suggested picture device for the evaluation of initial attitudes towards individual psychotherapy and hypnotic induction. Journal of Clinical and Experimental Hypnosis, 4 (3), 99-108.

NOTES

1:

Based on R. W. White's 1937 research using card 12 M of the TAT to assess needs and attitudes toward hypnosis, the author experimented with four less specific stimuli pictures. He posited that the attitudes and needs measured would influence hypnotizability. The four stimulus pictures were :

"I. Two people looking at each other, seen in profile. There is a double door in the background. Three alternative pictures are available: Male-Female, Male-Male and Female-Female. ...

II. A sitting person facing the observer, but looking at somebody who is completely hidden in a huge chair. Alternative combinations: M-? and F-? ...

III. The person facing the observer is sitting in a slightly bent forward position looking at a person sitting relaxed in a deep chair. The face of the latter can not be seen but the sex can be identified by the hands, feet and hair. Combinations: F-m, F-f, m-f, and M-m (m and f refer to the 'hidden' person). ...

IV. A person in a bent forward position with the back to the observer of the picture, leaning over the upper part of a person who is lying in supine position on a couch or divan. Both sexes can be identified but the faces can not be seen. Combinations: F-m, M-f and M-m (m and f refer to the 'hidden' person on the couch) (pp. 100-102).

1955

Fisher, Seymour (1955). An investigation of alleged conditioning phenomena under hypnosis. Journal of Clinical and Experimental Hypnosis, 3 (2), 71-103.

NOTES

1:

"Summary and Conclusions.

"The primary objective of the present investigation was to present rational and empirical evidence supporting a reinterpretation of a number of alleged 'conditioning' studies performed under hypnosis. An experiment which contained

no explicit verbal posthypnotic suggestion was conducted. The study was designed to expose the presence of characteristic features of an explicit posthypnotic act in hypnotically induced 'conditioned responses'; two responses, an olfactory hallucination and a coughing reaction, were induced under hypnosis by a conditioning procedure, and were examined under various experimental conditions in the subsequent waking state.

"Although the results are based upon a relatively small sample of Ss, the overall data seem to warrant the following principal conclusions:

"(1) Responses induced under hypnosis by means of a conditioning procedure do not conform to some of the expected principles of contemporary conditioning theory.

"(2) These responses do, however, show a marked similarity to behavior induced by explicit posthypnotic suggestion. Inasmuch as no significant discrepancies between these two classes of phenomena (posthypnotic behavior and the responses induced by a conditioning procedure) were observed, the results are interpreted as supporting the dual hypothesis that (a) evocation of the cough and olfactory hallucination by their respective stimuli is a function of hypnotically determined suggestive factors, and (b) aside from the omission of an explicit verbal suggestion, these responses differ in no essential way from a typical posthypnotic act.

"(3) As a corollary to the preceding conclusion, it follows that some deeply hypnotized Ss are capable of performing posthypnotic behavior solely on the basis of implicit hypnotic suggestion. Hence, the frequently accepted assumption that explicit verbal instructions are required to effect posthypnotic behavior seems untenable.

"(4) To the extent that these conclusions are valid, it seems doubtful whether the concept of 'conditioned response' is any more appropriate when applied to these hypnotically determined responses than when applied to typical posthypnotic behavior. It would appear, rather, that the only fundamental difference between these two forms of behavior lies in the degree to which E explicitly communicates his suggestions.

"The major implications of the results are discussed, and several secondary conclusions are suggested:

"(5) The results are interpreted to support the possible existence of 'operator attitude' as a significant variable in research with hypnosis.

"(6) The results seem best understood within a framework of role-taking theory which takes into consideration both S's expectations and the hypnotist's expectations.

"(7) Recognition of the active participation of hypnotic Ss prescribes extreme caution in the interpretation of results whenever hypnosis is utilized as a technique for controlling psychological variables" (p. 101).

Meares, Ainslie (1955). A note on the motivation for hypnosis. Journal of Clinical and Experimental Hypnosis, 3 (4), 222-228. (Abstracted in Psychological Abstracts 57: 1129)

NOTES

1:

"Summary. The logical reasons of the patient for desiring hypnosis, and of the therapist in advising it, operate on a background of unconscious mechanisms. These

mechanisms are important factors in determining whether or not the logical reasons become effective. An understanding of such motivation helps the therapist in the selection of cases and the choice of the particular form of hypnotherapy to be used" (p. 228).

Patient motivations for hypnosis include magical expectations, paranoid belief that one is under the control of a malevolent influence, a (paradoxical) belief that hypnosis will be ineffective with neurotic symptoms and therefore justify continuation of the symptoms, latent aggression ("hypnotize me if you can" attitude) or an excess of passivity ("humiliate me"), erotic motivation or a wish for a more intimate relationship with the therapist, search for new or unusual experiences in life, a last ditch effort to cope with chronic pain and illness, etc.

Patient motivations against hypnosis include fear of being overpowered or the threat of authority, aggressive feelings that would be motivated if the hypnotist seems to be an authority, or association of hypnosis with the erotic. The author has observed "a surprising number of people" with the latter association. "With these people, it is more of an attitude of mind in which any close or intimate relationship is regarded as erotic. They see in hypnosis an intimate relationship with the therapist, and they avoid it without being aware of their reasons for doing so" (p. 226).

Therapist motivations for hypnosis include unconscious mechanisms as well, such as a drive for power (sometimes manifested in desire to demonstrate the technique to a wider audience than simply colleagues in a workshop). When tinged with eroticism the drive can become sadistic. Also, erotic drives can find vicarious expression as "The intensity of the rapport between patient and psychotherapist in waking psychotherapy, is increased many times in hypnosis" (p. 227).

Therapist motivations against hypnosis include fear of failure (which is more obvious when a patient doesn't follow a suggestion than in lack of response to medicine), fear of erotic involvement, fear of one's own aggression, etc.

1954

Meares, Ainslie (1954). History-taking and physical examination in relation to subsequent hypnosis. Journal of Clinical and Experimental Hypnosis, 2 (4), 291-295.

NOTES

1:

"Summary. The history-taking and physical examination of the initial interview can be so structured as to facilitate the subsequent induction of hypnosis. Rapport is established, and negative transference feelings are not allowed to develop. There must be no holding back or hiding of the real complaint with screen symptoms. Physical examination is a symbolic surrender and paves the way for the real surrender of passive hypnosis. If induction by an active method is anticipated, authoritative attitudes are introduced into the history-taking and physical examination" (p. 295).

1953

Ellis, Albert (1953). Reactions of psychotherapy patients who resist hypnosis. Journal of Clinical and Experimental Hypnosis, 1 (3), 12-15.

## NOTES

1:

"When one of my psychotherapy patients has difficulty in remembering or bringing forth salient material, I or the patient sometimes suggests the use of hypnosis. At such times, I usually find one of two major modes of reaction: either the patient comfortably accepts the idea of hypnosis, and we proceed forthwith to establish a hypnotic relationship; or else the patient, even though he has himself first suggested using hypnosis, is visibly uncomfortable about engaging in it, and in one way or another resists being hypnotized.

"In the latter case, particularly where the patient backs down completely and manages to structure the therapeutic relationships so that hypnosis is never actually attempted, I frequently find that the threat of being hypnotized is so intense that, rather than submit to it, the patient begins to surrender some of his neurotic symptoms or makes unusual psychotherapeutic progress without it."

The author presents three case studies.

Glasner, Samuel (1953). Two experiments in the modification of attitude by the use of hypnotic and waking suggestion. Journal of Clinical and Experimental Hypnosis, 1, 71-75.

## NOTES

1:

Author's Conclusions: "In the light of the results, the following conclusions would appear to be justified:

1. Prestige suggestion can effect changes in an individual's response to an attitudes test.
2. Repeated prestige suggestion produces no more marked effect than does a single suggestion in changing social attitudes. However, the results seem to be more lasting with repeated suggestion.
3. Repeated hypnotic suggestion is considerably more effective than repeated waking suggestion in modifying social attitudes. But waking suggestion also seems to have some effect.
4. The effects of both hypnotic and waking suggestion vary greatly with different individuals.
5. The effect of repeated prestige suggestion in changing social attitudes apparently does not follow the pattern of the usual learning curve.
6. The changes noted seem to represent changes in basic attitude, and not merely changes in the response to a particular test" (P. 74).

The attitudes involved nationality preferences ("Negro, Turk, Hindu, or Chinamen" p. 71). The prestige suggestion, given in light hypnosis, was "The results on the test I gave you were rather disappointing. Most people think that we in the South are deeply prejudiced against the colored races. But that is a mis-understanding of our position. Certainly we University people have no actual dislike of Negroes, Chinamen, or Hindus. And it is our hope, in giving this test, to demonstrate our true attitude, which is far more tolerant than most people give us credit for. I am therefore going to give you the test again. I want you, of course, to give your honest preferences. But where you find a choice difficult, give the 'underdog' the benefit of the doubt. Do you understand? Give the 'underdog' the benefit of the doubt!" (p. 72).

## AUDIOTAPE/VIDEOTAPE

1995

Enqvist, Bjorn; von Konow, L.; Bystedt, H. (1995). Pre- and perioperative suggestion in maxillofacial surgery: Effects on blood loss and recovery. International Journal of Clinical and Experimental Hypnosis, 43 (3), 284-294.

The basic assumption underlying the present study was that emotional factors may influence not only recovery but also blood loss and blood pressure in maxillofacial surgery patients, where the surgery was performed under general anesthesia. Eighteen patients were administered a hypnosis tape containing preoperative therapeutic suggestions, 18 patients were administered hypnosis tapes containing pre- and perioperative suggestions, and 24 patients were administered a hypnosis tape containing perioperative suggestions only. The patients who received taped suggestions were compared to a group of matched control patients. The patients who received preoperative suggestions exhibited a 30% reduction in blood loss. A 26% reduction in blood loss was shown in the group of patients receiving pre- and perioperative suggestions, and the group of patients receiving perioperative suggestions only showed a 9% reduction in blood loss. Lower blood pressure was found in the groups that received pre- and perioperative and perioperative suggestions only. Rehabilitation was facilitated in the group of patients receiving perioperative suggestions only.

Repka, Renee J.; Nash, Michael R. (1995). Hypnotic responsivity of the deaf: The development of the University of Tennessee Hypnotic Susceptibility Scale for the Deaf. International Journal of Clinical and Experimental Hypnosis, 43 (3), 316-331.

The purpose of these two studies was to develop and test a measure that assesses the hypnotic responsivity of deaf individuals. The University of Tennessee Hypnotic Susceptibility Scale for the Deaf (UTHSS:D) is a signed, videotaped version of a standard hypnotic induction with 12 standard suggestions. Experiment 1 compared the behavioral and subjective hypnotic responsivity of deaf and hearing individuals using the UTHSS:D and the Field Depth Inventory (FDI), respectively. As compared to hearing subjects, deaf participants were found to be less responsive to hypnosis when assessed behaviorally (UTHSS:D) and equally responsive to hypnosis when assessed subjectively (FDI). Experiment 2 undertook a more comprehensive examination of the hypnotic responsivity of deaf individuals, using hearing individuals as controls. Three dimensions of hypnosis responsivity were assessed: behavioral (UTHSS:D), subjective (FDI), and interpersonal (Archaic Involvement Measure). Additionally, correlates of hypnotic responsivity (absorption, attitudes, expectations) were examined for the two groups. In Experiment 2, no significant differences were found between the deaf and hearing participant groups on any measures of hypnotic responsivity or on any measure of the correlates of hypnotic responsivity.

1993

Page, Roger A.; Handley, George W. (1993). The use of hypnosis in cocaine addiction. American Journal of Clinical Hypnosis, 36, 120-123.

An unusual case is presented in which hypnosis was successfully used to overcome a \$50-0 (five grams) per day cocaine addiction. The subject was a female in her twenties. Six months into her addiction, she acquired a commercial weight-control tape that she used successfully to stop smoking cigarettes (mentally substituting the word "smoking"), as well as to bring her down from her cocaine high and allow her to fall asleep. After approximately 8 months of addiction, she decided to use the tape in an attempt to overcome the addiction itself. Over the next 4 months, she listened to the tape three times a day, mentally substituting the word "coke." At the end of this period, her addiction was broken, and she has been drug free for the past 9 years. Her withdrawal and recovery were extraordinary because hypnosis was the only intervention, and no support network of any kind was available.

1992

Blankfield, Robert; Scheurman, Kathleen; Bittel, Sue; Alemagno, Sonia; Flocke, Sue; Zyzanski, Stephen (1992, October). Taped therapeutic suggestions and taped music as adjuncts in the care of coronary artery bypass graft patients. [Paper] Presented at the annual meeting of the Society for Clinical and Experimental Hypnosis, Arlington, VA.

NOTES

1:

18 studies have explored the issue with an experimental design; half used tapes, half didn't; majority of studies found benefits; 2 were of heart surgery patients.

This study used taped suggestions with coronary bypass patients. Used tape recorder rather than person delivering suggestions because it was more convenient; used tape intra-surgery and post-operatively for more impact.

We hypothesized: shorter length of stay, less narcotic analgesia, less anxiety, faster recovery, more positive mental outlook, resume activities sooner, have less symptoms postoperatively, etc.

Used a prospective, randomized, single-blind trial in 2 community hospitals in Cleveland with coronary artery bypass graft surgery patients. Study was done between Dec 1989 - Feb 1992.

3 groups were involved: (1) Suggestion, (2) music, and (3) tape. Control subjects had a blank tape. Tapes were played continuously and repeatedly with headphones. Postoperatively, a different tape was played.

Excluded: Patients with emergent surgery, hearing impairment, poor comprehension of English, patients who died in hospital, patients whose hospital stay lasted longer than 14 days (3 of them). 5% of sample were eliminated for last 2 reasons.

Music: Herb Ernst, Dreamflight II. Suggestions: Music background, permissive, based on Evans & Richardson's study.

Outcome Measures: Nurse assessment of anxiety and progress post operatively, Symptom scale, Depression scale.

Mean age 62, 3/4 men, 92% white, 75% married. The groups were same on a variety of preoperative variables (status of heart and arteries). Length of stay was 6.5 in all 3 groups. No difference in narcotics use, in nurse assessment of anxiety or of progress; of depression scale, or activities of daily living.

Recategorized data into patients who said the tapes were helpful (both music and suggestion) N = 33 vs the other patients N = 62. No difference in the variables evaluated.

Grant, Carolyn D.; Nash, Michael R.; Roberts, Laura L.; Lynch, Greg V. (1992, August). The validation and standardization of the Computer-Assisted Hypnosis Scale. [Paper] Presented at the annual meeting of the American Psychological Association, Washington, DC.

**ABSTRACT:** This research investigates the reliability and validity of the Computer-Assisted Hypnosis Scale (CAHS), a twelve-item computer administered hypnotic ability scale. In a counter-balanced, within-subjects, repeated measures design, 130 subjects experienced both a computerized hypnosis (CAHS) and hetero-hypnosis (SHSS:C). For each hypnosis session, responsiveness was assessed along three dimensions: Behavioral (using the CAHS and SHSS:C), subjective depth (using the Field Depth Inventory), and relational involvement (using the Archaic Involvement Measure). Subjects also completed a SHSS:C self-scoring measure and the Tellegen Absorption Scale. The CAHS was shown to be a psychometrically sound instrument for measuring hypnotic ability. The various dimensions of CAHS hypnotic responsiveness were highly positively related, and the CAHS compared favorably with the SHSS:C across the three dimensions assessed. However, an unexpected interaction was noted: For the three dimensions of hypnotic responsiveness assessed, SHSS:C scores were lower when the SHSS:C was preceded by a CAHS than when the SHSS:C administration was first. CAHS scores for the three dimensions were not significantly affected regardless of whether or not a SHSS:C administration preceded the CAHS administration. Results are discussed in terms of the theory and practice of hypnotic ability assessment, and directions for future research are noted. (ABSTRACT from Bulletin of Division 30, Psychological Hypnosis, Fall 1992, Vol. 1, No.3.)

Sheehan, Peter W. (1992). The phenomenology of hypnosis and the Experiential Analysis Technique. In Fromm, Erika; Nash, Michael R. (Ed.), Contemporary hypnosis research (pp. 364-389). New York: Guilford Press.

#### NOTES

1:

The problem with behavioral assessment methods such as hypnotizability scales is that similar behavioral responses to hypnotic suggestions may occur for very different reasons. It is important to assess the phenomenological experience of hypnotic Ss. The Experience Analysis Technique (EAT) is a method for assessing the phenomenology of hypnosis. The EAT "consists of gathering the comments of hypnotic subjects about their hypnotic behavior and experience, as they view the video playback of their hypnotic sessions" (p. 372). The EAT draws its origins from Kagan's method of Interpersonal Process Recall [IPR], in which "counselors in training could review and react to, their contact with clients immediately after

therapy sessions. An independent person, present at the review of the session, would inquire into the interaction between the counselor and client by stopping the tape and questioning the client about his or her underlying feelings and thoughts, so facilitating and clarifying the information being recalled" (p. 371). It is important that the interviewer be a different person than the hypnotist.

1978

Hammer, Walker & Diment (1978) applied the IPR to hypnosis, using audiotape.

Using the videotape EAT with hypnosis, Sheehan & McConkey (1982; Sheehan, McConkey & Cross, 1978) noted that hypnotic Ss might exhibit any of three different response styles, sometimes related to hypnotic task complexity: 1. Concentrative/cooperative style - S focuses on hypnotist's words, imagining a literal interpretation 2. Independent style - S interprets hypnotist's words in a way that is meaningful to them 3. Constructive style - S considers the communications "from a position of preparedness to process incoming stimuli in a schematic way, so as to structure or re-organize events according to the hypnotist's suggestions"

Some Ss who are high in susceptibility show greater flexibility in the use of cognitive styles than low susceptibility Ss.

Examples of the use of the EAT to evaluate several phenomena observed in experimental and clinical settings are provided: 'duality' during age regression, trance logic, posthypnotic amnesia, pseudomemories, and rapport.

The author reviews the concept of 'countering.' "Countering occurs when a S responds in accord with the wishes of the hypnotist when social influences to respond otherwise are also present in the situation. ... Counterers display a constructive (i.e. active and idiosyncratic) style of cognizing which enables them to make personal sense of the conflicting demands by preserving the integrity of each. ... Counterers, even though they demonstrate a higher degree of involvement with the hypnotist, fail reliably to score as highly on standard tests of susceptibility (e.g. the Stanford Hypnotic Susceptibility Scale, Form C) as subjects who do not counter (Sheehan, 1980). This second finding points to differential effects of rapport on Ss which are not explicable in terms of level of hypnotic susceptibility or simple willingness to comply with anticipated, obvious suggestions. Techniques like the EAT, which are sensitively attuned to detect the personal commitment of subjects to the hypnotist, are needed to detect subtle processes of this kind" (pp. 385- 386).

The author evaluates different reporting techniques used to examine the phenomenological experience of hypnosis (the Chicago Paradigm of Fromm & Kahn, 1990; Shor's phenomenological method; the Field's Inventory Scale of Hypnotic Depth) and evaluates the effects of rapport with the E on the measurement of subjective response. He suggests various experimental controls (e.g. disguising the true aims of the experiment). A measure of rapport or psychodynamic transference to the hypnotist, the Archaic Involvement Measure (AIM) has been developed by Nash and Spinler (1989).

"Experience cannot simply be observed objectively; it may not be reported spontaneously by the experiencer; and it may not even be elicited through ordinary forms of interaction" (p. 388).

"What phenomenological research has shown over the last decade is that hypnotic experience is both multifaceted and complex. It has given us a view of the hypnotic subject as a person who participates actively in the hypnotic process, who is susceptible to the influence of motivations and expectations, and who employs a variety of cognitive strategies so as to manage and respond to multiple levels of communication received in the hypnotic setting. Standard techniques of assessment, especially those emphasizing the primacy of behavioral data and those offering structured choices, are not equipped to reveal the full meaning of hypnotic responsiveness" (p. 388).

"If an instrument of assessment assumes a unidimensional underlying process when there are multiple dimensions operating, then that instrument will be deficient in measuring experience by producing equivalent ratings for very different experiences, and thus will be deficient in measuring overall experience. Measurement of trance-depth poses just such a problem, and measurement of hypnotic experience in its full complexity even more so" (pp. 388-389).

1991

Kirkeby, Judith L.; Payne, Paul A.; Hovanitz, Christine; Moser, Steven (1991). Increasing hypnotizability: A comparison of a multimedia form of the Carleton Skills Training Program with a self-administered written form. Contemporary Hypnosis, 8, 161-165.

Compared a group-administered form of the multimedia Carleton Skills Training Program (CSTP) to a self-administered training program similar in content, but limited to written materials. One hundred and forty-one female subjects were administered one of four conditions: (1) the multimedia CSTP; (2) the self-administering booklet training; (3) a practice-only condition; or (4) a no-practice control condition. Subjects then responded to a shortened form of the Harvard Group Scale of Hypnotic Susceptibility, Form A (HGSHS:A). [6 items: arm lowering, arm rigidity, hands together, fly hallucination, eye catalepsy, and amnesia.] Results indicated that objective and subjective hypnotizability measures were higher in both of the training conditions than in the practice-only or control conditions. In comparisons of the two training conditions, the booklet program was judged to be equal in effectiveness to the multi-media group form of the CSTP.

Kaye, J. M.; Schindler, B. A. (1990). Hypnosis on a consultation-liaison service. General Hospital Psychiatry, 12, 379-383.

Studied the use of hypnosis on a consultation-liaison service with a broad spectrum of medically hospitalized patients. Autohypnosis tapes were used for reinforcement. Twenty-nine women and eight men from 24-75 years of age were hypnotized for relief of depression, pain, anxiety, or side effects of chemotherapy. Results were excellent (total to almost total relief of symptoms) in 68%, fair in 22%, and poor in 11%, with no differences among the results with the various conditions. This demonstrates that hypnotherapy is an extremely useful tool in medical management of patients in consultation-liaison psychiatry.

McLintock, T. T.; Aitken, H.; Downie, C. F.; Kenny, G. N. (1990). Postoperative analgesic requirements in patients exposed to positive intraoperative suggestions. British Medical Journal, 301 (6755), 788-790.

Sixty-three women undergoing elective abdominal hysterectomy were randomly assigned to a tape of positive suggestions or a blank tape during the operation. Anesthesia was standardized for all of the women. Postoperative analgesia was provided through a patient-controlled analgesia system for the first 24 hours. Pain scores were recorded every 6 hours. The outcome measures were morphine consumption in the first 24 hours and pain scores. Mean morphine requirements were 51.0 mg in women who were played positive suggestions, and 65.7 mg in those played a blank tape ( $p = 0.028$ ). Pain scores were similar in the two groups. It was concluded that intraoperative suggestions seem to have a positive effect in reducing patients' morphine requirements in the early postoperative period.

Wood, W. E.; Gibson, W.; Longo, D. (1990). Moderation of morbidity following tonsillectomy and adenoidectomy: A study of awareness under anesthesia. International Journal of Pediatric Otorhinolaryngology, 20, 93-105.

In a double-blind study, 67 children, ages 3-10, were randomly assigned to one of three groups: tape recorded therapeutic suggestions repetitively recited in English or in French, and a control of continuous white noise. The English condition was associated with more favorable outcome on all parameters, although statistical significance could not be demonstrated. Favorable outcomes appeared most significant for those patients at highest risk for poor convalescence (i.e., poor status preoperative patients).

1989

Bryant, Richard A.; McConkey, Kevin M. (1989). Hypnotic blindness: A behavioral and experiential analysis. Journal of Abnormal Psychology, 98, 71-77.

NOTES

1:

"This research examined the influence of visual information on a decision task that subjects were administered during hypnotically suggested blindness. Real, hypnotizable subjects and simulating, un hypnotizable subjects were tested in two experiments. Experiment 1 focused on behavioral responses, and Exper. 2 focused on experiential reactions. In both experiments, the findings indicated that the

behavioral responses of reals were influenced by visual info. despite their reported blindness. The behavioral responses of reals and simulators were essentially similar. The experiential data in Experiment 2 provided information about the phenomenal nature of subjects' reported blindness. The experiential reactions of reals and simulators were essentially different. The research is discussed in terms of the issues that need to be considered in the development of a model of hypnotic blindness" (p. 71).

Grant, Guy (1989, June). An investigation of hypnotic susceptibility in self-hypnosis and imagery (Dissertation, University of Utah). Dissertation Abstracts International, 49 (12), 5517-5518-B.

#### NOTES

1:

"There were two phases in the study. In Phase One hypnotic susceptibility scores were assessed for 43 graduate student subjects by the Harvard Group Scale of Hypnotic Susceptibility: Form A (HGSHS:A). In addition, the Self-Hypnosis Research Questionnaire (an experimental scale) provided performance scores for subjects under three hypnosis conditions: heterohypnosis, self-directed self-hypnosis, and tape-assisted self-hypnosis. The first purpose in Phase One was to calculate correlations between hypnotic susceptibility and each of the hypnosis conditions. The second purpose was to determine if there were significant differences across the three types of hypnosis. The third purpose was to discover if any existing differences were dependent on level (e.g., low, medium, or high) of hypnotic susceptibility. Analysis of the data yielded significant correlations between hypnotic susceptibility and (a) heterohypnosis, (b) self-directed self-hypnosis, and (c) tape-assisted self-hypnosis. There were significant performance differences across the three hypnosis conditions with heterohypnosis being somewhat superior to tape-assisted self-hypnosis, and tape-assisted self-hypnosis being slightly superior to self-directed self-hypnosis. This relationship held true regardless of level of hypnotic susceptibility (e.g., low, medium, and high).

"In Phase Two, 49 graduate student subjects were administered the shortened form of the Betts' Questionnaire Upon Mental Imagery (QMI) as well as the HGSHS:A, and to determine if mental imagery is an important component of hypnotic susceptibility. Analysis yielded a significant correlation between the two measures.

"Based on the current data, it was concluded that the HGSHS:A had some utility for predicting performance in hypnosis. It was noted that, as compared with self-hypnosis, heterohypnosis provided the greatest chance of eliciting a positive hypnotic response from subjects not trained or experienced in hypnosis. It was also concluded that the QMI was correlated with and had some utility for predicting performance on the HGSHS:A. It had difficulty, however, differentiating between low and medium hypnotizability" (pp. 5517- 5518).

**Hammond, D. Corydon; Haskins-Bartsch, Catherine; Grant, Claude W.; McGhee, Melanie (1988). Comparison of self-directed and tape-assisted self-hypnosis. American Journal of Clinical Hypnosis, 31, 129-137.**

Previous research on self-hypnosis has concentrated on the relationship between heterohypnosis and either self-directed self-hypnosis or self-initiated self-hypnosis. Despite widespread use of audiotapes to assist the process of self-hypnosis, no previous research has compared tape-assisted and self-directed self-hypnosis. Forty-eight inexperienced volunteers were hypnotized and taught self-hypnosis by posthypnotic suggestion and immediate practice in the office. They were randomly assigned to one of two experimental orders to practice self-directed and tape-assisted self-hypnosis. No differences were found between heterohypnosis or either type of self-hypnosis in response to behavioral suggestions. Experiential ratings, however, consistently favored heterohypnosis over either type of self-hypnosis. Tape-assisted self-hypnosis was consistently evaluated as superior to self-directed practice by newly trained subjects.

#### **NOTES**

**1:**

The tapes were more or less identical with the in-office hypnosis, including voice of the hypnotist, except that those doing self-directed self hypnosis received a posthypnotic suggestion for how to enter hypnosis by themselves. (All Subjects received written instructions to remind them about the procedures for home practice.)

When self hypnosis was evaluated, use of a tape produced greater concentration and absorption, less distraction, greater subjective depth, greater perception of nonvoluntary response to suggestion, and more changes in body perception (e.g. loss of awareness of the body, feelings of heaviness or of floating). Therefore, the tape-assisted experience could be viewed as more convincing to the Subjects. People tended to fall asleep more when they did self-directed self hypnosis than when they used a tape. However, people enjoyed heterohypnosis more than either self hypnosis experience, and reported more nonvoluntary experiences. The more positive response to heterohypnosis replicates research by Johnson et al. (1983), in which preceding self-hypnosis by a heterohypnosis induction may results in less positive experiences with the self-directed self hypnosis.

In their Discussion, the authors note that finding no differences between self hypnosis and heterohypnosis in the number of behavioral suggestions successfully passed replicates earlier research (Shor & Easton, 1973; Ruch, 1975; Johnson, 1979; Johnson, Dawson, Clark, & Sikorsky, 1983).

"Thus, our present study has replicated previous findings concerning the relationship of heterohypnosis and self-directed self-hypnosis. In clinical practice, it appears that a heterohypnosis experience virtually always precedes training in self-hypnosis. Our findings and those of the Johnson (1983) study suggest, however, that generally patients will experience self-hypnosis as significantly less powerful than their previous office experience. But, by using a tape to assist the patient in initial practice, the discrepancy between the quality of the experiences appears reduced. It should be noted that Johnson et al. (1983) provide the innovative suggestion that

there may be something gained by having self-hypnotic instruction and practice precede a hypnotic experience by a therapist. Initial self-hypnotic experience may create a mental set of being more actively involved" (p. 136).

"However, we know nothing about how tape-assisted vs self-directed experiences are perceived by Ss with more self-hypnotic and heterohypnotic experience, and particularly if they are utilizing the same tape recording(s) over and over again. Other research (Hammond, 1987) recently followed up premenstrual syndrome patients who were trained in self-hypnosis. In this study, patients showed a clear preference for using tapes to assist them in self-hypnosis shortly after initial training. However, on 6-month follow-up, patients were found to be utilizing self-directed self-hypnosis much more frequently than tapes, with which they may have become somewhat bored. The issue of boredom has thus far not been adequately addressed in the self-hypnosis literature" (p. 136).

Omer, H.; Darnel, A.; Silberman, N.; Shuval, D.; Palti, T. (1988). The use of hypnotic-relaxation cassettes in a gynecologic-obstetric ward. In Lankton, S. R.; Zeig, J. K. (Ed.), Research, comparisons and medical applications of Ericksonian techniques (pp. 28-36). New York: Brunner-Mazel.

#### NOTES

1:

They did three studies in which they gave women having gynecologic procedures tapes with a Rapid Induction Analgesia hypnosis experience.

STUDY 1. Women heard tapes before a painful Fallopian tube procedure (salpingography). The patients reported less pain, tension, anxiety, and fear than control patients. (N.B. Physicians' ratings did not show that difference.)

STUDY 2. Women practiced with the tapes at home before labor and delivery. One day after delivery, there was no difference in pain report or experience report between treated and control patients.

STUDY 3. Women used the tapes during labor. They reported worse pain and labor experiences than the control patients.

The authors conclude that their research does not support the hypothesis that Rapid Induction Analgesia is useful for acute pain.

#### 1986

Aronson, David M. (1986). The adolescent as hypnotist: Hypnosis and self-hypnosis with adolescent psychiatric inpatients. American Journal of Clinical Hypnosis, 28 (3), 163-169.

This paper describes the theoretical rationale, pragmatic implementation issues, and procedure for a particular technique of clinical hypnosis which is designed as an adjunctive therapy within a multidisciplinary adolescent inpatient treatment program. A model of combined auto- and heterohypnosis which features collaborative production of audiocassettes is presented. Advantages and indications for this technique are discussed, and a case study is presented. - Journal Abstract

#### 1984

Morrow, Gary R. (1984). Appropriateness of taped versus live relaxation in the systematic desensitization of anticipatory nausea and vomiting in cancer patients. Journal of Consulting and Clinical Psychology, 52 (6), 1098-1099.

Investigated the suggestion that the relaxation part of systematic desensitization--an effective treatment for the nausea and vomiting experienced by approximately 25% of cancer patients in anticipation of chemotherapeutic treatments-- could be learned from a prerecorded audiotape prior to meeting a psychologist for treatment. 10 cancer patients who had developed anticipatory nausea or vomiting were assigned to either a live-relaxation or a tape-relaxation group. Results show that 4 of 5 Ss assigned to the tape-relaxation group experienced nausea while listening to the prerecorded audiotape, while none of the patients in the live-relaxation group reported nausea when subsequently listening to an audiotape made during the live presentation of relaxation.

1983

Brattberg, G. (1983). An alternative method of treating tinnitus: Relaxation-hypnotherapy primarily through the home use of a recorded audio cassette. International Journal of Clinical and Experimental Hypnosis, 31 (2), 90-97.

32 patients, variously diagnosed as suffering from tinnitus, were treated with hypnosis. Treatment consisted of a 1-hour consultation with the physician followed by 4 weeks of daily home practice while listening to an audio-tape recording of approximately 15 minutes duration. 22 of the patients treated learned in 1 month to disregard the disturbing noise, a considerable gain in the ratio of therapy to time required.

NOTES

1:

The audio tape was of a 15-minute hypnotherapy session done on the first office visit, so that the home practice was more or less the same as the first visit in office. "The hypnotherapy was aimed at inducing the patient into as relaxed a state as possible, and thereafter implanting the suggestio that the patient would no longer be troubled by the noise" (p. 93).

Nogrady, Heather; McConkey, Kevin M.; Laurence, Jean-Roch; Perry, Campbell (1983). Dissociation, duality, and demand characteristics in hypnosis. Journal of Abnormal Psychology.

Examined hypnotic dissociation (as indexed by the "hidden-observer" method), duality in age regression, and the potential impact of situational cues on these phenomena. 12 high- and 9 low-susceptible undergraduates (as determined by the Stanford Hypnotic Susceptibility Scale) were tested in an application of the real-simulating paradigm of hypnosis; 10 high- to medium-susceptible Ss were also employed. Inquiry into Ss' experiences was conducted through the experiential analysis technique, which involves Ss viewing and commenting on a videotape playback of their hypnotic session. Results demonstrate that neither the hidden-

observer effect nor duality could be explained solely in terms of the demand characteristics of the test situation. The hidden-observer effect was observed in high-susceptible Ss only; all Ss who displayed the hidden-observer effect also displayed duality in age regression. High-susceptible Ss were distinctive in their reports of multiple levels of awareness during hypnosis. Findings are discussed in terms of the cognitive skills that Ss bring to hypnosis and the degree to which the hypnotic setting encourages the use of dissociative cognitive processes. (43 ref).

1982

Lehrer, Paul M. (1982). How to relax and how not to relax: A re-evaluation of the work of Edmund Jacobson: I. Behaviour Research and Therapy, 20 (5), 417-428.

Contrasts E. Jacobson's (1928-1970) method of progressive relaxation with modified techniques that emphasize suggestion, brevity, and the feeling of large differences between tension and relaxation. The literature suggests that the modifications may have been premature. The psychophysiological effects of suggestion are weaker than those of progressive relaxation. Tape-recorded instruction appears to be completely ineffective as a method for teaching relaxation as a skill that can be used across situations. Live training contributes more than simple feedback; its effectiveness may lie in individualized adaptation of training technique. EMG biofeedback makes taped training more effective but contributes nothing to intensive live training. Despite its greater length, Jacobson's original technique is preferred to the modified techniques, particularly when psychophysiological effects are important. Length of training does not appear to be a critical factor. (116 ref)

1981

McConkey, Kevin M.; Sheehan, Peter W. (1981). The impact of videotape playback of hypnotic events on posthypnotic amnesia. Journal of Abnormal Psychology, 90 (1), 46-54.

Examined the breakdown of amnesia by showing 48 hypnotic and nonhypnotic undergraduates (Harvard Group Scale of Hypnotic Susceptibility) a videotape of the hypnotic events they had experienced. The extent of the amnesia for these events was defined precisely, and simulating procedures were employed to analyze the cues in the overall test situation. Videotape display of the hypnotic events was presented via the Experiential Analysis Technique and served to optimize conditions for breakdown. Some hypnotic Ss' amnesia could not be broken down even though they were exposed via videotape playback to the events to be recalled and when suggestions for the period of amnesia were quite explicit. Simulators showed breaching of amnesia but attributed their recall to the videotape rather than to the hypnotic session. Hypnotic Ss were distinctive in their inability to recall experiential aspects of their performance even though they could recall behavioral aspects. The data are discussed in relation to the hypothesis that dissociative cognitive mechanisms underlie posthypnotic amnesia. (22 ref).

#### NOTES

1:

This is the introduction to a film about a woman who was indicted for murder in the alleged fatal shooting of her husband. The woman was amnesic, had been drinking alcohol before the shooting. The author also provides a verbatim account of what the patient said following suggestions that "you are going to remember every detail." On the basis of the woman's hypnotically refreshed recall, the charge was changed from first degree murder to self-defense.

Hart, R. (1980). The influence of a taped hypnotic induction treatment procedure on the recovery of surgery patients. International Journal of Clinical and Experimental Hypnosis, 28, 324-331.

A study of 40 open heart surgery patients assigned to 1 of 2 equal size treatment groups sought to evaluate the efficacy and utility of a tape-recorded hypnotic induction procedure that preoperatively prepared patients for surgery. The dependent variables included daily blood pressure measurements and postsurgical outcome data pertaining to postoperative units of blood required, state/trait anxiety, and locus of control dimensions. Results of the study tended to provide some support for the tape-recorded hypnotic induction procedure in lessening state anxiety and in promoting a more self-directed attitude toward surgical recovery.

1979

Johnson, L. S.; Wiese, K. F. (1979). Live versus tape-recorded assessments of hypnotic responsiveness in pain control patients. International Journal of Clinical and Experimental Hypnosis, 27 (2), 74-84.

This study compared the effectiveness of live versus tape-recorded hypnotic procedures in producing general hypnotic responsiveness in hospitalized pain patients. 30 patients individually received in counterbalanced order both a live and an audiotaped presentation of the Stanford Hypnotic Clinical Scale (Hilgard & Hilgard, 1975), which contains an induction and a 5-item test of hypnotic susceptibility suitable for bed-ridden patients. The live presentation produced a significantly higher total score than the taped procedure ( $p < .05$ ), with no significant order effects. The correlation between modes of presentation was .66. Order effects were not significant but a trend in that direction was discussed. The differences were found to hold for the high and medium ranges of susceptibility. Tentative conclusions were drawn that one cannot assume taped procedures to be equivalent to live in hypnotic analgesia research with clinical populations. The non-equivalence of live and taped procedures need not invalidate the clinical use of the latter, should they prove empirically effective. A case study of low back pain is added to illustrate effective tape-induced analgesia for patients unsuccessful with self-hypnosis.

1978

Shipley, R. H.; Butt, J. H.; Horowitz, B.; Farbry, J. E. (1978). Preparation for a stressful medical procedure: Effect of amount of stimulus preexposure and coping style. Journal of Consulting and Clinical Psychology, 46, 499-507.

Anxiety during the stressful medical procedure of endoscopy was studied as a function of the number of prior viewings of an explicit preparation videotape and of repression-sensitization coping style. Sixty naive patients viewed a videotaped endoscopy either zero, one, or three times. Dependent measures included heart rate, behavioral ratings, tranquilizer required, and self-report. On each dependent measure, three viewings generally resulted in the least distress; one, more distress; and zero, the most distress. Most comparisons reached statistical significance. These results are interpreted as resulting from extinction and/or habituation of anxiety. The repression-sensitization factor interacted with heart rate change. Sensitizers showed a monotonic decrease in heart rate as a function of number of tape exposures. Repressors showed an inverted-U-shaped function, with one viewing producing the highest heart rate; this is interpreted as resulting from a disruption of repressing defenses by one tape exposure followed by extinction of fear by three exposures.

1977

Lick, John R.; Heffler, David (1977). Relaxation training and attention placebo in the treatment of severe insomnia. Journal of Consulting and Clinical Psychology, 45 (2), 153-161.

This study compared the effectiveness of progressive relaxation training with and without a supplementary relaxation recording, which the subjects played at home, and an attention placebo manipulation in the modification of severe insomnia in adult volunteers. The results indicated that the relaxation training procedures were significantly more effective than placebo and no-treatment controls in modifying several parameters of sleeping behavior, in reducing consumption of sleep-inducing medication, and in influencing a self-report anxiety measure. The supplementary relaxation tape did not increase the effectiveness of relaxation training conducted in the clinic, and there was no difference in the efficacy of the placebo and no-treatment conditions. Physiological data gathered during the last treatment session indicated few significant correlations between reductions in arousal associated with relaxation training and treatment outcome.

1975

Bean, Bruce W.; Duff, James L. (1975). The effects of video tape, and of situational and generalized locus of control, upon hypnotic susceptibility. American Journal of Clinical Hypnosis, 18 (1), 28-33.

This study examined the effects of mode of induction (video tape vs. live), general locus of control, and situational locus of control upon hypnotic susceptibility. A total of 62 student volunteers was hypnotized in eight small groups using the Harvard Group Scale of Hypnotic Susceptibility. Results confirmed that video taped

inductions were as effective as live inductions. None of the other variables, singly or in interaction, significantly affected susceptibility scores. An analysis of variance was also performed upon subjects' subjective ratings of having experienced hypnosis. Results revealed that subjects with an external general locus of control (Rotter's I-E scale) rated themselves as having experienced hypnosis more fully. This was interpreted as a greater response to the demand characteristics of the hypnosis situation by externally controlled subjects. Discussion explores the potential flexibility provided by video tape hypnosis.

**Spear, J. E. (1975). The utilization of non-drug induced altered states of consciousness in borderline recidivists. American Journal of Clinical Hypnosis, 18, 111-126.**

Utilizing non-drug induced altered states of consciousness, various modes of interior reflection, behavior modification and reprogramming of conscious attitudes and values were utilized with 49 borderline recidivists. Such offenders were so determined by the Department of Corrections, Probation and Parole Office, District II. No coercion was used to induce such individuals to enter the program and there was no reprisal for stopping therapy at any time. Over a two and one-half year period the recidivist rate among this group was less than 5%. It is suggested that non-drug induced altered states of consciousness combined with indirect as well as symbolic techniques may prove to be the most effective means of criminal rehabilitation.

#### **NOTES**

**1:**

Berderline recidivists were "individuals, who, in the opinion of the P.O. [probation officer] were, in all probability, to be returned to prison within a few months, or less, if there wasn't a major change in attitude and actions" (p. 111). Therapy employed closed circuit TV with bi-directional audio and induction of altered state of consciousness using an ophthalmology-type rotary prism. Therapy involved (s) recall of relaxed state when under stress, (2) exploration of early conditioning events, (3) self evaluation during the ASC, (4) use of symbolic mental exercises and mental practice for similar circumstances in normal waking state, (5) suggestions for setting goals and ideals, (7) a type of logotherapy, (7) 'nudging' the person to examine their relationship with their concept of God. The author noted in the parolees: (1) low levels of self esteem, (2) depression, (3) going into deep levels of altered states once trust was established with the therapist.

**1974**

**Field, Peter B. (1974). Effects of tape-recorded hypnotic preparation for surgery. International Journal of Clinical and Experimental Hypnosis, 22, 54-61.**

The day before surgery, 30 patients heard a tape recording that gave suggestions of relaxation, drowsiness, comfort during the operation, and quick recovery, and which also gave simple information about the forthcoming operation. A control

group of 30 additional surgical patients heard a recording describing facilities available in the hospital. No differences between the 2 groups were found on surgeons' ratings of degree of nervousness on the day of the operation, or on speed of recovery. However, there was a significant correlation within the experimental group between depth of relaxation while listening to the recording and absence of nervousness the day of the operation, and also between depth of relaxation and speed of recovery. Verbal reports of benefit from listening to the recording were unrelated to depth of relaxation.

#### NOTES

1:

The surgeons and other ward staff were unaware of group assignment. Patients were rated by observer for: eye closure, relaxation vs. restlessness, change to a slow and regular breathing pattern, and whether they complied with a recorded instruction to take a deep breath.

In terms of results, degree of rated relaxation related to nervousness during surgery, to faster recovery from the operation, but not to length of hospital stay. No significant differences between the experimental and control groups were found. Contrary to expectations, there was a tendency for more nervousness in the experimental group. Thus, though patients who relaxed more easily were less nervous during surgery and recovered more rapidly than expected, the difference cannot be attributed to the experimental intervention.

In contrast to objective outcome measures, verbal reports indicated that 17 of 30 experimental group patients but only 1 of 30 control patients felt that the tape had helped them. (In the experimental group, 25% used terms like "wonderful," "terrific," "very helpful," statements never made by the control group patients.) Also, 73% of experimental vs. 23% of control patients said that they would like to hear (or wouldn't mind hearing) the recording again if they had another operation. Extensive post-operative interview data did not support a conclusion that the intervention influenced postoperative pain, anorexia, or insomnia; postoperative dreams; or self-reported anxiety during the operation. Thus, patients who claimed the intervention was helpful did not necessarily report reduced anxiety or pain. They reported greater relaxation, better knowledge of what would happen, or better ability to cope with the stress.

In his Discussion the author notes that the variable of "depth of relaxation" was supposed to reflect depth of hypnosis but may not be actually a measure of hypnotic depth or of hypnotizability. The results might be due to an individual difference effect (people who can relax easily would find surgery a less stressful experience whether or not they heard a tape recording), or to the interaction between such an individual-difference variable and the experimental treatment. In the latter case, the recording might have some added effect on its own.

Finally, results suggest that recordings with suggestions of this nature influence patient satisfaction rather than postoperative course.

Horan, John S. (1953). Hypnosis and recorded suggestions in the treatment of migraine: Case report. Journal of Clinical and Experimental Hypnosis, 1 (4), 7-10. Psychological Abstracts 54: 6399)

NOTES

1:

Author's Discussion: "The case above is presented because of its rather bizarre features. It is notable in that in the hypnotic sessions no attempt was made to explore the dynamics of the patient's resentment or her illness, no insight was given into psychic mechanisms connected with the migraine. This had been done before, in conventional psychiatric interviewing, without much result. Under hypnosis, the only suggestions given were concerned with direct symptomatic relief of headache,

insomnia and anorexia. For the patient's purposes, these were sufficient. Just how the pathological physiological state causing the migraine attacks was altered by direct and recorded suggestion is a mystery to this writer. It may be that hypnotic states can cause a dissociation of the subject from the emotional stress related to the attacks. Or perhaps the strangeness and the mystery of hypnosis was sufficient. It would be absurd to make any claims about the efficacy of hypnosis in migraine patients in general on the basis of this one case. In a disease which causes as much disability and suffering as migraine, however, it is profitable to report any safe means that gives a satisfactory result" (pp. 9-10).

## AUTITION

1999

Kallio, Sakari; Revonsuo, Antti; Lauerma, Hannu; Hdmldinen, Heikki; Lang, Heikki (1999). The MMN amplitude increases in hypnosis - a case study. Neuroreport, 10 (17), 3579-3582.

The neural mechanisms associated with hypnosis were investigated in a single highly hypnotizable subject by measuring the mismatch negativity (MMN) component of auditory ERP, reflecting the preattentive discrimination of change in stimulus flow, in normal baseline state and under hypnosis. It has been proposed that the frontal inhibition associated with hypnosis can be measured as a decrease in MMN. ERPs were elicited using the passive oddball paradigm with standard and deviant sine tone stimuli of 500 and 553 Hz respectively. The measurement was repeated in five separate sessions. In hypnosis the MMN was significantly larger compared to baseline. The results indicate that hypnosis can give rise to altered information processing in the brain even at a relatively early, i.e. preattentive level and that the larger MMN measured under hypnosis does not support frontal inhibition theory.

1995

Mason, J.; Rogerson, D. (1995). Client-centered hypnotherapy for tinnitus: Who is likely to benefit?. American Journal of Clinical Hypnosis, 37 (4), 294-299.

## NOTES

1:

The study involved 41 patients, mean age 54, who had three sessions of hypnosis. On three-month followup evaluation, those who benefitted most from hypnosis had less hearing loss in their better-hearing ear.

Matthews, William J.; Isenberg, Gail L. (1995). A comparison of the hypnotic experience between signing deaf and hearing participants. International Journal of Clinical and Experimental Hypnosis, 43 (4), 375-385.

This study compared the hypnotic responsiveness of 17 hearing and 34 deaf individuals, all of whom received visual induction and hypnotic suggestions via some form of signing. The comparison between deaf and hearing participants was analyzed on five dependent measures: (a) the Stanford Hypnotic Susceptibility

Scale, Form C (SHSS:C); (b) participants' individual item performance; (c) overall trance depth; (d) a rapport scale; and (e) a resistance scale measuring attitudes of participants toward the hypnotist. Although all participants showed at least a moderate level of hypnotic responsiveness, the data did not indicate a significant main effect between deaf and hearing participants on any of the dependent measures. However, there was a tendency ( $p < .08$ ) for hearing participants to show a greater hypnotic responsiveness than deaf participants. Additionally, there was a significant difference between all the signing participants combined when compared to the norming population on three items of the SHSS:C. Clinical and theoretical implications of these data are discussed.

**1993**

**Dabic-Jeftic, Mirjana; Barnes, Graham (1993). Event-related potentials (P300) during cognitive processing in hypnotic and non-hypnotic conditions. Psychiatria Danubina, 5 (1-2), 47-61.**

In this study authors investigated to find out if there were any specific changes of event related potentials in subjects before hypnosis, entering hypnosis, in deep hypnosis and leaving hypnosis, and to compare mental activities of subjects such as capability of correctly calculating and remembering the exact number of unexpected stimuli delivered by stimulator with their verbal or nonverbal reports during any of the conditions investigated. The methodology was of testing the cognitive evoked potentials elicited by auditory stimuli, using the oddball paradigm. Obtained results show that the most constant values of shortest latency and highest amplitudes of the cognitive waves, especially P300 were found during deep hypnosis. All five subjects in the investigation answered with the exact number of delivered target stimuli only after deep hypnosis. Conversely, in all other conditions their answers were approximate to the correct number of delivered target stimuli. (Author abstract.)

**NOTES**

**1:**

In this experiment, 5 adult volunteers were told to attend to one of two tones delivered through headphones. The tones were randomly delivered but one occurred 85% of the time (the 'frequent, non-target tone') and the other occurred 15% of the time (the 'rare, target tone'). The subjects were to notice, remember, and count the target tone. Measures were taken during five periods: pre-hypnosis, entering hypnosis, deep hypnosis, leaving hypnosis, and post-hypnosis.

Some subjects had extensive hypnosis experience prior to the experiment; others had little.

The EEG P300 wave was sensitive to condition. Latency of P300 was significantly shorter in deep hypnosis compared with other periods. Higher amplitude of P300 also occurred during deep hypnosis compared with other periods. (Notes taken from secondary reference, Ericksonian Newsletter.)

**Lyskov, E.; Juutilainen, J.; Jousmaki, V.; Hanninen, O.; Medvedev, S.; Partanen, J. (1993). Influence of short-term exposure of magnetic field on the bioelectrical**

processes of the brain and performance. International Journal of Psychophysiology, **14**, 227-231.

The influence of an extremely-low-frequency (ELF) magnetic field on the bioelectrical processes of brain and performance was studied by EEG spectral analysis, auditory-evoked potentials (AEP), reaction time (Roletaking) and target-deletion test (TDT). Fourteen volunteers were exposed for 15 min to an intermittent (1 s on/off) 45- Hz magnetic field at 1000 A/m (1.26 mT). Each person received one real and one sham exposure. Statistically significant increases in spectral power through alpha- and beta- bands, as well as in mean frequency of the EEG spectrum were observed after magnetic field exposure. Field-dependent changes of N100 were also revealed. No changes in the amplitudes or latencies of the earlier peaks were observed. No direct effects on Roletaking, nor on TDT performance were seen. However, practice effects on Roletaking (decrease of Roletaking in the course of the test-sessions) seemed to be interrupted by exposure to the magnetic field.

1992

Matthews, William J.; Isenberg, Gail L. (1992). Hypnotic inductions with deaf and hearing subjects - an initial comparison: A brief communication. International Journal of Clinical and Experimental Hypnosis, **40** (1), 7-11.

17 volunteer deaf Ss were compared with 18 volunteer hearing Ss on the Stanford Hypnotic Clinical Scale (SHCS) of Morgan and J. R. Hilgard (1975), and the Indirect Suggestion Scale (ISS) of Matthews and Mosher (1985) in a 2 x 2 ANOVA design. 5 dependent measures: (a) objective scale score; (b) self-report scale score; (c) S rapport with the hypnotist; (d) S resistance to the hypnotist; and (e) overall subjective rating of trance experience were employed to measure any differences between the 2 groups. For SHCS behavioral items, the two-way ANOVA failed to reveal any significant main effect or interaction differences between either group (deaf/hearing) or method of induction (direct/indirect). There was a significant main effect for deaf/hearing groups in level of resistance to the hypnotist. Deaf Ss reported feeling more resistant to the hypnotist than did hearing Ss. This may be due to the mode of communication or the fact that the hypnotist was hearing. Implications and limitations of the study are discussed.

Spanos, Nicholas P.; Burgess, C. A.; Cross, P. A.; MacLeod, G. (1992). Hypnosis, reporting bias, and suggested negative hallucinations. Journal of Abnormal Psychology, **101**, 192-199.

Examined the role of reporting bias in hypnotic negative hallucinations by using a paradigm in which reporting bias was assessed independently of perceptual change. In Experiment 1, highly hypnotizable subjects reported significant loudness reductions when tested for hypnotic deafness. Later, however, these subjects biased their reported loudness reductions in the absence of perceptual change, and their reporting bias scores were almost as large as their hypnotic deafness reports. Subjects also biased their ratings of strategy use. In Experiment 2, ratings of

blindness given in response to a hypnotic negative visual hallucination suggestion were significantly correlated with reporting bias scores obtained in this paradigm. Although hypnotic blindness and hypnotic deafness correlated significantly, the partial correlation between these variables was nonsignificant when reporting bias scores were statistically controlled. Results are used to support a skeptical view of hypnotic response as being based on compliance.

**1991**

Cochrane, Gordon J. (1991). Client-therapist collaboration in the preparation of hypnosis interventions: Case illustrations. American Journal of Clinical Hypnosis, 33, 254-262.

Therapists can use hypnosis in a variety of situations to help clients utilize their own resources effectively. In both heterohypnosis and tape-assisted self-hypnosis, the respectful collaboration of therapist and client in the development of specific intervention strategies can be effective. I have described four cases to illustrate the collaborative aspect of heterohypnosis in a surgical setting and tape-assisted self-hypnosis for anxiety, tinnitus, and situational depression. In each case the clients were willing and able participants.

**NOTES**

**1:**

"Hypnotic interventions as adjunctive therapeutic modalities for a variety of surgical procedures have been well documented (Frankel, 1987; Gravitz, 1988; Nathan, Morris, Goebel, & Blass, 1987). The availability, relative safety, dependability, and ease of use have made chemical agents the anesthetic of choice in the majority of surgical situations, but hypnosis, either alone or in conjunction with chemical agents, can have a number of advantages for some patients (Udolf, 1987, p. 248). Some patients who have extreme preoperative pain and anxiety can learn to use self-hypnosis (Frankel, 1987); others may use hypnosis when experiencing postoperative nausea and other uncomfortable side effects of chemical anesthetics. Some may fear death under general anesthesia or react to a previous trauma arising from general anesthesia and the operating room procedures in general (Udolf, 1987, p. 250) and therefore choose hypnotic strategies. In the following case illustration the patient feared general anesthesia because of a previous negative postoperative experience" (p. 255).

While collaboratively planned hypnosis often empowers the patient, contributing to a sense of personal control and well being, some patients are not able to participate in that manner. Cochrane cites patients who are severely depressed or "who struggle with narcissism and other severe pathologies" (p. 260). He notes that audiotapes are useful for supplementing in-session therapy, contributing to skill development, attitude change, and a sense of self-worth. He cites Eisen and Fromm (1983) as indicating that self hypnosis is also useful for clients "who struggle with issues of control and intimacy" (p. 260).

**1990**

Wood, W. E.; Gibson, W.; Longo, D. (1990). Moderation of morbidity following tonsillectomy and adenoidectomy: A study of awareness under anesthesia. International Journal of Pediatric Otorhinolaryngology, 20, 93-105.

In a double-blind study, 67 children, ages 3-10, were randomly assigned to one of three groups: tape recorded therapeutic suggestions repetitively recited in English or in French, and a control of continuous white noise. The English condition was associated with more favorable outcome on all parameters, although statistical significance could not be demonstrated. Favorable outcomes appeared most significant for those patients at highest risk for poor convalescence (i.e., poor status preoperative patients).

1989

Hall, H.; Minnes, L. (1989). Psychological modulation of auditory responses. International Journal of Psychosomatics, 36 (1-4), 59-63.

Psychological modulation of auditory response, the effects of imagery and suggestion on auditory thresholds were examined in naive subjects. After a hypnosis-like induction, the subjects, who were not aware of the purpose of the study, were asked to generate and maintain a specific set of images before, during, and after which their auditory thresholds were tested. Following the imagery, which represented cooling and vasoconstriction in the cochlea, audiograms revealed a temporary auditory threshold shift (TTS) in the experimental group only. This TTS pattern was similar to that produced by exposure to loud noise. Information carried in the image is suggested as the basis for the observed auditory changes. Although a hypnosis-like induction was employed, the subjects' level of hypnotizability did not appear to be related to the findings.

1988

Aravindakshan, K. K.; Jenner, F. A.; Souster, L. P. (1988). A study of the effects of hypnotic regression on the auditory evoked response. International Journal of Clinical and Experimental Hypnosis, 36, 89-95.

Hypnotic regression in 6 hypnotizable Ss experienced in regression was studied by means of the auditory evoked response (AER). AER latency and amplitude is affected by arousal, attention, stimulus strength, and age. Ss aged between 27 and 61 years were regressed to the age of 7-9 years, and AERs were compared among three states of consciousness: normal awareness, hypnotic relaxation, and hypnotic regression. There was no change in AER morphology in the direction of that seen in children. Thus, age regression is not seen as a reversion to an earlier stage of neurological development but perhaps as role playing which is spontaneous and uninhibited, with the benefit of innocent belief in its accuracy.

NOTES

1:  
Raikov (1982) regressed 2 experienced Ss, comparing his results with those of actors acting as children and low hypnotizable subjects; he claimed to be able to reproduce

neonatal reflexes in the highly hypnotizable Ss but not in the actors and low hypnotizable subjects.

AER's were used "because latency of the major waves and amplitude of the response is affected by level of arousal and attention..., strength of the stimulus, and, more importantly for this study, by age.... Surwillo (1981) noted that peak latencies of AERs were 16-21 msec longer in children aged 9-13 than in adults..." (p. 90)

DISCUSSION reviews the literature. "Changes in the intensity of light stimulation can cause significant shifts in the amplitude and latency of the visual evoked response, but neither the amplitude nor the latency have been changed by suggested alterations in stimulus intensity during hypnosis (Andreassi, Balinsky, Gallichio, de Simone, & Mellers, 1976; Beck & Barolin, 1965; Beck, Dustman, & Beier, 1966; Zakrzewski & Szelenberger, 1981). Similarly, significant changes were seldom found in the AER with suggested variations of sound intensity during hypnosis (Amadeo &

Yanovski, 1975) and in somatosensory responses to electrical stimuli applied to the fingers with suggested anesthesia during hypnosis (Halliday & Mason, 1964). Deehan and Robertson (1980) were able to abolish the AER completely during hypnosis, but their stimuli were very different from that used in the present study.

"In all such studies, hypnosis and suggestions were aimed at changing the intensity of the stimulus to S's awareness, while the actual intensity of the stimulus was unaltered. In the present study, the authors attempted to find whether the morphology of the AER in children could be reproduced by age regression, without altering the nature or intensity of the stimulus in its delivery.... Like previous investigators, the present authors noticed that the tracings were cleaner and easier to produce during hypnosis (see Figure 1), although the changes in neurological development observed by Raikov (1982) were not evident" (pp. 93-94).

1987

Nash, Michael R.; Lynn, Steven Jay; Stanley, Scott; Carlson, Victor (1987). Subjectively complete hypnotic deafness and auditory priming. International Journal of Clinical and Experimental Hypnosis, 35 (1), 32-40

The present study examined the cognitive and attentional mechanisms by which auditory information is maintained out of awareness during complete hypnotic deafness. Adopting a methodology from recent work on subliminally presented pattern- masked words and dichotic listening, the study tested whether spoken words presented during complete hypnotic deafness affect lexical decisions concerning subsequently presented word choices. The response of 9 hypnotized and 15 simulating Ss to spoken stimulus words presented following hypnotic deafness instructions was compared to the response of 20 baseline control Ss who never were exposed to the stimulus words. While the response pattern of hypnosis Ss appeared different from that of baseline control Ss, hypnotic Ss showed no evidence of the priming effect found in subliminal perception and dichotic listening studies. Simulator response deviated significantly from hypnotized and baseline control responses.

**NOTES**

**1:**

10 highs capable of hypnotic deafness, screened by Harvard Group and Stanford Profile Scales (Means 11.0 and 24.7, respectively) and 15 lows (means 1.7 and 1.7, respectively) participated in the study; the low hypnotizables being in the simulation group. For the experimental session, a different E administered a standard hypnotic induction and the deafness suggestion, testing for deafness by snapping fingers near S's ear and making loud requests for motor responses.

An experimental trial consisted of tapping an S on the hand, saying the stimulus word out loud, and visually presenting four words for the S to read out loud and circle one. "Of the 18 main experimental trials, the four-word array consisted of two words which were related to the stimulus (one word which was semantically related to the spoken stimulus word and one word which was phonetically related), and two neutral unrelated words" (p. 34). For example, if the spoken word were 'dream,' the word array might include 'cream, tennis, sell, sleep.' There also were "3 phonetically unrelated trials (whose arrays consisted of one phonetically related choice and 3 unrelated choices) and 2 stimulus word-unrelated trials (whose arrays consisted of the stimulus word and 3 unrelated choices) ... [and] 7 dummy trials with 4 unrelated choices only" (p. 34). Ss rated their degree of deafness on a 10-point scale after hypnosis was terminated.

Possible sources of bias were examined by having 20 control Ss respond to blank tachistoscopic slides with the instructions that they were participating in a study of 'subliminal perception.' Another 22 Ss were asked to identify the semantically and phonetically related words from the word array, which for the most part they did successfully.

All Ss rated themselves as '10' on the deafness scale, indicating total deafness. The principal results are seen in Tables 1 and 2.

**Table 1 Mean Number of Related and Unrelated Responses (Percentage of Responses) for all S Groups on the 18 Mean Experimental Trials**

Response Category	S	Group	N	Related	Unrelated	Total
Hypnotized	9	7.22	10.78	18		
	(40.13%)	(59.88%)	(100%)			
Simulating	15	12.13	5.87	18		
	(67.43%)	(32.61%)	(100%)			
Baseline	19	8.79	9.21	18	Controls	(48.82%) (51.17%) (100%)

**Table 2 Mean Number of Phonetic and Semantic Responses within the Related Response Category on the 18 Main Experimental Trials**

Related Responses	S	Group	Phonetic	Semantic
Hypnotized	1.78	5.44		
	(9.89%)	(30.24%)		
Simulating	7.07	5.07		
	(39.27%)	(28.16%)		
Baseline	4.21	4.58	Controls	(23.38%) (25.44%)

Hypnotized Ss were significantly different from simulators (Table 1) in number of related responses. Simulators gave significantly more related responses than baseline controls. Simulators also gave more phonetically related words than either the hypnotized or baseline Ss (Table 2); there was no difference between groups on semantically related words. (Authors performed other useful and detailed analyses.) In their Discussion section, the authors note that they did not obtain the expected results of hypnotized Ss producing more related responses than baseline Ss. "In

fact, internal analyses of hypnotized and baseline responses revealed that the pattern of choices for hypnotic deaf Ss was opposite to the direction predicted by subception. Hypnotic Ss appeared to avoid phonetically related word choices, even for items on which baseline control Ss scored above chance. ...

"This kind of non-baseline performance by hypnotic Ss can be accounted for by either a strategic enactment conceptualization of hypnosis (Spanos, 1982; Wagstaff, 1981) or Hilgard's (1979) neo-dissociation theory. Spanos might emphasize the hypnotic S's active strivings to meet the hypnotist's perceived expectations. ... Neo-dissociation theory might stress the mechanisms by which processing of auditory inputs are maintained outside of awareness via a dissociative barrier.

" ... Given the tendency for simulating Ss to 'overplay' hypnotic phenomena (Levitt & Chapman, 1979), one might have expected simulators to pointedly avoid related responses, thus producing a lower frequency of related words than either the hypnotic Ss or the baseline controls (in effect being more deaf than the deaf). Just the opposite occurred. One possible explanation for this behavior presents itself: In their work with posthypnotic suggestion and the 'disappearing hypnotist' ... M. T. Orne and others found that simulating Ss may be more alert and responsive to demand cues than are hypnotic Ss. In the present study, the authors' original hypothesis was that hypnotic Ss might reveal a subception effect by above-chance responding on related word choices. If we assume that this expectation was somehow communicated to Ss by some subtle aspect of the experimental procedure, then it is conceivable that simulating Ss were able to detect and act upon these cues, while hypnotized Ss remained relatively unattuned to such subtleties.

"In sum, the priming effect noted in the subliminal perception research does not appear to be a feature of complete hypnotic deafness, at least as measured in this study. The behavior of simulating Ss in the present study should be another caution to researchers that differences between hypnotized and simulating Ss may reflect simulation effects in addition to, or instead of, hypnotic effects" (pp. 37-38).

Spellacy, F.; Wilkinson, R. (1987). Dichotic listening and hypnotizability: Variability in ear preference. Perceptual and Motor Skills, 64, 1279-1284.

28 right-handed, English-speaking Ss were administered the SHSS:C and a whole-word dichotic listening test, which was given in both waking and hypnotized states. Lows showed the usual right-ear advantage in both waking and hypnotized states. Highs showed a different pattern of ear advantage: half of them showed left-ear advantage in the waking state, but all showed right-ear advantage in the hypnotized state. Results are interpreted to show that for subjects of high hypnotizability the narrowed attention characteristic of hypnosis produces the expected lateralizing effect. Ss of low hypnotizability showed a consistent right-ear preference in both the hypnotized and nonhypnotized conditions. The results suggest that much of the atypical ear preference shown in dichotic listening experiments may be associated with the variability in cognitive states found in persons of high hypnotic susceptibility.

1985

Marks, N. J.; Onisiphorou, C. (1985). A controlled trial of hypnotherapy in tinnitus. Journal of Otolaryngology, **10**, 43-46.

#### NOTES

1:

14 patients with unilateral tinnitus were selected because of the constant nature of their tinnitus, and its resistance to all other forms of therapy. They were subjected to hypnosis in 3 forms in random order. The induction of a trance state alone formed the control arm of the trial. Compared to this were the effects of 'ego boosting' and active suppression of tinnitus whilst in a trance state. One of the 14 patients showed a highly significant response to the latter treatment as judged by visual analogue scales. Five of the 14 patients (35%) found the induction of a hypnotic state of value. This seemed to help them tolerate their tinnitus better, although its loudness and quality were unaltered.

1984

Hogan, Marjorie; MacDonald, John; Olness, Karen (1984). Voluntary control of auditory evoked responses by children with and without hypnosis. American Journal of Clinical Hypnosis, **27** (2), 91-94.

Reports ability of children to voluntarily change brainstem auditory evoked responses (BAER). Fifteen children were studied. Both control and hypnosis groups showed changes in interwave latencies after verbal suggestions when compared to a normal control group. These findings suggest that children may be able to modify peripheral auditory input into the brainstem through simple suggestion alone. Children in the formal hypnosis group did have more specific control for the task suggested. However, it is possible that children in the control group moved into an altered state of consciousness after listening to a taped story, reading a book, or spontaneously. They may have attained the observed changes in BAER while in a hypnosis-like state. This study encourages additional research in self-regulatory skills of autonomic processes in children.

1983

Borgeat, Francois; Goulet, Jean (1983). Psychophysiological changes following auditory subliminal suggestions for activation and deactivation. Perceptual and Motor Skills, **56**, 759-766.

This study was to measure eventual psychophysiological changes resulting from auditory subliminal activation or deactivation suggestions. 18 subjects were alternately exposed to a control situation and to 25-dB activating and deactivating suggestions masked by a 40-dB white noise. Physiological measures (EMG, heart rate, skin-conductance levels and responses, and skin temperature) were recorded while subjects listened passively to the suggestions, during a stressing task that followed and after that task. Multi-variate analysis of variance showed a significant effect of the activation subliminal suggestions during and following the stressing task. This result is discussed as indicating effects of consciously unrecognized perceptions on psycho- physiological responses.

**Brattberg, G. (1983). An alternative method of treating tinnitus: Relaxation-hypnotherapy primarily through the home use of a recorded audio cassette. International Journal of Clinical and Experimental Hypnosis, 31 (2), 90-97.**

32 patients, variously diagnosed as suffering from tinnitus, were treated with hypnosis. Treatment consisted of a 1-hour consultation with the physician followed by 4 weeks of daily home practice while listening to an audio-tape recording of approximately 15 minutes duration. 22 of the patients treated learned in 1 month to disregard the disturbing noise, a considerable gain in the ratio of therapy to time required.

#### **NOTES**

1:

The audio tape was of a 15-minute hypnotherapy session done on the first office visit, so that the home practice was more or less the same as the first visit in office. "The hypnotherapy was aimed at inducing the patient into as relaxed a state as possible, and thereafter implanting the suggestion that the patient would no longer be troubled by the noise" (p. 93).

**Smyth, Larry D.; Lowy, Doug (1983). Auditory vigilance during hypnosis: A brief communication. International Journal of Clinical and Experimental Hypnosis, 31 (2), 67-71.**

Attention during hypnosis was measured by means of auditory vigilance tasks which Ss performed while being administered the Stanford Hypnotic Susceptibility Scale, Form C (Weitzenhoffer & Hilgard, 1962). Hypnotic responsivity was significantly and negatively correlated with Ss' performance of the tasks, indicating that relatively responsive Ss detected fewer extraneous environmental stimuli in the form of vigilance task signals than did the less responsive Ss. Discussion ensued as to how this apparent reduction in attention to environmental stimuli came about.

#### **1982**

**Macleod-Morgan, Crisetta; Court, John; Roberts, Russell (1982). Cognitive restructuring: A technique for the relief of chronic tinnitus. Australian Journal of Clinical and Experimental Hypnosis, 10 (1), 27-33.**

A combination of relaxation and imagery was used to teach an altered perception of their chronic tinnitus to a series of clients, for all of whom medical intervention had proved ineffective. Over a number of visits to the Flinders Psychology Clinic, the hum which had been troubling them became a cue for relaxation and peace. Thus, whenever they became aware of their tinnitus it came to be welcomed where prior to intervention it had been a constant irritant

## NOTES

1:

This second volume of four has five sections, with chapters as follows. I. Visual Processes

1. The hypnotic induction of hallucinatory color vision followed by pseudonegative afterimages (written with E. M. Erickson)
2. Discussion: Critical comments on Hibler's presentation of his work on negative afterimages of hypnotically induced hallucinated colors (written by E. M. Erickson)
3. The induction of color blindness by a technique of hypnotic suggestion
4. An experimental investigation of the hypnotic subject's apparent ability to become unaware of stimuli
5. The development of an acute limited obsessional hysterical state in a normal hypnotic subject
6. Observations concerning alterations in hypnosis of visual perceptions (written by E. M. Erickson)
7. Further observations on hypnotic alteration of visual perception (written by E. M. Erickson)
8. An investigation of optokinetic nystagmus
9. Acquired control of pupillary responses II. Auditory Processes
10. A study of clinical and experimental findings on hypnotic deafness: I. Clinical experimentation and findings
11. A study of clinical and experimental findings on hypnotic deafness: II. Experimental findings with a conditioned response technique
12. Chemo-anaesthesia in relation to hearing and memory
13. A field investigation by hypnosis of sound loci importance in human behavior III. Psychophysiological Processes
14. Hypnotic investigation of psychosomatic phenomena: Psychosomatic interrelationships studied by experimental hypnosis
15. Hypnotic investigation of psychosomatic phenomena: The development of aphasiatic reactions from hypnotically induced amnesias (written with R. M. Brickner)
16. Hypnotic investigation of psychosomatic phenomena: A controlled experimental use of hypnotic regression in the therapy of an acquired food intolerance
17. Experimentally elicited salivary and related responses to hypnotic visual hallucinations confirmed by personality reactions
18. Control of physiological functions by hypnosis
19. The hypnotic alteration of blood flow: An experiment comparing waking and hypnotic responsiveness
20. A clinical experimental approach to psychogenic infertility
21. Breast development possibly influenced by hypnosis: Two instances and the psychotherapeutic results
22. Psychogenic alteration of menstrual functioning: Three instances
23. The appearance in three generations of an atypical pattern of the sneezing reflex
24. An addendum to a report of the appearance in three generations of an atypical pattern of the sneezing reflex IV. Time Distortion
25. Time distortion in hypnosis, I (written by L. F. Cooper)
26. Time distortion in hypnosis, II (written with L. F. Cooper)

- 27. The clinical and therapeutic applications of time distortion
- 28. Further considerations of time distortion: Subjective time condensation as distinct from time expansion (written with E. M. Erickson) V. Research Problems
- 29. Clinical and experimental trance: Hypnotic training and time required for their development
- 30. Laboratory and clinical hypnosis: The same or different phenomena?
- 31. Explorations in hypnosis research (with a discussion by T. X. Barber, R. Dorcus, H. Guze, T. Sarbin, and A. Weitzenhoffer)
- 32. Expectancy and minimal sensory cues in hypnosis
- 33. Basic psychological problems in hypnotic research
- 34. The experience of interviewing in the presence of observers

1979

Bennett, Henry L.; Giannini, Jeffrey A.; Kline, Mark D. (1979, September). Consequences of hearing during general anesthesia. [Paper] Presented at the annual meeting of the American Psychological Association, New York.

A double blind 2X2 study exposed 23 herniorrhaphy and cholecystectomy patients to either a 45 minute suggestion tape or to the actual sounds of the operation. Structured interviews conducted postoperatively assessed hypnotic susceptibility and regressed patients under hypnosis to operative events. Ten patients accurately recalled significant events from surgery but only under hypnosis. Recall was greater and more accurate in patients scoring high on the Stanford Clinical Hypnosis Scale. Fewest number of pain medications were given postoperatively to patients receiving the suggestion tape. Hernia patients showed better recall than gallbladder patients.

1977

Ryan, M. L.; Sheehan, Peter W. (1977). Reality testing in hypnosis - subjective versus objective effects. International Journal of Clinical and Experimental Hypnosis, 25, 27-51.

90 unselected Ss were assigned to a 2 x 3 (Request for Honesty x Suggestibility Instruction) factorial design to test the hypothesis that hypnotic Ss would show pronounced impairment of reality testing by expressing a degree of conviction substantially out of phase with their objective performance. Barber's operational model of hypnosis was adopted to test the prediction on an unusually distinctive auditory comprehension task. The 2 interdependent measures, confidence and accuracy, were highly positively related indicating that, generally speaking, hypnotic Ss performed adaptively, as did task motivated and control Ss. Results for the difficult aspects of the task were most distinctive. Here, degree of confidence about behavior as expressed by Ss who performed well on the suggestibility tests was relatively greater than the confidence expressed by those who performed poorly; further, hypnotic Ss were distinctively willing to respond on the least intelligible parts of the task. The inconsistent nature of certain features of hypnotic behavior was discussed in some detail.

Trustman, R.; Dubovsky, S.; Titley, R. (1977). Auditory perception during general anesthesia -- myth or fact. International Journal of Clinical and Experimental Hypnosis, 25 (2), 88-105.

Reports have appeared periodically in the literature indicating that surgical patients can hear and be influenced by remarks occurring while they are under general anesthesia. Much of the evidence has been obtained by postoperatively studying patients under deep hypnosis. The present article discusses the empirical status of this phenomenon, "auditory perception during anesthesia." 14 selected studies regarding auditory perception during general anesthesia were critically reviewed. All were found to have serious deficiencies as evidence for or against the occurrence of auditory perception during general anesthesia. Methodological and theoretical difficulties of conducting research into auditory perception during general anesthesia were discussed, and suggestions for future research were offered.

1976

Slade, P. D. (1976). An investigation of psychological factors involved in the predisposition to auditory hallucinations. Psychological Medicine, 6 (1), 123-132.

Previous research by the author (Slade, 1972, 1973) and others has suggested that psychological stress plays an important role in triggering off the experience of auditory hallucinations. Clearly, however, predispositional factors are involved as well. The present study is an attempt to investigate some of the psychological factors which may predispose the individual to such experiences. A battery of tests involving cognitive, personality and mental imagery variables and the verbal transformation effect was administered to two small groups of psychotic patients differing only in respect of a history of auditory hallucinations and a normal control group. The main conclusion was that the results lend direct support to the proposition of Mintz & Alpert (1972) that a combination of vivid mental imagery and poor reality-testing in the auditory modality provides the basic predisposition for the experience of auditory hallucinations.

1968

Scheibe, Karl E.; Gray, Arne L.; Kleim, C. Stephen (1968). Hypnotically induced deafness and delayed auditory feedback: A comparison of real and simulating subjects. International Journal of Clinical and Experimental Hypnosis, 16, 158-164.

PRELIMINARY RESEARCH INDICATES THAT HYPNOTICALLY INDUCED DEAFNESS MAY REDUCE THE SPEECH INHIBITING EFFECTS OF DELAYED AUDITORY FEEDBACK (DAF). REAL AND SIMULATING HYPNOTIC SS WERE COMPARED WITH RESPECT TO THE IMPROVEMENT IN SPEECH CONSEQUENT TO THE SUGGESTION OF DEAFNESS. RESULTS INDICATE VERY SIMILAR IMPROVEMENTS OF DAF SPEECH FOR BOTH GROUPS. AN INCIDENTAL FINDING IS THAT REAL SS HAD LONGER SIMPLE READING TIMES UNDER HYPNOSIS THAN DID

1954

Kline, Milton V.; Guze, Henry; Haggerty, Arthur D. (1954). An experimental study of the nature of hypnotic deafness: Effects of delayed speech feedback. Journal of Clinical and Experimental Hypnosis, 2 (2), 145-156.

NOTES

1:

The research subject was a 29 year old college student who was given delayed speech feedback in both the waking state and deeply hypnotized with suggestions of deafness. (Clinically, during hypnotic deafness he lacked the startle reflex in response to auditory stimuli and lost a conditioned response based on auditory stimulus.) Following the experimental procedures, the authors concluded:

"1. Delayed feed-back in the state of hypnotically induced deafness produces distinct impairment in speech performance. This impairment involves loss of motility, increased errors in enunciation and increasing impairment in proportion to increasing difficulty of vocabulary.

2. The speech impairment found in hypnotically induced deafness is very significantly less than the impairment found in waking feed-back performance.

3. The pattern of speech performance in hypnotic deafness shows a pattern very similar to that of non feed-back with respect to constancy of performance and the linear relationship between performance efficiency and difficulty of verbal stimuli.

4. Waking feed-back performance is significantly more variable and erratic than the non feed-back or hypnotic deafness series.

5. Hypnotic deafness does not appear to follow the same neurophysiological pattern as organic deafness with regard to auditory feed-back.

6. Hypnotic deafness does alter certain behavioral [sic] responses to audition and appears to alter the character and nature of hearing.

7. Hypnotically induced deafness would appear to represent a valid alteration of hearing function but not a state akin to organic deafness.

8. Hypnosis appears to be capable of altering feed-back mechanism of an auditory nature" (p. 155).

Malmo, Robert B.; Boag, Thomas J.; Raginsky, Bernard B. (1954). Electromyographic study of hypnotic deafness. Journal of Clinical and Experimental Hypnosis, 2 (4), 305-317.

NOTES

1:

The main purpose of the present study was to investigate the question of similarities and differences between hysterical deafness, previously studied, and hypnotically induced deafness. The study was designed to repeat the objective physiological tests previously carried out with a case of 'total hysterical deafness.' There was also the more general aim of securing objective data to enrich our general understanding of hypnosis.

"Similarities between hysteria and hypnosis which we observed may be listed as follows: (a) Significantly reduced motor reaction (exclusive of blink) to strong

auditory stimulation in the deaf state. (b) Complete hearing loss in the hysteric and in one of the hypnotic subjects, even with strong auditory stimulation (i.e., denial of any auditory sensation). (c) With elicitation of strong startle reaction to the first stimulus in the deaf state, much smaller reaction to the next stimulus than would have been predicted on the basis of habituation. (d) Suggestion of substitution of somesthetic for auditory sensations in all subjects (although this was much less definite in the hypnotic subjects than the hysteric).

"The most outstanding dissimilarity lay in the absence of emotional reaction when 'hypnotic defense against sound' was broken through, in contrast to marked affective reaction in the hysterical subject under these conditions.

"The question of inhibitory mechanisms in hysteria and hypnosis was discussed" (pp. 316-317).

Schneck, Jerome M. (1954). A hypnoanalytic investigation of psychogenic dyspnea with the use of induced auditory hallucinations and special additional hypnotic techniques. Journal of Clinical and Experimental Hypnosis, 2, 80-90.

This paper describes in detail and with discussion the hypnoanalytic session which was instrumental in relieving a patient of severe dyspnea and fatigue based on intense, long standing psychological conflict. The conflict entailed the intermingling of past concerns and current pressing problems. These had to do with the patient's long repressed feelings about having been told that her birth had been unplanned. They related to current indecision about becoming pregnant. Attitudes toward her parents were significant and these involved mixed feelings with the significance of her conscious and unconscious images of them. Into this picture there were projected the patient's attitudes toward herself and her methods of functioning somatically as well as psychologically. The symbolic connotation of her symptoms as deterioration and dying in relation to needs for self-destruction were clarified. The symptoms of one and a half to two years duration were dissipated within a few hours and improvement had been maintained for more than a year at the time of writing.

"The use of induced music associations in order to make inroads into the core of the conflict is described. The dynamic significance of spontaneous choice of such theme [sic] is discussed. Other hypnotic techniques involve visual imagery with dream-like qualities and in the form of scene visualizations (8, 9). Attention is centered on induced auditory hallucinations and interesting facets of such experiences are discussed in relation to subjective and objective qualities of such hallucinations and the issue of dynamic validity" (p. 90).

Schneck, Jerome M. (1954). An experimental study of hypnotically induced auditory hallucinations. Journal of Clinical and Experimental Hypnosis, 2, 163-170.

"Summary. An experimental study of hypnotically induced auditory hallucinations was incorporated into therapeutic contact with a patient at a time when an exploratory phase of treatment process seemed appropriate. The study was divided roughly into ten parts, nine of which involved attempts to induce hallucinations on

an auditory level following an initial control procedure involving 'imagined' conversation. Choice of persons to be hallucinated was made at times by the therapist and at times this was left for spontaneous development by the patient. Some of the episodes involved marked emotional participation by the patient. Others were less intense. 'Imagined' conversations were distinct from hallucinated comments. Her own voice when hallucinated emanated from within herself. Other hallucinated voices had external origins. Some were far away. Her aunt's voice was in the same room. Spatial and temporal elements were divorced from their conventional relationships and distorted in keeping with psychodynamic needs. The patient was able to discuss her experiences and evaluate certain descriptive and dynamic qualities. Certain parts of the total experience served as controls in the evaluation of other parts. The beginning of hallucinatory behavior did not set a pattern for continuous similar activity. Responsive behavior varied from time to time. A hallucinatory episode might be followed by an 'imagined' conversation, although instructions remained the same. Deceased persons were hallucinated on an auditory level. This type of episode with her mother had considerable emotional impact. Her aunt died twenty years ago. Her husband was not hallucinated. Responses involving her daughter showed greater complexity.

"Further studies are in order in connection with the neuropsychological and neurophysiological elements in such hypnotic hallucinatory activity. Such elements as they play a role in visual imagery as described here and in visual hallucinations are also to be examined further. Aside from extensions of the type of investigation presented here, inroads may be made into an understanding of spontaneous hallucinatory activity among psychotic patients through the utilization of hypnotic exploratory methods. This would have to be preceded by more extensive studies of hypnosis in relation to psychotic patients than have been attempted thus far. The procedure discussed here and many potential ramifications makes possible a wide variety of investigations which can be planned for the future" (pp. 169-170).

## **AUTOGENIC TRAINING**

**1999**

Wickramasekera, Ian (1999). How does biofeedback reduce clinical symptoms and do memories and beliefs have biological consequences? Toward a model of mind-body healing. *Applied Psychophysiology and Biofeedback*, 24 (2), 91-105.

Changes in the magnitude and direction of physiological measures (EMG, EEG, temperature, etc.) are not strongly related to the reduction of clinical symptoms in biofeedback therapy. Previously, nonspecified perceptual, cognitive, and emotional factors related to threat perception (Wickramasekera, 1979, 1988, 1998) may account for the bulk of the variance in the reduction of clinical symptoms. The mean magnitude of these previously nonspecified or placebo factors is closer to 70% when both the therapist and patient believe in the efficacy of the therapy. This powerful placebo effect is hypothesized to be an elicited conditioned response (Wickramasekera, 1977a, 1977c, 1980, 1985) based on the memory of prior healing. These memories of healing are more resistant to extinction if originally acquired on

a partial rather than continuous reinforcement schedule. High and low hypnotic ability in interaction with threat perception (negative affect) is hypothesized to contribute to both the production and reduction of clinical symptoms. High and low hypnotic ability respectively are hypothesized to be related to dysregulation of the sympathetic and parasympathetic arms of the autonomic nervous system. Biofeedback is hypothesized to be the most effective for reducing clinical symptoms in people of low to moderate hypnotic ability. For people high in trait hypnotic ability, training in self-hypnosis or other instructional procedures (e.g., autogenic training, progressive muscle relaxation, meditation, CBT, etc.) will produce the most rapid reduction in clinical symptoms.

**1994**

Ter Kuile, Moniek M.; Spinhoven, Philip; Linssen, A. Corry G.; Zitman, Frans G.; et al. (1994). Autogenic training and cognitive self-hypnosis for the treatment of recurrent headaches in three different subject groups. *Pain*, 58 (3), 331-340.

The aims of this study were to (a) investigate the efficacy of autogenic training (AT) and cognitive self-hypnosis training (CSH) for the treatment of chronic headaches in comparison with a waiting-list control (WLC) condition, (b) investigate the influence of subject recruitment on treatment outcome and (c) explore whether the level of hypnotizability is related to therapy outcome. Three different subject groups (group 1, patients (n = 58) who were referred by a neurological outpatient clinic; group 2, members (n = 48) of the community who responded to an advertisement in a newspaper; and group 3, students (n = 40) who responded to an advertisement in a university newspaper) were allocated at random to a therapy or WLC condition. During treatment, there was a significant reduction in the Headache Index scores of the subjects in contrast with the controls. At post-treatment and follow-up almost no significant differences were observed between the 2 treatment conditions or the 3 referral sources regarding the Headache Index, psychological distress (SCL-90) scores and medication use. Follow-up measurements indicated that therapeutic improvement was maintained. In both treatment conditions, the high-hypnotizable subjects achieved a greater reduction in headache pain at post-treatment and follow-up than did the low-hypnotizable subjects. It is concluded that a relatively simple and highly structured relaxation technique for the treatment of chronic headache subjects may be preferable to more complex cognitive hypnotherapeutic procedures, irrespective of the source of recruitment. The level of hypnotic susceptibility seems to be a subject characteristic which is associated with a more favourable outcome in subjects treated with AT or CSH.

**1992**

Zitman, Frans G.; Van Dyck, Richard; Spinhoven, Philip; Linssen, A. Corrie G. (1992). Hypnosis and autogenic training in the treatment of tension headaches: A two-phase constructive design study with follow-up. *Journal of Psychosomatic Research*, 36, 219-228.

Tension headaches can form a chronic (very long duration) condition. EMG biofeedback, relaxation training and analgesia by hypnotic suggestion can reduce the pain. So far, no differences have been demonstrated between the effects of various psychological treatments. In a constructively designed study, we firstly compared an abbreviated form of autogenic training to a form of hypnotherapy (future oriented hypnotic imagery) which was not presented as hypnosis and secondly we compared both treatments to the same future oriented hypnotic imagery, but this time explicitly presented as hypnosis. The three treatments were equally effective at post-treatment, but after a 6- month follow-up period, the future oriented hypnotic imagery which had been explicitly presented as hypnosis was superior to autogenic training. Contrary to common belief, it could be demonstrated that the therapists were as effective with the treatment modality they preferred as with the treatment modality they felt to be less remedial.

## NOTES

1:

An earlier review by these authors found that EMG biofeedback and relaxation training were equally effective with headache [Zitman, 1983, Biofeedback and chronic pain, In *Advances in Pain Research and Therapy* (Edit by Bonica, Lindblom, Iggo) V. 5, pp 794-809. N. Y.: Raven Press]. Other authors also found that hypnotic suggestion, EMG biofeedback and EMG biofeedback plus progressive relaxation training were equally effective [Schlutter, Golden, Blume, 1980, A comparison of treatments for prefrontal muscle contraction headache. *Br J. Med Psychol*, 53, 47-52.]. The authors raise the question whether any treatment element or perhaps combination of elements can enhance a basic relaxation training procedure, with respect to chronic headache.

The first phase of this research compared autogenic training (AT) and future oriented hypnotic imagery (FI) which was not labeled as hypnosis. Results were the same for both groups, and were reported earlier [van Dyck, Zitman, Linssen et al. *International Journal of Clinical and Experimental Hypnosis*, 1991, 39, 6-23]. The current study added a third group which received future oriented hypnotic imagery but also was told that they were getting hypnosis (FI-H). Thus the AT and FI groups were 'historical' comparison groups for the FI-H group in this study.

Patients were described as having headache complaints of at least 6 months (76% had been suffering for >2 years), were over 18 years old, had no drug dependence and no psychiatric disorder, and no previous therapy with autogenic training or hypnosis; no other treatment during the project; fluent in Dutch.

The autogenic training consisted of six exercises learned in a fixed order. The FI method, in which the hypnotized patient imagines himself in a future, pain-free, situation, had been described by Milton Erickson [1954, Pseudo-orientation in time as a hypnotherapeutic procedure. *JCEH*, 2, 261-283]. For that future situation the investigators used descriptions that the patients provided. Both kinds of intervention taught patients muscular and mental relaxation. Both methods required home practice of the technique, using audio cassettes.

In order to substantiate the labeling of the hypnotic procedure as hypnotic future oriented imagery (FI-H) "hand levitation induction was employed during session two with the purpose of inducing positive expectancies concerning hypnosis as a

procedure capable of changing ordinary experiences in an unexpected way [17]. This hand levitation procedure, however, was not presented on tape. Except for the labeling as hypnosis and the hand levitation induction, the hypnotic future oriented imagery procedure was identical to the future oriented imagery procedure in the first phase" (p. 221).

Treatment lasted for 8 weeks and provided 2 1/2 hours of therapist and 24 1/2 hours of home training with taped instructions. The outcome measures included: 1. Budzinsky-type headache index (mean daily sum of intensity rating for each hour of headache activity recorded during 3 separate days of the week of an assessment session) 2. State Anxiety 3. Zung-type Self-rating Depression Scale 4. Perceived credibility of treatment (4 Question's developed by Borkovec & Nau using a visual analogue scale) 5. Neuroticism from the CPI

**RESULTS.** Of 96 patients who agreed to participate, 17 dropped out before the post-treatment assessment. Of the remaining 79, 28 completed AT treatment, 27 FI, and 24 FI-H. Sixty-six attended the follow-up assessment; there were no dropouts from the FI-H, and the drop-outs were equally divided between the AT and FI condition. The headache index scores were logarithmically transformed because the distribution was positively skewed.

Using ANOVA, in terms of post-treatment scores, there were no significant main effects for therapist or treatment, nor were there any significant interaction effects when analyzing headache index, state anxiety, and depression. There was a significant main effect for Time for three outcome measures: headache index score, state anxiety, and depression.

Post-treatment, neither amount of medication used nor subjective estimates of headaches differed by treatment or by therapist. However, over time there were beneficial results for both treatment groups. "Patients rated their headaches as significantly reduced compared to pre-treatment (a mean pain reduction of 40%). ...they had significantly reduced their use of analgesic medication (a mean decrease of 14%)" (p. 224).

Using ANOVA, in terms of follow-up scores, again there were no significant main effects for Treatment or Therapist on the outcome measures of headache index, state anxiety, or depression. There now were three time periods (pre-, post-, and follow-up), and once again there was significant main effect for Time for headache index (though not for state anxiety). That is, people benefitted over the time of the treatment and follow-up. Moreover, there was a significant interaction effect between Therapy and Time on the headache index measure. "A posteriori contrasts revealed that the patients from the FI-H condition showed a greater reduction in their headaches between pre-treatment and follow-up than patients from the AT condition" (p. 225).

The authors write in their Discussion, "Our data indicate that at least in tension headache patients, defining a procedure explicitly as hypnotherapy may not lead to greater effects at post-treatment, but does lead to longer lasting effects" (p. 226).

"The paucity of differences between the three conditions may be a consequence of the study design: the small number of patients and the large SD may have prevented the detection of more differences in effect between the three conditions" (p. 226).

"Other critical remarks are related to the difference in headache reduction at follow-up between AT and FI-H. Firstly, the differences at follow-up were found only with respect to the headache index and not with respect to the subjective estimate of the pain. Secondly, in defining future oriented hypnotic imagery explicitly as hypnosis, we hoped to enhance the efficacy via increased credibility. We found increased efficacy, but we did not find enhanced credibility. Therefore, the differences in effect at follow-up must have another cause. The different effects at follow-up could be linked to the fact that the FI-H condition was the only one without drop-outs. This absence of drop-outs was due to a new research assistant who tried extraordinarily hard to make the patients return for follow-up. By doing so, she may have prevented the patients who gained much from the treatment from dropping out as well as those who gained little" (p. 226-227).

"In this study, despite the differences in therapists' preferences, both therapists were equally effective with all three treatments. This is an intriguing finding which goes against the belief commonly held by clinicians that therapists are more effective with the type of therapy they prefer" (p. 227).

"The effects were modest, but it must be kept in mind that most of our patients referred by a neurologist were chronic headache sufferers (76% had been suffering for > 2 yr). In such a group of patients even small effects are important, especially when these effects are long-lasting" (p. 227).

#### 1991

Van Dyck, Richard; Zitman, Frans G.; Linssen, A. Corry G.; Spinhoven, Philip (1991). Autogenic training and future oriented hypnotic imagery in the treatment of tension headache: Outcome and process. International Journal of Clinical and Experimental Hypnosis, 39, 6-23.

The aim of the present study was (a) to investigate the relative efficacy of autogenic training and future oriented hypnotic imagery in the treatment of tension headache and (b) to explore the extent to which therapy factors such as relaxation, imagery skills, and hypnotizability mediate therapy outcome. Patients were randomly assigned to the 2 therapy conditions and therapists. 55 patients (28 in autogenic therapy and 27 in future oriented hypnotic imagery condition) completed the 4 therapy sessions and 2 assessment sessions. Patients were to practice at home. No significant main effect or interaction effects for treatment condition or therapist was revealed. A significant effect for time in analyzing scores for headache pain, pain medication usage, depression, and state anxiety was found. In the self-hypnosis condition, pain reduction proved to be associated with depth of relaxation during home practice (as assessed with diaries) and capacity to involve in imagery (as assessed with the Dutch version of the Creative Imagination Scale). After statistically controlling for relaxation and imagery, hypnotizability scores (assessed by Stanford Hypnotic Clinical Scale) were significantly correlated with ratings of pain reduction. Results are discussed in the context of the neo- dissociation and social-cognitive models of hypnoanalgesia. The clinical relevance and the methodological shortcomings of the present study are also critically assessed.

## NOTES

1:

" Unexpectedly, pain reduction occurring in AT [autogenic training] appears to be brought about by different means than in hypnotic treatment. Not only imagery skills and hypnotizability, but also level of relaxation were unrelated to pain reduction achieved during AT. Since the first two therapy sessions of AT and hypnosis were identical and in both treatment conditions patients are explicitly instructed to relax, the absence of a relationship between depth of relaxation and pain reduction in AT cannot be easily explained" (p. 19).

1988

Malone, M.; Strube, M. (1988). Meta-analysis of non-medical treatment for chronic pain. Pain, 34, 231-234.

Conducted a meta-analysis of 109 published studies which assessed the outcome of various nonmedical treatments for chronic pain, 48 of which had sufficient information to calculate effect sizes. The remainder were examined according to proportion of patients rated as improved. Mood and number of subjective symptoms consistently showed greater responses to treatment than did pain intensity, pain duration, or frequency of pain, indicating the importance of using a multidimensional framework for pain assessment. Effect sizes for treatments were 2.74 for autogenic training, 2.67 for hypnosis, 2.23 for pill placebo, 1.33 for package treatments that allowed patients to choose from diverse pain management strategies, .95 for biofeedback, .76 for cognitive therapy, .67 for relaxation, .55 for operant conditioning, and .46 for TENS units. However, the largest numbers of studies were in the area of biofeedback, a treatment package, and relaxation, and we must be cautious in interpreting the effect sizes due to the small number of studies in the sample.

1987

Meyer, von H. K.; Diehl, B. J. M.; Ulrich, P.; Meinig, G. (1987). Kurz- und langfristige Änderungen der kortikalen Durchblutung bei Autogenem Training[Short and long-term changes in cortical circulation caused by autogenic training]. Zeitschrift für Psychosomatische Medizin und Psychoanalyse, 33 (1), 52-62.

The well-known hyperfrontal pattern of hemispheric blood flow measured with 133-Xenon is not found in 12 healthy resting men who have been practicing Autogenic Training at least six months. This might indicate a long-term decrease in the level of activation. Successfully practiced exercises of Autogenic Training lead to an increased blood flow in the Rolandic area representing the body scem (sic) and to a decreased blood flow in regions related to acoustical attention and to autonomic functions. Left hemispheric cerebral blood flow is lower in rest. The relative activation of the left hemisphere during Autogenic Training is discussed.

Ulrich, P.; Meyer, H. J.; Diehl, B.; Meinig, G. (1987). Cerebral blood flow in autogenic training and hypnosis. Neurosurgery Review, 10, 305-307. (Abstracted in American Journal of Clinical Hypnosis, 1989)

In 12 healthy volunteers with at least an experience of 6 months in autogenic training (AT), the cerebral blood flow (CBF) was measured at rest, in AT, and in hypnosis (H). The results were correlated with individual test profiles. The cortical flow pattern at rest of our AT-trained volunteers did not show the hyperfrontality which is described in the literature. This may be interpreted as an effect of better and habitualized relaxation in long-trained AT practitioners. This flow pattern corresponds to the low grades of neuroticism and aggressivity found in the tests. Furthermore, an activation in central cortical areas and a deactivation in regions which are associated with acoustic and autonomous functions occur. Possible explanations for these phenomena as well as for the relatively low perfusion of the left hemisphere at rest and activation in AT are discussed. The global rise of CBF in Hypnosis may be an activation effect caused by resistance against the hypnotizer: the deeper the trance, the smaller the catalepsy of the right arm and in temporal cortical fields processing acoustic inputs.

NOTES

1:

Reviews changes that have occurred in progressive relaxation training and their effects. The authors conclude:

"Jacobson's original progressive relaxation technique differs from the types of progressive relaxation used by many current practitioners in a number of fundamental respects. Jacobson emphasized relaxation as a method of learning to control one's excess muscle tension 24 hours per day. In his mind, progressive relaxation was not a method by which something is done\_ to\_ a person. Rather, it is a method by which the individual learns to control his or her own body. Jacobson, therefore, rejected the use of suggestion and of various biofeedback instruments and conditioning techniques that may induce relaxation during a training session. Empirical evaluations of most elements of the two progressive relaxation techniques have not yet been done. Thus, although many studies have compared progressive relaxation with a number of hypnotic, cognitive, and combined somatic-cognitive techniques, no one has dismantled the progressive relaxation technique Jacobson's or modified versions, in order to study the exact contribution of suggestion or cognitive interventions to the modified progressive relaxation technique, or of teaching one muscle at a time. The evidence reviewed above, however, does lead us to hypothesize that Jacobson's original technique would be relatively more effective in producing lasting somatic changes, whereas the revised technique might be more effective in producing cognitive changes or even short-term somatic changes. If

these hypotheses are borne out, we predict that for many applications in behavioral medicine Jacobson's original technique will be found to be preferable. This will be especially true for those disorders which cannot be assessed by asking the patient how he or she feels but must be evaluated physiologically (e.g., hypertension and various cardiac arrhythmias, where the patient may sometimes even feel worse when the problem is controlled than when it is not).

"In the 'big picture' of therapy, of course, the distinctions between the two techniques may be overshadowed by such overriding issues as whether relaxation therapy is even relevant for the individual. We have extensively discussed this issue elsewhere (Woolfolk & Lehrer, 1984b) but we reemphasize here that we see relaxation training as a specific method for overcoming definable problems and not as a panacea nor as a way of life. Nevertheless, we believe that the various approaches to the progressive relaxation technique are sufficiently different, both in practice and in philosophy, that we would do well to evaluate these differences in a rigorous fashion" (Lehrer, Woolfolk, Goldman 209- 210).

Sargent, Joseph; Solbach, Patricia; Coyne, Lolafaye; Spohn, Herbert; Segerson, John (1986). Results of a controlled, experimental, outcome study of nondrug treatments for the control of migraine headaches. Journal of Behavioral Medicine, 9, 291-323.

Headache variables were examined for 136 subjects who participated for 36 weeks in one of four groups: No Treatment, Autogenic Phrases, EMG Biofeedback, Thermal Biofeedback. All subjects kept daily records of headache activity and medication usage and participated in 22 laboratory sessions during which frontalis EMG and hand temperature measurements were taken; those in the 3 treatment groups practiced at home. There was a substantial reduction in headache variables in all groups. The No- Treatment Group differed significantly from the treatment groups combined, with the least reduction in headache variables. The thermal biofeedback group vs EMG biofeedback and autogenic phrases groups showed a suggestive trend toward improvement in the frequency and intensity of total headache.

1985

Stumpfe, Von Klaus-Dietrich (1985). Psychosomatic reactions of near-death experiences. A state of affective dissociation. Zeitschrift fur Psychosomatische Medizin, 31, 215-225.

The feelings of persons who had encountered life-threatening danger were analyzed and compared with the feelings of persons, who are in hypnoses or trained in autogenic training. The symptoms are widely alike. The result of the comparison is, that there exists a state of affective dissociation, which can be caused by conscious or unconscious actions.

1984

Krenz, Eric W. (1984). Improving competitive performance with hypnotic suggestions and modified autogenic training: Case reports. American Journal of Clinical Hypnosis, 27, 58-63.

Although traditionally trainers of athletes have emphasized physiological refinements for the optimal performance of complex motor skills, research has revealed that heightened levels of stress and anxiety may adversely affect performance. As a result, many athletic training programs, taking into consideration the complex interrelationship of the mind and the body, include "mental training" in an attempt to reduce the negative effects of excess stress. These programs have incorporated various psychological interventions such as post hypnotic suggestions, sensory conditioning, and mental imagery and rehearsal. Modified Autogenic Training, a teaching model based on Standard Autogenic Training, synthesizes the strengths of hypnotic techniques to achieve optimal athletic performance. Athletes trained in these concepts can manage unexpected incidences during competition. The concepts of Modified Autogenic Training are described and four case studies are reported.

1982

Stoyva, J. M.; Anderson, C. (1982). A coping-rest model of relaxation and stress management. In Goldberger, L.; Breznitz, S. (Ed.), Handbook of stress: Theoretical and clinical aspects (pp. 745-763). New York: The Free Press.

NOTES

1:

"Patients with psychosomatic or stress linked disorders are likely to show signs of high physiological arousal, and they are likely, under stress, to react strongly in the symptomatic system and to show evidence of being deficient in the ability to shift from the coping to the rest mode (e.g., slowness of habituation to, and recovery from, stressful stimulation). A corollary inference is that such patients ... show activity in the symptomatic system for a higher percentage of the time that [sic] do normal subjects. We suggest that this defect in the capacity to shift to a rest condition is the principal reason that various relaxation procedures have so often proved successful in the alleviation of stress related symptoms" (p. 748).

The authors refer to a number of different stress management procedures. Among those associated with primary focus on the rest phase they include: Relaxation training (progressive relaxation, autogenic training, EMG feedback, meditation [Zen, TM]), Specific biofeedback (hand temperature, electrodermal response [EDR], EMG from particular muscle group), and Systematic desensitization. Among those associated with primary focus on coping phase are: Assertiveness training, Social skills retraining and motor skills retraining, Self-statements, Imagery (Guided waking imagery, autogenic abreaction, covert reinforcement and covert sensitization, behavior rehearsal). These various procedures may reflect three dimensions or aspects of the stress response, with some addressing physiology and others addressing cognition or behavior change.

"Rachman (1978) ... found it useful to divide the phenomenon of fear into physiological, cognitive, and behavioral components. Similarly, Davidson and Schwartz (1976) conceptualized relaxation as consisting of somatic, cognitive, and attentional components. Phillips (1977) argued that pain, such as headache pain, can be viewed as consisting of cognitive, behavioral, and physiological aspects (and that, consequently, we should not expect high correlations between headache pain and a particular physiological measure such as forehead EMG level). ...

"... In discussing contemporary studies of dreaming, they [Stoyva and Kamiya (1968)] proposed that there is no single, totally valid indicator of dreaming as a mental experience. Instead, there are several imperfect indicators of the dream experience--verbal report, rapid eye movements, and certain electroencephalographic (EEG) stages. ... Discrepancies among the indicators can serve to generate hypotheses" (p. 749).

The authors discuss different ways of retraining the capacity to rest: relaxation training (including biofeedback, etc.), systematic desensitization; and of reshaping the coping response: assertiveness training, social skills and motor skills retraining, self-statements, imagery techniques; and discuss controllability. These notes cover only a very small part of their extensive review, the material most relevant to hypnosis and suggestion.

"Although imagery techniques are often employed by stress management therapists, one approaches this area with ambivalence. In part, this uneasiness springs from the unsettling awareness that imagery techniques have been embraced by a freewheeling assortment of lay psychologists such as Emil Coue, Dale Carnegie, and Norman Vincent Peale, not to mention a diverse throng of contemporary 'mind controllers' and self-styled healers. A more serious source of uneasiness is ignorance of the specific processes at work. What are the mechanisms by which imagery affects the stress response?" (p. 756).

"There is intriguing recent evidence that simply the illusion of control may exert beneficial effects. Stern, Miller, Ewy, and Grant (1980) noted that subjects who were led to believe by means of bogus information feedback that they were successfully lowering their heart rates showed a reduction in stress type symptoms, especially those of a cardiovascular nature. It seems possible that the feeling of control may be an important part of what we have called 'placebo responding.' Stoyva (1979b) suggested that this phenomenon is probably not a unitary entity but, rather, a cluster of processes, of which the feeling of developing control over factors affecting one's disorder is an important and potentially manipulable component of therapeutic interventions" (p. 758).

## 1978

Raikov, V. L. (1978). Specific features of suggested anesthesia in some forms of hypnosis in which the subject is active. International Journal of Clinical and Experimental Hypnosis, 26 (3), 158-166.

Experiments are reported in which highly hypnotizable Ss while imagining themselves, during hypnosis, to be cosmonauts with "jammed legs" in a space capsule did not feel an unannounced needle prick that pierced the skin. Control

experiments with nonhypnotizable, professional actors showed that imagination alone was unsuccessful in producing this result. Additional experiments using autogenic training showed that the autogenic training alone, without analgesia training, did not alleviate the pain but may have reduced the anxiety connected with the pain; further training involving analgesia reduced the felt-pain as well. Theoretical discussion stresses the importance of attention, imagination, and orientation for experiencing analgesia as well as the added and decisive role played by the modifications of consciousness brought about in deep hypnosis.

1975

Cowings, Patricia S. (1975, September). Observed differences in learning ability of heart rate self-regulation as a function of hypnotic susceptibility. [Paper] Presented at the 3rd Congress of the International College of Psychosomatic Medicine, Rome.

Three groups of eight men and women were given personality tests and were taught to control their own heart rates. Experimental group I and the control group had low hypnotic susceptibility (Stanford Hypnotic Susceptibility Scale), and subjects in experimental group II had high hypnotic susceptibility. The experimental groups received autogenic therapy and biofeedback, while the control group was given biofeedback only. Subjects who received autogenic therapy and biofeedback performed better than the control group. Significant differences, however, were found in all psychological test scores between high and low hypnotic susceptibles.

## AUTOMATIC NERVOUS SYSTEM

1999

Rainville, P.; Carrier, B.; Hofbauer, R. K.; Bushnell, M. C.; Duncan, G. H. (1999). Dissociation of sensory and affective dimensions of pain using hypnotic modulation. Pain, 82 (2), 159-171.

Understanding the complex nature of pain perception requires the ability to separately analyze its psychological dimensions and their interaction, and relate them to specific variables and responses. The present study, therefore, attempted to selectively modulate the sensory and affective dimensions of pain, using a cognitive intervention, and to assess the possible relationship between these psychological dimensions of pain and changes in physiological responses to the noxious stimuli. In three experiments, normal subjects trained in hypnosis rated pain intensity and pain unpleasantness produced by a tonic heat-pain stimulus (1-min immersion of the hand in 45.0-47.5 degrees C water). Two experiments were designed to test hypnotic suggestions to decrease (Experiment one (Section 2.5.1)), or increase and decrease (Experiment two (Section 2.5.2)) pain affect. Suggestions in Experiment three (Section 2.5.3) were directed towards an increase or decrease in pain sensation. In Experiments one and two (Sections 2.5.1 and 2.5.2), the significant modulation in pain unpleasantness ratings was largely independent of variations in perceived pain intensity. Moreover, in Experiment two (Section 2.5.2), there was a significant correlation between the stimulus-evoked heart-rate increase and ratings

of pain unpleasantness, but not of pain intensity, suggesting a direct functional interaction between pain affect and autonomic activation. In Experiment three (Section 2.5.3), suggestions to modulate the sensory aspect of pain produced significant modulation of pain intensity ratings, with secondary changes in pain unpleasantness ratings. Hypnotic susceptibility (Stanford Hypnotic Susceptibility Scale form A) was specifically correlated to pain unpleasantness modulation in Experiment two (Section 2.5.2) and to pain intensity modulation in Experiment three (Section 2.5.3), suggesting that this factor relates to the primary process toward which hypnotic suggestions are directed. The specific pain dimension on which hypnotic suggestions act depends on the content of the instructions and is not a characteristic of hypnosis itself. Results are consistent with a successive-stage model of pain perception (e.g. Wade JB, Dougherty LM, Archer CR, Price DD. Assessing the stages of pain processing: a multivariate analytical approach. *Pain* 1996;68:157-167) which provides a conceptual framework necessary to study the cerebral representation of pain perception.

1998

Danziger, N.; Fournier, E.; Bouhassira, D.; Michaud, D.; De Broucker, T.; Santarcangelo, E.; Carli, G.; Chertock, L.; Willer, J. C. (1998). Different strategies of modulation can be operative during hypnotic analgesia: A neurophysiological study. *Pain*, 75 (1), 85-92.

Nociceptive electrical stimuli were applied to the sural nerve during hypnotically-suggested analgesia in the left lower limb of 18 highly susceptible subjects. During this procedure, the verbally reported pain threshold, the nociceptive flexion (RIII) reflex and late somatosensory evoked potentials were investigated in parallel with autonomic responses and the spontaneous electroencephalogram (EEG). The hypnotic suggestion of analgesia induced a significant increase in pain threshold in all the selected subjects. All the subjects showed large changes (i.e., by 20% or more) in the amplitudes of their RIII reflexes during hypnotic analgesia by comparison with control conditions. Although the extent of the increase in pain threshold was similar in all the subjects, two distinct patterns of modulation of the RIII reflex were observed during the hypnotic analgesia: in 11 subjects (subgroup 1), a strong inhibition of the reflex was observed whereas in the other seven subjects (subgroup 2) there was a strong facilitation of the reflex. All the subjects in both subgroups displayed similar decreases in the amplitude of late somatosensory evoked cerebral potentials during the hypnotic analgesia. No modification in the autonomic parameters or the EEG was observed. These data suggest that different strategies of modulation can be operative during effective hypnotic analgesia and that these are subject-dependent. Although all subjects may shift their attention away from the painful stimulus (which could explain the decrease of the late somatosensory evoked potentials), some of them inhibit their motor reaction to the stimulus at the spinal level, while in others, in contrast, this reaction is facilitated.

Abstract from National Library of Medicine, PubMed

Wickramasekera, Ian E.; Kolm, Paul; Pope, Alan; Turner, Marsha (1998). Observation of a paradoxical temperature increase during cognitive stress in some chronic pain patients. Applied Psychophysiology and Biofeedback, 23 (4), 233-241.

A total of 224 chronic pain somatoform disorder patients without obvious pathophysiology or psychopathology were found to have colder hands than nonpatients. A paradoxical temperature increase (PTI) in response to a cognitive stressor (mental arithmetic) was noted in a subset of these chronic pain patients. Patients were defined as "PTI" responders if, during cognitive stress, an increase in digital temperature occurred over a prior eyes closed resting condition. It was found that 49.4% of males and 42.6% of females in a total sample of 224 patients demonstrated PTI. The PTI patients had significantly colder hands than non-PTI patients prior to stress. A concurrent SCL measure of sympathetic activation found no difference between the PTI and non-PTI groups either at baseline or during cognitive stress. It appears from this data that PTI is specific to the peripheral vascular system of these patients and may be a marker of psychophysiological dissociation or trauma blocked from consciousness.

Enqvist, Bjorn; von Konow, L.; Bystedt, H. (1995). Pre- and perioperative suggestion in maxillofacial surgery: Effects on blood loss and recovery. International Journal of Clinical and Experimental Hypnosis, 43 (3), 284-294.

The basic assumption underlying the present study was that emotional factors may influence not only recovery but also blood loss and blood pressure in maxillofacial surgery patients, where the surgery was performed under general anesthesia. Eighteen patients were administered a hypnosis tape containing preoperative therapeutic suggestions, 18 patients were administered hypnosis tapes containing pre- and perioperative suggestions, and 24 patients were administered a hypnosis tape containing perioperative suggestions only. The patients who received taped suggestions were compared to a group of matched control patients. The patients who received preoperative suggestions exhibited a 30% reduction in blood loss. A 26% reduction in blood loss was shown in the group of patients receiving pre- and perioperative suggestions, and the group of patients receiving perioperative suggestions only showed a 9% reduction in blood loss. Lower blood pressure was found in the groups that received pre- and perioperative and perioperative suggestions only. Rehabilitation was facilitated in the group of patients receiving perioperative suggestions only.

Olness, Karen N.; Lee, Lai (1995, November). Effects of self-induced mental imagery on autonomic reactivity in children. [Paper] Presented at the annual meeting of the Society for Clinical and Experimental Hypnosis, San Antonio, TX.

NOTES

1:

NOTES: One study that shows an IgA increase with hypnotic suggestion has been replicated and is in press.

The present study emerges from work using hypnosis with biofeedback. Morgan's work with athletes has suggested the relationship between imagery and physiological activation. This has been observed clinically but not heretofore documented.

We are not using formal hypnosis. Each child was asked to think about being in a quiet place, doing exciting activities, baseline, etc. The children exhibited no neurological disorders, cognitive dysfunction, nor were they on medications at time of the study.

We confirmed our clinical experience: there was an increase in pulse rate when imagery changed to activity. Skin temperature continued to go up during the period (despite imagery of being active like being on roller coaster). Skin conduction went down during baseline. EDA [electrodermal activities] was higher during active imagery.

How do average daily thinking processes impact on autonomic changes over long periods of time? Do these changes affect cardiovascular status?

Clinically we observed that some children are more labile in different modalities, and under stress they react more in that system.

DeBenedittis, Giuseppe; Cigada, Mario; Bianchi, Anna; Signorini, Maria Gabriella; Cerutti, Sergio (1994). Autonomic changes during hypnosis: A heart rate variability power spectrum analysis as a marker of sympatho-vagal balance. International Journal of Clinical and Experimental Hypnosis, 42 (2), 140-152.

Spectral analysis of beat-to-beat variability in electrocardiography is a simple, noninvasive method to analyze sympatho-vagal interaction. The electrocardiogram is analyzed by means of an automatic, autoregressive modeling algorithm that provides a quantitative estimate of R-R interval variability by the computation of power spectral density. Two major peaks are recognizable in this specter: a low-frequency peak (LF, -0.2 Hz), related to the overall autonomic activity (ortho + parasympathetic) and a high-frequency peak (HF, -0.25 hz), representative of the vagal activity. The LF/HF ratio is an index of the sympatho-vagal interaction. This technique was applied, using a computer-assisted electrocardiograph, to 10 healthy volunteers (6 high and 4 low hypnotizable subjects as determined by the Stanford Hypnotic Susceptibility Scale, Form C) in randomized awake and neutral hypnosis conditions. Preliminary results indicated that hypnosis affects heart rate variability, shifting the balance of the sympatho-vagal interaction toward an enhanced parasympathetic activity, concomitant with a reduction of the sympathetic tone. A positive correlation between hypnotic susceptibility and autonomic responsiveness during hypnosis was also found, with high hypnotizable subjects showing a trend toward a greater increase of vagal efferent activity than did low hypnotizables

Harris, Ruth M.; Porges, Stephen W.; Carpenter, Myrna E. Clemenson; Vincenz, Lilli M. (1993). Hypnotic susceptibility, mood state, and cardiovascular reactivity. American Journal of Clinical Hypnosis, 36 (1), 15-25.

In this study we explored the relationship between hypnotic susceptibility measured with the Harvard Group Scale of Hypnotic Susceptibility (HGSHS) and cardiovascular parameters. After assessing their degree of hypnotic susceptibility, we induced 21 female students into happy mood states and into sad mood states. During the mood state induction we monitored blood pressure, heart rate, and cardiac vagal tone continuously. The study demonstrated a strong relationship between hypnotic susceptibility and both cardiac vagal tone and heart rate reactivity. Subjects with lower heart rate and greater vagal tone during baseline and greater heart rate increases during mood induction were more susceptible to hypnosis. Multiple regression analyses indicated that approximately 40% of the individual difference variance of hypnotic susceptibility was accounted for by baseline cardiac vagal tone and heart rate reactivity during mood state. The data demonstrate that autonomic tone, assessed by cardiac vagal tone and heart rate reactivity, are related to hypnotic susceptibility as measured by the HGSHS. - Journal Abstract

1992

Gainer, Michael J. (1992). Hypnotherapy for reflex sympathetic dystrophy. American Journal of Clinical Hypnosis, 34, 227-232.

Reflex sympathetic dystrophy (RSD) is an unusual, debilitating, chronic pain syndrome thought to be the result of a continuous excessive discharge of regional sympathetic nerves. Supportive and stress-reduction psychotherapies are commonly recommended as adjunctive treatments. Biofeedback is a more direct symptomatic treatment. Although hypnotherapy is effective in altering sympathetic reflex and pain responses, there are no reports of its use for the treatment of RSD. This article reviews some promising results of hypnotherapy with three RSD sufferers. I discuss the role of hypnotherapy as a supportive adjunct to medical treatment. I also explore the possible role of hypnotherapy as a complementary treatment.

NOTES

1:

"Hypothetically, RSD represents a continuous excessive discharge of the regional sympathetic nerves. Such discharge normally occurs in response to an injury. In RSD this reflex response is unremitting despite the cessation or absence of an external stimulus" (p. 227).

The psychosomatic aspects of RSD are highly disputed. Some studies suggest a relationship between RSD and various psychopathological conditions. Also proposed is a predisposing character type, sometimes termed 'Sudeck personality' ... patients who are generally anxious, inactive, and hypertensive. ... Others cite chronic pain as the cause, not the result, of certain 'typical' behavior patterns and emotional responses (Abram, 1990; Ecker, 1984)" (p. 228).

"Reports of four cases described RSD treatment with temperature biofeedback. These studies suggest that the patients learned to warm the affected limb through increasing cutaneous circulation. The temperature change was associated with decreased regional sympathetic activity and decreased pain. Complete remission of symptoms is reported in three of these cases; significant improvement is reported in the fourth" (p. 228).

"Abram (1990) reported that in two independent studies the incidence of RSD was 6.3% and 10.7% of patients admitted to pain clinics" (p. 228).

"I hypothesized that hypnotic interventions could facilitate a decrease in local sympathetic nervous discharge. This would result in vasodilation and warming of the affected limb, decreased spasticity, and decreased pain. The following is a report of the effective treatment of three RSD cases with hypnotherapy" (p. 228).

Case #1. "The eventual resolution of her RSD symptoms was due, in part, to resolution of psychodynamic conflicts. ... She had a grade-four profile on the Hypnotic Induction Profile (Spiegel & Spiegel, 1978). In later sessions she readily demonstrated superior hypnotic capacity, achieving such phenomena as spontaneous amnesia, negative hallucination, and somnambulism" (p. 229).

Case #2. ... "She had a grade-three profile on the Hypnotic Induction Profile (Spiegel & Spiegel, 1978) Because of the success with the first patient, I used visualization techniques initially. ... She responded more readily to kinesthetic and tactile suggestions. ... These interventions produced dramatic improvement in the RSD symptoms" (p. 230).

Case #3. ... "He had a grade-three profile on the Hypnotic Induction Profile (Spiegel & Spiegel, 1978). He was readily able to use visualization techniques. He was able to affect dramatic temperature changes (8-10 degrees F) by visualizing 'warm' vacation scenes and imagining the feeling of the 'warm sun' on the affected limb" (p. 231).

DISCUSSION mentioned, "The patients presented in this report were all highly motivated and demonstrated an above-average to superior hypnotic capacity. Despite the obvious limitations of such a selective sample, the actual treatment results support the initial hypothesis. The treatment results of these three cases indicate that hypnotherapy can be an adjunctive treatment to alleviate pain. Moreover, these results indicate that hypnotherapy can be a complementary treatment in RSD.

Morse, Donald R.; Martin, John; Moshonov, Joshua (1992). Stress induced sudden cardiac death: Can it be prevented?. Stress Medicine, 8, 35-46.

Previously, psychosomatically induced death relative to stress, hypnosis, mind control, and voodoo was discussed. In this article, emphasis is on one aspect of that - stress induced sudden cardiac death (SCD). A brief review is presented of the sympathetic aspects of the acute stress response and stress induced SCD. Findings from previous studies are presented to highlight sympathetic aspects of the acute stress response. This is followed by a presentation of various strategies to prevent or decrease the possibilities for stress induced SCD. These include long-term measures (e.g. diet control, smoking control, hypertension control, stress management strategies) and immediate measures (e.g. calm, controlled approach, elicitation of the relaxation response, selected use of drugs, and heart rate variability monitoring). Relative to prevention strategies, findings are presented both from previous studies and new investigations.

Spanos, Nicholas P.; Brice, Peter; Gabora, Natalie J. (1992). Suggested imagery and salivation in hypnotic and non-hypnotic subjects. Contemporary Hypnosis, 9, 105-111.

Salivation was measured in 100 subjects on both a baseline and post-test trial. Subjects in hypnotic, relaxation, and suggestion alone treatments were asked to imagine tasting a lemon during the post-test trial. Subjects in the suggestion alone and relaxation treatments exhibited significant baseline to post-test increments in salivation and, on the post-test trial suggestion alone subjects exhibited greater salivation than either hypnotic subjects or no treatment controls. Neither hypnotizability nor imagery vividness correlated significantly with suggestion-induced increments in salivation.

#### NOTES

1:

"Our findings, like those of numerous earlier studies (reviewed by White, 1978) indicate that instruction to imagine food substances enhance salivation. The fact that imagery-alone instructions were more effective in this regard than hypnotic imagery instructions was unexpected, but this finding is certainly consistent with the large body of evidence which indicates that hypnotic procedures are no more effective than non-hypnotic procedures at enhancing responsiveness to suggestions. Moreover, the present findings, along with those concerning wart regression (Spanos et al., 1988), contradict the hypothesis that hypnotic procedures are particularly effective at enhancing responsiveness to suggestion when the target response is not under direct voluntary control.

"The reasons for the superiority of the imagery-alone treatment to the hypnotic treatment at inducing saliva production remain unclear. Subjects in the three treated groups reported equivalent levels of suggested imagery vividness and, therefore, differences on that variable could not have mediated treatment differences in the amount salivated. On the post-test trial the two treatments that received relaxation instructions (hypnosis and relaxation groups) failed to differ significantly from controls in amount salivated, whereas imagery alone subjects did differ from controls in this respect. Perhaps high levels of relaxation produce a slight inhibition of salivation which at least partly offsets the enhancement produced by suggested imagery. This hypothesis is, of course, highly tentative, and the finding of somewhat less salivation in groups administered relaxation instructions requires replication before further speculation is warranted.

"The finding that controls exhibited a significant decrease in salivation was also unexpected, and the reason for this finding remains unclear.

"Neither the Betts QMI nor any of the hypnotizability indexes correlated significantly with the suggestion induced increments in salivation. On the one hand, these findings are consistent with those of previous studies, which reported no relationship between imagery and/or hypnotizability and suggestion-induced changes in target responses that were not under subjects' direct control (e.g. Surman et al., 1973; Swirsky-Sacchetti & Margolis, 1986; Spanos et al., 1988). On the other hand, our results failed to replicate White's (1978) finding of a significant correlation between suggestion-induced salivation and Betts QMI scores. Our study

differed from that of White (1978) in several important respects. White asked subjects to imagine several foods which they preferred to differing degrees. Significant differences in salivation for subjects classified as high, medium or low on the QMI were found only when subjects imagined preferred foods. Furthermore, subjects classified as high and medium on the QMI tended to salivate to similar degrees when imagining preferred foods, but salivated more under these conditions than low QMI scorers. In the present study all subjects imagined the same food stimulus regardless of preference, and subjects were not selected for extreme scores on the QMI. These differences between our study and that of White (1978) may account for our failure to obtain a significant relationship between QMI scores and imagery-induced salivation" (p. 109).

Van Der Kolk, Bessel; Van Der Hart, O. (1991). The intrusive past: The flexibility of memory and the engraving of trauma. American Imago, 48, 425-454.

Describes the work of Janet concerning narrative versus traumatic memory, dissociation, and subconscious fixed ideas. Janet (1904) believed PTSD patients suffer from a phobia for the traumatic memory. Repression and dissociation are distinguished. Contemporary concepts of memory processing and the concept of schemas are then reviewed. Finally, a model is presented about how the mind freezes some memories. Evidence for the involvement of autonomic hyperarousal, triggering, and state dependent learning in PTSD is reviewed. They conclude that helplessness and the inability of the PTSD victim to take action (psychological and physical immobilization) facilitates dissociation. Includes practical ideas for the working through of trauma.

NOTES

1:

p. 443 "Traumatic memories are triggered by autonomic arousal ... and are thought to be mediated via hyper-potentiated noradrenergic pathways originating in the locus coeruleus of the brain... The locus coeruleus is the 'alarm bell' of the central nervous system, which properly goes off only under situations of threat, but which, in traumatized people, is liable to respond to any number of triggering conditions akin to the saliva in Pavlov's dogs. When the locus coeruleus alarm gets activated, it secretes noradrenaline, and, if rung repeatedly, endogenous opioids. These, in turn, dampen perception of pain, physical as well as psychological (van der Kolk et al. 1989). These neurotransmitters which are activated by alarm affect the hippocampus, the amygdala and the frontal lobes, where stress-induced neurochemical alterations affect the interpretation of incoming stimuli further in the direction of 'emergency' and fight/flight responses" (p. 443).

Ader, Robert; Felton, David; Cohen, Nicholas (1990). Interactions between the brain and the immune system. In Cho, Arthur K.; George, Robert; Blaschke, Terrence (Ed.), null (30, pp. 561-602). Palo Alto, CA: Annual Reviews Inc..

NOTES:

**"Without attempting to cover all the literature, we have used stress effects and conditioning phenomena as illustrations to point out that behavior can influence immune function. We have also described data indicating that the immune system can receive and respond to neural and endocrine signals. Conversely, behavioral, neural, and endocrine responses seem to be influenced by an activated immune system. Thus, a traditional view of immune function that is confined to cellular interactions occurring within lymphoid tissues is insufficient to account for changes in immunity observed in subhuman animals and man under real world conditions.**

**"These data question seriously the notion of an autonomous immune system. ... The immune system is, indeed, capable of considerable self-regulation, and immune responses can be made to take place in vitro. The functions of that component of adaptive processes known as the immune system that are of ultimate concern, however, are those that take place in vivo. There are now compelling reasons to believe that in vivo immunoregulatory processes influence and are influenced by the neuroendocrine environment in which such processes actually take place ... . The immune system appears to be modulated, not only by feedback mechanisms mediated through neural and endocrine processes, but by feedforward mechanisms as well. The immunologic effects of learning, an essential feedforward mechanism, suggest that, like direct neural and endocrine processes, behavior can, under appropriate circumstances, serve an immunoregulatory function in vivo. Conceptually, the capacity to suppress or enhance immune responses by conditioning has raised innumerable questions about the normal operation and modifiability of the immune system via neural and endocrine processes.**

**"We do not yet know the nature of all the channels of communication between the brain and the immune system or the functional significance of the neural and endocrine interrelationships that have been established....**

**"This integrated circuitry has extensive ascending and descending connections among the regions cited. These regions also share many similarities. They are sites intimately involved in visceral, autonomic, and neuroendocrine regulation. The cortical and limbic forebrain regions mediate both affective and cognitive processes and may be involved in the response to stressors, in affective states and disorders such as depression, in aversive conditioning, and in the emotional context of sensory inputs from the outside as well as the inside world. From an immunologic perspective, these regions are the sites in which lesions result in altered responses of cells of the immune system; they are the regions that respond to immunization or cytokines by altered neuronal activity or altered monoamine metabolism; and they are the regions that possess the highest concentration of glucocorticoid receptors and link some endocrine systems with neuronal outflow to the autonomic and neuroendocrine systems. Thus, this circuitry is the major system of the CNS suspected to play a key role in responding to immune signals and regulating CNS outflow to the immune system" (pp. 587-589).**

**Kramer, Richard L. (1989). The treatment of childhood night terrors through the use of hypnosis - a case study: A brief communication. International Journal of Clinical and Experimental Hypnosis, 37 (4), 283-284.**

Night terrors are nocturnal episodes of intense autonomic arousal which are manifested by loud shouting or screaming in terror. The sufferer is not awake and is generally completely amnesic for the episodes. Night terrors and other sleep disturbances, such as somnambulism, are disorders of arousal (Broughton, 1968; Fisher, Kahn, Edwards, & Davis, 1973; Guilleminault, 1987). A 10-year-old white male was treated for a 6-year-long bout of night terrors. The hypnotic induction consisted of the finger lowering technique where the middle 2 fingers were raised and the individual was asked to watch the fingers as they "go to sleep." He was given suggestions for dropping off to sleep gradually and for rotating cycles of sleep. The regularity and continual movement of the cycles of sleep were emphasized. He was also given direct suggestions for not dropping too quickly into an extremely deep stage of sleep. He has not had a recurrence of night terrors since that time (approximately 2 years). Psychodynamic issues are discussed as is the need for further research.

**Meyer, von H. K.; Diehl, B. J. M.; Ulrich, P.; Meinig, G. (1987). Kurz- und langfristige Änderungen der kortikalen Durchblutung bei Autogenem Training[Short and long-term changes in cortical circulation caused by autogenic training]. Zeitschrift für Psychosomatische Medizin und Psychoanalyse, 33 (1), 52-62.**

English Summary. The well-known hyperfrontal pattern of hemispheric blood flow measured with 133-Xenon is not found in 12 healthy resting men who have been practicing Autogenic Training at least six months. This might indicate a long-term decrease in the level of activation. Successfully practiced exercises of Autogenic Training lead to an increased blood flow in the Rolandic area representing the body scem (sic) and to a decreased blood flow in regions related to acoustical attention and to autonomic functions. Left hemispheric cerebral blood flow is lower in rest. The relative activation of the left hemisphere during Autogenic Training is discussed.

**Minichiello, William E. (1987). Treatment of hyperhidrosis of amputation site with hypnosis and suggestions involving classical conditioning. International Journal of Psychosomatics, 7-8.**

Hyperhidrosis of an amputation site utilizing hypnosis and/or behavioral strategies has not been reported in the literature. This case report is on the successful use of hypnosis utilizing principles of classical conditioning in the treatment of a patient with hyperhidrosis of an amputated limb with two previous unsuccessful sympathectomies. The patient possessing moderate hypnotic ability as measured by the Stanford Hypnotic Clinical Scale (SHCS), reported a pre-treatment score of 10

on a 0-10 severity and intensity of sweating scale, and a post-treatment score of 0. All gains were maintained at the two-year follow-up.

#### NOTES

1:

The patient was hypnotized while an electric fan was blowing on his stump and prosthesis. Direct suggestions were given according to procedures of thermal biofeedback. The suggestions were: 1. You will notice in days ahead that your stump feels increasingly cooler and drier. 2. You will feel throughout the day as if a cool breeze from a fan is blowing on your stump. 3. Whenever you pay attention to your leg during the day, particularly after the first few hours of the morning, you will associate that leg with a cool dry breeze from a fan blowing on it. 4. You will increasingly develop the power to cool and dry your stump.

The results were that 2 1/2 weeks later patient reported reduced frequency and intensity of sweating and significant healing of the stump ulcers; rating = 2. One month later, patient reported continued progress with almost normal skin color and stump condition; the patient discontinued disability, and returned to work. Patient returned one month later reporting, "It's cured and my physician can't believe it." Rating = 0. Author concludes that hypnosis should be tried prior to more invasive traditional procedures. In this case two previous sympathectomies failed to correct the condition and a third sympathectomy was being contemplated.

#### 1986

Olness, Karen N. (1986, March). Hypnotherapy in children: New approach to solving common pediatric problems. Postgraduate Medicine, 79 (4), 95-105.

Hypnotherapy, once thought of as magical and mysterious, is rapidly becoming accepted as an appropriate form of treatment for a wide range of disorders. Some primary care physicians are beginning to discover the value of hypnotherapy in controlling chronic disease and pain, in changing negative behavior, and in facilitating self-regulation of autonomic responses. Dr. Olness explores such use of hypnotherapy in children, the age-group that most readily acquires self-hypnosis skills and in which this technique has had dramatic results.

Omer, Haim; Friedlander, Dov; Palti, Zvi (1986). Hypnotic relaxation in the treatment of premature labor. Psychosomatic Medicine, 48, 351-361.

Hypnotic relaxation was used as an adjunct to pharmacologic treatment with 39 women hospitalized for premature contractions in pregnancy. The control group received medication alone and consisted of 70 women. Treatment was started at the time of hospitalization and lasted for 3 hr on the average. Patients were also given cassettes with a hypnotic - relaxation exercise for daily practice. The rate of pregnancy prolongation was significantly higher for the hypnotic - relaxation than for the medication-alone group. Infant weight also showed the advantage of the hypnotic - relaxation treatment. Background variables of the two groups were compared and it was shown that they could not have explained the treatment effect obtained.

Wickramasakera, Ian (1986). A model of people at high risk to develop chronic stress-related somatic symptoms: Some predictions. Professional Psychology: Research and Practice, 17, 437-447.

Certain measurable high-risk factors that predispose people to develop functionally based somatic disorders are identified. These risk factors compose a multidimensional model that encompasses variables involved in the predisposition, the precipitation, and the buffering of stress-related symptoms. These high-risk factors are (a) high or low hypnotic ability, (b) habitual catastrophizing cognitions and pessimistic belief systems, (c) autonomic lability or neuroticism, (d) multiple major life changes or multiple minor hassles over a short period of time, and (e) a deficit in support systems or coping skills or both.

1985

Tranel, Daniel; Damasio, Antonio R. (1985, June). Knowledge without awareness: An autonomic index of facial recognition by prosopagnosics. Science, 208 (4706), 1453-1454.

Prosopagnosia, the inability to recognize visually the faces of familiar persons who continue to be normally recognized through other sensory channels, is caused by bilateral cerebral lesions involving the visual system. Two patients with prosopagnosia generated frequent and large electrodermal skin conductance responses to faces of persons they had previously known but were now unable to recognize. They did not generate such responses to unfamiliar faces. The results suggest that an early step of the physiological process of recognition is still taking place in these patients, without their awareness but with an autonomic index.

1984

Conn, Lois; Mott, Thurman, Jr. (1984). Plethysmographic demonstration of rapid vasodilation by direct suggestions: A case of Raynaud's Disease treated by hypnosis. American Journal of Clinical Hypnosis, 26, 166-170.

Raynaud's Disease is a painful vasospastic disorder of the fingers and toes precipitated by cold or emotional stimuli. Treatment has usually included protection from cold stimuli and vasodilators. Biofeedback, imagery, relaxation, and hypnosis have also been used. The relationship between response to treatment and hypnotizability has been inconclusive. A case of Raynaud's Disease was treated using hypnosis. The patient was highly hypnotizable and responded rapidly to direct suggestion with a fourfold increase in her blood volume. The implications of this rapid response and its relationship to hypnotizability are discussed with suggestions for further studies.

NOTES

1:  
The authors review experimental literature on the usefulness of hypnosis in modifying peripheral circulation, finding both positive (Barabasz and McGeorge, 1978, Roberts, Kewman, and MacDonald, 1973) and negative (Peters, Lundy, and

Stern, 1973; Black, Edholm, Fox, and Kidd, 1963) outcomes. Experiments relating outcome to hypnotizability also have positive (Block, Levitsky, Teitelbaum, and Valletta, 1977) and negative (Crosson, 1980; Roberts et al, 1973) results.

Clinical literature found that peripheral circulation could be influenced (Crasilneck & Hall, 1975; Norris & Huston, 1956; Jacobson et al., 1973) but none of those studies reported the hypnotizability of the patients. In the Crasilneck and Hall (1975) investigation, 60% of their 48 Raynaud's patients experienced marked improvement in symptoms or remission.

Hypnotizability has been investigated with respect to biofeedback results, finding both no relationship (Holroyd et al., 1982) and a positive relationship (Andreychuk and Skriver, 1975).

In this investigation, the highly hypnotizable (Stanford Hypnotic Susceptibility Scale, Form A, score = 11) female patient was treated with hypnosis when the blood vessels in her hands were constricted. Either she had arrived at the office with poor circulation, or a Raynaud's attack was induced with ice water. Hypnosis involved progressive relaxation followed by suggestions to visualize the blood vessels in her hand opening up, the blood warming and nourishing her hands. "With each beat of your pulse your hand becomes warmer as more blood reaches your fingers. It is as though you are lying in the warm sun. Try to visualize the blood vessels in your hand opening up...." (P. 168).

The patient was asked to use self hypnosis and a cassette of the office session twice a week between sessions, but in fact she either failed to practice or did the exercise once between weekly sessions.

With neutral hypnosis (no specific suggestions about circulation) there was little change in pulse volume; with suggestions to open up her blood vessels, there was an increase in blood volume that began within 20 seconds, reaching four times the baseline in 45 seconds. This increase was reproduced in later sessions, and a somewhat lesser degree of change could be produced with self hypnosis.

In their Discussion, the authors question whether the positive results depend on someone who is high in hypnotizability, and/or on someone with a labile vascular system. They refer to a model of biological information processing to explain how suggestions might have been incorporated by the patient. "Bowers (1977) has speculated that hypnotized patients process information in a way different from when they are not hypnotized. He presents a number of different studies which have shown a significant relationship between hypnotizability and treatment response in patients with illnesses with a clear cut physiological component, including asthma, warts, and ichthyosis. He then speculates that 'suggestions delivered to deeply hypnotized subjects can be transduced into information that is somatically encodable, thereby producing a selective and specific impact on body function and structure.' This kind of processing of information could explain the very rapid response described in the patient presented here.

"In reviewing the cases in which blistering has been produced by hypnotic suggestion, Chertok (1981) states, 'It therefore clearly emerges that these experiments have all been conducted with highly hypnotizable subjects, including a very large proportion of true somnambulists. Inversely, there is not a single

known case where a blister has been produced without the subject having been deeply hypnotized beforehand" (p. 169).

1983

Braun, Bennett G. (1983). Psychophysiological phenomena in multiple personalities and hypnosis. American Journal of Clinical Hypnosis, 26 (2), 124-137.

NOTES

1:

"Conclusion. As can be seen from the above example, the final common pathway, physiologic expression, which is seen in multiple personality is not bizarre when compared with physiologic changes achieved in non-multiples using hypnosis or, in certain cases, non-multiples without the use of hypnosis. A form of hypnosis/autohypnosis\* may be a common denominator. The neurophysiologic changes shown by Putnam et. al. (1982), but not observed by Coons (1982), may well have a similar explanation. The question of the neurophysiologic effect of hypnotic suggestion has not as yet been studied with appropriate controls or safeguards.

"That multiples do show significant changes in their psychophysiological response patterns cannot be denied. To consider that the psychophysiological changes of multiple personality are so rare or different as to make multiples 'freaks' is not only a disservice to them, but to medical science, since it blocks thinking. The study of multiple personality will further our understanding, theorizing, and treatment of mental and physical illness" (p. 134). "\*These terms are being used here in the generic sense" (p. 134).

1980

Bauer, K. E.; McCanne, T. R. (1980). Autonomic and central nervous system responding during hypnosis and simulation of hypnosis. International Journal of Clinical and Experimental Hypnosis, 28 (2), 148-163.

Heart rate, electrodermal responding, respiratory rate, frontalis muscle tension, and occipital electroencephalographic activity were monitored while 6 female Ss were experiencing hypnosis and while 6 other female Ss simulated the experience of hypnosis. Physiological data were collected during 7 sessions on 7 consecutive days. The results indicated no differences in physiological responding between hypnotized and simulating Ss. Both groups of Ss exhibited significant decreases in heart rate and amount of electroencephalographic alpha activity during their experiences, relative to pre- and posthypnotic or simulating levels. In addition, both groups of Ss exhibited significant increases in electroencephalographic beta activity during their experiences. Both groups of Ss also displayed lowered levels of electrodermal activity, skin conductance, and respiratory rate during their experiences. The changes in these modalities, however, were significant for hypnotized Ss, but were generally not significant for simulating Ss. Both groups of Ss also manifested lowered levels of muscle responding during their experiences, but these changes in responding were not significant for either group of Ss. The results are discussed in terms of several current theories of the nature of the hypnotic experience.

1975

Cowings, Patricia S. (1975, September). Observed differences in learning ability of heart rate self-regulation as a function of hypnotic susceptibility. [Paper] Presented at the 3rd Congress of the International College of Psychosomatic Medicine, Rome.

Three groups of eight men and women were given personality tests and were taught to control their own heart rates. Experimental group I and the control group had low hypnotic susceptibility (Stanford Hypnotic Susceptibility Scale), and subjects in experimental group II had high hypnotic susceptibility. The experimental groups received autogenic therapy and biofeedback, while the control group was given biofeedback only. Subjects who received autogenic therapy and biofeedback performed better than the control group. Significant differences, however, were found in all psychological test scores between high and low hypnotic susceptibles.

1974

Bloom, Richard F. (1974). Validation of suggestion-induced stress.

NOTES

1:

Technical Memorandum 23-74 (October 1974), US Army Human Engineering Laboratory, Aberdeen Proving Ground, Maryland 21005, AMCMS Code 5910.21.68629, Contract No. DAAD05-73-C-0243, Dunlap and Associates, Inc. (now Stamford, CT), AD002557.

Sixty college men, divided into three equal groups, each attended two induced stress sessions in which their physiological, psychological and performance reactions were measured. Their responses were compared to determine if valid stress reactions could be induced through suggestion in an altered state (in this case, hypnosis), and also to determine the validity of such reactions if the subject had never before experienced that stress situation. It was demonstrated that valid stress reactions can be induced in an individual with the aid of suggestions, especially if the real stress situation has been experienced before. If no previous experience with that real situation exists, the subject still exhibits stressful reactions; however, the closest resemblance to real stress is found in the subjective or psychological measures, less similarity is found in the physiological measures, and the least similarity is found in the performance measures.

Schneck, Jerome M. (1957). Hypnoanalytic observations on the psychopathology of fainting. Journal of Clinical and Experimental Hypnosis, 5 (4), 167-171. (Abstracted in Psychological Abstracts 62: 3 II 67S)

NOTES

1:

"Summary

Varieties of fainting have been described as hysterical syncope, vasodepressor syncope, and carotid sinus reactions, among others. Fainting has been linked in general with personality problems, emotional instability, and immaturity. It has been called a mechanism for blocking of ego functions in its role of primitive defense against overwhelming stimuli. The present paper gives in greater detail the specific dynamics in a patient with fainting episodes. A crucial event incorporating major dynamic ingredients was an operative procedure in childhood. The psychological

impact of this trauma was revived during a spontaneous hypnotic regression. The personality matrix significant for this patient in relation to the fainting episodes consisted of passive, masochistic submission to a dominant, highly influential mother whose pressure was felt by the patient as pervasive and stifling. Circumstances associated psychologically with this feeling apparently triggered the fainting reactions. As he matured through the years and cast off increasingly this type of maternal influence, the tendency toward fainting reactions diminished" (p. 170).

Bigelow, Newton; Cameron, G. H.; Koroljow, S. A. (1956). Two cases of deep hypnotic sleep investigated by the strain gauge plethysmograph. Journal of Clinical and Experimental Hypnosis, 4 (4), 160-164.

NOTES

1:

"Two subjects, studied by means of a strain gauge plethysmograph, have shown greater changes in the peripheral pulse and the finger volume during deep hypnosis than they did immediately before or after. In the absence of external stimuli, the presence and the degree of such changes reflect the activity of the autonomic nervous system. This result suggests that in hypnosis the inhibiting tendency of the cortex on the autonomic nervous system is reduced or nullified" (p. 164).

1955

Stolzenberg, Jacob (1955). Clinical application of hypnosis in producing hypno-anesthesia control of hemorrhage and salivation during surgery. A case report. Journal of Clinical and Experimental Hypnosis, 3 (1), 24-27.

NOTES

1:

The patient was a 14 year old male with an impacted mandibular left first molar. A series of surgical interventions were required to remove granulation tissue, overlying bone, and fibrotic tissue prior to orthodontic procedures. Hypnoanesthesia and suggestions to stop bleeding and salivating were successfully employed. In fact "It was noticeable with the last two procedures that spontaneous dryness occurred without any suggestion by the operator" (p. 26).

West, Louis Jolyon; Niell, Karleen C.; Hardy, James D. (1952). Effects of hypnotic suggestion on pain perception and galvanic skin response. A. M. A. Archives of Neurology and Psychiatry, 68, 549-560.

A study is reported in which pain perception and galvanic skin responses of seven subjects were measured before and during hypnosis. The depths of hypnotic trance varied from light to deep. Stimuli of measured intensity were administered, and changes in pain threshold were measured. Quantitative estimates of pain intensity were made by the subjects. Alterations in ability to discriminate between pains of differing intensities were noted. Quantitative records of galvanic skin responses

were utilized, permitting statistical analysis of data from matched pairs. Data were collected at 45 experimental sessions, during which a total of 478 painful stimuli were administered, the stimuli varying in intensity from threshold to blister-producing levels. At each session, the subject's sensations from and responses to stimuli during a control period were compared with sensations from and responses to identical stimuli administered after hypnotic suggestions of anesthesia. The following observations were made: 1. Hypnotic suggestions of anesthesia influence pain perception by causing elevation of pain threshold, hypalgesia, and analgesia. 2. When hypnotic suggestions of anesthesia caused hypalgesia and elevation of pain threshold, ability to discriminate among stimuli of different intensities was impaired. 3. There was a general correlation between the depth of hypnotic trance and the degree to which pain perception was altered by hypnotic suggestion. 4. The galvanic skin response to noxious stimulation was diminished, and it sometimes disappeared, as a result of hypnotic suggestions of anesthesia. The galvanic skin response was affected even when there was no alteration in pain perception, according to subjective reports.

**NOTES:** The authors review literature on the effects of analgesia suggestions on the galvanic skin response and other autonomic nervous system responses. The present study differs from previous studies in the following ways: "1. The subjects were studied in various stages of hypnosis. 2. Quantitatively determined noxious stimuli were used instead of pinching or pinprick. 3. Changes in pain threshold were measured. 4. Quantitative estimates of pain intensity were made by the subject in the hypnotized and the un hypnotized state. 5. Changes in ability to discriminate between pains of differing intensity were noted. 6. Quantitative records of galvanic skin responses in the control and in the hypnotized state were utilized" (p. 552).

Analgesia was defined as "that state in which none of the noxious stimuli administered were reported as painful;" hypalgesia was defined as "a state in which noxious stimuli were reported as less painful than would be expected on the basis of reports of the same subject regarding the same stimuli in control situations" (p. 554).

In their Discussion, the authors state, "As a result of hypnotic suggestions of anesthesia, the following effects on sensation were observed: (1) no alteration in reports of pain intensity; (2) hypalgesia for higher-intensity stimuli without elevation of the pain threshold; (3) definite elevation of pain threshold with hypalgesia; (4) analgesia; (5) disturbances in pain discrimination.

" The third effect was observed in the majority of trials. The threshold elevation in light trances may be similar to that which can be produced by suggestion in the un hypnotized subject, but in deeper trances the effectiveness of hypnotic suggestion is much greater. The progression of effects 1 through 4 appears to be directly related to the depth of trance. The fifth effect was variable and was seen only in conjunction with the third effect. It is described as a separate phenomenon because the disturbance of ability to discriminate relatively between stimuli of differing intensities was only clearly observed when we were remeasuring pain thresholds. In actuality, it may merely represent a facet of altered pain perception, and the variability of its appearance may be related to the variable psychological state of the

subject. It must be kept in mind that the hypnotic trance is not a static state" (p. 558). For one Subject, analgesia decreased in successive hypnotic sessions, while for four Subjects analgesia increased; a sixth Subject exhibited overall variability in hypnotic depth and analgesia from session to session.

The authors indicate that their review of the literature found no evidence that hypnosis, absent suggestions for analgesia, affects the galvanic skin response. In the present study, diminishment of the GSR is related to, though not dependent on, the effectiveness of the suggestion of anesthesia. "Thus, in Subject 2, with only moderate hypalgesia, the GSR to noxious stimuli was diminished by 64%; in S 6, with analgesia on nearly all trials, only 57%. It is particularly interesting that S 1 had a reduction in GSR of 26% after hypnotic suggestions which apparently had no effect upon his pain perception, and which seemed even to make him anxious. S 5 showed a direct correlation between depth of trance and decrease of GSR while Subjects 6 and 7 showed no such correlation" (p. 559).

"It is important to realize that on some occasions hypnotic anesthesia apparently led to complete disappearance of the GSR to all stimuli during a given session, such stimuli evoking pain of 6 or 7 dols in the control period. This phenomenon was seen twice with Subject 3, twice with Subject 5, and once with Subject 6. In several trials there was only a very slight GSR to the higher stimuli during hypnosis. In all the control periods there was only one occasion on which a stimulus evoking pain of 6 or 7 dols failed to produce a GSR, while equally intense stimulation failed to produce a GSR on 14 occasions after hypnotic suggestions of anesthesia. This observation is stressed because it suggests a need for caution in the clinical use of the GSR to distinguish organic from hysterical anesthetics" (pp. 559-560).

## **B RESEARCH**

### **Body Image**

**1989**

**Van Denberg, Eric J.; Kurtz, Richard M. (1989). Changes in body attitude as a function of posthypnotic suggestions. International Journal of Clinical and Experimental Hypnosis, 37, 15-30.**

Hypothesized that highly hypnotizable subjects who remained amnesic for posthypnotic suggestions to improve body attitude would show greater changes than subjects who were not amnesic. Subjects given simulating instructions were used as a comparison group to assess experimental demands. 48 females were screened with the Harvard and assigned to one of 4 conditions: (a) high hypnotizable with amnesia suggestions, (b) high hypnotizable without suggested amnesia, (c) low hypnotizable simulator with amnesia, and (d) low hypnotizable simulator without suggested amnesia. A fifth group was formed of those high hypnotizable subjects who remembered the suggestion despite instructions to the contrary. The Body Attitude Scale (Kurtz, 1966) was administered prior to and 3 days after the experimental suggestions. Results generally demonstrated that high hypnotizable amnesic subjects manifested the greatest attitudinal and phenomenological changes as a

result of the posthypnotic suggestion, although conclusions were tempered by performance of simulating subjects. The implications for hypnosis research and clinical practice are discussed.

**NOTES:**

"The hypothesis that hypnotized subjects would report greater positive changes in affect, self-esteem, and social functioning than simulators was tested using a brief structured questionnaire. An analysis of Subjects responses to the questionnaire while with the 'blind' research assistant (simulators in role) revealed number significant differences between groups (N = 48) on six of the seven questions. ... An analysis of Subjects' responses to the questionnaire while being debriefed by the primary investigator (simulators out of role) revealed significant differences among groups (N = 48) on three of the seven questions. ... High hypnotizable subjects with maintained amnesia demonstrated a strong tendency to be the most responsive of all groups of subjects on the first and second assessment. In contrast, the high hypnotizable Ss for whom amnesia 'broke down' reported the fewest phenomenological changes of any of the five groups during the first assessment, and comparatively few during the second assessment. Also of note is that once out of their role, simulators in both conditions dramatically reduced their reporting of positive change" (pp. 23-24).

"Moreover, a closer examination of the data demonstrated that phenomenological and behavioral differences in the groups did appear at several points during the experiment. For example, the 10 high hypnotizable subjects told to explicitly remember the suggestion did so, while 3 of the 10 simulators in this condition claimed to have forgotten it. On debriefing, these Subjects reported they did this because they believed 'really hypnotized subjects wouldn't be able to remember anything, even if they were told they could.' Further, no simulator in the amnesia condition reported they could recall the suggestion, in contrast to the high hypnotizable subjects, 44% of whom said they did remember it. With regard to phenomenological differences, simulators stated during debriefing with the primary investigator that they intentionally faked changes on BAS, and that they experienced no true effects from the suggestion for positive body attitude change. In contrast, high hypnotizability amnesic subjects reported global, pervasive changes in their mood and self-esteem that went beyond specific alterations in attitudes toward their appearance. By comparison, high hypnotizable subjects told to remember the suggestion reported greatly increased self-absorption and acute awareness of the suggestion, 'sort of like a broken record in my head'" (pp. 25-26).

"As shown by the present study, amnesia maintenance can be quite problematic. Of 18 high hypnotizable subjects for whom amnesia was suggested, only 10 remained fully amnesic for the suggestion after 3 days. In addition, those 8 subjects for whom amnesia 'broke down' showed minimal shifts on BAS, or in reports of phenomenological changes. Such frequent amnesia failure has been reported by other researchers, although the effectiveness of the suggestion is not always so compromised" (p. 26).

Barabasz, Marianne (1987). Trichotillomania: A new treatment. International Journal of Clinical and Experimental Hypnosis, 35 (3), 146-154.

The details of easily replicable interventions using hypnosis and restricted environmental stimulation therapy in the treatment of 4 cases of trichotillomania are presented. Hypnosis or hypnosis combined with brief restricted environmental stimulation appeared to be effective in 3 of the 4 cases. Factors affecting treatment outcomes are discussed.

#### NOTES

1:

Patients were given practice with hypnosis and also restricted environmental stimulation sessions to maximize response to hypnotic suggestions, as previous research indicated that only highly hypnotizable people responded to hypnotherapy for trichotillomania. The treatment itself consisted of simple posthypnotic suggestions, as "You will be acutely aware whenever you put your hand to your head, then it is entirely up to you, you have the power, the control, no one else, no habit controls you. You can pull your hair if you want to or you can choose to control the habit" (p. 149).

#### 1984

Gross, Meir (1984). Hypnosis in the therapy of anorexia nervosa. American Journal of Clinical Hypnosis, 26, 175-181.

Hypnosis was used successfully in treating 50 patients suffering from anorexia nervosa. Hypnotherapeutic intervention is most effective in treating such symptoms of this disorder as hyperactivity, distorted body image, failure of interoceptive awareness, feelings of inadequacy, perfectionist tendencies, and resistance to therapy.

Pekala, Ronald J.; Kumar, V. K. (1984). Predicting hypnotic susceptibility by a self-report phenomenological state instrument. American Journal of Clinical Hypnosis, 114-121.

In an attempt to predict hypnotic susceptibility (as measured by the Harvard Group Scale of Hypnotic Susceptibility, HGSHS) the phenomenological experiences of an hypnotic induction (HI) procedure and a baseline comparison condition (eyes closed, EC, sitting quietly) were assessed. After each experience the subjects (n=217) completed the Phenomenology of Consciousness Inventory (PCI), a self-report phenomenological state instrument, dealing with that condition. Step-wise multiple regression and discriminant analyses were then performed on data using the subject's HGSHS score as the dependent variable and the PCI (sub)dimensions as the independent variables. Regression analyses that held up under cross-validation during HI suggest that the PCI may be an appropriate instrument for predicting susceptibility. The possible clinical usefulness of this approach is discussed.

#### 1965

**Halpern, Seymore (1965). Body-image symbols of repression. International Journal of Clinical and Experimental Hypnosis, 13 (2), 83-91.**

Hypnointrospection, a method of hypnoanalysis which emphasizes self-perception during voluntary immobilization, is of demonstrable value in the elucidation of the problem of body-image. Hypnointrospective fragments of a case history showing the reorganization of the body-image during therapy are presented. The sequence of body-image phenomena is interpreted as an expression of attitudinal compromises among conflicting wishes implemented through neuromuscular channels. The continuous reorganization of the physical self as perceived by the patient during hypnointrospective analysis appears to be of significance for a general theory of body-image. (PsycINFO Database Record (c) 2002 APA, all rights reserved)

**1963**

**Fisher, S. (1963). Body image and hypnotic response. International Journal of Clinical and Experimental Hypnosis, 11, 152-162.**

This study had 2 principal objectives: (a) To test the hypothesis that hypnotizability is negatively related to the definiteness of the individual's body image boundary, as measured by barrier and penetration scores derived from the Rorschach. (b) To ascertain what body image experiences are characteristic of the hypnotic state. Hypnotizability was evaluated with the Stanford Hypnotic Susceptibility Scale. In the male group only, hypnotizability was negatively correlated with boundary definiteness. Depersonalization proved to be the most characteristic body image change. **1953**

**Guze, Henry (1953). Posture, postural redintegration and hypnotherapy. Journal of Clinical and Experimental Hypnosis, 1, 76-82. (Abstracted in Psychological Abstracts 53: 6559)**

**SUMMARY.** The use of postural analysis, and directives regarding posture and their importance in hypnotherapy are discussed. Theoretically, it is indicated that a chronic postural condition may act to elicit an emotional state with which it was originally associated. Such an emotional condition may have caused the posture in the first place, and then established a feed-back relationship with it. The breaking of feed-back mechanisms of this kind depends largely upon postural change when a chronic situation is established in the absence of realistic cause for the emotion. Posture may also act redintegratively, when directly suggested, in rearousing traumatic memories. Several clinical cases are reported.

**Brain**

**1995**

**Barabasz, Arreed F.; Barabasz, Marianne; Jensen, Stacia (1995, November). Effects of hypnosis on cortical event-related potentials during visual and olfactory hypnotic**

**hallucinations.** [Paper] Presented at the annual meeting of the Society for Clinical and Experimental Hypnosis, San Antonio, TX.

**NOTES:** Slotnick and London showed that different wording of suggestions led to very different results, which explains why our study on negative hallucinations and Spiegel's study had opposite results.

This study is still ongoing. Screened for highs who passed visual and olfactory hallucinations and lows who passed only motoric items on hypnotizability tests. Trained Ss with eyes open induction, and lows had instructions to simulate hypnosis. (Used the eyeroll induction, eyes open.)

Did waking administration of alternating checkerboard pattern on computer screen. Then did eyes open hypnotic induction plus a depth check to make sure they were deep (assign number; then instructed raise a finger when you double it; then again, raise a finger when you double it). Then used checkerboard design again.

Obstructive visual hallucination - "imagine traveling through space, a dark nebula" (better than imagining you are blind. Lows had no difference in waking, obstructive hallucination, and negative hallucination. The highs did--looks like they had to see it before they couldn't see it. "The dark nebula envelopes you completely, and now you can see nothing."

De Pascalis, Vilfredo (1995, November). **Psychophysiological correlates of hypnosis and hypnotic susceptibility.** [Paper] Presented at the annual meeting of the Society for Clinical and Experimental Hypnosis, San Antonio, TX.

**NOTES**

**STUDY 1 and STUDY 2.**

They recorded 40-Hz EEG temporal density (35-45 Hz band) from the left and right temporo-parietal-occipital scalp regions in four emotional conditions (gladness, happiness, fear, and anger). When measures were made in the waking state, for Highs, during positive emotions they found increase in left and right hemisphere activity compared with resting condition. During fear and anger there was reduction in the left hemisphere and an increase in the right, but for some subjects no left hemisphere change.

Low hypnotizables did not show large or reliable differences across emotions. With the hypnotic state, they found the trend was even greater for Highs.

Jasiukaitis, Paul; Spiegel, David (1995, November). **Relateralizing hypnosis, or have we been barking up the wrong hemisphere?.** [Paper] Presented at the annual meeting of the Society for Clinical and Experimental Hypnosis, San Antonio, TX.

**NOTES**

The association between the right hemisphere and hypnotizability dates to the Gurs and Bakan; and to Hilgard and Morgan who developed a measure based on EEG power spectrum. Results from the body of research using alpha are conflicting. De Pascalis, 1988, also couldn't show a large alpha difference between hemispheres.

Research on hypnotic hallucination with Pribram found Highs in a visual obstruction condition reduced P200 and P300; there was a slightly greater response

at O2 than O1 EEG leads, leading us to think it was maybe a Right hemisphere task. But it was a foveal stimulus.

We tested with hemifield stimuli, blocking perception of 1/2 of the visual monitor; had them do the obstruction hallucination. P200 had the greatest reduction, with stimuli presented on the left. With obstruction of left visual field, we got little response. So ERP results were greater in right visual field (left hemisphere). This suggests the earlier observation was predominantly due to left, not right, hemisphere influence.

Martha Farah's work on imagery is instructive. Also Steve Kosslyn. The Right hemisphere answers "Where" do you see something. The Left answers "What is it you see?" The left hemisphere generates image patterns that match what you see. When you ask people to generate an image, the activity is in O1 area. Also, patients with left hemisphere damage can't generate images; callosotomy patient also gave evidence. Many inductions use generation of images (left occipital and temporal regions). So when asking subjects to generate a hallucinated image blocking the screen, they are using that area.

The cortex can serve as an amplifier or a suppressor of response. In earlier study of somatosensory potential we observed bigger response when asking person to be more aware of pain. The cortex has an arousal system. There are two relevant systems in the brain (see Posner)--posterior and anterior. Hypnotizability is correlated with a metabolite of dopamine, which is associated with the anterior system which is dopaminergic.

Tucker & Williamson, in article in Psychological Review, 1984, write that activation is "the determination of information control by previous, stored internal representations" as opposed to arousal which is the "determination by novel [missed words...]"

Kinsbourne, in Consciousness and Contemporary Science, 1988. wrote that if at any time a hemisphere works like an automaton, it is the left hemisphere. With R. Davidson, he has shown the left hemisphere elevates affect, the right depresses it. Many people report that hypnosis is a pleasurable thing to do, maybe because it elevates mood.

One obstacle to this formulation is the idea that the left hemisphere governs logical thought.

We may disturb the relationship between words and images in hypnosis; you start to manipulate images and passively receive words, so that language is now a passive, receptive experience and images are active (instead of the usual pattern of actively using words and passively using images).

## 1994

Crawford, Helen J. (1994). Brain dynamics and hypnosis: Attentional and disattentional processes. International Journal of Clinical and Experimental Hypnosis, 42 (3), 204-232.

This article reviews recent research findings, expanding an evolving neuropsychophysiological model of hypnosis (Crawford, 1989; Crawford & Gruzelier, 1992), that support the view that highly hypnotizable persons (highs)

possess stronger attentional filtering abilities than do low hypnotizable persons, and that these differences are reflected in underlying brain dynamics. Behavioral, cognitive, and neurophysiological evidence is reviewed that suggests that highs can both better focus and sustain their attention as well as better ignore irrelevant stimuli in the environment. It is proposed that hypnosis is a state of enhanced attention that activates an interplay between cortical and subcortical brain dynamics during hypnotic phenomena, such as hypnotic analgesia. A body of research is reviewed that suggests that both attentional and disattentional processes, among others, are important in the experiencing of hypnosis and hypnotic phenomena. Findings from studies of electrocortical activity, event-related potentials, and regional cerebral blood flow during waking and hypnosis are presented to suggest that these attentional differences are reflected in underlying neurophysiological differences in the far fronto-limbic attentional system.

Crawford, Helen J. (1994). Brain systems involved in attention and disattention (hypnotic analgesia) to pain. In Pribram, Karl H. (Ed.), Origins: Brain and self organization (pp. 661-679). Hillsdale, NJ: Lawrence Erlbaum Associates.

Data are reviewed from regional cerebral blood flow, EEG, and somatosensory event-related potential (SERP; both scalp and intracranial) studies of attention to and disattention (hypnotic analgesia) of painful stimuli to provide further evidence for two neurophysiological systems of pain involving the cortex: (1) the epicritic, sensory system of pain associated with the parietal, posterior region, and (2) the protocritic, distress, comfort-discomfort system of pain associated with the far fronto- limbic region. Studies of neurophysiological changes accompanying suggested hypnotic analgesia support the hypothesis that the executive controller of the far frontal cortex, via the far fronto-limbic attentional system, acts as a gate against the ascent of painful stimuli into conscious awareness by 'directing' downward the inhibition of incoming somatosensory information coming from the thalamic region. In hypnotically responsive individuals who could eliminate the perception of pain, reviewed studies demonstrated increased regional cerebral blood in the frontal and somatosensory regions, shifts in hemispheric dominance of EEG theta power, differential surface SERP topographical patterns in the anterior and posterior regions of the brain, and reduction of the intracranial SERP P160 waveform in the gyrus cingulus.

#### NOTES

Paradoxically, there may be physiological reactivity to pain stimuli while the hypnotized Subject reports they are not consciously aware of pain. Posner's proposal of two different attentional systems may account for why there is physiological reactivity concurrent with lack of awareness of pain. Posner suggested that the posterior brain is involved with engaging and disengaging attention while the anterior brain is involved in attention for action or effortful attention. "Thus, the posterior region is involved in space and time, the epicritic processes, whereas the anterior region is involved in comfort- discomfort, the protocritic processes (Pribram, 1991)" (p. 665).

In parallel, there appear to be two systems of pain involving the cortex, as revealed in positron emission tomography research. Also relevant is clinical data showing that "removal of the frontal or cingulate cortex in patients with intractable pain leads to the amelioration of distress while not eliminating sensory pain (Bouckoms, 1989)" (p. 665).

The author proposes a neuropsychophysiology of hypnotic analgesia based on Hilgard's (1986) neodissociation theory of hypnosis, together with Pribram and McGuinness' (1975, 1992) attention model. In this view, "Hilgard's executive control system is the far frontal cortex 'directing' the inhibition of incoming painful stimuli" (p. 666) after determining that the somatosensory signal is 'irrelevant.'

"Highly hypnotizable individuals ('highs') have greater attentional and disattentional abilities than low hypnotizable individuals ('lows'). ... Recent neuroimaging techniques (PET, SPECT, CBF) that assess regional brain metabolism have found no differences in waking conditions between low and highly hypnotizable individuals, but have consistently reported that only highs show increased cerebral blood flow during hypnosis, suggestive of enhanced cognitive effort (Crawford, Gur et al., 1993; Halama, 1989; Meyer, Diehl, Ulrich, & Meinig, 1989; Walter, 1992)" (p. 666).

The hippocampus appears to be involved as a gating mechanism in selective attention (Crowne, Konow, Drake & Pribram, 1972; Isaacson, 1982, Isaacson & Pribram, 1986; R. Miller, 1991; Pribram, 1991; Arnolds et al., 1980) This gating function may be promoted "through a cortico-hippocampal relay [that] transmits information by theta wave modulation and Hebbian synaptic modification so that there is selective disattention" (p. 667). The author suggests that hypnotic pain control may involve directing attention away from pain sensory signals.

Highly hypnotizable people generate more EEG theta than low hypnotizables whether they are hypnotized or not, and Crawford (1990) observed marked hemispheric shifts in theta when highs (but not lows) were attempting to control pain with hypnosis.

This paper reports on preliminary results of SERP studies of people given hypnotic analgesia suggestions to reduce electric shock stimulus evoked pain. The results were analyzed individual by individual, because group data obscured pronounced shifts in SERP patterns (e.g. habituation rates differed among Subjects). For highs, the SERP tended to be reduced, and the lower amplitudes were observed as early as the N100-P200 components. This did not occur for low hypnotizables.

Different kinds of mechanisms may be operative for high hypnotizables, however. "In over half of the high hypnotizable subjects the far frontal region (Fp1, Fp2) showed strong arousal during attention to pain, but during hypnotic analgesia there was a flattening out of the SERPs to the point they are hard to measure. By contrast, the more posterior SERPs (including F3 and F4), while reduced in amplitude, were still evident. The other half of highs showed little SERP activity in the far frontal region in either attend or disattend conditions, but substantial reductions of SERPs at all locations during hypnotic analgesia" (p. 670). Additionally, some of the highs evidenced a contingent negative variation (CNV) or a late 400-500 msec negativity in the far frontal region, which author is inclined to interpret as "a preparation for a response or for an inhibition of a response" (p. 670).

Case studies of two patients with intracranial electrodes and scalp electrodes recording SERPs are presented in support of the experimental data. The two female patients were diagnosed with obsessive compulsive disorder; one was highly hypnotizable and one was not. They received 30 moderately painful stimuli to the left middle finger under sequential conditions: waking attention, hypnosis with analgesia suggestions, and hypnosis with attention instructions. The highly hypnotizable patient reported significantly less pain during suggested analgesia, and that reduction in pain was associated temporally with reduction of SERP at P160 in the gyrus cingulus (and at no other recording sites). The 'unhypnotizable' patient showed no SERP changes. As an aside, the author notes that "Subsequent to the hypnotic analgesia, when the pain was attended to again during waking this patient showed a significant enhancement of the same positivity wave at Fz, as if there was a rebound effect (something we have also observed in some of our SERP subjects at the BRAINS Center)" (p. 674).

Freeman, R.; Barabasz, A.; Barabasz, M. (1994, October). EEG topographic differences between dissociation and distraction during cold pressor pain in high and low hypnotizables. [Paper] Presented at the annual meeting of the Society for Clinical and Experimental Hypnosis, San Francisco.

#### NOTES

Hilgard once said we should study what is going on inside the skull when we study hypnotic behavior. Theta EEG was studied, in 3.5 and 5.5-7.5 band widths, based on Crawford's research (no differences between high and low hypnotizables in low range but significant differences in waking state, eyes closed condition).

Also employed new type of distraction procedure. Previously used as comparison conditions things like imagine a pleasant scene, do whatever you can do to reduce pain, or imagine an instructor giving a lecture. Barabasz theorized that highs, given the opportunity, may spontaneously get involved in imagery; so distraction used in some experiments may actually become hypnosis. Here, distraction involved using a storage box, with plexiglass covering front, and 3 lights--subjects were to recall sequence of light changes that occurred during 60 sec when arm was in the cold water.

Cold pressor pain. 3 immersions with simultaneous pain reporting and EEG monitoring. --Waking State --Light array distraction --Hypnotic induction and suggested analgesia (Distraction and hypnosis with analgesia were presented in a balanced design)

Pain Ratings ranged from 0 = no pain, 10 = level would very much like to remove arm from water (rating could exceed 10 however). After removing arm, subjects were to report the maximum amount of pain that they had felt. Pain Scores were obtained at 30 seconds and 60 seconds after immersion in the cold water.

Also got qualitative data. During recovery period after each arm immersion, Subjects were asked what if anything they had done to reduce the pain felt.

30 second pain scores: Waking 7.60 vs 7.50 Distraction 8.60 vs 6.80 Hypnotic analgesia 7.80 vs 4.10 (Significantly different).

60 second pain scores: Showed same trend

There was no difference whatsoever for the lows.

Results for the 2 EEG sites: P3 left hemisphere parietal in waking and hypnotic analgesia, high theta, had significantly different activity O1 left hemisphere in waking and hypnotic analgesia, was significantly different between highs and lows (same as above).

Results for two theta ranges: Low theta range, T4 temporal right hemisphere, for lows in waking and [missed words] condition--hard to interpret this finding.

## RESULTS

Highs demonstrated pain reduction in hypnotic analgesia compared to waking and distraction conditions and compared to lows. Lows had no differences in any condition.

Enhanced EEG theta in left parietal area differentiated highs and lows. This suggests that highs generate enhanced disattention that may be controlled by these areas.

P3 area regulates the integration and association of somatic perceptions. The O1 area controls processing of visual imagery. Perhaps high hypnotizables have more ability to alter afferent sensory information through focused attentional processes. Also, the ability to alter the suffering portion of pain experience may involve visual imagery activity.

State and trait differences are apparent.

The low theta range may be more closely related to slower delta range 0-3.5 that is associated with sleep and drowsiness. High theta = low arousal and attention capacity. That's why theta seems associated with wide range of behaviors that appear contradictory

The qualitative data shows highs reported they spontaneously preferred strategies that were more than distraction (associating colors with warmth, thinking of warm water) and the most frequent responses of lows were "nothing" or "told myself it would be over soon."

Highs in analgesia condition used no specific strategy: 8/10 reported the arm simply felt more numb.

Lynn, Steven Jay (1994, October). Toward an integrative theory of hypnosis. [Paper] Presented at the annual meeting of the Society for Clinical and Experimental Hypnosis, San Francisco.

NOTES: This is a re-evaluation of neodissociation and cognitive models of hypnosis, and an attempt to be integrative. This paper focuses more on ideomotor behaviors but we will extend the model to other hypnotic behaviors in the future.

Automaticity of behavior in hypnosis can be accounted for without using a concept of divided consciousness or weakened consciousness. Parapraxes (doing one behavior while intending another) are not instances of decreased control of behavior, but relate to where attention is drawn. This requires a different use of the hierarchy concept from Hilgard's model (which in turn comes from Hull's concept of habit hierarchy).

Here hierarchy is a concept drawn from Miller, Galanter, & Pribram: acts are comprised of molecular units, that are comprised of even more molecular units. Behavior only needs to be processed at an executive level when unusual events occur. But one or more hierarchies may be set into motion at the same time.

Dissociation is not an infrequent event. Behavior is controlled by subroutines rather than by an executive control structure; subroutines operate in parallel rather than in a hierarchy. Parapraxes are due to an overlap between two subfunctions.

Parapraxes are different from ideomotor responses, where we pay close attention and involuntariness is reported not just post facto but as part of the experience.

### 1993

Attias, J.; Shemesh, Z.; Sohmer, H.; Gold, S.; Shoham, C.; Faraggi, D. (1993). Comparison between self-hypnosis, masking and attentiveness for alleviation of chronic tinnitus. Audiology, 32, 205-212.

A total of 45 male patients close in age with chronic tinnitus related to acoustic trauma were assigned to three matched subgroups: self-hypnosis (SH), masking (MA), and attentiveness to the patients' complaints (AT). The therapeutic stimuli in the SH and MA sessions, recorded on audio cassettes, were given to the patients for use when needed. SH significantly reduced the severity of tinnitus, AT partially relieved the tinnitus, and MA had no significant effect.

Crawford, Helen J.; Gur, Ruben C.; Skolnick, Brett; Gur, Raquel E.; Benson, Deborah M. (1993). Effects of hypnosis on regional cerebral blood flow during ischemic pain with and without suggested hypnotic analgesia. International Journal of Psychophysiology, 15, 181-195.

Using <sup>133</sup>Xe regional cerebral blood flow (CBF) imaging, two male groups having high and low hypnotic susceptibility were compared in waking and after hypnotic induction, while at rest and while experiencing ischemic pain to both arms under two conditions: attend to pain and suggested analgesia. Differences between low and highly-hypnotizable persons were observed during all hypnosis conditions: only highly-hypnotizable persons showed a significant increase in overall CBF, suggesting that hypnosis requires cognitive effort. As anticipated, ischemic pain produced CBF increases in the somatosensory region. Of major theoretical interest is a highly-significant bilateral CBF activation of the orbito-frontal cortex in the highly-hypnotizable group only during hypnotic analgesia. During hypnotic analgesia, highly-hypnotizable persons showed CBF increase over the somatosensory cortex, while low-hypnotizable persons showed decreases. Research is supportive of a neuropsychophysiological model of hypnosis (Crawford, 1991; Crawford and Gruzelier, 1992) and suggests that hypnotic analgesia involves the supervisory, attentional control system of the far-frontal cortex in a topographically specific inhibitory feedback circuit that cooperates in the regulation of thalamocortical activities.

De Pascalis, Vilfredo (1993). EEG spectral analysis during hypnotic induction, hypnotic dream and age regression. International Journal of Psychophysiology, 15, 153-166.

EEG was recorded monopolarly at frontal (F3, F4), central (C3, C4) and posterior (in the middle of O1-P3-T5 and O2-P4-T6 triangles) derivations during the hypnotic induction of the Stanford Hypnotic Clinical Scale (SHCS) and during performance following suggestions of hypnotic dream and age-regression as expressed in the before-mentioned scale. 10 low-hypnotizable and 9 highly-hypnotizable and right-handed female students participated in one experimental session. Evaluations were Fast-Fourier spectral analyses during the following conditions: waking-rest in eyes-open and eyes-closed condition; early, middle, and late phases of hypnotic induction; rest-hypnosis in eyes closed condition; hypnotic dream and age regression. After spectral analysis of 0 to 44 Hz, the mean spectral amplitude estimates across seven Hz bands (theta 1, 4-6 Hz; theta 2, 6-8 Hz; alpha 1, 8-10 Hz; alpha 2, 10-13 Hz; beta 1, 13-16 Hz; beta 2, 16-20 Hz; beta 3, 20-36 Hz) and the 40-Hz EEG band (36-44 Hz) for each experimental condition were extracted. In eyes-open and -closed conditions in waking and hypnosis highly-hypnotizable subjects produced a greater 40-Hz EEG amplitude than did low hypnotizable subjects at all frontal, central and posterior locations. In the early and middle hypnotic induction highly-hypnotizables displayed a greater amount of beta 3 than did low hypnotizables and this difference was even more pronounced in the left hemisphere. With posterior scalp recordings, during hypnotic dream and age regression, high hypnotizables displayed, as compared with the rest-hypnosis condition, a decrease in alpha 1 and alpha 2 amplitudes. This effect was absent for low hypnotizables. Beta 1, beta 2 and beta 3 amplitudes increased in the left hemisphere during age regression for high hypnotizable; low hypnotizables, in contrast, displayed hemispheric balance across imaginative tasks. High hypnotizables during the hypnotic dream also displayed in the right hemisphere a greater 40-Hz EEG amplitude as compared with the left hemisphere. This difference was even more evident for posterior recording sites. This hemispheric trend was not evidenced for low hypnotizable subjects. Theta power was never a predictor of hypnotic susceptibility, 40-Hz EEG amplitude displayed a very high main effect ( $p < 0.004$ ) for hypnotizability in hypnotic conditions by displaying a greater 40-Hz EEG amplitude in high hypnotizables with respect to lows.

#### NOTES:

In the Discussion section, the authors indicate that they have no idea why they didn't replicate results of other theta studies, including their own, except maybe due to complex interaction among personality, subject selection, situation-specific factors, and hypnotizability.

They observe that the alpha results conform with previous findings (p. 163). Beta bands were sensitive. Highs showed left-hemisphere prevalence in all beta bands during age regression; they also showed hemispheric balance in the hypnotic dream condition. Beta 3 amplitude was also greater among highs than lows. "among high hypnotizables, beta 3 amplitude in the early hypnotic condition was greater in the left hemisphere as compared to the right and as the hypnotic induction proceeded hemisphere balancing, with reduced beta 3 amplitude, was displayed. This result appears in agreement with the predictions of the neurophysiological model proposed by Gruzelier et al. (1984) and Gruzelier (1988) as well as with other studies in which

beta rhythm was found to discriminate performances between high and low hypnotizables (e.g., Meszaros et al., 1986, 1989; Sabourin et al., 1990)" (p. 163-164). 40 Hz amplitude was higher in highs and increased in right hemisphere during the hypnotic dream, especially in posterior areas. "This pattern of hemispheric activation may be interpreted as an expression of the greater right-hemisphere activation and of the release of posterior cortical functions during the hypnotic dream and is compatible with the predictions of the Gruzelier model of hypnosis, however, the results obtained in this study for 40-Hz EEG amplitude failed to reveal an inhibition of the left-hemisphere activity with the progress of the hypnotic induction" (p. 164).

(They note that De Pascalis & Penna, 1990, agreed with the Gruzelier 1988 model: highs in early induction had increase of 40-Hz in both hemispheres, but as induction proceeded they had inhibition of left and increase in right hemisphere activity. In this current experiment, only beta 3 showed the hemispheric trend of Gruzelier's model. They cite other details of current study, p. 164, not consonant with Gruzelier.)

"The 40-Hz EEG rhythm, which according to Sheer (1976) is the physiological representation of focused arousal, appeared to discriminate between differential patterns of high and low hypnotizables. Both during hypnotic induction and during hypnotic dream and age regression highly hypnotizables exhibit greater 40-Hz EEG amplitude with respect to the lows. These findings support the validity of the assumption that hypnosis is characterized by a state of focused attention (Hilgard, 1965) and that 40-Hz EEG activity reflects differential attentional patterns among subjects high and low in hypnotizability. On the basis of these findings it would appear that 40-Hz EEG and beta 3 spectral amplitudes may prove to be useful measures of individual hypnotizability" (p. 164).

Gruzelier, John; Warren, Kristen (1993). Neuropsychological evidence of reductions on left frontal tests with hypnosis. Psychological Medicine, 23, 93-101.

Individuals with high and low susceptibility to hypnosis were compared in a baseline condition and after instructions of hypnosis on tests of anterior left and right hemispheric functions of word fluency to letter categories, word fluency to semantic categories, design fluency and bilateral finger tapping dexterity. With hypnosis high susceptibles showed a reduction in word generation to letter categories, no significant change in word generation to semantic categories, an improvement in design fluency, and bilateral reductions in finger tapping dexterity. Low susceptibles showed the opposite changes except for the improvement in design fluency. These results, together with correlational results, were interpreted as evidence of central inhibitory processes, particularly of the left hemisphere, in response to instructions of hypnosis in high susceptibles.

#### NOTES:

The authors discussion of their study includes the following statements. "The main result of the study was the differential influence of instructions of hypnosis on high

and low susceptibles for word fluency to letter designated categories, as distinct from semantic categories, and design fluency" (p. 98).

"The absence of effects of hypnosis on word generation to semantic categories (left fronto-temporoparietal) versus letter categories (left frontal) has a bearing on evoked potential evidence (Gruzelier et al. 1987). Bilateral comparisons at temporal lobe and central locations showed that high susceptibles were characterized by asymmetric changes in evoked potential amplitude (N116 component) with hypnosis. Activity at the central electrodes was compatible with a left-to-right hemispheric shift of function, but this was not the case at the temporal electrodes. Instead of an inhibition of left temporal activity with hypnosis activation was maintained. Maintenance of activity in the left temporal lobe follows consideration of the fact that hypnosis requires sustained attention to the voice of the hypnotist, which is predominantly a left temporal function" (p. 99).

"The absence of differences in the pre-hypnotic condition between high and low susceptibles indicates that hemisphericity *per se* may not be a factor that characterizes susceptibility. The fact that lateral differences were found in some experiments (e.g. Gruzelier et al. 1984; Gruzelier & Brow, 1985) but not others (e.g. Cikurel & Gruzelier, 1990; McCormack & Gruzelier, 1993) may indicate that such effects, when apparent, were secondary to another factor such as cognitive flexibility as conceptualized by Crawford (1989)" (p. 99).

Jutai, Jeffrey; Gruzelier, John; Golds, John; Thomas, Martin (1993). Bilateral auditory-evoked potentials in conditions of hypnosis and focused attention. International Journal of Psychophysiology, 15, 167-176.

Brain event-related potentials (ERPs) evoked by auditory stimulation were used to study cerebral hemispheric activity during hypnosis. ERPs were recorded from bilateral central (C3 and C4) and temporal (T3 and T4) scalp locations in response to tone pips in 6 medium-high and 6 low-susceptible subjects in three conditions: baseline (tones only), hypnosis (tones plus hypnotic induction), and a focused attention control (tones plus a newspaper story read by the hypnotist). Task asymmetries were individually adjusted for baseline asymmetries. Responses from central locations did not differentiate hypnosis from focused attention for either group. The same was true of temporal locations for the low-susceptible group. The predominant temporal lobe pattern for both conditions and groups was larger left than right responses. The exception was the hypnosis condition for the medium-high susceptible group where there was an increase in responses in the right temporal lobe.

Lindsay, Suzanne; Kurtz, Richard M.; Stern, John A. (1993). Hypnotic susceptibility and the endogenous eyeblink: A brief communication. International Journal of Clinical and Experimental Hypnosis, 41, 92-96.

This study investigated the relationship between hypnotic susceptibility, hypnotic state, and the endogenous eyeblink with 36 undergraduates, who were assigned to four independent groups (waking-low, hypnotized-low, waking-high, and hypnotized- high susceptibles) on the basis of combined cutoff scores on both the

Creative Imagination Scale and the Stanford Hypnotic Clinical Scale for Adults. The auditory vigilance task required subjects to discriminate between 200 ms and 300 ms tones over a 35-minute period. Hypnotic depth was controlled across trials using the Long Stanford Scale of Hypnotic Depth. As predicted, high-susceptible subjects had a significantly lower blink rate than low-susceptible subjects. The predicted interaction between susceptibility and hypnotic state was also confirmed. High-susceptible subjects showed a significant decrease in blinking for the hypnotized condition, whereas low-susceptible subjects did not. The need for replication with more adequate measures of susceptibility is discussed.

**NOTES:**

"In a preliminary study, Weitzenhoffer (1979) found significant differences between high- and low-susceptible subjects following a hypnotic induction. The highs showed a 66% decrease in blink rate from a baseline reading. More recently, Tada, Yamada, and Hariu (1990) reported a series of studies suggesting that blink rate was dramatically reduced during the hypnotic state, as well as finding a relationship between high susceptibility and decreased blink rate. Although these studies tend to support Weitzenhoffer's (1979) research, they are poorly controlled and report no quantitative data" (p. 93).

In the present study, "to assure that subjects kept their eyes open, they were required to maintain their gaze on a dimly lighted box (12" x 12") placed one meter in front of them. Subjects in both conditions were asked to rate their hypnotic depth by using the Long Stanford Scale of Hypnotic Depth (Tart, 1970) before being given a practice trial of 20 tones. Following the practice trial, participants were again asked to rate their hypnotic depth, and the trial period began. Subjects gave subsequent depth ratings every 10 minutes for the remainder of the 35-minute trial. The hypnotic state was maintained across time periods by using deepening instructions when necessary" (p. 94).

In their Discussion, the authors noted that "High-susceptible subjects in the hypnotized state have a significantly lower blink rate and presumably greater attentional focus than lows. Although the interaction was significant and in the predicted direction, it accounted for only a small portion of the overall variance, suggesting that trait differences are more robust than those for state" (p. 95).

Lyskov, E.; Juutilainen, J.; Jousmaki, V.; Hanninen, O.; Medvedev, S.; Partanen, J. (1993). Influence of short-term exposure of magnetic field on the bioelectrical processes of the brain and performance. International Journal of Psychophysiology, 14, 227-231.

The influence of an extremely-low-frequency (ELF) magnetic field on the bioelectrical processes of brain and performance was studied by EEG spectral analysis, auditory-evoked potentials (AEP), reaction time (Roletaking) and target-deletion test (TDT). Fourteen volunteers were exposed for 15 min to an intermittent (1 s on/off) 45- Hz magnetic field at 1000 A/m (1.26 mT). Each person received one real and one sham exposure. Statistically significant increases in spectral power through alpha- and beta- bands, as well as in mean frequency of the EEG spectrum were observed after magnetic field exposure. Field-dependent changes of N100

were also revealed. No changes in the amplitudes or latencies of the earlier peaks were observed. No direct effects on Roletaking, nor on TDT performance were seen. However, practice effects on Roletaking (decrease of Roletaking in the course of the test-sessions) seemed to be interrupted by exposure to the magnetic field.

## 1992

Atkinson, Richard P.; Crawford, Helen J. (1992). Individual differences in afterimage persistence: Relationships to hypnotic susceptibility and visuospatial skills. American Journal of Psychology, 105 (4), 527-539.

To investigate the moderating role of individual differences in hypnotic susceptibility and visuospatial skills on afterimage persistence, we presented a codable (cross) flash of light to 40 men and 46 women who had been dark adapted for 20 minutes. In an unrelated classroom setting, subjects had previously been given two standardized scales of hypnotic susceptibility (Harvard Group Scale of Hypnotic Susceptibility, Shor & Orne, 1962; Group Stanford Hypnotic Susceptibility Scale, Form C, Crawford & Allen, 1982) and the Mental Rotations Test (Vandenberg & Kuse, 1978). The first afterimage interval and the afterimage duration correlated significantly with hypnotic responsiveness, supporting Wallace (1979), but did not show the anticipated relationships with mental rotation visuospatial skills. Individuals in the high hypnotizable group had (a) significantly longer afterimage intervals between its first appearance and first disappearance than did those in low groups, but those in medium groups did not differ significantly from the other groups. Discriminant analysis using the afterimage persistence measures classified correctly 65.2% of high hypnotizables, 37.5% of medium hypnotizables, and 54.8% of low hypnotizables. Hypothesized cognitive skills that assist in the maintenance of afterimages and underlie hypnotic susceptibility include abilities to maintain focused attention and resist distractions over time and to maintain vivid visual images.

## NOTES

"Because there is no apparent evidence for physiological differences of the visual system between low and high hypnotizables (e.g., Wallace, 1979), cognitive factors are suggested as possible moderators of afterimage persistence.

"Hypnotic susceptibility per se is not the moderator of afterimage duration. Rather, we argue that hypnotic susceptibility represents a constellation of underlying cognitive skills (e.g., for reviews, see Crawford, 1989; Kihlstrom, 1985) that assist an individual to respond to hypnotic suggestions as well as assist in the persistence of afterimages by interacting with more primary casual mechanisms that are physiological in origin. These cognitive skills are thought to include the abilities to focus attention selectively upon both external stimuli and internally generated images, to maintain vivid visual images, to sustain attention over time and remain absorbed in the experience at hand, and to resist distractions. The relationships between these cognitive skills and hypnotic susceptibility are reported in a large body of literature (e.g., Crawford, 1982, 1989; Crawford et al., 1991; Crawford &

Grumbles, 1988; Finke & Macdonald, 1978; Grumbles & Crawford, 1981; Mitchell, 1970; Tellegen & Atkinson, 1974)....

"Sustained and selective attention without interference from extraneous stimuli plays an important role in hypnosis. Individuals who are responsive to hypnosis demonstrate greater skills in extremely focused and sustained attention (e.g., Crawford et al., 1991; Tellegen & Atkinson, 1974). Electrophysiological research had found that high hypnotizables often generate substantially more theta electroencephalogram (EEG) power than do low hypnotizables (e.g., Crawford 1990, 1991; Crawford & Gruzelier, 1992; Sabourin, Cutcomb, Crawford, & Pribam, 1990). Such a relationship may be interpreted as further evidence of greater attentional skills in highs, because certain theta waves have been correlated with enhanced problem solving and attentional task performance (e.g., Crawford & Gruzelier, 1992; Schacter, 1977)....

"Hypnosis is seen often as a condition of amplified attention, where attention can be either more focused or diffuse dependent upon set (e.g., Krippner & Binder, 1974). Increases in vigilant performance during hypnosis have been reported, albeit inconsistently (e.g., Barabasz, 1980; Fehr & Stern, 1967; Kissen, Reifler, & Thaler, 1964; Smyth & Lowy, 1983). Fehr and Stern's results suggest that hypnotized subjects devote more attention to a primary task with less available attentional resources for a secondary task. Hypnosis has been found to have an enhancing effect on the imaginal processing of information-to-be-remembered that consists of literal or untransformed representations of pictorial or nonverbal information for high but not low hypnotizables (Crawford & Allen, 1983; Crawford, Nomura, & Slater, 1983; Crawford, Wallace, Nomura, & Slater, 1986). This may possibly be the result of increased attention and/or shifts in cognitive strategies. Supportive of the hypothesis that sustained attention can be enhanced during hypnosis, Atkinson (1991) recently found that high but not low hypnotizables report significantly more persistent afterimages in hypnosis than in waking.

"Although we have argued for a cognitive explanation for individual differences in afterimage persistence and their possible relationship to hypnotic susceptibility and sustained attentional abilities, as has Wallace (1979, 1990), we must point out the possibility that high hypnotizables may be more suggestible to imagery instructions or more willing to discuss or experience imagery than low hypnotizables, particularly in the context of hypnosis and hypnotic susceptibility testing (e.g., Zamansky, Scharf, & Brightbill, 1964). A contextual account of the longstanding relationship between hypnotic susceptibility and absorption was raised by Council, Kirsch, and Hafner (1986), but was not supported by two independent, and more methodologically sound, studies reported by Nadon, Hoyt, Register, and Kihlstrom (1991). The context of hypnosis was not an issue in the present study, because none of the subjects was aware of the investigated relationship between afterimage persistence and hypnotic susceptibility at the time of recruitment or participation" (pp. 533-535).

Barinaga, Marcia (1992). Giving personal magnetism a whole new meaning. Science, 256, 967.

**NOTES:** Cited in Noetic Sciences Review, Autumn, 1992. This geobiologist has discovered that the human brain contains billions of tiny magnets--some 7 billion of them, each so small that their total weight is only one/millionth of an ounce. In magnetite- containing bacteria, the crystals are used as a compass needle which orients the bacteria with respect to the Earth's magnetic field. In birds, bees, and fish, where concentration of the mineral is a few orders of magnitude higher than he found in the human brain, it is used as a navigational aid. He plays down the possible connection to weak electromagnetic fields that supposedly cause cancer (unless fields could induce very weak electrical fields inside the cells, disrupting cellular function). Other possible interpretations: a means for cells to store excess iron, or part of a magnetic sensing system, or a vestigial system left over in evolution from when we were more directly connected with the earth's magnetic field and may have relied on it for navigation or migratory movement.

**Greenwald, Anthony G. (1992). New Look 3: Unconscious cognition reclaimed. American Psychologist, 47, 766-779.**

**ABSTRACT:** Recent research has established several empirical results that are widely agreed to merit description in terms of unconscious cognition. These findings come from experiments that use indirect tests for immediate or long- term residues of barely perceptible, perceptible-but-unattended, or attended-but-forgotten events. Importantly, these well-established phenomena--insofar as they occur without initially involving focal attention--are limited to relatively minor cognitive feats. Unconscious cognition is now solidly established in empirical research, but it appears to be intellectually much simpler than the sophisticated agency portrayed in psychoanalytic theory. The strengthened position of unconscious cognitive phenomena can be related to their fit with the developing neural network (connectionist) theoretical framework in psychology.

**Holroyd, Jean (1992). Hypnosis as a methodology in psychological research. In Contemporary hypnosis research (pp. 201-226). New York: Guilford Press.**

#### **NOTES**

This chapter deals with how the changes brought about by hypnosis (in cognition, behavior, motivation, etc.) may be used in research in other areas of psychology. "The distinction between experimental effects attributable to a personality trait (i.e. hypnotizability), hypnosis context (i.e. an induction), and interaction between the two is particularly important in using hypnosis as a research strategy.

The author discusses suggestibility, imagery enhancement, and changes in the mind-body relationship (immunology, pain, cognitive neuropsychology, attention, learning and memory, and awareness) as they might be employed in social psychology or psychophysiology research. She reviews problems inherent in using hypnosis as part of the research methodology, while noting that hypnosis nevertheless offers new information when introduced into traditional content areas. "For example, in cognitive psychology it has re-introduced the importance of studying experiential

aspects of cognition, i.e. I think, I remember, or self reference (Kihlstrom, 1987)" (p. 223).

She concludes, "Hypnosis as a research method will continue to benefit from contributions of radically different theoretical views of hypnotic phenomena. Social-cognitive psychologists have contributed significantly toward unifying the fields of hypnosis research and general experimental psychology. At the same time, advances in neurophysiology and psychosomatic medicine employing hypnosis indicate that there is a role for hypnosis as a research strategy, solely because of its altered-state characteristics. If theoretical physics can reconcile both wave and particle theories of light, it is conceivable that psychology can accommodate both behavioral and state theories of hypnosis" (p. 224).

Lippincott, Brian (1992). Owls and larks in hypnosis: Individual differences in hypnotic susceptibility relating to biological rhythms. American Journal of Clinical Hypnosis, 34, 185-192.

In 1986 Coleman developed the Owl and Lark Questionnaire to differentiate morning people from evening people, with owl individuals being more alert during the evening phase and lark individuals being more alert during the morning phase. Rossi has hypothesized that the bimodal peaks of hypnotizability found by Aldrich and Bernstein in 1987 were caused by alterations in owl and lark circadian rhythms. In the current study I used the Harvard Group Scale of Hypnotic Susceptibility, Form A to test compliance with hypnotic suggestions among 42 graduate students at three times of the day: in the morning, in the evening, and, as a control, in the middle of the night. Owls were more hypnotizable than larks in the morning, and larks were also significantly more hypnotizable in the evening than owls. There was no difference between the two groups in the middle of the night. A possible implication of this study is that one fundamental mechanism of therapeutic hypnosis is the entrainment of psychobiological rhythms.

NOTES: The author tested Subjects at 8-10 a.m., 4-6 p.m., and midnight to 2 a.m. because they were the times when owls and larks could be most easily differentiated (morning and late afternoon) or were most equal (night). The goal was "to determine if individuals differentiated by the Owl and Lark Questionnaire have different peaks of hypnotizability associated with the rest phases of their biological rhythms." (P. 187).

"To control for practice effects (Cooper, Banford, Schubot, & Tart, 1967), one third of the subjects started rotating at each of the three test times and proceeded in clockwise order (morning-evening-night; evening-night-morning; night-morning-evening).

"There were at least 24 hours between tests to assure that boredom from the testing was not a factor" (p. 188).

#### DISCUSSION.

"Rossi has extended Erickson's naturalistic approach and has hypothesized the entrainment of the ultradian biological rhythms as a possible factor in therapeutic hypnosis. ... Rossi states: 'The ultradian theory of hypnotherapeutic healing

proposes that (1) the source of psychosomatic reactions is in stress-induced distortions of the normal periodicity of ultradian cycles and, (2) the naturalistic approach to hypnotherapy facilitates healing by permitting a normalization of these ultradian processes.' (Rossi, 1982, p. 23)" (pp. 189-190).

"If owls and larks were not separated, the results of this study would show no differences in hypnosis. Perhaps this is why Hollander et al. (1988) found no change in hypnotizability using a direct-suggestion measure after a 2-day training in Ericksonian techniques" (p. 190).

## 1991

Brown, Jason W. (1991). Self and process: Brain states and the conscious present. New York: Springer-Verlag.

## NOTES

Author, from the Department of Neurology at New York University Medical School, presents a theory about the genetic unfolding of mental content (mind) through stages, from mental state into consciousness or into behavior. He relates the genesis of mind to brain development but avoids assuming that there is a straightforward correlation between brain development (e.g. myelination) and cognitive development or perception. To some degree, the theory is based on subjective report data and psychological symptoms. The author discusses issues that bear on the phenomena of nonvoluntary responding and dissociation that are reported or described by hypnotized persons.

"The nature of the mental state will determine the relation between self and world, and thus the interpretation given to agency and choice. ... The crossing of the boundary from self to world is a shift from one level in mind to another" (pp. 10-11).

"... if we begin with mind as primary and seek to explain objects from inner states and private experience, the discontinuity between inner and outer evaporates: mind is everywhere, a universe. ... Whereas before we thought to perceive objects, now we understand that we think them" (p. 19).

"The concept of a stratified cognition is central to the notion of a mental state .... This entails an unfolding from depth to surface, not from one surface to the next, a direction crucial to agency and the causal or decisional properties of consciousness" (p. 52). By unfolding from depth to surface, he means from Core, through Subconscious, then Conscious Private Events, and finally Extra-Personal Space.

He goes on to provide a definition of mental states. "A mental state is the minimal state of a mind, an absolute unit from the standpoint of its spatial and temporal structure. ... The state also has to include the prehistory of the organism. ... The concept of a mental state implies a fundamental unit that has gestalt-like properties, in that specific contents-- words, thoughts, percepts--appear in the context of mind as a whole (p. 53).

"The entire multitiered system arborizes like a tree, with levels in each component linked to corresponding levels in other components. For example, an early (e.g., limbic) state in language (e.g., word meaning) is linked to an early stage in action (e.g., drive, proximal motility) and perception (e.g., hallucination, personal memory)

... In sum, a description of the spatial and temporal features of a single unfolding series amounts to a description of the minimal unit of mind, the absolute mental state" (p. 54).

The author's discussion of an individual's physical movement relates to the concept of nonvoluntary movement (or movement without awareness of volition) in hypnosis. "More precisely, levels in the brain state constitute the action structure. As it unfolds, this structure generates the conviction that a self-initiated act has occurred. This structure--the action representation--does not elaborate content in consciousness. ... As with the sensory-perceptual interface, the transition to movement occurs across an abrupt boundary. In some manner, perhaps through a translation of cognitive rhythms in the action to kinetic patterns in the movement, levels in the emerging act discharge into motor (physical) events" (p. 57).

"The self has the nature of a global image or early representation within which objects-to-be are embedded. ... The self is the accumulation of all the momentary cognitions developing in a brain configured by heredity and experience in a particular way (p. 70).

"The deposition of a holistic representation ... creates the deception of a self that stands behind and propagates events. The feeling of the self as an agent is reinforced by the forward thrust of the process and the deeper locus of the self in relation to surface objects. The self appears to be an instigator of acts and images when in fact it is given up in their formation. The self does not cause or initiate, it only anticipates (p. 70).

The foregoing notes cover only the first five chapters, less than half the book. Other chapters relevant to hypnosis would be those titled 'The Nature of Voluntary Action,' 'Psychology of Time Awareness,' 'From Will to Compassion,' and 'Mind and Brain.'

Brown, Peter (1991). The hypnotic brain: Hypnotherapy and social communication. New Haven, CT: Yale University Press.

## NOTES

Notes are taken from a review of this book: Diamond, Michael (1993). Book review. *Bulletin of the Menninger Clinic*, 57 (Winter), 120-121.

Brown "posits that because the fundamental matrix of the human brain is metaphoric, hypnosis results from skillful matching of metaphorical communication with the brain's biological, rhythmic alterations. The most significant feature of trance experience is thereby located in the hypnotist-subject interaction" (p. 120).

"The middle section [of the book is comprised largely of] literature reviews in support of Rossi's (1986) ultradian rhythm theory of hypnosis and Lakoff and Johnson's (Johnson, 1987; Lakoff & Johnson, 1980) experientialist theory of conceptual thought" (p. 120). The final section includes "research evidence on medical uses of hypnosis, a theory of dissociation and multiple personality disorders, and an uncritical discussion of Milton Erickson's naturalistic hypnotherapeutic approach ... [and also] a brief discussion of the social-cultural functions of possession states among the Mayotte culture" (p. 120).

Brown, Peter (1991). Ultradian rhythms of cerebral function and hypnosis. Contemporary Hypnosis, 8, 17-24.

As a consequence of his observations of the clinical work of Milton Erickson, Ernest Rossi has proposed an 'ultradian rhythm theory of hypnosis'. Rossi demonstrated that the spontaneous changes in cognition, affect and behaviour which occur as part of the ultradian cycle (which Erickson referred to as 'the common everyday trance') are similar to the changes which occur during hypnosis. A review of studies of the phasic changes in hemispheric function suggests that ultradian changes do parallel the changes found in hypnosis.

**NOTES:** Falling asleep and waking up are regulated by two separate mechanisms rather than being opposite poles of one mechanism (Winfrey, 1980). Kleitman (1961) suggested a 90-min cycle, the basic rest-activity cycle (BRAC). In addition to physiological alterations, there are alterations in cognition, mood and behavior (Rossi & Cheek, 1988); vigilance (Okawa, Matousek & Petersen 1984); peripheral blood flow (Ramano & Gizdulich, 1980); respiratory amplitude (Horne & Whitehead, 1976); visual evoked potentials (Zimmerman, Gortelmeyer & Wiemann, 1983); pupillary diameter, stability and reactivity to light, and saccadic eye movements (Lavie & Kripke, 1981).

These diurnal variations may relate to hypnotic behavior. There is a recurring increase in daydream and fantasy, as well as visual imagery (Kripke & Sonnenschein, 1978). "There is evidence for a parallel recurring cognitive and emotional cycle with increased emotional responsiveness and a more subjective cognitive processing of information (Evans, 1972; Holloway, 1978; Overton, 1978; Thayer, 1987). Subjects appear to repeat the cycle approximately 16 times per day, with a range of 70-120 minutes. Kripke and Sonnenschein (1978) noted that the subjects were personally unaware of any repeating cycle in their mental lives" (p. 19).

The brainstem arousal mechanisms seem to be implicated in periodic changes in the EEG. Ultradian rhythms are "more easily detected under conditions of increased sleep need, reduced external performance demand and lowered motivation to focus externally (Broughton, 1985)" (p. 20). Sterman (1985) observed that the rhythm was most marked in resting state and disappears during complex visuomotor tasks. Relationship of EEG patterns to attentional patterns indicate there may be two different forms of attention, one for focused awareness (often thought to be associated with trance state) and the other a generalized vigilance (which would be reduced in hypnosis). Ultradian changes in consciousness reflected in the EEG may suggest increased internal absorption associated with visual imagery, a feature of the trance state.

"There has recently been a partial direct confirmation of Rossi's hypothesis. Aldrich and Bernstein (1987 [International Journal of Clinical and Experimental Hypnosis]) reported a bimodal distribution of Harvard Group Scale Hypnotic Susceptibility (HGSHS) scores when they are done at different times throughout the day. They note the parallel of the changes in HGSHS scores and the circadian variations in body temperature which suggest changes in hypnotic responsiveness coinciding with the fluctuations of physiological rhythms.

"Other support comes from some highly original work involving breathing rhythms. There are cyclic alterations in relative air flow between the left and right nostrils with an average period of 2-3 hours (Hasegawa & Kern, 1977). This nasal ultradian rhythm is correlated with an increase in contralateral cerebral hemispheric activity (Werntz, Bickford, Bloom & Shannahoff-Khalsa, 1981, 1983; Klein, Pilon, Prosser & Shannahoff-Khalsa, 1986). The alterations in hemispheric function do appear to be related to changes both in the style of cognition, particularly in an increase in vivid visual imagery, and in performance on specific tasks (Klein et al., 1986). Thus these studies support the notion of an ultradian rhythm of cerebral function which is associated with characteristic physical manifestations mediated by the autonomic nervous system. Whether or not these changes are directly related to the findings reported by Aldrich and Bernstein has yet to be established" (p. 21).

The authors conclude that "the most consistent evidence for ultradian rhythms is demonstrated by the mechanisms of the hypothalamic-limbic system and by brain-stem mechanisms that regulate arousal and attention processes (Parmeggiani, 1987); neuroendocrine regulatory mechanisms (Follenius, Simon, Brandenberger & Lenzi, 1987) and autonomic nervous system function (Bossom, Natelson, Levin & Stokes, 1983; Gordon & Lavie, 1986). These studies also suggest an ongoing dynamic interaction between cortical and subcortical structures throughout the ultradian cycle (Parmeggiani, 1987), and suggest that these interactions may be of great significance in hypnosis" (p. 21).

Graffin, N. W. (1991, October). EEG concomitants of hypnotic susceptibility and hypnosis (Dissertation, Pennsylvania State University). Dissertation Abstracts International, 52 (4), 2296.

"Many previous studies of EEG and hypnosis were completed prior to development of spectral analysis and typically included data from a limited number of electrode sites. The categorization of subjects as high and low hypnotizables was often done inappropriately, and disparate findings were obtained. In this study, subjects scoring 10 or more and 3 or less on the Stanford Hypnotic Susceptibility Scale, Form C were defined as high and low respectively. EEG was monitored during resting baseline, mental arithmetic, and mental spatial rotation, and before, during, and after hypnotic induction. EEG was recorded monopolarly at frontal (F3,F4), parietal (P3,P4), temporal (T3,T4), and occipital (O1,O2) derivations, and data were fast Fourier analyzed. Mental arithmetic and mental spatial rotation did not produce differential hemispheric activation. High hypnotizables had greater frontal and temporal theta at baseline than lows. All subjects showed increases in parietal and occipital theta during hypnotic induction. During prehypnotic induction baseline, highs had greater parietal and occipital theta than lows, but this difference was smaller after induction. Baseline temporal alpha was greater for highs than lows, but after hypnotic induction, all subjects had less alpha at all sites than before induction. Increases in alpha at all sites for all subjects occurred during hypnotic induction. Beta activity was unrelated to susceptibility but was greater in waking than in hypnotic states for all subjects at all sites. Increases in alpha at all sites for

all subjects occurred during hypnotic induction. The theta activity observed suggests that high hypnotizables have a greater capacity for selective attention and imagery and that during hypnosis all subjects experience enhancement of these abilities. The alpha results may suggest an increase in the focusing of subjects on internal processes during hypnosis and greater scanning of the environment after induction" (p. 2296).

**Kleinhauz, Moris (1991). Prolonged hypnosis with individualized therapy. International Journal of Clinical and Experimental Hypnosis, 39 (2), 82-92.**

A therapeutic approach is presented which involves the use of prolonged hypnosis for the treatment of diverse medical and/or psychological conditions, including intractable pain. This approach may be indicated either as a complementary tool used in conjunction with other treatment approaches or as the only method of intervention. The technique is based on achieving a prolonged hypnotic response, during which hypno-relaxation serves as the foundation for the delivery of an individualized therapeutic plan which includes self-hypnosis, suggestive procedures, metaphors, and constructive imagery techniques. In debilitated patients, medical supervision and nursing care are essential, and hospitalization is recommended if necessary. Theoretical assumptions underlying this approach are presented, and clinical implications are discussed. The method is illustrated through case presentations.

#### **NOTES:**

The general procedure involves: 1. A flexible plan concerning the duration of treatment: days, weeks, or longer. 2. Information is given to the patient, the family and the medical staff if in hospital. Emphasize that while the patient may be in a 'twilight-like' state, most of the time he/she is able to fulfill his or her basic physiological needs, (drinking, eating, taking care of personal cleanliness, etc.). 3. The method of hypnotic induction is individualized. 4. The patient is trained in self-hypnosis, and for using signals for induction and dehypnotization either for self hypnosis or for the hypnotist to use. Thus if there is a physiological or emotional need for self-hypnosis the patient can do it. Suggestions and training are given and reinforced concerning the patient's capability to fulfill his/her basic physiological needs. 5. The family and/or the medical staff are instructed and trained in induction and dehypnotization, until the patient responds to them satisfactorily. 6. At this stage, therapeutic suggestions aimed at ego-boosting and a change of attitudes and meanings towards the symptom and symptom removal/amelioration/substitution are added. 7. Metaphoric constructive imagery is introduced when indicated. 8. If required, other hypnotic phenomena are elicited and used (e.g. dissociation, time distortion, age regression, rehearsal, hypno/analgesia, change of muscular tonus, displacement of emotions, abreaction, etc.). 9. An audio cassette which contains the wording of the therapeutic intervention is used with some patients. 10. The family and/or the medical staff are instructed to supervise the patient properly and to avoid potential complications. 11. Termination of prolonged hypnosis with

individualized therapy is gradual to permit appropriate re-orientation towards reality. 12. Treatment is evaluated and a posttreatment plan is outlined.

They provide case reports and discuss precautions. All the cases reported were treated while the patients were hospitalized for their physical condition (although in Case 3, prolonged hypnosis with individualized therapy was also continued at home after the patient's discharge from the hospital), and the patients were monitored by the medical staff. In very debilitated patients, special care should be taken to avoid potential complications arising from their passivity, mainly the development of decubitus ulcer and of aspiration/choking while drinking or eating. Although precaution is taken routinely with these patients, these measures should be emphasized while the patient is in a state of prolonged hypno-relaxation.

Lubar, J. F.; Gordon, D. M.; Harrist, R. S.; Nash, M. R.; Mann, C. A.; Lacy, J. E. (1991). EEG correlates of hypnotic susceptibility based upon fast Fourier power spectral analysis. Biofeedback and Self-regulation, 16, 75-85.

Examined whether there were differences between high and low hypnotic susceptible subjects based upon fast Fourier power spectral analysis of the EEG recorded both before and during hypnotic tasks. Significant differences were obtained based upon EEG recording electrode location, EEG frequency within six different frequency domains, and hypnotic tasks. However, no main effect differences were obtained based upon hypnotic susceptibility. In contrast to some evoked potential studies in which a few differences have been obtained based on hypnotic susceptibility, the lack of any EEG differences in this study even when positive and negative hallucination tasks were employed may have implications for the role of the neocortex in mediating hypnotic phenomena.

#### NOTES:

When this study was presented at the annual meeting of the Society for Clinical and Experimental Hypnosis in 1988, in Ashville, the authors remarked that, "Since EEG comes from cortex, the results might be due to subcortical levels. Therefore one should look at cerebral blood flow and metabolism."

#### 1990

Ader, Robert; Felton, David; Cohen, Nicholas (1990). Interactions between the brain and the immune system. In Cho, Arthur K.; George, Robert; Blaschke, Terrence (Ed.), null (30, pp. 561-602). Palo Alto, CA: Annual Reviews Inc..

#### NOTES:

"Without attempting to cover all the literature, we have used stress effects and conditioning phenomena as illustrations to point out that behavior can influence immune function. We have also described data indicating that the immune system can receive and respond to neural and endocrine signals. Conversely, behavioral, neural, and endocrine responses seem to be influenced by an activated immune system. Thus, a traditional view of immune function that is confined to cellular

interactions occurring within lymphoid tissues is insufficient to account for changes in immunity observed in subhuman animals and man under real world conditions.

"These data question seriously the notion of an autonomous immune system. ... The immune system is, indeed, capable of considerable self-regulation, and immune responses can be made to take place in vitro. The functions of that component of adaptive processes known as the immune system that are of ultimate concern, however, are those that take place in vivo. There are now compelling reasons to believe that in vivo immunoregulatory processes influence and are influenced by the neuroendocrine environment in which such processes actually take place ... . The immune system appears to be modulated, not only by feedback mechanisms mediated through neural and endocrine processes, but by feedforward mechanisms as well. The immunologic effects of learning, an essential feedforward mechanism, suggest that, like direct neural and endocrine processes, behavior can, under appropriate circumstances, serve an immunoregulatory function in vivo. Conceptually, the capacity to suppress or enhance immune responses by conditioning has raised innumerable questions about the normal operation and modifiability of the immune system via neural and endocrine processes.

"We do not yet know the nature of all the channels of communication between the brain and the immune system or the functional significance of the neural and endocrine interrelationships that have been established....

"This integrated circuitry has extensive ascending and descending connections among the regions cited. These regions also share many similarities. They are sites intimately involved in visceral, autonomic, and neuroendocrine regulation. The cortical and limbic forebrain regions mediate both affective and cognitive processes and may be involved in the response to stressors, in affective states and disorders such as depression, in aversive conditioning, and in the emotional context of sensory inputs from the outside as well as the inside world. From an immunologic perspective, these regions are the sites in which lesions result in altered responses of cells of the immune system; they are the regions that respond to immunization or cytokines by altered neuronal activity or altered monoamine metabolism; and they are the regions that possess the highest concentration of glucocorticoid receptors and link some endocrine systems with neuronal outflow to the autonomic and neuroendocrine systems. Thus, this circuitry is the major system of the CNS suspected to play a key role in responding to immune signals and regulating CNS outflow to the immune system" (pp. 587-589).

Badia, Pietro (1990). Memories in sleep: Old and new. In Bootzin, Richard R.; Kihlstrom, John F.; Schacter, Daniel L. (Ed.), Sleep and cognition (pp. 67-76). Washington, DC: American Psychological Association.

#### NOTES:

Reviews literature. Conclusion: First, with reinforcement for responding, control of learned behavior can be maintained reliably by stimuli presented during sleep. Second, when stimuli are presented 4 min or more apart, behavioral control results in little or no change in sleep structure, in daytime sleepiness, or in perceptions of sleep quality. Neither perceived wakefulness nor wakefulness as it is scored on the sleep record are necessary for responding, although stimulus/response events

typically result in brief EEG or EMG change. Third, within-subject, within-night variance in responsiveness is complexly related to time of night, sleep stage, and REM/NREM cycle.

Cikurel, Katia; Gruzelier, John (1990). The effect of an active-alert hypnotic induction on lateral asymmetry in haptic processing. British Journal of Experimental and Clinical Hypnosis, 7, 17-25.

In order to elucidate further left hemispherical inhibitory dynamics in response to instructions of hypnosis, bilateral haptic processing times were compared before and during a traditional hypnotic relaxation procedure and an active-alert procedure in which subjects pedaled a bicycle ergometer and instructions on mental alertness were incorporated with hypnosis. Previous evidence suggesting a slowing of left hemispherical processing and a facilitation of right hemispherical processing in susceptible subjects was replicated, and was shown to characterize high rather than medium susceptibles, the latter showing a bilateral slowing of processing. These effects occurred with both induction procedures whose influence on susceptibility was highly correlated. In fact the lateral shift in processing in the direction of left hemispherical inhibition and right hemispherical facilitation was favoured by the active-alert procedure, indicating that neuropsychological changes which occur with hypnosis cannot be discounted as a by-product of relaxation.

De Pascalis, Vilfredo; Penna, Pietronilla M. (1990). 40-Hz EEG activity during hypnotic induction and hypnotic testing. International Journal of Clinical and Experimental Hypnosis, 38 (2), 125-138.

Edmonston, William E., Jr.; Moscovitz, Harry C. (1990). Hypnosis and lateralized brain functions. International Journal of Clinical and Experimental Hypnosis, 38, 70-84.

Bilateral EEG measures were obtained on 16 high hypnotizable Ss (scores of >8 on the Harvard Group Scale of Hypnotic Susceptibility, Form A, Shor & E. Orne, 1962), while performing hemisphere-specific tasks during hypnosis and a no-hypnosis control condition. Conditions and tasks were presented in counterbalanced order, and Ss served as their own controls. The data call into question the right hemisphere activation interpretation of lateralized brain function during hypnosis; rather, the data suggest a lack of task appropriate activity during hypnosis. The failure to attend to baseline activity measurements and the use of ratios to evaluate interhemispheric lateralization may contribute to potential misinterpretations of data. It is critical that activity changes of the separate hemispheres be taken into account in the interpretative process.

Henninger, Polly (1990, August). Conditional handedness: Handedness changes in multiple personality disordered subject reflect shift in hemispheric dominance. [Unpublished manuscript] Presented at the annual meeting of the American Psychological Association, Boston.

**This study investigates whether the host personality (Pe) and the primary alter personality (Pa) of a woman with multiple personality disorder are controlled by the left and right hemispheres respectively. Results support the hypothesis. Behavioral and preference measures indicate that Pe is strongly right-handed and Pa is left-handed. Verbal and musical dichotic tests show significantly greater accuracy for stimuli presented to the left ear for Pa and to the right ear for Pe. It is concluded that shifts in hemisphericity involve redistribution of attentional resources and callosal suppression. "Conditional handedness" is proposed as a handedness subtype characterizing persons who alternate personalities and consistently display alternate hand preferences linked to specific personality characteristics.**

**NOTES:**

**She uses the model of the split brain subject for dissociation in personality. The shift in personality reflects a shift in hemispheric dominance. "Dichotic testing of children suggests greater right hemisphere involvement in cognitive processing in children than in adults (Henninger, 1991). This finding suggests that in cases of dual personality, the younger alternate personality is more likely than the older to be lateralized to the right hemisphere." [N.B. Jancke et al's meta analysis doesn't say this about children.] She also indicates that Henninger-Pechstedt, 1986, 1989, found that commissurotomy Ss tested with increasing strings of digits showed increased volume to the left ear shifted attention to the left side when task demands were low, but as task demands increased, right ear performance increased and left ear performance decreased.**

**Putnam et al (1986) indicates 37% of 100 MPDs changed handedness across alters, suggesting a relationship between MPD and lateralized functioning.**

**Patient was 19 yr old woman with six alters, a typical history of abuse, amnesia of primary personality for the 9 yr old alter tested here with the adult alter. Method included a cutting exercise, drawing exercise, verbal dichotic test, and music test.**

**Dichotic test used monosyllabic digits (1-12, excluding 7 and 11) of 307 msec duration, in which number of stimuli to be encoded increased from one to four as the test progressed (Henninger-Pechstedt, 1989). Presented in blocks of single, double, triple and quadruple pairs at rate of two pairs per second. Volume was set where S said stimuli presented to each ear sounded equal and appeared to be located at the center of her head.**

**On the initial tests Pa (child) asked for a decrease in volume in the left ear (6 dB); Pe requested a slight increase (2 dB). On the music test, the overall volume level on Pe's initial test inadvertently was lower than that used for Pa, and she was recalled for a second testing at the same level as Pa. To make the volume equivalent, Pa (child) asked for a slight increase in the left channel (2 dB) and Pe (adult) asked for a greater increase (y dB).**

**Results: 1. Drawings were at same developmental level for both alters. 2. Adult alter was less accurate in cutting than child alter. All cuttings made by child's left hand were superior to those made by right hand; all cuttings made by adult's right hand were superior to those made by her left hand. The child was more accurate when cutting with left hand; adult was more accurate when cutting with right hand.**

Difference in dexterity between alters was statistically significant. 3. Dichotic listening: child showed a small right ear advantage; adult showed a large right ear advantage. The child's small REA resulted from a shift from left to right ear report at the highest level of task difficulty; at the lower levels of difficulty (1-3 digit pairs) she showed a left ear advantage.

On music test the child more accurately identified melodies presented to her left ear and adult more accurately identified melodies presented to her right ear. In summary, on the lateralized tests the two personalities differed significantly with the child performing the tasks better on the left side and the adult performing them better on the right side.

Her explanation is that the results indicate a difference in hemisphericity, i.e. the preferential use of one hemisphere over the other. When one or the other personality is in control, the corresponding hemisphere is more active and controls processing. As Kinsbourne (1973) has shown, the more active hemisphere draws the subject's attention to the contralateral side of space. Control is most visible in the side of greater manual preference and dexterity. The change in personality reflects a switch in hemispheric control.

In the dichotic tests, each personality requested that the volume be decreased on the side which subsequently performed better, suggesting that the differential activity of the hemispheres increased the perceptual salience of the stimuli contralateral to the active hemisphere which was perceived as increased volume. ... That the child began the verbal test with a LEA but shifted to a REA when the task load increased suggests conflict between the hemisphere that is in control of the personality (right) and the hemisphere that is specialized to do the task (left). It suggests that when the task is simple and cognitively undemanding, the subject's preferred mode of processing (hemisphericity), and thus the corresponding hemisphere, controls behavior. However, when a task becomes more cognitively demanding, the hemisphere specialized to do the processing takes control. Similar performance on this task has been observed in commissurotomy subjects (Henninger-Pechstedt, 1986, 1989) and learning disabled boys (Henninger & Bloch, in preparation).

The adult's chance level of performance in the left ear on the musical dichotic test, when compared to that of the child who identified 3/4 of the left ear melodies, suggests that the adult's dominance involves suppression of the right hemisphere. It suggests that personality changes are modulated by the degree of callosal suppression produced by one hemisphere over the other.

She mentions only one study (Burrows, Collison & Dennerstein, 1979--in Proceedings of the 8th International Congress of Hypnosis and Psychosomatic Medicine, Melbourne, Australia)--indicating that the more hypnotizable a person is, the greater the relative difference in hemispheric activation while performing hemispheric specific tasks.

She suggests that her results suggest that shifts in hemisphericity involve both a redistribution of attentional resources and callosal suppression. The shift in the child's ear advantage as the task load increased suggests that perceptual advantages in laterality tests reflect effects due to both hemisphericity and hemispheric specialization. IN most laterality experiments perceptual differences due to

hemispheric specialization are confounded with those due to hemisphericity. Experiments need to be designed in which these effects can be deconfounded.

There are no data on callosal function in persons with MPD, and the shift in ear advantage as difficulty increases suggests possible atypical callosal function in patients with MPD.

Although the commissurotomy model informs these results, there are areas in which it does not fit the data. In the callosally disconnected patient, each hemisphere may be unaware of the perception and cognition of the other hemisphere, but the patient is not amnesic for the behaviors. When he or she observes contradictory behavior in him/herself, he/she tries to interpret it. No commissurotomy patient manifests multiple personalities and none changes personality when he or she changes from operating his/her right to left hand. Most patients with MPD have more than two personalities which does not fit the commissurotomy model. This woman has six or more. Perhaps the initial two personalities are lateralized to opposite hemispheres and additional personalities align within this primary subdivision. Co-consciousness between personalities might indicate co-existence in the same hemisphere. Lastly, in a person with intact commissures, laterality differences reflect changes in the balance of brain activity between the two hemispheres, not the exclusive use of one. Shifts in consciousness in MPD patients may utilize the corpus callosum. It is likely that the inhibition of processing and suppression of awareness observed in this study are functions of the patient's intact corpus callosum.

It is proposed that early severe trauma in some cases leads to the development of an extreme form of hemisphericity, marked by conditional handedness, as a means of escaping the emotional pain. Whether early trauma influences the development of ambilaterality or whether people born predisposed to bilateral representation of function are better able to use disassociation as a means of coping with abuse is an important question for further research to investigate.

Hughes, Dureen J.; Melville, Norbert T. (1990). Changes in brainwave activity during trance channeling: A pilot study. Journal of Transpersonal Psychology, 22, 175-189.

#### NOTES:

Authors studied 10 people known trance channels--all had been channeling for more than one year. Used an anthropological field method. Electrode was placed only on left occipital (O1) area, referenced to left ear. Calculated difference between each S's pre- trance and trance EEG beta percentages, for alpha and theta percentages also.

Basically, the pre-trance versus trance sums of differences scores were greater than the post-trance versus trance sums of different scores for each of the three frequency bands--indicating a residual of the trance state. There were large, statistically significant increases in amount and percentage of beta, alpha and theta brainwave activity, and some suggestion of a pattern. The large amount of beta differentiates these Ss from what has been observed with meditators (increases in alpha and theta). Among the Subjects, large amounts of beta activity were recorded continuously throughout the trance period and were coupled with large amounts of high amplitude alpha and theta (relative to the pre- and post-trance states).

The authors compare these results to older hypnosis literature. They conclude that the trance channeling state may be a distinctive state characterized by a particular EEG profile that differs from that found in certain meditative states, hypnotic states, various pathological states, or the waking states of the trance channel Subjects who participated in the study. Authors also liken the differences seen between trance and non-trance states of these Subjects to the differences seen for different alter personalities among people diagnosed with Multiple Personality Disorder.

**DISCUSSION.** The foregoing research suggests that the trance channeling state, as measured in the current study, is characterized by large, statistically significant increases in amount and percentage of beta, alpha and theta brainwave activity. There appear to be definite neurophysiological correlates to the trance channeling state, and furthermore there is some evidence that these correlates may be patterned. This pattern might be provisionally compared to those associated with other altered states of consciousness.

Alexieva, A.; Nicolov, N.A. (1989). Brain mechanisms in classical conditioning. Behavioral and Brain Sciences, 12, 137.

**NOTES:**

This is a Commentary on article by J. S. Turkkan (1989), Classical Conditioning: The new hegemony. In Behavioral and Brain Sciences.

Commentators note that the objective of the target article is to show how current thinking about Pavlovian conditioning differs substantially from the historical view; also that this has been recently emphasized by Rescorla (1988). Commentators note that the neural pathways and neural mechanisms involved in Pavlovian conditioning are of great interest and are investigated by many neuroscientists all over the world (Grigoryan & Tchilingaryan 1988; Kositsyn N.S. & Dorochoy 1986; Onifer & Durkovic 1988; Storzhuk 1986; Vartanyan & Pirrgov 1986). Commentators also note the work of Ramachandran & Pearce (1987) and Uryvaev Yu.V. et al. (1988).

They express the opinion that Turkkan's review affords a thorough description and interpretation not only of basic data and new conceptual views, but also of certain key notions in the modern theories of Pavlovian associative learning.

Bick, C. H. (1989). An EEG-mapping study of 'laughing': Coherence and brain dominances. International Journal of Neuroscience, 47, 31-40.

Laughter is triggered by pleasurable psychoemotional stimuli and may have healing potential. According to split-brain studies, psychoemotional stimuli are bound up with emotional activity in the right side of the brain. This suggested the idea of studying laughter generated by different sources with regard to electrical brain activity in the right and left hemispheres. This study first used subjects in normal consciousness and with laughter under hypnosis to study the neurophysiological processes connected with laughter.

De Pascalis, Vilfredo; Marucci, Francesco S.; Penna, Pietronilla M. (1989). 40-Hz EEG asymmetry during recall of emotional events in waking and hypnosis: Differences between low and high hypnotizables. International Journal of Psychophysiology, 7, 85-96.

#### NOTES

1:

Sixteen high and thirteen low hypnotizability women, who had participated in our previous study (De Pascalis et al., 1987), were enrolled in a hypnotic session. After the hypnotic induction they were requested to recollect 2 positive and 2 negative personal life experiences. IN our previous study subjects performed similar tasks in a waking-state. Hypnotizability was evaluated the first time with the HGSHS and, a second time, individually, with the Stanford C. The State Trait Anxiety Inventory, Maudsley Personality Inventory, and Tellegen Absorption Scale were administered. Upper-trapezius electromyogram (EMG) and bilateral electroencephalogram (EEG) activities within the 35-45 Hz band were recorded. Self-report rating scores for vividness of visual imagery and emotional feeling of the material recalled were evaluated. The 40-Hz EEG amplitude and the left and right hemisphere 40-Hz EEG densities were obtained.

The data collected in hypnosis were compared with those in the waking-state. High hypnotizables, while they were in hypnosis, showed an increase of 40-Hz EEG density during emotional recall compared with rest periods. In contrast, low hypnotizables, after hypnotic induction, showed no density during emotional recall compared with rest periods. In contrast, low hypnotizables, after hypnotic induction, showed no density change during tasks compared to the rest conditions. Different hemispheric trends were found between groups. Highs showed an increase of 40-Hz EEG density over both hemispheres during positive emotions and a density increase in the right and a density reduction in the left during negative ones. This hemispheric trend was found in waking and hypnotic conditions although in the hypnotic condition more pronounced hemispheric patterns were observed. The Tellegen Absorption Scale was found positively related to hypnotizability and with the level of 40-Hz density increase on the right hemisphere during emotional tasks. High hypnotizables, with respect to the lows, were able to access affects more readily. They also showed a greater hemispheric specificity in waking and hypnotic conditions.

Hall, H.; Minnes, L. (1989). Psychological modulation of auditory responses. International Journal of Psychosomatics, 36 (1-4), 59-63.

Psychological modulation of auditory response, the effects of imagery and suggestion on auditory thresholds were examined in naive subjects. After a hypnosis-like induction, the subjects, who were not aware of the purpose of the study, were asked to generate and maintain a specific set of images before, during, and after which their auditory thresholds were tested. Following the imagery, which represented cooling and vasoconstriction in the cochlea, audiograms revealed a temporary auditory threshold shift (TTS) in the experimental group only. This TTS pattern was similar to that produced by exposure to loud noise. Information carried

in the image is suggested as the basis for the observed auditory changes. Although a hypnosis-like induction was employed, the subjects' level of hypnotizability did not appear to be related to the findings.

Holroyd, Jean; Hill, Alexis (1989). Pushing the limits of recovery: Hypnotherapy with a stroke patient. International Journal of Clinical and Experimental Hypnosis, 37, 189-191.

Hypnotherapy was used to assist recovery of left arm function following stroke in a 66-year-old woman. Treatment protocol is described, and results are discussed in terms of how hypnosis may facilitate voluntary motor movement. Recent literature on cortical changes in hypnosis and motor improvement during hypnosis is discussed in relation to the present results.

#### NOTES:

The patient was 6 months post-stroke and physicians did not expect much additional improvement. She improved despite the fact that she measured as a low hypnotizable on the Stanford Scale, Form C. However, she appeared very absorbed in the hypnotic imagery, and she was highly motivated and exhibited much hope or positive expectation. Also, the author notes that "remarkable improvements in brain functioning have been reported through the use of sophisticated behavioral technology," (p. 124), as in the use of EEG biofeedback to treat untractable seizures (Sterman & Lanz, 1981).

In rehabilitation cases, hypnotic dissociation may enhance pain control during the performance of exercises; more vivid hypnotic imagery may facilitate mental rehearsal of movements; attitudes may be reframed using hypnotic suggestion; and focusing attention on bodily sensations may be enhanced with hypnosis. Hypnosis also may improve expectancy, reduce anxiety, increase hope, provide general relaxation (reducing involuntary spasticity), increase cerebral blood flow, or in other ways promote healing.

Research by Pajntar, Roskar, & Vodovnik (1985) has demonstrated improved motor response during hypnosis for patients with hemiparesis. They attributed EMG changes under hypnosis "to a facilitory influx from supraspinal motor centers. They hypothesized that new motor units of paretic muscles were being activated or that there was an increased recruitment of the motor units already active, and they suggested that relaxation of the spastic antagonist muscle permits the paralyzed muscle to move" (p. 125).

Borgens, Richard B. (1988). Stimulation of neuronal regeneration and development by steady electrical fields. In Waxman, S. G. (Ed.), Functional recovery in neurological disease (47, pp. 547-564). New York: Raven Press.

#### NOTES:

At the end of the review, author notes that a combination of electromyography and computer modeling of agonist-antagonist, flexor-extensor muscle contraction

patterns in the functional body parts of hemiparetic patients, artificially imposed on the paralyzed portions of the body using repetitive electrical stimulation to effect more normal movement, sometimes leads to functional recovery. Such recovery has been observed in some chronic cases of paralysis associated with head injury, stroke, and cerebral palsy. These clinical observations challenge the way we should view paralysis in general. Perhaps there are many redundant pathways in the CNS that will support certain kinds of functional return in the absence of the original pathways destroyed by trauma. Perhaps CNS-associated paralysis is a problem, at least in part, of too much competing signal in spared pathways, not one of impoverished signal. Can use of these neuronal pathways be entrained or retrained? Is the return of function in patients who experience repetitive functional electrical stimulation due to a reorganization within the CNS? These are exciting questions whose answers will possibly lead to our ability to further modify the plasticity of the brain and spinal cord.

[This would fit with the inhibition model of hypnosis, and with the high theta power findings during hypnosis, the implication being that hypnosis facilitates filtering out non-essential competing stimuli.]

De Pascalis, Vilfredo; Silveri, Alessandra; Palumbo, Giovanni (1988). EEG asymmetry during covert mental activity and its relationship with hypnotizability. International Journal of Clinical and Experimental Hypnosis, 36, 38-52.

Parietal-occipital EEG was recorded bilaterally while 20 high and 20 low hypnotizable Ss performed, in the eyes-closed condition, 2 covert right-hemisphere tasks (visual long-term memory and fantasy) and 2 covert left-hemisphere tasks (multiplication and verbal long-term memory). Ss were not, however, hypnotized during any aspect of the psychophysiological testing. After each task, Ss rated orally their degree of involvement in the tasks. The integrated amplitude alpha, the alpha density, and the alpha ratio as a measure of hemispheric asymmetry, were evaluated. Finally, the proportion of relatively greater right activation periods during right-hemisphere tasks minus the analogous proportion during left-hemisphere tasks was used as index of hemispheric specificity. The high hypnotizable Ss showed significantly higher alpha amplitude than the low hypnotizables; the alpha amplitude was correlated with hypnotizability, while the alpha density was not. The alpha amplitude of the right hemisphere during right-hemisphere tasks was significantly lower than the same amplitude during left-hemisphere tasks, while no significant differences related to task-type were detected in the left hemisphere. The pattern of task-effect on alpha ratio scores was the same as that on alpha amplitudes. Verbal and multiplication ratings were related to the alpha ratio, imaginative- visual memory ratings were not. No differences in hemispheric specificity between high and low hypnotizable Ss were found to exist, and no relationship between hypnotizability and hemispheric specificity was observed.

#### NOTES:

The authors review the literature on differences between the two hemispheres' involvement during hemisphere-specialized tasks. The ratio between left- and right-

hemisphere alpha amplitudes has been shown to be a reliable measure of hemisphere lateralization as a function of task demands (Amochaev & Salamy, 1979).

They also review the literature on EEG asymmetry and hypnotizability. Most investigations used tasks with a problem solving component, whereas this study used "a covert numeric task and other covert self-generated tasks in which the range of cognitive activities resembled natural thinking" (p. 40).

Purposes of this research were "to investigate whether (a) the amount of alpha in EEG is correlated with hypnotizability, (b) high hypnotizable Ss would reveal higher hemispheric specificities during covert mental tasks than low hypnotizable Ss, and (c) verbal-numeric tasks involve more left-hemisphere activation and imaginative-visual tasks more right-hemisphere activation" (p. 40).

The subjects were 40 women (from an original pool of 71), aged 19-23, with no previous experience using hypnosis. To minimize the possible effects of expectation, hypnosis was not mentioned in the invitation to participate in research. All subjects were tested first with the Harvard Group Scale of Hypnotic Susceptibility, then with the Stanford Scale of Hypnotic Susceptibility (SHSS:C). The SHSS:C was used to select 20 high hypnotizables (defined as having a score 1 standard deviation above the group mean of 6.51) and 20 low hypnotizables (with scores 1 standard deviation below the group mean). The mean score for highs was 10.05 (S.D. = .88) and mean score for lows was 2.75 (S.D. = 1.49).

Although subjects were selected on the basis of their measured hypnotizability, hypnosis was not used during the investigation's psychophysiological testing. However, they were required to relax and keep eyes closed during trials on the tasks. After each trial, the subjects rated their involvement in the task.

Tasks used for this research were: 1. Visual long-term memory. Ss were asked to recall from memory pictures, places, faces, or visual scenes that were in a movie, but not scenes with a negative content. 2. Fantasy. Ss were requested to fantasize about something new that they like (nothing from past experience, and nothing sexual). 3. Multiplication. Ss were asked to multiply 2 serially, as,  $2 \times 2 = 4$ ,  $\times 2 = 8$ , etc., and to do it verbally without visual representation. 4. Verbal long-term memory. Ss were requested to think of some poem, speech, or other verbal material that they could recall from memory, and to repeat it mentally, to themselves.

Results can be summarized as follows.

Hypnotizability correlated .38 and .35 with right alpha amplitude and left alpha amplitude during baseline (statistically significant).

There was a significant association between alpha density and hypnotizability, when the group was divided at the median on density. (Alpha density = the time periods in which the alpha was present over the 6-second epochs accumulated during each 1-minute period which preceded the tasks). This association may be seen in the Table that follows:

SHSS:C Alpha Density Low High

+ 6 13

- 14 7

Chi Square = 3.61,  $p < .05$

There was a significant interaction between type of task (verbal-numeric, imaginative-visual memory) and hemisphere, which was attributable to changes in alpha amplitudes in right hemisphere, according to tasks. "Alpha amplitude of the right hemisphere during right-hemisphere tasks was significantly lower than during left-hemisphere tasks, while no significant differences were detected in the left hemisphere as a result of the differences between left- and right-hemisphere tasks" (p. 44)

Alpha ratio = (Right-hemisphere alpha - Left-hemisphere alpha) / (Right-hemisphere alpha + Left-hemisphere alpha) exhibited the same pattern as for alpha amplitudes. The ANOVA 2 (high/low) x 2 (right tasks/left tasks) repeated measures on alpha ratio revealed a significant main effect for tasks, and a significant interaction between right-left tasks and hypnotizability. "During right-hemisphere tasks there were no significant differences ( $p < .5$ ) [sic] in alpha ratio between high and low hypnotizable groups, while during the multiplication task, the low hypnotizable Ss evidenced a higher mean alpha ratio ( $p < .05$ ) than the high hypnotizable group (.08 & .04, respectively); identical ratios were found during verbal tasks" (p. 45).

Task involvement was expected to be positively related with left-hemisphere tasks, but negatively related to right-hemisphere tasks (i.e. greater subjective involvement in the task would be associated with more negative alpha ratios, showing a bias towards right-hemisphere activation. "Verbal ratings were substantially related to alpha ratios ( $\rho = 0.82$ ;  $p < .01$ ), and multiplication ratings moderately related to alpha ratios ( $\rho = 0.31$ ;  $p < .05$ ); visual memory and fantasy ratings were not related to alpha ratios ( $r = -.04$  &  $r = -.18$ , respectively)" (p. 45).

Hemispheric specificity was defined as the proportion of greater relative right-hemisphere activation periods during right-hemisphere tasks minus the analogous proportion during left-hemisphere tasks. The authors did an analysis to "verify whether the task rating moderates the hemispheric specificity (i.e., the level of subjective involvement in a task is related to the level of hemispheric lateralization, while S is carrying it out)" (p. 46). They concluded that hypnotizability (SHSS:C) is not significantly related to Ss' hemispheric specificity.

In the discussion, the authors present a Table summarizing the results of similar investigations. They mention that the alpha-hypnotizability relationship may depend on which alpha variable is taken into account, or whether eyes-open/closed is varied. They conclude that the different methodological procedures render any comparison of results across studies very difficult.

They note that there was a significant correlation between alpha amplitude and hypnotizability even though Ss did not know in advance that hypnosis would be part of the experiment (the hypothesis proposed by Dumas, 1977, to account for this type of correlation). "One possible explanation of these data might lie in a different level of arousal in the high and low hypnotizable Ss: the high hypnotizable Ss might have been simply more relaxed than the lows.

"Nevertheless, his explanation must be taken with caution. The study of Paskewitz and M. T. Orne (1973), in fact, pointed out that in dark-adapted Ss, the relaxation condition does not produce increases of alpha activity. In a further study, contrary to previous reports, M. T. Orne and Paskewitz (1974) also found that a reduction in

alpha activity is not a necessary consequence of apprehension or heightened arousal. Thus, it is not yet clear whether a decrease in anxiety tends to cause an increase in alpha density and vice versa" (p. 48).

DeBenedittis, Giuseppe; Sironi, Vittorio A. (1988). Arousal effects of electrical deep brain stimulation in hypnosis. International Journal of Clinical and Experimental Hypnosis, 36, 96-106.

In an earlier study, DeBenedittis and Sironi (1986) demonstrated that during depth EEG studies, electrophysiological correlates of hypnotic behavior emphasize the role of the limbic system in mediating the trance experience. In the case of a young man who was affected by medically resistant temporal lobe epilepsy and who was a potential candidate for surgical treatment, diagnostic depth EEG in hypnotic and non-hypnotic conditions offered a unique opportunity to stimulate limbic structures. This permitted an evaluation of the subjective and behavioral responses, as well as of the electrophysiological correlates. During hypnosis, repeated stimulations of the left and the right amygdala produced arousal from the hypnotic state each time, whereas the stimulation of other cerebral structures (e.g., temporal neocortex, Ammon's horn) or pseudostimulations were ineffective on the hypnotic state. These data represent the first experimental, controlled evidence of the amygdala's effects on the arousal from the hypnotic state in man, thus suggesting that hypnotic behavior is mediated, at least in part, by a dynamic balance of antagonizing effects of discrete limbic structures—the amygdala and the hippocampus.

**NOTES:** The patient was a 30-year-old man who had suffered from medically resistant psychomotor temporal lobe epilepsy since age 7; a diagnostic EEG showed right temporal seizure focus, concomitant with independent, contralateral, temporal spiking abnormalities. Hypnotizability was measured at 6 on the SHSS:C; the patient was given two training sessions in hypnosis, with suggestions for "dissociation, rehearsal and reframing of spontaneous seizure events, desensitization of their negative emotional impact, and amnesia" (p. 99).

Electrodes were implanted in deep cerebral structures (amygdala, Ammon's horn) and corresponding superficial areas of temporal cortex, with confirmation of placement by X-ray. Two weeks later the patient's brain was stimulated on two consecutive days, first in the waking state (Session 1) and then in hypnosis (Session 2). (Antiepileptic medication was discontinued three days before the stimulation sessions.) False (placebo) stimulations were randomly provided along with the true stimulations.

The false (placebo) stimulations did not result in subjective or behavioral changes in either the waking or the hypnosis condition.

In the waking condition, a psychomotor seizure was produced by stimulation of Right amygdala and Left Ammon's horn; stimulation of Left amygdala evoked only the aura patient usually had before a seizure, or a brief lapse of consciousness. Stimulating the temporal neocortex did not evoke seizure activity.

In the hypnosis condition, arousal from hypnosis into the waking condition occurred with stimulation of amygdala (either Right or Left). Stimulation of the temporal

neocortex or of the Right Ammon's horn did not arouse the patient. Stimulation of Left Ammon's horn led to abortive seizures, such that it could not be determined whether the hypnotic state had been interrupted. Stimulating the Right amygdala "triggered a psychomotor attack similar to that recorded during the waking stimulation, but with reduced emotional involvement" (p. 100). For the Left Ammon's horn, "waking stimulation always induced clinical seizures with prolonged after-discharge, whereas hypnotic stimulation evoked only abortive seizures, without after-discharge" (p. 100).

In their Discussion, the authors note that animal experimental literature suggests that stimulation of the cortico-medial amygdala facilitates arousal functions, of the baso-lateral amygdala diminishes arousal and produces sleep, and lesions of the amygdala lead to 'amygdala hangover' (Weiskrantz, 1956). "The animal with amygdala destruction appears tame and placid, with reduced social reactivity, insensitive to environmental changes and reluctant to initiate new behavior, unless highly motivated (Isaacson, 1976)" (p. 101-102).

In contrast, the animal research on hippocampus suggests it is involved in inhibitory functions (Isaacson, 1976), and may be the 'internal inhibitor' theorized by Pavlov (1955) to be responsible for animal hypnosis. With lesions, animals are more willing to undertake new behaviors, less inactive, less distractible during goal-oriented behavior (Isaacson, 1976). "Moreover, normal hippocampograms show typical, slow (theta) synchronous activity opposed to the arousal desynchronized activity of the electroencephalogram. During hypnosis, desynchronization of the normal, slow activity of the hippocampal Ammon's horn has been registered as compared with the waking hippocampogram, opposite to the slow synchronous activity of the amygdala" (p. 102).

The authors note that their results are at variance with the finding by Crasilneck et al. (1956) that their patient, during brain surgery for an epileptogenic focus, aroused from hypnosis each time they stimulated the hippocampus. They explain the discrepancy as due to the fact that the hippocampus was not simply stimulated, but in fact there was 'coagulation' of a hippocampal vessel each time. Quoting from Crasilneck et al. "'The patient did not complain of pain during this [brain] excision [in hypnosis] except on one noteworthy occasion, when a blood vessel of the hippocampal region was being coagulated. The patient suddenly awoke from the hypnotic trance ... She was immediately rehypnotized. ... The surgeon then purposefully 'restimulated' the same region of the hippocampus. Once again, the patient abruptly awakened from trance... [p. 1607].'" To the present authors, the description appears misleading and responsible for subsequent misinterpretation of the observation. Because on the first occasion the hypnotic arousal effect followed 'coagulation' of the hippocampal region, it may be assumed that 'restimulation' is a misnomer for repeated coagulation. From this it may be inferred that the arousal effect observed by Crasilneck et al. (1956) could probably be ascribed to a hippocampal microlesion rather than to hippocampal stimulation. This could explain the apparent discrepancy" (p. 104).

**Gabel, Stewart (1988). The right hemisphere in imagery, hypnosis, rapid eye movement sleep, and dreaming: Empirical studies and tentative conclusions. Journal of Nervous and Mental Disease, 176, 323-331.**

Reviews studies that have addressed the issue of whether there is an increased activation or efficiency of right-hemispheric processes during imagery, hypnosis, REM sleep, and dreaming. Evidence strongly supports the notion of increased right-hemispheric activation in simple imaginal or visual states during usual consciousness. There are also studies supporting this view of REM sleep, dreaming, and hypnotic phenomena. It is concluded, however, that the lack of adequate studies, contradictory or negative findings, and moderating variables (e.g., task difficulty, cognitive style) make it difficult to draw definitive conclusions concerning right-hemispheric processes.

**Hawkins, Russell; Le Page, Keith (1988). Hypnotic analgesia and reflex inhibition. Australian Journal of Clinical and Experimental Hypnosis, 16, 133-139.**

The major change in thinking about models of analgesia over the last decade or so may be seen as a shift away from the earlier emphasis on a one-way afferent transmission sequence. Analgesia was effected, according to the older models, by a simple blocking of afferent impulses at some level (as achieved by local anaesthesia). Recent models suggest that there are at least two CNS analgesia control systems, each operating via an active mechanism for the inhibition of nociception which includes reciprocal efferent impulses able to respond to input from lower centres by sending control signals which modify their output. One CNS analgesia system has now been quite well described. This "opiate" analgesia system has proved to be naloxone reversible and seems to be mediated by reciprocal pathways between brain stem structures and the dorsal horn and trigeminal caudalis. This is not likely to be the system responsible for all cases of hypnotic analgesia, since the common experience of continued awareness of some elements of a normally painful stimulus, in spite of a freedom from pain, implicates a higher level involvement such as input from the prefrontal cortex.

#### **NOTES:**

The authors present a surgery case (of a cystoscopy and urethrotomy performed under hypnotic analgesia, with a highly hypnotizable patient) as an illustration of their position. The patient grimaced when the urethrotome was inserted into the urethra and dilated, but she denied discomfort and did not exhibit a reflex adduction of the thighs that is often observed even under standard general anaesthesia. She had spontaneous amnesia for the entire surgery. Later, under hypnosis, the patient could remember "discomfort and a sharp pain" which lasted for "seconds, if that" (p. 134).

The authors refer to Melzack and Wall's (1965) gate control theory as well as Hilgard's (1973) neodissociation interpretation of pain reduction in hypnosis. They review research by Hardy and Leichnetz (1981) with monkeys, in which they "traced the projections of the periaqueductal gray (PAG) to determine the extent of

any possible cortical involvement in the endogenous analgesic system. Their work showed that the prefrontal cortex was the principal source of projections to the PAG" (p. 136). They quote the latter as writing that, "Patients who have had prefrontal lobotomies for relief of chronic pain report that while they still feel the pain they are no longer bothered by it ... the prefrontal cortex by virtue of its projections to the PAG may play a role in modulating nociception at the spinal level" (Hardy & Leichnetz, 1981, p. 99).

"Hardy and Leichnetz have also suggested that there may be more than one analgesic system within the CNS. The first system is a naloxone-reversible mechanism which can be activated by opiates (presumably both endogenous and exogenous) and by acupuncture. Since hypnotic analgesia has shown itself not to be naloxone-reversible (Goldstein & Hilgard, 1975) it may have little to do with the opiate reception analgesia system. Instead the mechanism of hypnotic analgesia may lie in Hardy and Leichnetz's second system which is sensitive to affective and cognitive influences" (pp. 136-137).

The authors include a review of the work by Mayer and Price (1976) which established the importance of brain stem structures in analgesia, especially for eliciting stimulation-produced analgesia. They cite Mayer and Price as drawing a distinction between "analgesia achieved by incapacitating a component in a pain transmission system or by activating a pain inhibition system" (p. 137). They also report that Mayer and Price conclude that stimulation-produced analgesia does not result from a "functional lesion" in the brain stem, but results from stimulation of a pain-inhibiting mechanism, suggesting the dorsal horn and trigeminal nucleus caudalis may be involved. This would be consistent with the inhibition of spinal reflexes (the adductor reflex) observed in their urethrotomy case, and the spinal reflex to nociception has also been reported by Finer (1974).

"The concomitant inhibition of reflexes in humans during hypnotic analgesia can be interpreted as evidence that nociception is probably not ascending to the cerebral cortex and that therefore the source of analgesia can be localized to the brain stem areas. It may be the case, however, that the locus of effect of hypnotic analgesia is not uniform across cases and may be identified by the overall pattern of subjective reports and physiological responses. Hypnotic analgesia may be experienced in more than one way subjectively and these differences may be attributable to differing underlying physiological mechanisms. On some occasions the relevant body part may be experienced as totally anaesthetised and all sensation (not only painful sensation) may be lost. This experience matches well with a brain stem involvement, which presumably inhibits any further afferent action. On other occasions, however, and more commonly, patients are still aware of a variety of sensations, which might include pressure in the case of childbirth or even cutting in the case of surgery, but these sensations are not described as painful. This is reminiscent of the effect of frontal lobotomy and it is tempting to focus on the frontal lobe as the locus of hypnotic analgesia effects in such instances" (p. 138).

Hobson, J. Allan (1988). The dreaming brain. New York: Basic Books.

**NOTES: Hypnosis and Sleep Ramon y Cajal and Freud shared an interest in hypnosis, as an experimental method of inducing an altered state of consciousness, introducing dynamic principles into both neurology and psychiatry (rather than simply static descriptions). The author contrasts the hypnosis "artificially altered state of consciousness" with sleep as a "naturally altered state of consciousness, asking whether similar rules govern the transition of state change in both cases. He notes that induction of both states involve rhythmic stimulation and eye fixation, and both may facilitate gaining control over brain-stem centers implicated in conscious-state regulation.**

**"The brain stem is the nightly battleground of warring neuronal factions, and REM sleep and dreaming are the result of temporary domination of one neuronal population over another. Victorious is a troop of reticular-formation neurons concentrated mainly in the pontine portion of the brain stem; owing to their fusillades of firing in association with REM-sleep events, these pontine reticular neurons are likely to play the executive role in the generation of REM sleep and dreaming. Sharing the white flag of temporary surrender is a population of aminergic neurons located in the locus ceruleus, the raphe nuclei, and the peribrachial regions of the anterior pontine brain stem; hardly a shot is fired by this neuronal phalanx during REM sleep. By virtue of this cease-fire, these aminergic neurons are likely to play a permissive role in the generation of REM sleep" (p. 183).**

**The Reciprocal-Interaction Model suggests that "the continuous competition between the excitatory reticular neurons and the inhibitory aminergic neurons is the basic physiological process underlying sleep-cycle alternation" (p. 184). Neurotransmitters (aminergic for inhibition, cholinergic for excitation) are implicated as well. The width of the brain stem correlates with sleep-cycle. The brain seems to "undergo a periodic shift in neurotransmitter ration, from a predominantly aminergic mode in waking to a predominantly cholinergic mode during REM sleep" (p. 192). Thus, there is a major shift in metabolic orientation as we change from waking externally generated information and action to REM-sleep internally generated information and suppressed action.**

**The author proposes an activation-synthesis hypothesis to account for dreaming and envisions the brain as a "Dream Machine." "The recognition that the brain is switched on periodically during sleep answers the question of where dreaming comes from: it is simply the awareness that is normal to an auto-activated brain-mind. This causal inference is continued in the term activation in the new dream theory's title. The question of why dreams are paradoxically both coherent and strange is in turn suggested by the term synthesis, which denotes the best possible fit of intrinsically inchoate data produced by the auto-activated brain-mind.**

**"The original dream theory thus had two parts: activation, provided by the brain stem; and synthesis, provided by the forebrain, especially the cortex and those subcortical regions concerned with memory. The physiology that is now in hand best supports the first part of the theory; much more work needs to be done on the synthetic aspects of the process. But I now add a third major component to the theory, the concept of node switching, which accounts for the differences in the way the activated fore-brain synthesizes information in dreaming (compared with**

waking): for the twin paradoxes of dream bizarreness and insight failure (where the system has lost self-reference as well as its orientation to the outside world) and for dream forgetting" (p. 204).

The author assumes a formal isomorphism between subjective (dream report) and objective (brain activity) levels of investigation. Thus, the report of experiencing visual images in dreams implicates the brain's visual system.

In terms of psychophysiology, Hobson proposes that "the on-off switch for dream mentation is the reciprocal-interacting neuronal populations comprising the aminergic neurons and the reticular neurons of the brain stem" (p. 205). For sleep (and dreaming) to be maintained, stimulation from the outside world must be minimized. This is accomplished in at least two ways. There is active inhibition of nerves at the pre-synaptic level (e.g. by depolarization by signals coming from the brain stem; Pompeiano, 1978) so that the nerves are less efficient in transmitting information from the environment, as there is less neurotransmitter available. Secondly, there is competition among higher levels of sensory and associative circuits, so that they ignore incoming signals (or incorporate them into internally generated dreaming activity). Hobson refers to these mechanisms as the sensory input blockade.

Hobson also describes the motor output blockade, which prevents us from taking actions based on dream content. There seems to be inhibition of motor-command neurons in the brainstem and spinal cord.

When dreams arise, there seems to be brain activation as evidenced by PGO (Pons, lateral Geniculate, Occipital cortex) waves originating in the brain stem. They are found in association with REM sleep and go via independent pathways to both visual and association cortex. "According to the activation-synthesis hypothesis of dreaming, the now auto-activated, disconnected, and auto-stimulated brain-mind processes these signals and interprets them in terms of information stored in memory" (p. 207).

Hobson states that the activation-synthesis hypothesis can account for five aspects of dreaming: visual and motor hallucinations, the acceptance of these hallucinations as 'real', bizarre spatial and temporal distortion, strong emotions, and amnesia for the events after waking up. The experiences of dreams are accepted as real because there is no concomitant external input.

Jones, Lynette A. (1988). Motor illusions: What do they reveal about proprioception. Psychological Bulletin, 103 (1), 72-86.

Five illusions involving distortions in the perception of limb position, movement, and weight are described in the context of their contribution to understanding the sensory processes involved in proprioception. In particular, these illusions demonstrate that the position sense representation of the body and the awareness of limb movement results from the cross-calibration of visual and proprioceptive signals. Studies of the vibration illusion and phantom-limb phenomenon indicate that the perception of limb movement and position are encoded independently and can be dissociated. Postural aftereffects and the illusions of movement induced by vibration highlight the remarkable lability of this sense of limb position, which is a

necessary feature for congruence between the spatial senses. Finally, I discuss the role of corollary discharges in the central processing of afferent information with respect to the size-weight and vibration illusions.

Kingsbury, Steven J. (1988). Hypnosis in the treatment of posttraumatic stress disorder: An isomorphic intervention. American Journal of Clinical Hypnosis, 31, 81-90.

**NOTES:**

Reviews literature on hypnosis treatment for PTSD and presents a rationale, based on the type of symptoms presented (blunting vs intrusions). Case presentations are provided.

"Several types of physiological processes may underlie dissociation. State-dependent learning, in which that learned during drug-induced alterations in consciousness may only be recalled during later similar alterations, is believed to be dependent upon hippocampal mechanisms (Gerrien & Chechile, 1977). The relationship of state-dependent learning to hypnosis has remained at the level of theory (Hilgard, 1977; Rossi, 1986). A second possible explanatory construct suggests everyday experience is primarily (but not exclusively) mediated by verbal, dominant hemisphere functioning. The images and sets mediating hypnosis, PTSD, and other forms of dissociation may be mediated by analogic processing and the nondominant hemisphere (Carter, Elkins, & Kraft, 1982; Galin, 1974; Hilgard, 1977; Watzlawick, 1978)" (p.83).

Loewenstein, R. J.; Putnam, F. W. (1988). A comparison study of dissociative symptoms in patients with complex partial seizures, MPD, and posttraumatic stress disorder. Dissociation, 1, 17-23.

Depersonalization and dissociative symptoms have been widely reported in chronic seizure disorder patients, especially those with temporal lobe involvement and complex partial seizures (CPS). It has been theorized that development of multiple personality disorder may be related to temporal lobe pathology. We administered the Dissociative Experiences Scale (DES) to 12 male patients with severe chronic epilepsy, primarily of the complex partial type. Patients had epilepsy from 1 to 30 years. Most were being evaluated for intractable seizures occurring several times per week. DES data on the epileptic patients were compared with DES data on 9 male MPD patients and 39 PTSD patients. MPD and PTSD patients were significantly different from CPS patients in median DES scores and all DES subscale scores. MPD and PTSD patients were far more similar on the DES, although MPD patients had a significantly higher score on the dissociation/psychogenic amnesia subscale of the DES. The authors conclude that there is little data to support a relationship between MPD, dissociation, and epilepsy.

Lorig, Tyler S.; Schwartz, Gary E. (1988-89). EEG activity during relaxation and focal imagery. Imagination, Cognition and Personality, 8, 201-208.

EEG activity was recorded in nine volunteer subjects while they engaged in eight cognitive tasks. The tasks involved mental arithmetic, relaxation imagery, food imagery and imagery related to "neutral" stimuli (bicycle and automobile). Period analysis of the EEG indicated significant differences in EEG factor activity related to tension and anxiety for the subtraction, relaxation and food imagery trials. Imagery of heaviness and the subject's favorite dessert produced EEG factor activity most characteristic of relaxation. Results of this study are discussed in terms of the relation of odor to food imagery and the ecological validity of the use of food imagery in relaxation training.

#### NOTES:

Lorig, in a comparison of spectral and period analysis techniques, found that period analysis had greater sensitivity to task-related EEG effects. More recently, Lorig and Schwartz applied factor analysis to EEG period data and found that the factors identified tended to show greater homogeneity and correspondence to self-report than the traditional EEG bands of alpha, theta and beta. Period analysis reduces data to a histogram of the number of waves of various frequencies which occur during each 10 second data collection epoch for each task.

As is evident from Finding 1, the 8 tasks tend to stratify into two groups which either increase or decrease in Factor 1/theta activity over time. Those tasks which decrease over time seem to be performance or practice-related and include Serial subtraction of threes, of sevens, relaxation imagery of heaviness (HVY) and instructions to concentrate on the word "one" as they inhaled and exhaled (BCON). These tasks may change little in their cognitive demands on the subjects over time. The other tasks (imagery of their first bicycle, imagery of their earliest ride in a car, imagery of their favorite main course, imagery of their favorite dessert) may be more evocative to the Ss since they were asked to recall events from their personal experience. The recall of some of these experiences may kindle the subsequent recall of other events and account for the increases in theta and Factor 1. It is also possible that theta and Factor 1 are attention-related. Thus, as the S participates in a task which changes little over time, attention is diminished. If, however, the task continues to evoke other personally relevant events, attention will be maintained and may even increase over time. If this later hypothesis is correct, the Favorite Dessert task may be of use clinically since it produces EEG patterns associated with less tension and anxiety and also less boredom. This task also produced self-reports of greater happiness ( $p = .0001$ ) and was not different from relaxation imagery of heaviness and instructions to concentrate on the word 'one' as they inhaled and exhaled in self reports of relaxation, tension or calm.

The results of this study indicate that imagery of food, especially one's favorite dessert, has relaxation effects apparent in EEG and self-report. These effects may indicate that food-related odorants exert their relaxation effects by producing imagery of food. Such effects should not be surprising given the early history of systematic desensitization training in which food was often used as a competing stimulus for anxiety-provoking stimuli.

De Pascalis, Vilfredo; Marucci, Francesco; Penna, Pietronilla M.; Pessa, Eliano (1987). Hemispheric activity of 40 Hz EEG during recall of emotional events: Differences between low and high hypnotizables. International Journal of Psychophysiology, 5, 167-180.

This study evaluates individual differences in hypnotizability as reflected in waking-state hemispheric engagement during recollection of 3 positively and 3 negatively valenced personal life events. The State-Trait Anxiety Inventory, Maudsley Personality Inventory, Tellegen Absorption Scale and Harvard Group Scale of Hypnotic Susceptibility (Form A) were administered. Electromyogram (EMG) and bilateral electroencephalogram (EEG) activities within the 40-Hz band were recorded during rest and task conditions in 22 high and 21 low hypnotizable women. Self-report rating scores for vividness of visual imagery and emotional feeling of the material recalled were evaluated. The 40-Hz EMG amplitude and both hemisphere 40-Hz EEG densities were obtained. A 40-Hz EEG ratio, as a measure of hemispheric asymmetry, and a hemispheric specificity index were also computed. High hypnotizables showed significantly lower 40-Hz EEG density than low hypnotizables in all experimental conditions. The relationship between lateralization of 40-Hz EEG and emotional processing was moderated by hypnotizability. High hypnotizables, with respect to rest condition, showed an increase of density over both left and right hemispheres during two of the three positive emotional tasks, while they showed a depressed activity over the left and an increased activity over the right during negative emotional tasks. Low hypnotizables, on the other hand, did not exhibit differential hemispheric patterns that could be attributed to different emotional valences. The high group showed greater hemispheric specificity in the predicted direction than the low group. High subjects exhibited greater ratings of absorptive ability and emotional feeling than low subjects. Anxiety and EMG levels did not differ between groups. EMG was dependent on the type of emotion which showed greater activity in the negative emotion condition compared with the positive one.

De Sano, Christine F.; Persinger, M. A. (1987). Geophysical variables and behavior: XXXIX. Alterations in imaginings and suggestibility during brief magnetic field exposures. Perceptual and Motor Skills, 64, 968-970.

12 male and 12 female volunteers were evaluated for their suggestibility before and after an approximately 15-min. exposure to either sham, 1-Hz or 4-Hz magnetic fields that were applied across their mid-superior temporal lobes. During the field application subjects were instructed to view a green light that was pulsating at the same frequency as the field and to imagine countering an alien situation. Results were commensurate with the hypothesis that weak brain-frequency fields may influence certain aspects of imaginings and alter suggestibility.

**NOTES:**

"Subjects who had been exposed to the 4-Hz fields showed a significant decrease ... in heart rate compared to those who had been exposed to either the 1 Hz or sham-field conditions. A significant ... interaction of sex by field ... was noted for the

change in HIP [Hypnotic Induction Profile] scales. Whereas both men and women in the sham-field condition tended to show less induction (~ 1 unit) on the second occasion ... women showed much greater (8.4 + 1.1) induction (= 3 units) if they had been exposed to the 1-Hz field while men showed much greater (8.0 + 1.5) induction (= 3 units) if they had been exposed to the 4-Hz fields. On the protocols, women reported significantly more fear responses than men. In addition, subjects who were exposed during the imaginings to the 4-Hz field showed more imaginings ... and more references to vestibular experiences (e.g., self or entity rising or floating) ... than those exposed to the other conditions" (p. 969).

"Dissociation scores on the HIP were correlated significantly ... with vestibular (0.44), imagery (0.43), and fear (-0.45) scores from the transcripts. Floating responses on the HIP were correlated with the amount of imagery. (0.46). There was a significant positive Pearson correlation between the compliance measure and the amount of arm levitation during the second induction only. These results suggest that hypnotic susceptibility may be increased following magnetic-field exposure but that the effective frequency is not the same for each sex. In addition, the amount of the imagery (particular vestibular experiences) increased if the person observed a light that was flashing at the same frequency as a 4-Hz applied magnetic field" (p. 969).

## 1986

De Pascalis, Vilfredo; Palumbo, Giovanni (1986). EEG alpha asymmetry: Task difficulty and hypnotizability. Perceptual and Motor Skills, 62, 139-150.

Parieto-occipital EEG alpha was recorded bilaterally, while 20 high- and 20 low-hypnotizable women performed one left-hemisphere and one right-hemisphere task of low difficulty and two other comparable tasks of high difficulty. Every task was performed twice, once with eyes open and once with eyes closed. All subjects were right-handed. The tasks were originally selected to be of high and low difficulty. The subjective rating of task-difficulty was also evaluated. The integrated amplitude alpha and the alpha ratio (R- L/R + L) were the dependent variables. The highly hypnotizable women showed significantly higher alpha amplitude in eyes-closed condition than the low scorers; this difference disappeared during task performance and in the eyes-open condition. The left- tasks showed lower alpha amplitude in both hemispheres than right-tasks and baseline. The right-hemisphere alpha amplitude was lower than left in all experimental conditions. On tasks of high and low difficulty there was different hemispheric behavior on right and left tasks. Performance reflecting the right and left hemispheres in the low-difficulty condition showed no changes between baseline, right- and left-tasks, while under high difficulty there was a decrease in alpha amplitude in the right and even more marked decrease in the left hemisphere during left-tasks. The pattern of task effects for ratio scores was the same as for alpha amplitude, however, despite the analysis of alpha scores, an interaction of hypnotizability x task-difficulty was detected. The highly hypnotizable women showed less negative alpha ratio during a task of low difficulty than during tasks of high difficulty; the reverse was true for the low-

hypnotizable women. Finally, the highly hypnotizable subjects showed less subjective difficulty during performance than the low scorers.

**DeBenedittis, Giuseppe; Sironi, Vittorio A. (1986). Depth cerebral electrical activity in man during hypnosis: A brief communication. International Journal of Clinical and Experimental Hypnosis, 34, 63-70.**

To the authors' knowledge, hypnosis has never been induced in epileptic patients during a depth EEG study. This neurosurgical diagnostic procedure has been routinely used in medically resistant epileptic patients for the preoperative exact delimitation of the epileptogenic lesion. It offers a unique opportunity to obtain fundamental information on the possible neurophysiological mechanisms implicated in hypnosis. Observations were carried out on 1 patient affected by medically resistant partial seizures with complex symptomatology. A chronic deep electrode study explored rhinencephalic structures as well as specific target areas of the cerebral cortex. Background electrical activity during hypnosis showed a significant decrease of slow waves and an increase of alpha and beta rhythms, with constant increase of amplitude, when compared to activity in the pre- and posthypnosis states. Focal interictal abnormalities were dramatically reduced during hypnosis.

#### **NOTES:**

Hypnotizability was assessed with the Barber Suggestibility Scale in order to test for suggestibility without a prior induction of hypnosis. The patient's score was 7 out of 8 possible. Patient was hypnotized with a standard induction procedure (Barber & Calverley, 1963).

Experimental Protocol: 15 minutes resting baseline; 15 minute test of mental imagery (waking suggestions with imagination instructions); hypnosis with progressive relaxation; suggestions for dissociation; suggestions for amnesia; arousal from hypnosis (the patient was successful with positive hallucinations, catalepsy, total amnesia, and spontaneous analgesia); and posthypnosis awake and alert (5 minutes eyes open, 5 minutes eyes closed, then 15-minute recording of post-treatment waking baseline).

EEG background activity was scored for the number of sec/minute of delta (0-4), theta (4-7), alpha (8-12), and beta (13-30) rhythms, for each 5-min period. Score = percent as related to the 1-minute epoch. Number, amplitude, and diffusion of interictal spikes also were measured but ictal activity was not recorded during the periods considered. Experimenters also measured heart rate, respiratory rate, and mean blood pressure.

ANOVA for 4 conditions (resting, waking suggestion, hypnosis, and posthypnosis) was computed for background and for focal interictal activities, and the t-test used to evaluate significant differences. ANOVA indicated a significant effect across the four experimental conditions for theta and alpha in the temporal anterior cortex, temporal posterior cortex, and frontal convexity cortex. The effect was attributable only to changes in theta and alpha between baseline and hypnosis (theta decreasing, alpha increasing as the patient went into hypnosis). No other significant difference

was found. Following arousal from hypnosis, EEG activity was similar to the EEG activity before the induction.

Interictal focal abnormalities were reduced during hypnosis, compared with before hypnosis. The effect was due to changes in the area of Ammon's horn, the amygdala, the posterior temporal cortex, the mesial temporal cortex, and the inferior temporal cortex.

In their Discussion, the authors note that their data supports earlier work indicating that the limbic system is implicated in hypnosis. They cite the publications of Arnold (1959, *International Journal of Clinical and Experimental Hypnosis*) and Crasilneck, McCranie, and Jenkins (1956). The latter authors observed EEG records taken during brain surgery on one patient. Hypnosis terminated every time the hippocampus was stimulated, leading them to suggest that the hippocampus is part of the neural circuit involved in hypnosis.

"If it is assumed that a convulsion can be considered a result of both pathophysiological and emotional events operating in the individual, emotions being the most common precipitating factor in epilepsy, then any amelioration of one will raise the convulsive threshold or lower the seizure level (Goldie, 1979; MacCabe & Habovick, 1963). Although 'voluntary control of the alpha rhythm' was achieved over 40 years ago (Jasper & Shagass, 1941), only since 1969 has such control been used for clinical purposes (Kamiya, 1969). One striking characteristic of the EEG pattern of many epileptics is the absence of a 12 to 14 c/s rhythm normally recorded from the anterior portions of the brain (sensorimotor rhythm) and the presence of a 4 to 7 c/s rhythm at the same location (Olton & Noonberg, 1980). Biofeedback may enable the individual to increase the amount of sensorimotor rhythm and to decrease the amount of 4 to 7 c/s activity. As a consequence, clinically significant decreases in seizure activity have been found after biofeedback training (Serman, 1973, 1977).

"The present data demonstrate that in this female patient hypnosis induced a highly significant reduction of the interictal activity, concomitant with an increase of alpha and sensorimotor rhythm and a decrease of slow activity, similar to biofeedback but without prior training.

" In conclusion, a depth EEG study in one epileptic patient comparing EEG activity during hypnosis and pre- and posthypnosis suggests the following conclusions: (a) hypnosis may be associated with significant decrease of slow activity and an increase of alpha and relatively high frequency, beta activity; (b) electrophysiological correlates of hypnotic behavior support the possible role of the limbic system in mediating the trance experience; and (c) hypnosis is effective in reducing focal interictal abnormalities in this patient and so it can be considered a promising technique to prevent and/or reduce emotional precipitating factors and the tendency to develop seizure activity" (p. 69).

The article referenced regarding biofeedback training to reduce ictal activity is: Serman, M. B. (1973). Neurophysiologic and clinical studies of sensorimotor EEG biofeedback training: some effects on epilepsy. In L. Birk (Ed.), *Biofeedback: Behavioral medicine*. New York: Grune & Stratton, Pp. 147-165.

Sterman, M. B. (1977). Effects of sensorimotor EEG feedback training on sleep and clinical manifestations of epilepsy. In J. Beatty & H. Legewie (Eds.), *Biofeedback: Behavioral medicine*. New York: Plenum, 1977, Pp. 167-200.

Friedman, Howard; Taub, Harvey A.; Sturr, Joseph F.; Church, Katherine L.; Monty, Richard A. (1986). Hypnotizability and speed of visual information processing. *International Journal of Clinical and Experimental Hypnosis*, 34, 234-241.

Following the determination of the luminance threshold of each S, high and low hypnotizable Ss were tested for speed of information processing using a backward masking paradigm with a bias-free and ceiling-free psychophysical task. No significant relationship between hypnotizability as measured by the Stanford Hypnotic Susceptibility Scale, Form A (SHSS:A) of Weitzenhoffer and Hilgard (1959) and speed of information processing was observed. The order of administering SHSS:A, pre- or postthreshold task, was significantly related to luminance threshold. Results were compared to other studies wherein some evidence for a relationship between hypnotizability and speed of visual information processing had been offered.

#### NOTES:

106 college students were tested using tachistoscopic presentation of stimuli. 52 Ss received the SHSS:A immediately prior to the experimental tasks, 54 immediately after, and testing was terminated for each Subject after they failed 3 successive items. The test flash was set at 0.3 log units above threshold, i.e. double the threshold intensity. A trial consisted of 2 observation intervals, separated by warning tones. The test flash occurred randomly in one of the two intervals. The S indicated which observation interval contained the test flash by pressing a button. Feedback tones gave S information about the correct response.

"The masking experiment was begun with the suprathreshold test flash occurring 250 milliseconds prior to the onset of the larger bright masking stimulus. As before, a two-interval forced-choice staircase procedure was used, but this time the test intensity was constant, and ISI was changed. If S 'hit' three trials in a row, ISI was decreased by 10 milliseconds. The ISIs continued to decrease in 10-millisecond steps, until S "missed," causing an increase in ISI" (p. 348).

RESULTS were analyzed by 2 x 2 x 2 ANOVA (Hypnotizability, sex, and order of hypnotizability measurement). High hypnotizables = 7-12 on the SHSS:A, and low hypnotizables = 0-6. Ss receiving SHSS:A prior to the tasks had a significantly lower luminance threshold (-1.99 log mL) than did those having it after tasks (-1.93 log mL),  $p < .05$ . None of the other analyses were significant. No significant relationships were observed vis a vis the masking task, and the mean masking thresholds were almost identical for the lows and highs.

DISCUSSION. "Spanos (1982), in studying the effects of hypnotizability and suggestions in altering auditory sensitivity, reviewed the difficulties inherent in the measurement of perceptual accuracy and emphasized the role of response bias in the confounding of results" (p. 239). Secondly, these tasks reflect more fundamental,

central processes and use more neutral stimuli than letter recognition used earlier. "Thus, while the masking effects of both the previous recognition tasks (masking by pattern) and the current detection tasks (masking by nearby contours) are presumably mediated through similar high level central processes, the differences in findings could possibly have been related to additional processing cues required in letter recognition" (p. 239). A footnote mentions, "Other studies have shown that with stimulus configurations similar to that used in the present study, there are significant central masking effects (Battersby & Wagman, 1962; Markoff & Sturr, 1971; Turvey, 1973)" (p. 239).

"Quite intriguing is the luminance threshold finding which, although not as robust as one would desire, suggests that a hypnotic induction procedure given prior to a task may significantly affect sensitivity on that task. Speculatively, the relaxation suggestions inherent in SHSS:A may account for the changes in luminance threshold" (p. 239).

**Kissin, Benjamin (1986). Conscious and unconscious programs in the brain. (1 ). New York: Plenum Press.**

**NOTES: Hypnosis is discussed in terms of inhibition/excitation mechanisms in the central nervous system, with both feedback and feedforward controls and lateralizing controls. The author employs a concept of engrams (neural representations of an idea, represented throughout the neocortex) to discuss sensation and perception as well as conscious and unconscious processes. Sensory information is processed serially with encoding of information mostly on the conscious level (but sometimes, less efficiently, on the unconscious level); and it also is processed in parallel. Parallel processing operates almost entirely at the unconscious level and is basic to perception.**

**Associative phenomena are explained in terms of overlapping engrams, so that two 'related hypercomplex engrams' could be assumed to have at least one simple engram in common. With Premack, he describes three types of engrams: veridical (primary sensory data perceived), abstract (formalized representations of concepts like line drawings of dog or house; Premack's iconic representations), and symbolic (more complex entities that encompass an entire class of objects, actions, or ideas and may have artificial symbols such as words).**

**With Neiser he suggests that thinking (verbal and nonverbal) involves logical sequential processing of cognitive engrams of external (environmental), internal (visceral), and intracerebral (ideational) origin. Evoked response investigations shed light on the nature of such engrams, their distribution in brain tissue. John, Bartlett, Slumokochi, & Kleiman (1973) found that an error in choice discrimination learning (cats learning colors) is accompanied by the cortical evoked potential of the stimulus associated with that (erroneous) behavior, not the evoked potential of the true stimulus. In other words, ERPs represented the idea, not the actual visual stimulus provided to the cat.**

**Emotional/motivational influences are part of every cognition (R. S. Lazarus's position). Interaction of motivational-emotional and cognitive engrams seems to occur primarily in the inferior temporal lobe and the entorhinal cortex. The interaction involves the upper rhinencephalon, the amygdaloid-hippocampal**

complex, the septal region, the cingulate gyrus, and the inferior and medial aspects of temporal lobe of the cortex. He also explains classical and operant conditioning (on pp. 75-76) in terms of the association of engrams.

The author's position is that consciousness is the subjective equivalent of brain activity in the 'alerting' and 'awareness' systems. Awareness of the environment ('general, vague') appears to involve the limbic area (thalamus and basal ganglia), while more specific awareness of the self entails a system stretching from the basal ganglia through the parietal lobe (posterior aspect).

Normal alert consciousness involves the noradrenergic reticular activating system, as well as associated excitation of the general awareness system in the involved thalamic- basal gangliar nuclei and the self-awareness system in the posterior inferior parietal lobe system. Altered states of consciousness characterized by a relaxed hazy sense of the world involves thalamic activation of the self-awareness system. Dreaming involves activation from cholinergic cells in the pons. "Impaired general awareness occurs with lesions of the thalamic-basal gangliar centers while impaired self-awareness occurs with lesions in the posterior inferior parietal lobes. Finally, in certain physiological states such as sleep, hypnosis, and so on, the entire awareness system--the thalamic-basal gangliar and posterior inferior parietal nuclei--may be activated by different activation systems, such as the cholinergic in the pons or the dopaminergic in the thalamus, to produce different states of consciousness" (p. 82).

Consciousness is described as having seven dimensions: alertness, attention, arousal (heart rate, GSR), activation (EEG, evoked potential), affect, and the two awarenesses. The seven are related, so that changes in any one usually are correlated with changes in others (though dissociation among the seven also can be demonstrated). Motivational-emotional arousal produces electrophysiological activation of the brain, which is translated epiphenomenally into alertness and awareness; awareness is focused through attention onto the cognitively and motivationally significant events in the internal and external environments to determine the final sequence of drive-oriented behavioral responses.

The EEG is useful for diagnosing different states of consciousness: beta and gamma waves alertness, stemming from locus coeruleus and reticular activating system delta (2-4/sec) waves coma alpha synchronized relaxing influences stemming from thalamus; low level of awareness as in twilight sleep

or hypnagogic states theta, delta inactivity due to less stimulus from locus coeruleus reticular activating system influences; associated with increased inhibitory thalamic and septal-hippocampal impulses radiating upward to the cortex.

In some altered states of consciousness there is theta-wave activity, indicating influences from the inhibitory septal-hippocampal circuit.

The reticular activating system (RAS) and thalamus interact in complex ways. The RAS is essential to maintain consciousness, but if destroyed stepwise (in animal research) a low-grade type of consciousness can be maintained by thalamus and basal ganglia. The thalamus has two kinds of influence: it inhibits the cortex, as in sleep; and stimulates the cortex in the form of activating alpha waves. "The median thalamus is also related in a feedforward-feedback circuit with the inhibitory septal-hippocampal complex which generates theta-wave activity, thus accounting for the

close association between alpha and theta wave activity in sleep and in other altered states of consciousness" (p. 86).

Thus there are two different activating systems originating in the lower brain stem: the norepinephrine locus coeruleus system that is associated with normal behavior, and the cholinergic FTG neurone system of REM sleep. The relationship of the latter to consciousness, awareness, self awareness, etc. is unknown, since the only time that it is readily observed is during REM sleep. The author reports that altered states of consciousness (e.g. hypnosis, fugue, alpha state) resemble Stage 1 sleep, rather than REM sleep, physiologically, with the central locus of activation in the medial thalamus rather than the RAS and locus coeruleus.

"It appears then that consciousness may be driven by one or another of three different activation centers: the norepinephrine RAS (emanating from the locus coeruleus), the cholinergic FTG cell system in the pons, and the dopaminergic alpha rhythm system radiating upward from the thalamus (Fig. 6-2). Brain activation by each of these centers is associated with a different state of awareness" (p. 91). The relative contribution from each center determines qualitative aspects of awareness.

The author refers to Mesulam and Geschwind (1978) who traced the self-awareness system from amygdala/hippocampus/midbrain to the inferior parietal lobe where they converge with the body's proprioceptive neural tracts. What results is "a sense of self that was not necessarily present in the sense of general awareness stemming from the median thalamic-basal gangliar complex" (p. 97).

The thalamic-basal gangliar complex is both a center for emotional reception and a relay station for somatosensory events. Both somatic sensory reception and somatosensory elements of emotion are also represented in the parietal lobe. "Affective and somatosensory stimuli, which are constant and persistent even though we are unaware of them most of the time, produce the sense of one's body which is the most basic element in the 'sense of self.'... It is most probable that a major component of the sense of self is produced by the constant barrage of affective and somatosensory stimuli converging from all parts of the body; the majority of these stimuli may not reach consciousness most of the time but they must register a sense of feeling in the thalamus and parietal cortex even though the individual may be unconscious of it" (p. 100).

The author presumes that most of the incoming stimuli that define self are unconscious. "Whether sense-of-self stimuli are unconscious because of constant habituation ... or whether they are unconscious because they are transmitted predominantly to the right hemisphere ..., it appears that the major components of the self-concept are unconscious rather than conscious" (p. 102).

"Even the acutely self-aware component of the self-concept, by definition conscious, varies markedly in different altered states of consciousness. The conscious awareness of oneself in the alert condition is different from (1) that in the twilight state, (2) that in dreams, (3) that in hypnosis, (4) that under the influence of alcohol, (5) that under the influence of other sedatives, (6) that under the influence of stimulants, and (7) that under the influence of hallucinogens. In that sense the acute sense of self is a function of the momentary chemical and physiological state of the brain" (p. 102).

" ... the decision-making apparatus of the brain is lodged largely in a consortium of neocortical centers including the prefrontal lobes (integration), the posterior inferior lobes (motivation and emotion), the anterior and posterior associational areas (cognition), the posterior inferior parietal lobes (self-awareness), the left-hemispheric language centers (language), and the precentral frontal lobe motor area (motor). Within the context of this integrated cortical complex, self-awareness functions are somewhat stronger on the right hemisphere while language and decisional activities are somewhat stronger on the left" (pp. 102-103). The Chapter titled "Attention as directed consciousness" is relevant for investigations of hypnosis but is not included in these notes.

## 1984

Bakker, Dirk J. (1984). The brain as a dependent variable. Journal of Clinical Neuropsychology, 6, 1-16.

The mainstream of neuropsychological research and practice has been devoted to the impact of the brain as an independent variable on behavior as a dependent variable. Evidence is currently available to make clear that the order of causation may be reversed: Behavioral changes can have a durable impact on the brain. The results of extensive research indicate that a large number of neuroanatomical, neurophysiological, neurochemical, and neuropsychological parameters of the animal brain can be modified through environmental manipulation, sensory experience, and systematic training. Some evidence is available to show that psychological stimulation has certain effects on the physiology of the human brain. For instance, hemisphere-specific stimulation through the presentation of words flashed in a visual hemifield appears to modify the electrophysiological activity of the contralateral hemisphere in dyslexic children and to affect their subsequent reading performance. Neuropsychology may profit from paying more attention to the ecology of the human brain.

## NOTES:

An 18th Century anatomist in Italy, Malacarne, demonstrated increased cerebellar folds in the brains of trained (vs. untrained) dogs and birds. His approach to neuroanatomy was not continued because psychology has been more concerned with innate traits of the individual, and because of philosophical rationalism (citing Walsh, 1981). Until very recently, scientists have viewed the brain as "structurally insensitive to environmental experience" (p. 3).

Now we have evidence that animal brains are modifiable by experience, in gross morphology, fine (synapse) morphology, and neurochemicals. "Rich environments [for rats] ... produce heavier and thicker cerebral cortices and callosal connections (Walsh, 1981), larger cortex/subcortex weight ratios, larger cell bodies and nuclei (Walsh, 1981), and higher metabolic activity as suggested by increased RNA/DNA ratios (Rosenzweig, Bennett, & Diamond, 1972)" (p. 4). Enrichment leads to more extensive dendritic fields (occipital and temporal cortex, some hippocampal regions); this implies that each neuron has more synapses. Researchers have found large Purkinje-cell bodies and many dendrites in richly educated monkeys.

"Some evidence is available to show that 'preventive' and 'therapeutic' environments positively affect behavioral performances of brain-lesioned animals. However, knowledge about the brain mechanisms which underly these effects is, as yet, lacking" (p. 6). Rats that were handled during the first 21 days of life exhibited different brain lateralization from rats that were not (Denenberg, cited by Marx, 1983). Those stimulated early stored memories mainly in the right hemisphere.

The author also reviews evidence that human brains are psychologically modifiable. Children with astigmatism generate weakened cortical response to visual stimulation (Freeman & Thibos, 1973), because they experience difficulty in processing some visual-spatial patterns. People who have visual-field defects due to brain damage can improve in vision when forced to make eye movements toward lighted targets flashed in the blind areas (Zihl, 1981).

Bakker theorizes that hemispheric control of reading shifts from right to left during the learning-to-read process of normal readers; at least some aspects of reading are successively mediated by the right hemisphere at age 6 and by the left hemisphere at age 8, according to electrophysiological data in a longitudinal study (Licht, Bakker, Kok, & Bouma, 1983). He thinks P-type dyslexia results from continuing to rely on right-hemispheric strategies, leading to slow reading with fragmentation errors and repetitions. L-type dyslexia results from prematurely adopting a left-hemispheric strategy, i.e. at the very beginning of the learning process, making child insensitive to the perceptual features of script with consequent substantive errors such as omissions and additions. Thus, P-type dyslexics presumably show functional overdevelopment of the right hemisphere and L-types of the left hemisphere. Treatment would involve specific stimulation of the hemisphere that they are ignoring.

He presents data suggesting that "some electrophysiological parameters of the cerebral hemispheres can be modified in dyslexic children through hemisphere-specific stimulation and loading, and that these modifications may induce better reading" (p. 12).

Gott, Peggy S.; Hughes, Everett C.; Whipple, Katherine (1984). Voluntary control of two lateralized conscious states: Validation by electrical and behavioral studies. Neuropsychologia, 22 (1), 65-72.

A subject is described who can voluntarily select and hold either of two qualitatively different states of consciousness. Evidence is presented which confirmed differential left or right hemisphere dominance in each state. Asymmetries of EEG alpha and task performance scores indicated a state-dependent shift in functional lateralization. Evoked response studies showed directional changes in rate of interhemispheric transmission correlated with state-related hemisphere dominance. These findings demonstrated the capability for voluntary endogenous control of cerebral dominance under natural conditions.

#### NOTES:

A personal communication (letter) from Gott indicates the S switches from one state to the other by visualizing her surroundings and imagining what it would look like

in the other state. Immediately she finds herself in that other state. Her drawings demonstrate that her perspective must differ in the two states.

La Briola, Flora; Karlin, Robert; Goldstein, L. (1984, October). Quantitated EEG changes from prehypnotic to hypnotic periods. [Paper] Presented at the annual meeting of the Society for Clinical and Experimental Hypnosis, San Antonio, TX.

**NOTES:**

Hemisphere EEG activation was measured before and during hypnosis, while Ss did tasks described as right-hemisphere (nonverbal) and left hemisphere (verbal). Highs shifted to relatively more task specificity as they went from prehypnosis into hypnosis, with a shift to right hemisphere as they went from prehypnosis to hypnosis periods. This is not due to relaxation, as both highs and lows relax. And the shift occurs not only on verbal-nonverbal tasks but on analgesia studies also.

Versions of this paper were presented at the 93rd Annual Meeting of the American Psychological Association, Toronto, Canada, 1984, at the Annual Meeting of the Society for Clinical and Experimental Hypnosis, San Antonio, TX, 1984, and at the 6th International Symposium on Clinical Neurophysiological Aspects of Psychiatric Conditions, Izmir, Turkey, 1985.

Lewith, G. T.; Kenyon, J. N. (1984). Physiological and psychological explanations for the mechanism of acupuncture as a treatment for chronic pain. Social Science & Medicine, 1367-1378.

Many suggestions have been made about the possible mechanism of acupuncture as an analgesic therapy. This review provides a comprehensive account of the neurological, neurohumoral and psychologically-based hypotheses put forward. Although the exact mechanism of this treatment remains unclear, it is apparent that reproducible neurological and chemical changes occur in response to acupuncture, and that these changes almost certainly modify the response to, and perception of, pain. The mechanism of chronic pain is incompletely understood, but within this framework we understand acupuncture as completely as most other types of analgesic treatment.

**1983**

Baars, B. J. (1983). Conscious contents provide the nervous system with coherent, global information. In Davidson, Richard J.; Schwartz, Gary E.; Shapiro, David (Ed.), Consciousness and self regulation (3, ). New York: Plenum Press.

**NOTES:**

We are conscious of some content when there exists an internal representation that is global, stable, and informative. Author views nervous system as a distributed information processing system, in which highly complex & efficient processing is performed by specialized processors in a relatively independent way. These processors may be 'data driven'--i.e. they may decide by their own criteria what is

worth processing..." p. 41 [See also Gazzaniga's (1985 Psychology Today article) idea that mind/brain consists of modules.]

p.44 gives references substantiating the above, e.g. Geschwind, Hilgard, La Berge, Shiffrin & Schneider.

p. 45 We are in habit of thinking hierarchically about nervous system rather than distributively.

p. 45 "Consciousness seems to be closely associated with a mechanism that permits interaction between specialized, dedicated processors" The 'global' data base' is like a TV station sending out information that can be processed or not by the viewer. It is not an executive, and in fact can sometimes be controlled by the processors. 'Consciousness ...[is] a certain operating mode of this medium, & consciousness can likewise be used by processors acting as executives, without itself being an executive "(p.49).

The global data base is a lingua franca, so that one sense modality can communicate with others. p. 51. [Synesthesia reported by high hypnotizables implicates this system--either the communicating tracks are greased between color and smell, or the name of the destination, in computer language, is lost, or equivalent.]

p. 52 Repression and the dynamic unconscious. explained in terms of controlled access to the global data base, with certain specialized processors given high priority.

Context, taken by itself, is unconscious; & input, taken by itself & in the absence of the appropriate context, is also unconscious. Only when both of these conditions exist- -when there is input that can be organized within a current context--are we conscious of some percept.

Contextual factors become conscious only when they are challenged.

Blum, Gerald S.; Nash, John K. (1982). EEG correlates of posthypnotically controlled degrees of cognitive arousal. Memory and Cognition, 10, 475-478.

Experimental control over five degrees of cognitive (as opposed to organismic) arousal has been developed by hypnotic programming techniques. Previously these posthypnotic manipulations have been applied to the investigation of diverse topics such as visual discrimination, performance on the Stroop test, selective concentration on color versus form of consonants, and cognitive "reverberation." The present study explored EEG correlates of the five degrees of cognitive arousal in a task requiring participants to visualize objects for one-minute periods while lying on a couch with eyes closed. Analysis of data from the occipital area in left and right hemispheres revealed that the highest degree of arousal was accompanied by larger amplitudes of alpha and beta power and smaller amplitudes of theta. This pattern of results was similar in both hemispheres, although more marked in the left. The findings, which provide an independent source of support for validity of the hypnotic programming, are discussed in relation to EEG literature on cognitive activity.

#### NOTES:

Hypnosis doesn't enhance imagery. It provides the conditions under which mental alertness may be manipulated, and very clear imagery is associated with the alert

condition whereas blurry imagery is associated with the lowest cognitive arousal condition. The other impression comes from clinical work, i.e. that hypnosis enhances imagery. This article is an example of hypnosis used in other research--see last page.

Larbig, W.; Elbert, T.; Lutzenberger W.; Rockstroh, B.; Schnerr, G.; Birbaumer, N. (1982). EEG and slow brain potentials during anticipation and control of painful stimulation. Electroencephalography and Clinical Neurophysiology, 53, 298-309.

Cerebral responses in anticipation of painful stimulation and while coping with it were investigated in a 'fakir' and 12 male volunteers. Experiment 1 consisted of 3 periods of 40 trials each. During period 1, subjects heard one of two acoustic warning stimuli of 6 sec duration signaling that either an aversive noise or a neutral tone would be presented at S1 offset. During period 2, subjects were asked to use any technique for coping with pain that they had ever found to be successful. During period 3, the neutral S2 was presented simultaneously with a weak electric shock and the aversive noise was presented simultaneously with a strong, painful shock, again under pain coping instructions. EEG activity within the theta band increased in anticipation of aversive events. Theta peak was most prominent in the fakir's EEG. A negative slow potential shift during the S1-S2 interval was generally more pronounced in anticipation of the aversive events than the neutral ones, even though no overt motor response was required. Negativity tended to increase across the three periods, opposite to the usually observed diminution. In Experiment 2, all subjects self-administered 21 strong shock-noise presentations. The fakir again showed more theta power and more pronounced EEG negativity after stimulus delivery compared with control subjects. Contrary to the controls, self-administration of shocks evoked a larger skin conductance response in the fakir than warned external application.

#### NOTES:

A published case study by Pelletier (1977) reported EEG theta enhancement during pain control states, which were maintained by EEG feedback of alpha and theta bands. That author concluded that EEG theta was necessary for the control of pain psychologically.

The authors of this article measured slow brain potentials (SBPs) and vertical eye movements (VEMs). Principal components analysis of the EEG wave forms found three components: theta (4-5.6 c/sec), alpha band (9-10 c/sec) and high frequencies (above 14.4 c/sec) plus harmonics loading in frequencies of 3.2-4.5 c/sec, 7.5-9, and above 15 c/sec. Alpha "decreased over periods in the parietal record and was virtually absent in the fakir's EEG during period 3" (p. 301). The fakir had a lot of non-sinusoidal, especially square wave, activity.

"Very pronounced negativity was recorded preceding the aversive S2, greater than under neutral stimulus conditions .... This difference was most pronounced at the vertex ... The late negativity increased over periods in control subjects ... especially in anticipation of the aversive S2 ... . This contrasts with the usually observed decrease of SBP components over trials. As is shown in Figure 2, the PCA [principal components analysis] yielded two components for the 2.0 sec S2 interval, a positive

deflection, which can be assigned to the P300 complex (here not reported), and a negative deflection, labeled post- imperative negative variation. ... This negative component increased over periods, being more pronounced in response to the aversive stimulation ... with increasing differentiation over period ..." (p. 302-303).

The fakir undertook an elaborate self hypnosis or trance induction to achieve analgesia that he had previously demonstrated in the laboratory (thrusting 4 unsterilized metal spikes into his abdomen, tongue, and neck without bleeding). This included "long- continued fixation on a point above the eye-brows. Blank facial expression, staring eyes, and a very low rate of eye-blinks indicated a trance-like state (periods without eye-blinks more than 30 min)" (p. 299). During the experiment itself, the fakir showed few ocular movements during the second and third periods. He also demonstrated large skin conductance responses, recorded from the second phalanges of the index and middle fingers of the left hand, to the aversive S1.

Experiment 2 was designed to emulate the self-administered aversive stimulation that the fakir routinely undertook, by having the volunteer Ss hold a switch that they pressed twice/minute, giving themselves a mild shock and an aversive noise. (These were the same aversive stimuli as were used in Experiment 1.) There were 21 self-paced button presses.

Three additional measures were taken: 1. Bereitschaftspotential (BP) - the mean negative shift during the 0.3 sec interval prior to the motor response of pressing the switch 2. Postimperative component (PINV) - the mean negative shift 0.9 to 1.9 sec after stimulus onset, i.e. elicited by closing the microswitch 3. Skin conductance response (SCR) - maximum change in skin conductance level during five second interval after the motor response of pressing the switch.

The fakir, but not the control Ss, showed a pronounced precentral PINV on each single trial of Experiment 2. He also showed pronounced SCRs (indicating autonomic arousal), which was even greater than the SCRs of control Ss. His subjective pain rating was 1 in Experiment 1 (compared with 6.4 for controls) but 8 during Experiment 2 (compared with 5.7 for controls), on a scale of 1 to 10 maximum. Thus the fakir's pain increased from Experiment 1 to 2, while for many volunteer Ss it decreased 2 or 3 points. When interviewed, he said that "intention and motor commands prevented the fakir from getting into 'trance' satisfactorily. Consequently, he reported to have experienced the aversive stimuli as more painful than in experiment 1. Thus it might be that the observed PINV indicates the noncontingency between the demand for coping and the failure to cope or the discrepancy between expected control and presently experienced control" (p. 307).

In their Discussion, the authors speculate that control of pain such as can be achieved by the fakir may involve dissociation of higher (possibly thalamic and cortical) and lower (reticular formation) arousal structures. Their observation of slow brain potentials (theta) recorded in anticipation of painful or aversive stimuli is in agreement with earlier published studies. However their observation of increasing negativity in anticipation of aversive stimuli is in contrast to previous research findings, in which diminution of negativity is generally observed.

Both the fakir and subjects showed a post-stimulus negative shift in response to the S2; this has been "observed in normal subjects under conditions of change from

controllable to uncontrollable aversive stimuli... and/or from obvious response-consequence contingencies to unpredictable control over the S2... PINVs were associated with an unexpected change in contingency or the inability to resolve ambiguity. Since a relationship was found between PINV amplitude and subjective ratings or experienced aversiveness of the painful stimulation, it may be speculated that obvious failure in coping with pain (i.e. more experienced pain) together with the requirement to cope (induced by instructions and experimental setting, giving rise to increased expectancy for control), produced a PINV (and probably feelings of uncontrollability together with a state of reactance and frustration) in the present experiments. In accordance with this point of view, it is of particular interest that only the fakir showed a more pronounced PINV in experiment 2, in which subjects delivered the painful stimuli to themselves. A postexperimental interview revealed that intention and motor commands prevented the fakir from getting into 'trance' satisfactorily" (p. 307).

## 1981

Chen, Andrew C.; Dworkin, Samuel F.; Bloomquist, Dale S. (1981). Cortical power spectrum analysis of hypnotic pain control in surgery. International Journal of Neuroscience, 13, 127-136

Cortical power spectrum (CPS) of brain potentials was recorded from the scalp between prefrontal and parietal regions in both right hemisphere (RH) and left hemisphere (LH). A pattern of laterality shift in CPS occurred at different stages during an extensive oral surgery, performed under hypnosis, in a young female patient. Video and audio recordings as well as psychophysiological recordings were obtained through the following 6 stages: Baseline, Hypnosis, Surgery (1 hr, no cortical recording), Immediate Postsurgery Procedure, Hypnotic Re-experience, Hypnotic Rest, and Posthypnotic Baseline. Indications of anxiety and pain scores were reported in writing by the patient through verbal command by the hypnotist. In each stage, 10 min of CPS (10 spectrum/stage, 8 epochs/spectrum, 6 seconds/epoch) were analyzed by a PDP-11 computer. The results of CPS analysis demonstrated significant large total power reduction at different stages. There was significant correlation between both hemispheres at baseline, but dissociation of hemispheric power output occurred during hypnosis stages. LH was more dominant than RH during baseline and presurgery hypnosis, but both were leveled-off immediately following the surgery procedure. However, RH became more dominant during all postsurgery hypnosis stages. Interestingly, this pattern shifted back to the original relationship during the posthypnotic baseline stage. Specific changes of spectral power in theta and alpha of EEG activities in both hemispheres also occurred in conjunction with hypnosis.

NOTES: Subject was a 25 year old woman, described as only medium in hypnotizability. She scored 3 on the 5-point Stanford Hypnotic Clinical Scale, 7 on the 12-point Stanford Hypnotic Susceptibility Scale, and 3 on up-gaze, between 2 and 3 on eye roll, on the Spiegel eye roll test.

The principal hypnotic approach was a suggestion of dissociation, i.e. that the patient "experience herself swimming freely and powerfully, in a deep cold

mountain lake, pre-occupied with the intensity of the blue-black color of the water, the shimmering of light from above, and the possibilities of exploration of rock formations, caves, etc. It was suggested that while she was experiencing the exhilaration and strenuous stimulation of the cold water and the vigorous exercise, an 'observing-self' would remain on the shore, watching and ensuring that no harm would come to the person. The suggestion was reinforced that any stimulation experienced was experienced in the body, not in the person" (p. 129).

The patient was trained in inductions and dissociation first in the therapist's office, then with two sessions in the research laboratory (where tooth pulp stimulation pain thresholds were measured), and then two sessions in the hospital dental operatory.

The results of the computerized CPS were analyzed by hemispheres. "Large reductions in total power occurred at different stages associated with hypnosis and these reductions in power output of the CPS showed significant left-right differences" (p. 130).

"The total energy output of LH [left hemisphere] continued to diminish as hypnosis continued by as much as 80% of baseline value, while RH [right hemisphere] power output tended to be stabilized from the initial hypnosis recording stage until the awake baseline stage" (p. 130).

"Those stages involving hypnosis were characterized by dominant RH energy output in the alpha spectrum.

"Alpha output for the LH decreased an average of 65% between awake baseline levels and postsurgery hypnosis stages, while RH alpha only decreased approximately 50% of resting levels. This resulted in a relative shift of alpha output which was approximately equal in both hemispheres prior to surgery, to a 2:1 shift in favor of RH alpha output as hypnosis progressed. This differential shift in laterality of alpha was reversed when the subject awakened from hypnosis.

"Of interest was the observation that total power reductions and laterality shifts associated with hypnosis were not altered by the profound instrumentation of surgery and postoperative pain, nor were observed laterality shifts affected by hypnotic suggestions aimed at recreating the surgical experience (see Stage 5)" (p. 130).

During the experiment when the investigators used hypnotic suggestion to recreate the surgical experience, LH output continued to diminish while RH output did not change, making the LH-RH contrast highly significant. "This suggests that the RH is active during deep stages of hypnosis and can remain so despite hypnotic suggestions which are presumed to be intensely aversive" (p. 131).

In their Discussion, the authors reinforced the conclusion that overall cortical functioning is reduced during hypnosis, and that the left cerebral hemisphere shows a greater reduction than the right. They discuss the increased theta density in RH and LH during the postsurgery hypnosis stage in terms of reports that theta is associated with altered states of consciousness (Tebecis et al., 1975; Ulett et al., 1972; Anad, China, & Singh, 1961; Banquet, 1973; Kasamatsu & Hirai, 1966; Wallace, 1970) and with cognitive tasks like mental arithmetic (Dolce et al., 1974).

The authors note that their results are congruent with Hilgard's neodissociation theory of hypnosis, and add that since their suggestions were dissociative in nature

rather than of local anesthesia, the EEG may reflect the brain physiology of dissociation.

Finally, they comment on the implications for pain neurophysiology. "The total power changes and shifting patterns in laterality of cortical functioning observed more closely tracked the hypnosis experience than the pain experience; this is, in fact, a very puzzling issue. It appears on the face of it that the EEG measurements recorded are not reflective of EEG-related pain phenomenology despite the strenuous and invasive surgical procedures used. The observations that overall power output continued to decrease during the several hypnosis stages after strenuous surgery and then increased as the patient came out of hypnosis makes reasonable the possibility that hypnosis has some functional brain correlates; we cannot conclude from the present cortical power spectrum analysis that any brain correlates of surgical pain were revealed. We are well aware that EEG recordings were not available during actual surgery itself, because of artifacts resulting from head movements, etc. Nevertheless, it can be fairly claimed that recordings obtained immediately after such oral surgery of one hour duration, could reasonably be expected to be associated with a person in pain. But, both by verbal report and available objective data, any surgically induced traumatic pain was of brief duration under hypnosis" (p. 135).

Bauer, Herbert; Berner, Peter; Steinringer, Hermann; Stacher, Georg (1980). Effects of hypnotic suggestions of sensory change on event-related cortical slow potential shifts. Archiv fur Psychologie, 133 (3), 161-169.

"The purpose of this study was to evaluate whether cortical slow potentials related to a S1-S2 paradigm are influenced by hypnotic suggestions of sensory change. Five healthy subjects susceptible to hypnosis participated each in two identical experiments with three conditions. In condition (1) and (2) each three intensities of 800 and 4000 Hz tones were presented. Preceding condition (2) hypnosis was induced and the subjects received the suggestion to hear the 800 but not the 4000 Hz tones. In condition (3), the tones were presented as S1 and a flash as S2. The subjects received the same suggestions as in (2) and a motor response to S2 was required. EEG was recorded from Cz. In (1) 800 and 4000 Hz tones caused negativities of equal amplitude, in (2) only minute negativities developed, possibly due to hypnosis induced deactivation. In (3) the S1-S2 related negativities were significantly smaller in amplitude during 4000 Hz tones than during 800 Hz tones, while the negativities preceding S2 differed only after the most intense S1. Hypnotic suggestions attenuate S1-S2 related negative potentials, possibly by affecting cognitive functions.

## 1978

Lehrer, Paul M. (1978). Psychophysiological effects of progressive relaxation in anxiety neurotic patients and of progressive relaxation and alpha feedback in nonpatients. Journal of Consulting and Clinical Psychology, 46 (3), 389-404.

Gave 10 anxiety neurotic patients 4 sessions of individual instruction in progressive relaxation; 10 patients served as waiting list controls. 10 nonpatients were assigned to each of the same conditions, and an additional 10 nonpatients were given 4 sessions of alpha feedback. Nonpatients showed more psychophysiological habituation over sessions than patients in response to hearing 5 very loud tones and to a reaction time task. Patients, however, showed greater physiological response to relaxation than did nonpatients. After relaxation, the autonomic responses of the patients resembled those of the nonpatients. The effects of relaxation were more pronounced in measures of physiological reactivity than in measures of physiological activity. Defensive reflexes yielded to orienting reflexes more readily in nonpatients than in patients. There was also a tendency for progressive relaxation to generalize to autonomic functions more than alpha feedback.

**Davidson, R. J.; Goleman, D. J. (1977). The role of attention in meditation and hypnosis: A psychobiological perspective on transformations of consciousness. International Journal of Clinical and Experimental Hypnosis, 25, 291-308.**

A temporally based scheme for investigation of changes in consciousness, applicable to areas such as meditation and hypnosis, is proposed and is divided into 3 basic epochs: before -- predispositional variables that affect response to consciousness altering techniques; during -- the state effects of the particular technique; and after -- the trait effects of the practice. Research is surveyed which indicates the role of attentional processes during each of these 3 basic epochs in both meditation and hypnosis. Attentional flexibility is a predispositional variable affecting response to both meditation and hypnosis. The state effects of concentrative meditation involve alterations in stimulus set while the state effects of hypnosis may reflect primarily response set. The trait effects elicited by meditation depend critically on the psychobiological systems which are called into play. Evidence is discussed which suggests that concentrative meditation shares with relaxation an autonomic quiescence, but in addition enhances some attentional skills. A mindfulness technique involving the adoption of a particular attentional stance toward all objects of awareness appears to enhance cortical specificity, but a concentration technique does not. Some implications of attentional self-regulation are discussed.

**Fisher, R. (1977). On flashback and hypnotic recall. International Journal of Clinical and Experimental Hypnosis, 217-235.**

This essay deals with both the intra-individual and inter-individual varieties of arousal state-bound experiences. The former are labelled as "flashbacks" while the latter embrace the great fantasies and repetitive schemes, the ever re-written plots and images of literature, art, and religion.

Flashbacks are both arousal-state and stage (i.e., set and setting) bound experiences. Flashback and hypnotic recall differ only in the ways by which they are induced. Induction methods should be distinguished from induced states on the hyperaroused perception-hallucination and hypoaroused perception-meditation continuum.

Flashbackers may be characterized by their (a) variability on perceptual-behavioral tasks; (b) tendency to minimize (or reduce) sensory input; (c) high resting heart rates; (d) hypnotizability; and, hence (e) preferential right-cerebral-hemispheric cognition; and (f) a display of EEG-alpha dominance in the resting, waking state.

## 1976

Cooper, Leslie M.; London, Perry (1976). Children's hypnotic susceptibility, personality, and EEG patterns. International Journal of Clinical and Experimental Hypnosis, 24, 140-148.

19 boys and 16 girls, aged 7 to 16, were given the EEG and then the Children's Hypnotic Susceptibility Scale, while a parent watched. About 1 week later, after some separate tests and interviews, each child was given a puzzle to solve in the parent's presence, while Es recorded offers and requests for help. Hypnotic susceptibility was positively correlated with the alpha duration with eyes open, but not with eyes closed. Both susceptibility and alpha duration tended to be negatively correlated with age. Highly susceptible children tended to wait longer than low susceptibles before asking parents for help with the puzzle, and their parents tended to be more strict, anxious, and impatient than did the parents of low susceptible children.

Lenox, J. R.; Bonny, H. (1976). The hypnotizability of chronic alcoholics. International Journal of Clinical and Experimental Hypnosis, 24, 419-425.

Research on the hypnotizability of alcoholics is rare, contradictory, and fails to consider the age of alcoholic samples, who are much older than college norm groups. 36 male chronic alcoholics were given the Harvard Group Scale of Hypnotic Susceptibility, Forms A and B of Shor and E. Orne (1962, 1963a), administered individually and then averaged. Alcoholics scored lower, but not significantly so, than controls matched for age and sex. An expected negative correlation of age with hypnotizability was not found. The implications of these results for past studies are discussed.

London, Perry (1976). Kidding around with hypnosis. International Journal of Clinical and Experimental Hypnosis, 24 (2), 105-121.

This paper reviews a long term research project relating hypnotic susceptibility to performance and personality variables. Several experiments indicated that people who are low in hypnotic susceptibility try harder than high susceptibles for maximum performances on strength, endurance, psychomotor coordination, and cognitive tests, though high susceptibles are generally more pleased with their own performances. Other experiments indicated that people of high hypnotic susceptibility have slower brain-wave patterns under relaxed, nonhypnotic conditions, than do low susceptibles. These findings, together with a third set of findings on the developmental character of hypnotic susceptibility, led to the theory that hypnotic susceptibility and brain-wave patterns are both inversely correlated

with achievement motivation and with its developmental roots in childhood independence training. An elaborate research program was initiated to investigate the hypothesized relationships.

**Galin, David (1974). Implications for psychiatry of left and right cerebral specialization: A neurophysiological context for unconscious processes. Archives of General Psychiatry, 31 (4), 572-583.**

A brief review is presented of hemispheric specialization for different cognitive modes, and of the symptoms that follow disconnection of the two hemispheres by commissurotomy. Our present knowledge of the hemispheres' cognitive specialization and potential for independent functioning provides a framework for thinking about the interaction of cognitive structures, defensive maneuvers, and variations in awareness. Parallels are noted between some aspects of the mental processes of the disconnected right hemisphere and some aspects of primary process thinking and repression. The hypothesis is proposed that in normal intact people mental events in the right hemisphere can become disconnected functionally from the left hemisphere (by inhibition of neuronal transmission across the cerebral commissures), and can continue a life of their own. This hypothesis suggests a neurophysiological mechanism for at least some instances of repression and an anatomical locus for the unconscious mental contents.

**Crasilneck, Harold B.; Hall, James A. (1970). The use of hypnosis in the rehabilitation of complicated vascular and post-traumatic neurological patients. International Journal of Clinical and Experimental Hypnosis, 18 (3), 152-158.**

Hypnotherapy has been found of value in rehabilitation of many patients experiencing difficulty in the usual procedures which follow cerebrovascular or traumatic brain injury. 3 cases are reported to illustrate the approach taken. Of 25 similar cases seen over a 9-year period, 4 were unresponsive to hypnosis. Although an increase in motivation for recovery seemed to be the major change elicited by hypnotherapy, other theoretical possibilities are mentioned. Hypnosis may be a useful way of approaching motivational problems in rehabilitating patients who manifest negativism toward conventional treatment.

**1968**

**Bartlett, Esther E. (1968). A proposed definition of hypnosis with a theory of its mechanism of action. American Journal of Clinical Hypnosis, 11, 69-73.**

A definition of hypnosis as a control of the normal control of input (information) for the purpose of controlling output (behavior) is proposed. A theory of the mechanism of action of hypnosis as an increasing integration of the neocortex and the subcortical areas of the brain, with the subcortical areas activated to a greater extent than normally, is postulated.

**Hammer, A. G.; Arkins, W. J. (1964). The role of photic stimulation in the induction of hypnotic trance. International Journal of Clinical and Experimental Hypnosis, 12, 81-87.**

The relative effectiveness of the ordinary verbal method of trance induction is compared with 2 forms of induction utilizing mechanical photic stimulation, and with methods combining the personal and mechanical features. The criterion of trance adopted was the compulsive carrying out of a difficult suggestion. Results show that mechanical procedures alone are ineffective. On the other hand, the addition of a particular sort of photic driving probably improves trance induction, which suggests that induction is a complex matter involving both social interactions and relatively nonmeaningful impacts on the brain. **Levendula, Dezso (1961). Two case presentations: Treatment of central pain with reconstruction of the body-image -- hypnoanalysis of a travel phobia. International Journal of Clinical and Experimental Hypnosis, 9, 283-289.**

**NOTES:**

Uses analogy of phantom limb (hallucinated pain which is a central pain) with a multiple sclerosis patient who had "excruciating" pain between her thighs despite paralysis from waist down due to multiple sclerosis. She valued her sex life though she couldn't feel sexual response, and felt that she "didn't have any legs" and her husband "had to carry her."

In giving her history the patient noted an increasing numbness and weakness in her legs five years earlier. At that time she also entered menopause and developed severe vaginitis. She became depressed when she became increasingly unable control her excretory functions. As the pain in the genital region increased, her ability to feel pleasant vaginal sensations diminished. Ultimately the pain was continually present.

The therapist attributed her problem to a faulty body image because she "denied the existence of her legs which were actually physically present, although, she could neither feel, nor see, nor move them" (p. 285). Secondly, it was most necessary for her to hold on to the myth [sic], that her vagina existed, because it made her feel wanted and needed by her husband. She was unconsciously afraid that by giving up her vagina she would lose the most important bond between herself and her husband" (p. 285).

The therapist speculated that "the pain, which was the last sensation perceived before the total sensory loss occurred, was fixated centrally. This "pain-image" served to maintain the pretense, unconsciously of course, that there was still feeling in the vagina even though it was only pain and not pleasure. The pain permitted her to avoid facing reality, just as in the case of an amputee who develops the fantasy of a phantom limb, because he cannot readjust his pre-existing body-image to the acceptance of mutilation" (p. 285). He offered the patient "the rather simple

explanation... that because she really did not feel where her lower body ended or began, the pain served her need to know where the body halves were separated. If she could learn to imagine and to accept herself as a full, whole person, the pain probably would leave her. This theory seemed very logical and acceptable to the patient" (p. 285).

"Hypnosis was extensively utilized in the following sessions to regress the patient toward her youth. She went again for long walks with her boyfriend, now her husband. It was fun to re-experience the feeling of walking in her father's apple orchard and stretch up for a red apple. Autohypnosis was taught and [he] told her to exercise "walking" while hypnotized twice daily" (p. 285-286). He also tapped on the soles of her feet repeatedly, until she could localize the vibrations. "She finally learned that she did have legs and also that other sensations besides pain could originate below the waist.... Gradually with the acceptance of her "wholeness and tallness" the pain became less and less. She was able to "forget" the pain for a longer period of time. ... Occasionally she does call. She tells [the therapist] that in a stressful situation, such as moving into a new house and not knowing where things are, the pain comes back temporarily, but it is much less and after [they] talk an hour she is relieved" (p. 287). The patient had a total of 20 visits. The author describes a second case, which is not described in these notes.

## 1960

Diamant, J.; Dufek, M.; Hoskovec, J.; Kristof, M.; Pekarek, V.; Roth, B.; Velek, M. (1960). An electroencephalographic study of the waking state and hypnosis with particular reference to subclinical manifestations of sleep activity. International Journal of Clinical and Experimental Hypnosis, 8, 199-212.

(Author's Conclusions) EEG records have been investigated in 10 patients in a waking state and under hypnosis. It was shown that no differences existed between these two states in terms of EEG. EEG signs of decreased wakefulness can be demonstrated in some of the patients, but these were also present without hypnosis. This latter effect appears to be subclinical sleep activity (Roth), frequently seen particularly in neurosis. Reactibility to external stimuli under hypnosis was also, in most cases, equivalent to reactions in the waking state. The authors incline to the view that EEG data does not support the concept that the nature of hypnosis and sleep is qualitatively the same.

Guinazu, S. (1960). Relajacion de Schultz e ionotoforesis calcica trans cerebral. Acta Hipnologia Latino-Americana, 1, 65-67. (Abstracted in American Journal of Clinical Hypnosis, 1962, 5, 75)

The author recommends the use of autogenic training in conjunction with transcerebral calcium iontoforesis for the treatment of neurotic and psychotic disorders. This combined therapy abbreviates treatment time and leads to greater percentage of recoveries. Four cases, taken from over two hundred, are presented and analyzed.

Hernandez-Peon, R.; Dittborn, J.; Borlone, M.; Davidovich, A. (1960). Changes of spinal excitability during hypnotically induced anesthesia and hyperesthesia. American Journal of Clinical Hypnosis, 3, 64. (From 21st International Congress of Physiology, Buenos Aires, 1959, pg. 124, Abstracts)

Although hypnosis is well established, the physiological mechanisms of the hypnotic state and their related sensory phenomena are far from clear. Hernandez-Peon and Donoso have found that the magnitude of photic evoked potentials in the optic radiations of awake human subjects changed in response to previous verbal suggestions concerning the intensity of the expected photic stimulus. This striking observation led the cited authors to propose that certain hypnotic sensory phenomena might be explained, at least partially, by changes occurring as far down as second-order sensory neurons by centrifugal mechanisms controlling the sensory input to the brain. In the intact subject it is impossible to record uncontaminated electrical indexes of afferent impulses from those lower sensory neurons. However, it is possible to gain indirect evidence of tactile sensory inflow to the spinal cord by recording cutaneous reflexes. In young males, a forearm skin reflex evoked by a single square pulse of 0-.1 msec. duration was recorded with cathode-ray oscilloscope. The amplitude of the evoked potentials was often reduced during the hypnotic state, and it was further reduced by verbally suggesting to the hypnotized subject complete anesthesia of the forearm. Reciprocally, during hypnotically suggested hyperesthesia the cutaneous reflex was enhanced. It is concluded that during hypnotic anesthesia and hyperesthesia excitability changes occur at the spinal level, and it is suggested that these changes probably involve the spinal internuncial system interposed between the dorsal root ganglion cells and the motoneurons. (From Abstracts, 21st Internat. Cong. Physiol., Buenos Aires, 1959, p. 124.

**1959**

#### NOTES

"[H]ypnosis is similar to sleep in that it usually begins with muscular relaxation and is accompanied by lack of spontaneous thinking, planning or talking. It is similar to deep concentration in that it excludes from attention everything that is irrelevant" (p. 110). The author summarizes research on brain functions associated with consciousness, especially those of the brain stem activating system, and research evidence of generalized cortical inhibition during sleep (possibly related to the diffuse thalamic system). She views hypnosis as having similar inhibitory effects because the hypnotized person inhibits irrelevant action impulses, "will literally neither act nor think except as the hypnotizer commands or implicitly permits" (p. 115). [Hypnotic] "analgesia can be explained as a depression of the somatosensory limbic cortex which results in appraising the organic sensation as indifferent rather than painful (i.e. as falling within the optimal range of sensitivity)" (p. 115). The author posits a mediating hippocampal action circuit that is associated with the diffuse thalamic system. "The latter mediates the reduction or intensification of neural conduction from sensory areas to limbic cortex and hippocampus, and thus is instrumental in the exclusion of sensory impressions, resulting in lack of pain

or of sensory experience or, conversely, in the production of pain and sensory hallucinations. Suggested action states (e.g. cataplexy) are mediated via the action circuit connecting with the premotor and motor cortex, and represent motor imagination transformed into action. Suggested sensations are mediated via the action circuit connecting with the association and sensory receiving areas, and represent projected memory images which are accepted as real because the impulse to appraise and evaluate has been excluded. Suggested goal-directed actions flow from the suggested situation and are mediated via the action circuit just like any action carried out without hypnosis" (pp. 117-118).

**Kline, Milton V. (1953). Hypnotic retrogression: A neuropsychological theory of age regression and progression. Journal of Clinical and Experimental Hypnosis, 1, 21-28.**

**Author's Summary - In a review of the salient aspects of research in hypnotic age regression an evaluation of the data tended to indicate that under certain conditions valid age regression is discussed in the light of a neuropsychological theory of age regression. This theory based upon a concept of hypnotic retrogression views regression and progression phenomena in hypnosis as a form of psychological activity involving disorientation for the subject and a reorganization of his perceptual equilibrium and control mechanisms with particular reference to time-space perception. The term hypnotic retrogression is used to describe the centrally induced state which alters time-space perception and renders hypnotic regression and progression possible.**

**Karlin, Robert (1997). Illusory safeguards: Legitimizing distortion in recall with guidelines for forensic hypnosis - two case reports. International Journal of Clinical and Experimental Hypnosis, 45, 18-40.**

**Two amnesic automobile accident victims remembered the information needed for their ongoing lawsuits during hypnosis. Meeting the recording requirements of the Hurd safeguards led to the admission of hypnotically influenced testimony in court in one case, whereas failure to record led to exclusion in the other. In both cases, closed-head trauma almost certainly prevented long-term memory consolidation. Thus adherence to guidelines for forensic hypnosis legitimized distortions in recall instead of preventing them. Hypnosis used to facilitate hypermnesia alters expectations about what can be remembered, makes memory more vulnerable to postevent information, and increases confidence without a corresponding increase in accuracy. Distortion of recall is an inherent problem with the use of hypnosis and hypnotic-like procedures and cannot be adequately prevented by any set of guidelines.**

**1993**

**Laidlaw, Tannis M. (1993). Hypnosis and attention deficits after closed head injury. International Journal of Clinical and Experimental Hypnosis, 31, 97-111.**

**In a controlled study of patients attending a concussion clinic because of ongoing postconcussion symptoms, attention deficits were recorded in the head-injured group for the aspects of alertness, assessed by the Continuous Performance Test (CPT), and processing capacity, assessed by a version of the Paced Auditory Serial Addition Test (PASAT). Selective attention was intact. Hypnotizability was assessed by the Harvard Group Scale of Hypnotic Susceptibility, Form A (HGSHS:A), with normal means and standard deviations found in both the concussed and control groups. There was a significant correlation, however, between HGSHS:A scores and PASAT scores in the concussed group only. The results of this preliminary study suggest that slower processing capacity after a closed head injury may predict higher hypnotizability and that hypnosis could be an appropriate rehabilitation technique for these patients who present with postconcussion symptoms.**

**Litwin, R. G.; Cardena, E. (1993, August). Dissociation and reported trauma in organic and psychogenic seizure patients. [Paper] Presented at the annual meeting of the American Psychological Association, Toronto, Canada.**

**Early detection and differential diagnosis of non-epileptic seizures (NES) versus epileptic seizures (ES) is a major clinical issue in comprehensive epilepsy centers. Recent research suggests that differences in dissociative experiences between NES and ES patients may prove useful for diagnostic purposes. Non-epileptic seizures are frequently conceptualized as a dissociative response to past emotional trauma or abuse; dissociation in ES occurs as a result of electrophysiological abnormalities, most often associated with the temporal lobes. The purpose of this study was to evaluate the effectiveness for the differential diagnosis of NES from ES of several measures of dissociation and of a self-report measure for physical and sexual abuse. Four quantitative measures of dissociation were utilized in this study: the dissociative disorders interview schedule (DDIS), dissociative experience scale (DES), Tellegen absorption scale (TAS) and the Stanford Hypnotic Clinical Scale (SHCS). The incidence of sexual and physical abuse was obtained from structured questions in the DDIS. Forty-one patients being evaluated for intractable seizures participated in this study; 13 ES patients with non-temporal lobe involvement (ES/NTL), 18 ES patients with temporal lobe focus (ES/TLE) and 10 patients with NES spells of psychiatric origin. The main researcher was blind to these diagnoses until the study was completed. Results show a trend toward greater incidence of dissociative experiences in the NES versus ES group on the DDIS, TAS and DES, although these differences tended to be modest and not statistically significant, perhaps given the small N of the study. There were no significant trends or differences in dissociative experiences reported by ES/NTL patients versus ES/TLE patients. Contrary to the study's hypothesis, ES patients were slightly more susceptible to being hypnotized than NES patients. As hypothesized, a significant**

difference was that NES patients reported physical and sexual abuse of higher incidence and longer duration than did ES patients. Logistic regression analysis for prediction of NES using the DES, TAS and SHCS instruments correctly predicted only 10% of NES patients. However, exploratory logistic regression analysis using the demographic variables of gender, months of sexual abuse and years of recurrent seizures suggest that these characteristics may be specific and sensitive in the prediction of NES. Being a female, having a higher incidence and longer duration of abuse and fewer years of recurrent seizures all predicted significantly the existence of non-epileptic seizure events, allowing for a 95% accuracy in diagnostic prediction. Our findings reinforce prior research indicating that dissociation is an important symptom component of both ES and NES events. The trend toward more prevalent dissociative experiences in the NES group suggests that in depth examination of these differences and of key demographic variables may help differentiate between these two groups. (ABSTRACT from Bulletin of Division 30, Psychological Hypnosis, Fall 1993, Vol. 2, No. 3.)

## 1992

Appel, Philip R. (1992). Performance enhancement in physical medicine and rehabilitation. American Journal of Clinical Hypnosis, 35, 11-19.

Performance enhancement or mental practice is the "symbolic rehearsal of a physical activity without any gross muscular movements" to facilitate skill acquisition and to increase performance in the production of that physical activity. Performance- enhancement interventions have been well known in the area of sports psychology and medicine. However, clinical applications in physical medicine and rehabilitation have not flourished to the same extent, though the demand for improved physical performance and the acquisition of various motor skills are as important. In this paper I will describe how hypnosis can potentiate mental practice, present a model of mental practice to enhance performance, and describe how to help patients access an ideal performance state of consciousness.

Weber, Alison Mary (1992, October). Hypnosis with brain-injured patients. [Paper] Presented at the annual meeting of the Society for Clinical and Experimental Hypnosis, Arlington, VA.

## NOTES: INTRODUCTION.

The purpose of this paper is a consciousness-raising one. The use of hypnosis with brain-injured people has been relatively neglected with respect to its potential benefit for the patients themselves and also for increasing our knowledge of hypnotic ability. Occasional reports concerning the use of hypnosis with brain-injured patients have appeared (e.g., Crasilneck & Hall, 1970 & 1975; LaClave & Blix, 1989; Manganiello, 1986). However, clinicians often assume that such patients are not able to utilise hypnotic techniques. This assumption appears to derive from three mistaken beliefs: 1. The belief that hypnotic trance ability requires an intact brain. Actually, a fully intact brain is not necessary for entering a hypnotic trance. 2. The belief that brain damage means that the person is totally mentally

incompetent, a "vegetable." In reality there are degrees of brain injury that vary from coma or vegetative state through to relatively mild changes in ability that may not be immediately obvious yet significantly impact the person's functioning in everyday life. 3. The belief that brain-damaged individuals are identical with respect to their type of cognitive disability. In actual fact, the cognitive and other effects of brain injury vary according to location within the brain's functional systems.

#### **CASE EXAMPLES.**

All four cases are people of apparently average or better ability prior to injury as judged from their educational and vocational history. Before discussing these examples, I should point out that the basic induction technique used has generally been the same one that I use with non-brain-injured people. This technique is one that encourages mental and physical relaxation and a mental attitude of passivity and dissociation (Weber, 1981). All were taught to use self-hypnosis as a means of making the benefits available as needed. No hypnotizability scales were used and the issue of using such scales with brain-injured people will be commented upon later.

CASE 1 is a 39 year-old man who fell hitting his head and sustaining a closed head injury. The main effect of that injury was severe slowing of information processing speed. This problem is a common one in cases of closed head injury, is thought to be related to diffuse microscopic axonal injury, and causes experiences of mental fatigue, overload, and stress. The mentally passive, relaxed dissociative state offered through hypnosis helps prevent and reduce these overload problems. In this patient's case, his use of the hypnotic technique enabled him to increase his daily activity level from one of mainly sleeping and resting in darkened rooms to one that included a live-in relationship with his former wife and engaging in hobbies and social activities.

CASE 2 is a 22 year-old man who had a malformation of blood vessels in the left temporoparietal area of the brain. He was undergoing surgical correction of this malformation when it hemorrhaged and he was left aphasic and paralysed down the right side of his body. At the time of hypnotic treatment, he had switched to using his left hand for writing, was able to walk though with a limp, and was able to converse intelligibly but with some underlying language difficulties. He particularly complained of right-sided pain and general numbness of his body. Post-hypnotic suggestions about his body feeling normal and solid together with imagery related to swimming were effective in eliminating the pain and reducing the numbness so that he experienced his body as comfortable and "more normal." He was so comfortable physically that he started earning a living by mowing lawns.

CASE 3 is a 40 year-old man who fell at work, sustained a closed head injury, was unconscious for 1.5 hours, and had no recall of events for 2.5 days after injury. Five years later he still showed a very disorganised and fragmented memory that was suggestive of frontal system dysfunction. He was also able to recall very little of his life prior to injury and this lack of autobiographical memory was very disconcerting to himself and to his family. He was able to benefit from post-hypnotic suggestions concerning his ability to form associations to pictures in the family photo album. These associations were then used as a basis for his making a written autobiographical outline to which he could refer as needed.

**CASE 4 is a 47 year-old man who was showing subtle changes in personality over about 10 years, suddenly had a severe grand mal seizure during which he stopped breathing, and was found to have a large meningioma arising from the falx and extending bilaterally over the top of his brain. There was also evidence of recent hemorrhage within the tumor. The tumor was surgically removed but due to its previous pressure on the brain and to possible anoxia when he stopped breathing, he was left with cognitive problems of poor planning and organizing, slowed mental processing, and memory problems secondary to these other problems. He also showed emotional lability and disinhibition and physical problems that at first involved paralysis but later improved to leg weakness and spasticity and arm weakness and incoordination. Hypnotic techniques helped this patient in several ways: (a) Mental relaxation and dissociation resulted in better emotional control and some relief of the painful knotting of his leg muscles. (b) Age regression was successful in improving his manual coordination for the purpose of accordion playing, an activity of great emotional significance to this patient and his wife. During regression to age 15 years, he reported a twitching of his arm muscles (also observed by the therapist), a feeling that his arms and hands could "move more freely and flexibly as if a resistant force had been removed," and a feeling like "electrical recharging and reconnecting." His accordion playing noticeably improved from about 15 percent to about 90 percent competency and he was able to play again from memory for the first time since his surgery. (c) Post-hypnotic suggestions about his brain connecting to his leg muscles and these muscles working smoothly resulted in his being able to walk around the block without cramping for the first time since his surgery and a few weeks later he was able to walk for four or five hours in the mall instead of being limited to 30 minutes. (d) The patient also reported generally improved well-being as "having more energy, like another veil has been taken off so that things look sharper and more in focus."**

**These four cases represent just a few of the ways brain-injured people can be helped by hypnosis. There are sure to be more ways just as there are for people with normal brains. In order to adapt hypnotic techniques to the needs of brain-injured people, some understanding of their particular brain-function problems is important.**

#### **HYPNOSIS AND BRAIN FUNCTION.**

**Because of time limits only a very quick and simplified overview of brain function can be provided but it should serve to give a general "feel" for a neuropsychological orientation to hypnosis with brain-injured people. It is based partly on Luria's model of brain function (Luria, 1973).**

**1. Arousal and Some Physiological Functions.** These functions involve the brain stem. Arousal functions include sleeping/waking, consciousness/coma, and level of general alertness. The brainstem also controls various physiological functions such as breathing, heart rate, and blood pressure.

**2. Knowledge.** Information from auditory, visual, and somesthetic path ways generally goes to the posterior half of the brain on the side opposite that of stimulus presentation. There are three levels of processing: (a) Primary processing involving initial registration and consciousness of stimuli; (b) Secondary perceptual

elaboration of sensory input so that it makes perceptual sense. For example, in the visual modality the lines and colors registered in the primary area are organized into cohesive shapes in the secondary area. (c) Tertiary processing involves integration of input across modalities, for example, the ability to associate an auditorally heard word with the visually presented object it symbolizes.

**3. Action.** This aspect of brain function includes both motor and mental performance and embraces physical action, speech, and active thinking such as generating ideas and problem-solving. It is located in the anterior half of the brain and also has three levels: (a) Primary control of discrete muscle groups which mainly involves one side of the brain controlling the opposite side of the body; (b) Secondary areas underlie the ability to organize discrete muscle groups into a sequence such as brushing one's teeth; (c) Tertiary executive areas which are critical to the generation of purposive behaviour, goals, plans, self-monitoring and adaptation.

**4. Lateralization of Cognitive Function.** The two cerebral hemispheres are usually specialized in the following way for most right-handed people: (a) Left Hemisphere language; symbolic, analytic, sequential type thinking; and probably motor planning. (b) Right Hemisphere visuospatial, melodic, holistic, synthetic thinking.

**5. Information Processing Speed.** This aspect of mental function seems to depend on the axonal connections that form the white matter of the brain. Speed of information processing refers to the amount of information that can be attended to and processed within a given amount of time and includes both external stimuli like sights and sounds and also internal ones such as thoughts and memories.

**6. New Learning and Memory.** This feature of our abilities involves moving initially registered information into long term storage. The hippocampus is particularly critical in this process. The thalamus is thought to play a part in cued recall. General strategies for encoding and retrieval are probably influenced by frontal system function.

**7. Emotional and Motivational Function.** These functions appear to relate to the limbic system and basomedial frontal areas of the brain. These areas influence emotional intensity, emotional and social self-control, and motivation to initiate action.

**8. Attention.** Attentional function involves several brain areas. The brainstem is responsible for general arousal and level of alertness, white matter connections contribute to how much information a person can attend to and process within a given time, and the frontal cortex and its connections direct and organize the purposive focus of attention.

Any given mental or behavioral ability depends upon a complex system of brain areas and levels of processing. The effects of brain injury vary according to location and severity of damage, and also the person's pre-injury condition and life style.

Obviously, the induction and suggestion techniques of hypnosis need to be based upon a neuropsychological understanding of the patient's cognitive strengths and weaknesses. These factors also need to be considered when interpreting hypnotizability scores on standard scales and perhaps special scales need to be devised for work with such patients. The most common cognitive deficits

encountered when working with brain-injured patients in the post-acute rehabilitation programs with which I have been associated have been those impacting memory, information processing speed, and executive function. Specific comments about these areas of deficit as they impact hypnosis are now given

**Memory.** A person with a defective ability to store new information (related to hippocampal dysfunction) is going to do well with post-hypnotic suggestions of amnesia but is probably not going to recall the items even when the amnestic suggestion is removed or if positive post-hypnotic suggestions are given. The patient with thalamic based memory difficulty may later be able to recall information but only provided a cuing structure of prompts or reminders is built into the suggestions. Whether or not memory ability in those with organically based memory deficit can be enhanced through hypnosis remains unclear. The patient presented earlier whose autobiographical memory difficulties were helped by hypnotic techniques did not have a storage problem per se but rather a very disorganized memory that probably stemmed from frontal type problems.

**Information Processing Speed.** Reduced speed of processing may necessitate giving instructions more slowly or in such a repetitive and redundant manner that some gaps in the patient's registering what is said don't matter. It is also important for such patients not to mentally overload them. For example, case #1 benefitted from the mental relaxation/ dissociation aspects of hypnosis and was able to mentally block out noise to which he was hypersensitive but the mental effort involved in such blocking-out resulted in his feeling mentally exhausted and stressed.

**Executive Function.** Patients with frontal system dysfunction show some deficits that are similar to hypnotic phenomena in people without brain dysfunction. From this point of view, they may be the most promising group to work with to clarify the nature of hypnosis. The hypnotized patient's responses in conforming to suggestion resemble the stimulus-bound and concrete focus and time-distortive aspects of frontally dysfunctional behavior and perhaps also its confabulatory tendencies. The frontal patient may also show a dissociation between knowing and doing that is similar to the split reported by some people in being aware of and observing their own behavior at the same time as they respond to hypnotic suggestions. There is a sense in which the hypnotist acts as the "frontal lobes" of the hypnotized person, giving direction to their perceptions and behavior. The similarities between the two groups certainly invite further exploration and research.

### **1991**

Sapp, Marty (1991, August). The effects of hypnosis in reducing anxiety and stress in adults with neurogenic impairment. [Paper] Presented at the annual meeting of the American Psychological Association, San Francisco.

A repeated measures design was utilized to investigate the effects of hypnosis in reducing anxiety and stress in 16 adults with neurogenic impairment. Seven sessions were used to measure the efficacy of hypnosis. Session one was used to obtain a baseline level of anxiety and stress and to initiate hypnosis. Sessions three and six were used to obtain repeated measures of these emotions. Sessions two, four, and five were the treatment sessions. Session seven was used to conduct a four week follow-up on the effects of hypnosis. Levels of anxiety were measured by the State-Trait Anxiety Inventory, while stress was measured by the State-Trait Anger Expression Inventory. The results indicated a statistically significant decrease in anxiety and stress. Hypnosis also significantly increased levels of self-esteem. Finally, follow-up data demonstrated that the treatment gains were maintained.

### **1989**

Holroyd, Jean; Hill, Alexis (1989). Pushing the limits of recovery: HypnoHypnotherapy was used to assist recovery of left arm function following stroke in a 66-year-old woman. Treatment protocol is described, and results are discussed in terms of how hypnosis may facilitate voluntary motor movement. Recent literature on cortical changes in hypnosis and motor improvement during hypnosis is discussed in relation to the present results.

### **NOTES:**

The patient was 6 months post-stroke and physicians did not expect much additional improvement. She improved despite the fact that she measured as a low hypnotizable on the Stanford Scale, Form C. However, she appeared very absorbed in the hypnotic imagery, and she was highly motivated and exhibited much hope or positive expectation. Also, the author notes that "remarkable improvements in brain functioning have been reported through the use of sophisticated behavioral technology," (p. 124), as in the use of EEG biofeedback to treat untractable seizures (Serman & Lanz, 1981).

In rehabilitation cases, hypnotic dissociation may enhance pain control during the performance of exercises; more vivid hypnotic imagery may facilitate mental rehearsal of movements; attitudes may be reframed using hypnotic suggestion; and focusing attention on bodily sensations may be enhanced with hypnosis. Hypnosis also may improve expectancy, reduce anxiety, increase hope, provide general relaxation (reducing involuntary spasticity), increase cerebral blood flow, or in other ways promote healing.

Research by Pajntar, Roskar, & Vodovnik (1985) has demonstrated improved motor response during hypnosis for patients with hemiparesis. They attributed EMG changes under hypnosis "to a facilitory influx from supraspinal motor centers. They hypothesized that new motor units of paretic muscles were being activated or that there was an increased recruitment of the motor units already active, and they suggested that relaxation of the spastic antagonist muscle permits the paralyzed muscle to move" (p. 125).

LaClave, Linda J.; Blix, Susanne (1989). Hypnosis in the management of symptoms in a young girl with malignant astrocytoma: A challenge to the therapist. International Journal of Clinical and Experimental Hypnosis, 37 (1), 6-14.

This paper presents the case of a 6.5-year-old girl with malignant astrocytoma of the left brain hemisphere. During the course of her chemotherapy treatment, severe vomiting developed to the degree that on several occasions she became dehydrated. Discontinuation of chemotherapy was being considered when she was referred for hypnotherapy. Despite severe neurological impairments which excluded many traditional techniques, hypnosis was successful in eliminating emesis. Hypnosis was also utilized to decrease pain and to improve sleep patterns. Drawings are presented to help show how this child resolved anxiety associated with treatment and fears surrounding the knowledge of her impending death.

Borgens, Richard B. (1988). Stimulation of neuronal regeneration and development by steady electrical fields. In Waxman, S. G. (Ed.), Functional recovery in neurological disease (47, pp. 547-564). New York: Raven Press.

## NOTES:

At the end of the review, author notes that a combination of electromyography and computer modeling of agonist-antagonist, flexor-extensor muscle contraction patterns in the functional body parts of hemiparetic patients, artificially imposed on the paralyzed portions of the body using repetitive electrical stimulation to effect more normal movement, sometimes leads to functional recovery. Such recovery has been observed in some chronic cases of paralysis associated with head injury, stroke, and cerebral palsy. These clinical observations challenge the way we should view paralysis in general. Perhaps there are many redundant pathways in the CNS that will support certain kinds of functional return in the absence of the original pathways destroyed by trauma. Perhaps CNS-associated paralysis is a problem, at least in part, of too much competing signal in spared pathways, not one of impoverished signal. Can use of these neuronal pathways be entrained or retrained? Is the return of function in patients who experience repetitive functional electrical stimulation due to a reorganization within the CNS? These are exciting questions whose answers will possibly lead to our ability to further modify the plasticity of the brain and spinal cord.

[This would fit with the inhibition model of hypnosis, and with the high theta power findings during hypnosis, the implication being that hypnosis facilitates filtering out non-essential competing stimuli.]

**1986**

**Thompson, Cynthia K.; Hall, Howard R.; Sison, Cecile E. (1986). Effects of hypnosis and imagery training on naming behavior in aphasia. Brain and Language, 28, 141-153.**

The effects of hypnosis and imagery training on the naming behavior of three subjects with Broca's aphasia were investigated using a multiple baseline design across subjects. Treatment consisted of the induction of hypnosis, followed by guided imagery focused on the physical and functional attributes of stimulus objects. Measures of naming ability on both trained and untrained items were taken at baseline, after every training session, and a few hours after training each day. Measures were also taken of imagery ability, hypnotic susceptibility, and psychological state. Results indicated that treatment facilitated improvement in naming ability, over baseline level, for two subjects. In the case of the third subject, the verbal label was incorporated into the imagery procedure following 10 training sessions. Subsequently, this subject's naming behavior improved over baseline level. The results are discussed in terms of current theory and research in neuropsychology and cognitive psychology.

**1985**

**Tranel, Daniel; Damasio, Antonio R. (1985, June). Knowledge without awareness: An autonomic index of facial recognition by prosopagnosics. Science, 208 (4706), 1453-1454.**

Prosopagnosia, the inability to recognize visually the faces of familiar persons who continue to be normally recognized through other sensory channels, is caused by bilateral cerebral lesions involving the visual system. Two patients with prosopagnosia generated frequent and large electrodermal skin conductance responses to faces of persons they had previously known but were now unable to recognize. They did not generate such responses to unfamiliar faces. The results suggest that an early step of the physiological process of recognition is still taking place in these patients, without their awareness but with an autonomic index.

**1984**

**Smith, Mark Scott; Kamitsuka, Michael (1984). Self-hypnosis misinterpreted as CNS deterioration in an adolescent with leukemia and Vincristine toxicity. American Journal of Clinical Hypnosis, 26 (4), 280-282.**

A thirteen year-old girl with leukemia was taught self-hypnosis techniques for symptom control. She was hospitalized with probable vincristine toxicity and a superimposed hyperventilation syndrome. Her spontaneous use of the self-hypnosis technique was misinterpreted as central nervous system deterioration until her apparently comatose state resolved with suggestions from the therapist.

**1981**

Gravitz, Melvin A. (1981). Non-verbal hypnotic techniques in a centrally deaf brain-damaged patient. International Journal of Clinical and Experimental Hypnosis, 29, 110-116.

Non-verbal techniques across several sensory dimensions were utilized with a brain-damaged centrally deaf 36-year-old female patient who had been referred for hypnotherapeutic relaxation. These included optical fixation on the therapist's hand with gradual thumb and fore-finger closure, vibratory stimuli, light shoulder pressures, arm stroking, manually facilitated air currents, and reinforcing homework assignments. With hypnotherapy, the patient's physical and emotional behavior was reported by her to have improved to a significant degree.

**1977**

Lazar, Billie S. (1977). Hypnotic imagery as a tool in working with a cerebral palsied child. International Journal of Clinical and Experimental Hypnosis, 25 (2), 78-87.

Hypnotic imagery was used with a moderately severe athetoid cerebral palsied 12-year-old boy who was mildly retarded and a poor hypnotic subject. Techniques included imagery, observation of the self, revivification of relaxing experiences, proprioceptive feedback about the athetoid movements, and dealing with feelings and motivation. Athetoid movements were reduced, results extended beyond the treatment situation, and improvement was made in practical skills.

**1976**

Cedercrentz, C.; Lahtenmaki, R.; Tulikoura, J. (1976). Hypnotic treatment of headache and vertigo in skull injured patients. International Journal of Clinical and Experimental Hypnosis, 24, 195-201.

Symptoms of headache and vertigo were treated using direct hypnotic suggestions of symptom relief in 155 consecutive skull injured patients. Posttraumatic headache and vertigo were completely relieved after an average observation period of 1 year 10 months in 50% and 58% of the patients, and partially relieved in 20% and 16% respectively. Most of the relief was achieved after about 4 weekly sessions and, particularly with the headaches, only if treatment began within a few weeks of the injury. Therapeutic outcome was correlated with depth of hypnosis achieved for both headache ( $r = .44, p < .0001$ ) and vertigo ( $r = .47, p < .0001$ ) symptoms. Patients who could not even achieve light hypnosis obtained no therapeutic improvement, but patients who experienced only light hypnosis were as clinically responsive as those achieving deep hypnosis.

**1970**

Crasilneck, Harold B.; Hall, James A. (1970). The use of hypnosis in the rehabilitation of complicated vascular and post-traumatic neurological patients. International Journal of Clinical and Experimental Hypnosis, 18 (3), 152-158.

Hypnotherapy has been found of value in rehabilitation of many patients experiencing difficulty in the usual procedures which follow cerebrovascular or traumatic brain injury. 3 cases are reported to illustrate the approach taken. Of 25 similar cases seen over a 9-year period, 4 were unresponsive to hypnosis. Although an increase in motivation for recovery seemed to be the major change elicited by hypnotherapy, other theoretical possibilities are mentioned. Hypnosis may be a useful way of approaching motivational problems in rehabilitating patients who manifest negativism toward conventional treatment.

#### **1964**

Webb, Robert A.; Nesmith, C. C. (1964). A normative study of suggestibility in a mental patient population. International Journal of Clinical and Experimental Hypnosis, 12 (3), 181-183.

The postural sway technique was used to make suggestibility measurements on a total of 490 Ss of which 279 were hospitalized psychiatric patients. The remaining Ss were "normal" college students. The "normal" Ss were significantly more suggestible than the psychiatric group. Within the psychiatric group, the psychotics, nonpsychotics, and organics differed significantly, with the nonpsychotics being least suggestible, the psychotics most suggestible, and the organics intermediate. The hospital group was further reduced into diagnostic subcategories and postural sway parameters were shown. The sample distributions were essentially normal although the sample drawn from a psychiatric population showed positive skewness. (PsycINFO Database Record (c) 2002 APA, all rights reserved)

#### **1960**

McCord, Hallack (1960). A note on a change in mental age accompanying hypnosis of a teen-age-girl. International Journal of Clinical and Experimental Hypnosis, 8 (4), 259-262.

#### **NOTES**

1:

An adolescent with questionable diagnosis (mental retardation due to organic brain damage or functional psychological disorder) was given the E-G-Y test for an estimate of verbal intelligence. After initial testing, in which attention span was limited and she was very negativistic, she was re-tested in light hypnosis. Her mental age "more than doubled -- went up by six years -- "in the intervening 24 hours. The author ascribes improvement to relaxation from light hypnosis and opined that the 10 year level achieved under hypnosis was close to her "true" level of functioning. Subsequent attempts to hypnotize her were not successful, possibly due to short attention span and negativistic tendencies.

#### **1953**

Kirkner, Frank J.; Dorcus, R. M.; Seacat, Gloria (1953). Hypnotic motivation of vocalization in an organic motor aphasic case. Journal of Clinical and Experimental Hypnosis, 1 (3), 47-49.

**Authors' Summary - A 41 year old male patient with a history of mutism on an organic basis for a year and a half failed to respond to speech retraining efforts. Comprehension was good and motivation poor. With the aid of hypnosis, he was induced to vocalize. Following vocalization, oral speech retraining progress was steady. Retraining efforts in writing met with repeated failure.**

**Anbar, Ron (2002, Dec 3). Hypnosis in pediatrics: applications at a pediatric pulmonary center.. BMC Pediatrics, 2 (1), 11-18.**

**This report describes the utility of hypnosis for patients who presented to a Pediatric Pulmonary Center over a 30 month period.**

**METHODS: Hypnotherapy was offered to 303 patients from May 1, 1998 - October 31, 2000. Patients offered hypnotherapy included those thought to have pulmonary symptoms due to psychological issues, discomfort due to medications, or fear of procedures. Improvement in symptoms following hypnosis was observed by the pulmonologist for most patients with habit cough and conversion reaction. Improvement of other conditions for which hypnosis was used was gauged based on patients'" subjective evaluations.**

**RESULTS: Hypnotherapy was associated with improvement in 80% of patients with persistent asthma, chest pain/pressure, habit cough, hyperventilation, shortness of breath, sighing, and vocal cord dysfunction. When improvement was reported, in some cases symptoms resolved immediately after hypnotherapy was first employed. For the others improvement was achieved after hypnosis was used for a few weeks. No patients'" symptoms worsened and no new symptoms emerged following hypnotherapy.**

**CONCLUSIONS: Patients described in this report were unlikely to have achieved rapid improvement in their symptoms without the use of hypnotherapy. Therefore, hypnotherapy can be an important complementary therapy for patients in a pediatric practice.**

## **1996**

**Kohen, Daniel (1996). Relaxation/mental imagery (self-hypnosis) for childhood asthma: Behavioural outcomes in a prospective, controlled study. Australian Journal of Clinical and Experimental Hypnosis, 24 (1), 12-28.**

Twenty-eight 7-12-year-old children entered a controlled study of the effects of self-hypnosis on asthma. Asthma belief and behavioural inventories were collected before, and at one and two years after intervention. Asthma diaries were kept daily and mailed monthly. Subjects were randomly assigned to (a) experimental (self-hypnosis), (b) waking suggestion (no hypnosis), (c) attention placebo (no hypnosis or asthma discussion), or (d) traditional control groups. Twenty-four completed one-month follow-up, 16 completed six months, and 13 completed two years. Results included: (a) fewer emergency room visits in the experimental group ( $p < 0.05$ ); (b) less school missed in the experimental group compared to the traditional control group ( $p < 0.001$ ) and to the waking suggestion group ( $p < 0.005$ ); (c) no differences in psychological evaluations between groups; and (d) surprising findings regarding hypnotic and hypnotic-like experiences among subjects.

**Jones, M. M. (1994). Apnea in postsurgical hypnotherapy of an esophageal cancer patient: A brief communication. International Journal of Clinical and Experimental Hypnosis, 42 (3), 179-183.**

Use of clinical hypnosis in the postsurgical psychotherapy of an esophageal cancer patient who could not swallow involved reenactment of the successful surgery and producing hallucinations of taste and smell, as well as working through emotions relating to the surgery and her disease. An apnea that occurred in a late phase of the treatment was addressed with the familiar arm pumping technique that had been used as a deepening technique, resulting in the patient's resuming normal breathing. The experience reminds the practitioner of the possible unexpected professional demands when working in a medical environment. It also provides clues as to the underlying psychological mechanisms and their role in successful symptom removal. A 6-year follow-up confirmed the lasting effect of this brief psychotherapy.

## **1993**

**Kraft, Tom (1993). Using hypnosis with cancer patients: Six case studies. Contemporary Hypnosis, 10, 43-48.**

Hypnosis can be used in a number of different ways for helping patients suffering from cancer. As well as pain relief, hypnosis may be used to correct insomnia that does not respond to sleeping tablets; for the reduction in skin irritation and dyspnoea when these are due to organic causes, and for treatment-related over-eating. Some patients will use hypnosis in a symbolic way. When this occurs, just as in dream interpretation, it is important to ask the patient for associations, so that these symbols can be understood. Hypnosis can be an extremely useful addition to the medical armamentarium, and should be employed as an adjunct to standard forms of cancer treatment. This paper reports six case studies in which hypnosis was used to help cancer patients.

Morgan, William P. (1993, October). Use of hypnosis in exercise and sport psychology. [Paper] Presented at the annual meeting of the Society for Clinical and Experimental Hypnosis, Arlington Heights, IL.

**NOTES:**

Performance of exercise is rated as equal effort with hypnosis and waking conditions; but with hypnotic suggestion they will perceive it as more or less effortful (uphill exercise vs going down the hill). When they think they are going up hill both cardiac and respiratory response increase physiologically, with catecholamine differences.

Mitchell (1981) suggests that respiration changes with exercise do not result from muscle feedback, but that central motor brain signals go to both the cardiovascular centers and to exercising muscle. Actually, it appears that both muscle and cortex give signals, and their synergy governs whether ventilation or heart rate increase.

Wang & Morgan, Psychophysiological responses to imagined exercise, Sport Psychology Lab, University of Wisconsin-Madison. Reported that both external (watching someone else) and internal (imagining oneself) visualizing give responses similar to actual exercise.

We have done research on the prediction of respiratory distress (dyspnea) - work we have done with fire fighters. The best predictor of this on treadmill with air supply is trait anxiety. Sometimes the firefighters who took off face mask even though they had air did not know why they did. It is an opportunity to use hypnotic age regression. SCUBA divers described in Lynn & Rhue also were age regressed to obtain information that was repressed. They have demonstrated stress responses like panic in a 12 foot tank also.

For active people and athletes there is an "iceberg" profile on the POMS, below average on tension, depression, anger, fatigue, and confusion, but higher on vigor. But the divers who panic have a flat profile, around the 50th percentile on all POMS scales.

Middleman et al used Navy divers in 25 degree C. water and used hypnosis to increase and decrease their body temperature--one of the best papers on the topic. Ss who were best able to use imagery, to think of a beach, had the poorest responses; the ones who could relax did poorest, because shivering produces heat and keeps you warm. It is opposite of what is needed.

In our work, we took 5 highest and 5 lowest anxiety Ss; the latter had higher rates of respiration than the former.

All Ss are similar in oxygen use whether volunteers or not. When people volunteer for research before they know hypnosis will be used, the males are lower than females [on hypnotizability?] when they finally volunteer. [He presents a lot of different tests on which volunteers do not differ from nonvolunteers personality wise.]

Ikai & Steinhaus is a classic study of Disinhibition of Inhibitory Mechanisms. Taking Ss up to their maximum (in weight training) to a plateau, Ikai & Steinhaus said this is a pseudomaximum. They showed that strength increases if - you fire a starter pistol behind them - you ask them to shout just as they do it - they have alcohol - they have amphetamine sulfate - they have hypnosis It is disinhibition of the inhibitory mechanisms.

[He referred to the book Mind of the Marathoner.]

In Tibet an anthropologist was amazed to see a man running into their camp, and he ran straight through--a monk carrying messages. He created a non-cultic form of meditation in the laboratory (trained to visually "fix" on mountaintop, to have respiration in synchrony with locomotion, and to use a pseudo mantra "down" each time they put their foot down). Placebo condition was used also. Ss were tested by blinded lab assistants. Endurance time increased from 16 minutes to 20, while controls decreased a minute.

Now we can predict who will win a race. Elite runners do not dissociate; they use association strategy. They pay close attention to race strategy, they monitor themselves constantly (they slow down when they feel bad), and attempt informally to stay loose, not get tight, and relax. Dissociation has, however, been used for the last 300 meters of a marathon (New Zealander Dixon).

## 1992

Garssen, Bert; de Ruiter, Corine; Van Dyck, Richard (1992). Breathing retraining: A rational placebo?. Clinical Psychology Review, 12, 141-153.

Breathing retraining of patients with Hyperventilation Syndrome (HVS) and/or panic disorder is discussed to evaluate its clinical effectiveness and to examine the mechanism that mediates its effect. In relation to this theoretical question, the validity of HVS as a scientific model is discussed and is deemed insufficient. It is concluded that breathing retraining and related procedures are therapeutically effective, but probably due to principles other than originally proposed, namely decreasing the tendency to hyperventilate. An alternative principle is the induction of a relaxation response, presenting a credible explanation for the threatening symptoms, giving a distracting task to practice when panic may occur, and promoting a feeling of control.

## NOTES:

Goal of treatment is to (1) reduce respiratory rate, and (2) cognitive reattribution of physical symptoms to hyperventilation instead of other more catastrophic causes. Reviews a number of studies, mostly small sample, including panic disorder studies,

and concludes that the majority point to a therapeutic effect of breathing retraining and cognitive reattribution of physical symptoms to hyperventilation for patients suffering HVS and the closely related panic disorder with or without agoraphobia. However, the specificity of these techniques for HVS is questionable. Vlaender-van der Giessen (1986) found relaxation training just as effective as breathing retraining; and Hibbert & Chan (1989) found breathing retraining equally effective as a placebo treatment, and not more effective with patients who had recognized symptoms at a hyperventilation provocation test than with those who had not.

Isenberg, S. A.; Lehrer, P. M.; Hochran, S. (1992). The effects of suggestions and emotional arousal on pulmonary functions in asthma: A review and a hypothesis regarding verbal mediation. Psychosomatic Medicine, 54, 192-216.

This paper reviews the empirical literature on the relation between asthma, suggestion, and emotion, and proposes the hypothesis that these effects are mediated parasympathetically. The literature indicates that, among asthmatics, suggestion can produce both bronchoconstriction and bronchodilation, and that stress can produce bronchoconstriction. The proportion of asthmatic subjects showing bronchoconstriction to both suggestion and stress averages 35%-40% across studies, but, because of methodological considerations, might be conservatively estimated as closer to 20%. The effect is smaller for suggestion of bronchodilation, and is very short-lived among nonasthmatics. No clear connection has been found between these responses and such subject variables as age, gender, asthma severity, atopy, or method of pulmonary assessment, although some nonsignificant tendencies appear. Most studies in this literature used small n's and did not systematically examine various somatic, environmental, and demographic factors that could influence results. A hypothesis is presented regarding vagal mediation of psychological effects on the airways, as well as possible alternative mechanisms, and recommendations for future research to evaluate these hypotheses.

Isenberg, S. A.; Lehrer, P. M.; Hochron, S. (1992). The effects of suggestion on airways of asthmatic subjects breathing room air as a suggested bronchoconstrictor and bronchodilator. Journal of Psychosomatic Research, 36, 769-776.

Thirty-three asthmatic subjects were told they were receiving, alternately, an inhaled bronchoconstrictor and inhaled bronchodilator, although they actually were only breathing room air. No subjects showed suggestion-produced effects on FEV1, although two (of the 19 on whom FEF50 was measured) showed effects of greater than 20% on measures of maximal midexpiratory flow. The incidence of the effect is smaller than reported previously, possibly because some subjects in previous studies inhaled saline, a mild bronchoconstrictor, and reversal of effect was not required for classification as a reactor. Higher percentages of subjects in this study showed decreased MMEF in response to the "bronchoconstrictor", but this appeared to reflect fatigue rather than suggestion effects. However, the fact that the effect occurred in a relatively non-effort-dependent measure suggests that real changes occurred in bronchial caliber, not just in test effort. Suggestion had a significant

effect on perception of bronchial changes, but the correlation between actual and perceived changes was minimal. There was an increase in FVC prior to administration of the "bronchoconstrictor", possibly reflecting a preparatory response to the expected drug. Correlations among self-report variables suggested the existence of three personality dimensions among our population related to suggestion and asthma: cognitive susceptibility to suggestion of bronchial change; feeling of physical vulnerability; and anxiety. However, there was no significant relationship between airway response to suggested changes and hypnotic susceptibility, as measured by the Harvard Group Scale of Hypnotic Susceptibility.

### **1991**

**Acosta-Austan, Frank (1991). Tolerance of chronic dyspnea using a hypnoeducational approach: A case report. American Journal of Clinical Hypnosis, 33, 272-277.**

A 48-year-old woman with severe, chronic obstructive pulmonary disease was instructed in the use of peak-flow feedback and hypnotically induced relaxation to reduce the intensity of dyspnea during periods of anxiety. Peak-flow information provided physiologic feedback as well as a safety feature in the event that subjective improvement did not correspond with objective physiologic improvement. I used a progressive relaxation method for inducing hypnosis and gave her suggestions of well-being and muscle relaxation. Peak-flow feedback was useful in enhancing the patient's confidence that hypnotic relaxation was successful in improving respiratory function.

**Kleinhaus, Moris (1991). Prolonged hypnosis with individualized therapy. International Journal of Clinical and Experimental Hypnosis, 39 (2), 82-92.**

A therapeutic approach is presented which involves the use of prolonged hypnosis for the treatment of diverse medical and/or psychological conditions, including intractable pain. This approach may be indicated either as a complementary tool used in conjunction with other treatment approaches or as the only method of intervention. The technique is based on achieving a prolonged hypnotic response, during which hypno-relaxation serves as the foundation for the delivery of an individualized therapeutic plan which includes self-hypnosis, suggestive procedures, metaphors, and constructive imagery techniques. In debilitated patients, medical supervision and nursing care are essential, and hospitalization is recommended if necessary. Theoretical assumptions underlying this approach are presented, and clinical implications are discussed. The method is illustrated through case presentations.

### **NOTES:**

The general procedure involves: 1. A flexible plan concerning the duration of treatment: days, weeks, or longer. 2. Information is given to the patient, the family and the medical staff if in hospital. Emphasize that while the patient may be in a 'twilight-like' state, most of the time he/she is able to fulfill his or her basic

physiological needs, (drinking, eating, taking care of personal cleanliness, etc.). 3. The method of hypnotic induction is individualized. 4. The patient is trained in self-hypnosis, and for using signals for induction and dehypnotization either for self hypnosis or for the hypnotist to use. Thus if there is a physiological or emotional need for self-hypnosis the patient can do it. Suggestions and training are given and reinforced concerning the patient's capability to fulfill his/her basic physiological needs. 5. The family and/or the medical staff are instructed and trained in induction and dehypnotization, until the patient responds to them satisfactorily. 6. At this stage, therapeutic suggestions aimed at ego-boosting and a change of attitudes and meanings towards the symptom and symptom removal/amelioration/substitution are added. 7. Metaphoric constructive imagery is introduced when indicated. 8. If required, other hypnotic phenomena are elicited and used (e.g. dissociation, time distortion, age regression, rehearsal, hypno/analgesia, change of muscular tonus, displacement of emotions, abreaction, etc.). 9. An audio cassette which contains the wording of the therapeutic intervention is used with some patients. 10. The family and/or the medical staff are instructed to supervise the patient properly and to avoid potential complications. 11. Termination of prolonged hypnosis with individualized therapy is gradual to permit appropriate re-orientation towards reality. 12. Treatment is evaluated and a posttreatment plan is outlined.

They provide case reports and discuss precautions. All the cases reported were treated while the patients were hospitalized for their physical condition (although in Case 3, prolonged hypnosis with individualized therapy was also continued at home after the patient's discharge from the hospital), and the patients were monitored by the medical staff. In very debilitated patients, special care should be taken to avoid potential complications arising from their passivity, mainly the development of decubitus ulcer and of aspiration/choking while drinking or eating. Although precaution is taken routinely with these patients, these measures should be emphasized while the patient is in a state of prolonged hypno-relaxation.

**1990**

**Pekala, Ronald J.; Forbes, Elizabeth J. (1990, Spring). Subjective effects of several stress management strategies: With reference to attention. Behavioural Medicine, 39-43.**

This study assessed variations in reported attentional experience associated with several stress management techniques (hypnosis, progressive relaxation, deep abdominal breathing) and baseline (eyes closed) as a function of hypnotic susceptibility. Three hundred nursing students experienced the stress management conditions and afterward completed a self-report inventory, the Dimensions of Attention Questionnaire (DAQ), in reference to each condition. The DAQ quantifies 12 aspects of attentional experience in a reliable and valid manner. The results demonstrated that progressive relaxation, hypnosis, and deep abdominal breathing are characterized by differences in reported attentional experience that are further moderated by an individual's hypnotic susceptibility. The clinical implications of these results are discussed.

## NOTES:

"Significant main effects were found for conditions for perspicacity, absorption, and control, with progressive relaxation associated with increased perspicacity and absorption, but with decreased control vis-a-vis hypnosis.

"Significant main effects for groups were found for perspicacity, locus, direction of attention, absorption, control, and vigilance. ... [Post-hoc comparisons] revealed that high susceptibles (vis-a-vis low susceptibles) reported increased perspicacity, absorption, a more inward-focused attention, more feelings of being out of their bodies, and decreased control and vigilance. High-mediums were also different from lows (in the same direction) for all of the above comparisons except for direction of attention. Low-mediums, along with lows, were different from highs for absorption and control.

"Significant interactions between conditions and groups were found for absorption, control, and vigilance. Whereas low susceptibles reported significantly increased absorption but significantly decreased control and vigilance during progressive relaxation than during hypnosis, high susceptibles reported no significant differences between relaxation and hypnosis for absorption, control, or vigilance" (p. 41).

The authors describe the differences found for deep abdominal breathing on p. 41.

"The interaction effects suggest that the experience of hypnosis and progressive relaxation are moderated by a person's hypnotic susceptibility--low susceptibles experience significantly greater absorption, but decreased control and vigilance during progressive relaxation than during hypnosis, although there are no such differences for high susceptibles. This suggests that progressive relaxation may be a 'better' procedure than hypnosis to use with low susceptibles, at least if one wants to increase absorption and decrease vigilance and control" (p. 42).

The authors also note that "deep abdominal breathing is associated with increased 'calmness of mind,' in reference to a baseline condition, as demonstrated by increased attentional detachment and equanimity, and decreased vigilance and density (the 'amount' of thoughts going through one's mind)" (p. 42).

Sturgis, Laura M.; Coe, William C. (1990). Physiological responsiveness during hypnosis. International Journal of Clinical and Experimental Hypnosis, 38, 196-207.

Four physiological measures - electromyogram, respiration rate, heart rate, and skin conductance - were recorded for 11 high and 11 low hypnotizability Ss. It was hypothesized (a) that physiological responsiveness during hypnosis would vary depending on the nature of the task instructions, and (b) that high hypnotizability Ss would show more physiological responsiveness than low hypnotizability Ss. The first hypothesis was substantiated across all 4 measures. Only heart rate levels supported the second hypothesis. The results are discussed as they relate to the 1 hypotheses and to future research.

## 1989

Murphy, A. I.; Lehrer, P. M.; Karlin, R.; Swartzman, L.; Hochron, S.; McCann, B. (1989). Hypnotic susceptibility and its relationship to outcome in the behavioral treatment of asthma: Some preliminary data. Psychological Reports, 65, 691-698.

#### **NOTES:**

Twelve subjects from an experiment on relaxation therapy for asthma were given the Harvard. Hypnotizability was positively correlated, at a borderline significance, with improvement in the methacholine challenge test, a measure of asthma severity. Performance on the amnesia item of the Harvard was correlated with improvement in self-reported symptoms of asthma.

#### **1988**

Anderson, Edgar L.; Frischholz, Edward J.; Trentalange, Mark J. (1988). Hypnotic and nonhypnotic control of ventilation. American Journal of Clinical Hypnosis, 31, 118-128.

The present study examined the effects of: 1) breathing air versus breathing 5% CO<sub>2</sub>; 2) waking versus self-hypnotic conditions; and 3) neutral versus reduced respiratory rate instructions on four measures of ventilatory functioning (respiratory rate, tidal volume, expired minute ventilation, and end-tidal Pco<sub>2</sub>). Twelve high-hypnotizable normal volunteer subjects were studied in a repeated-measures, multivariate analysis of variance design; Significant main effects were observed for each experimental condition, whereas none of the two or three way interactions proved noteworthy. Breathing 5% CO<sub>2</sub> produced increased ventilatory functions (e.g., increased respiratory rate, tidal volume, expired minute ventilation, and end-tidal Pco<sub>2</sub>). Being in a state of self-hypnosis is associated with reduced respiratory rate, with a significant increase in expired minute ventilation and end-tidal Pco<sub>2</sub>, but with no significant increase in tidal volume. Finally, reduced respiratory rate instructions were effective in significantly reducing respiratory rate and expired minute ventilation when breathing 5% CO<sub>2</sub> as evidenced by increases in end-tidal Pco<sub>2</sub> levels that were used to monitor ventilation outcomes.

Dougherty, John E.; Payne, Paul A. (1988). The use of breathing rhythm to enhance the vividness of mental imagery. Imagination, Cognition and Personality, 8 (2), 175-179.

The study assessed Jencks' claim that responses to certain suggestions are enhanced by being paced with different phases of the breathing cycle. Following hypnotic induction, twenty-four subjects were given four treatments in counterbalanced order: 1) exhalation-enhanced suggestions paced to exhalation, 2) inhalation-enhanced suggestions paced to inhalation, 3) inhalation-enhanced suggestions counterpaced to exhalation, and 4) exhalation-enhanced suggestions counterpaced to inhalation. Subjects' reports of imagery vividness provided marginal support ( $p < .06$ ) for Jencks' hypothesis. Post-experimental inquiry indicated subjects were unaware of the breathing contingency. Results suggest that appropriate pacing may make a greater difference for the energy-confidence group of suggestions (inhalation-paced) than for the calm-relaxation group (exhalation-paced).

Morrison, J. B. (1988). Chronic asthma and improvement with relaxation induced by hypnotherapy. Journal of the Royal Society of Medicine, 81, 701-704.

After one year of hypnotherapy, 16 chronic asthmatic patients inadequately controlled by drugs had a fall in admissions from 44 in the year before starting therapy to 13 in the year after. Duration of stay was reduced for 13 patients by 249 days; prednisone was withdrawn in 6, reduced in 8, and increased in none. Side effects of drugs were reduced. Although 62% reported improvement on a visual analogue scale, observations of air flow gave variable results.

Pagano, Robert R.; Akots, Normund J.; Wall, Thomas W. (1988). Hypnosis, cerebral laterality and relaxation. International Journal of Clinical and Experimental Hypnosis, 36, 350-358.

This study attempted to determine if hypnosis produces a shift towards more dominant right hemisphere functioning and if this increased dominance can be adequately explained by general somatic relaxation rather than being due to some other aspect of the hypnotic process. 14 right-handed, medium to highly hypnotizability Ss performed a dichotic listening task while in a prehypnosis, hypnosis, and post-hypnosis repeated measures design. Throughout the experiment, somatic relaxation was monitored physiologically by recording heart rate, respiration rate, and frontalis EMG. The results showed a highly significant shift toward a greater left ear advantage during hypnosis. There was no change in EMG. Respiration rate increased during the hypnosis condition and remained at an increased rate during the posthypnosis condition. Heart rate decreased during the hypnosis condition and remained at a decreased rate or decreased further during the posthypnosis condition. These results replicate and extend those reported by Frumkin, Ripley, and Cox (1978) and do not support the view that changes in general somatic relaxation can adequately account for this hypnotic effect.

NOTES: Frumkin et al. (1978) presented syllables simultaneously to two ears of subjects, requiring them to state which syllable they heard most clearly (e.g. 'Ka' vs 'Ga'). They found a right ear advantage (REA) during waking conditions, which shifted toward a left ear advantage (LEA) during hypnosis. Their interpretation was that hypnosis results in more right cerebral hemisphere involvement. Two recent investigations did not find the shift in ear with advantage (H. J. Crawford, K. Crawford, & Koperski, 1983; Levine, Kurtz, & Lauter, 1984) but they were not actual replications of the Frumkin et al. (1978) investigation. This study is a replication of Frumkin et al., and is designed to learn whether relaxation could account for the results.

Subjects were 14 volunteer students of medium to high hypnotizability (Stanford Hypnotic Clinical Scale: Adult scores of 3-5). The dichotic listening tape has been used in other research at Haskins Laboratories (Yale University), and was developed by Dr. Terry Halwes. "Each run of the tape consisted of 96 dichotic pairs presented in 4 groups of 24. Six syllables from the English stop consonants k, g, p, d,

b, and t preceded and followed by the vowel a, composed the pairs" (p. 352). The experimenters also recorded heart rate (HR), respiration rate (RR), and EMG.

There were two sessions for each subject: (1) screening and measuring hypnotizability with SHCS: Adult, (2) dichotic listening task within three conditions: pre-hypnosis, hypnosis, and posthypnosis. Table 1 (not shown here) gives for each S the SHCS score and the Laterality Quotient for each of the three conditions.

**RESULTS.** "Laterality quotients were computed for each S by the formula  $(R-L/R+L) \times 100$ , where R = right ear score and L = left ear score. A positive score indicates a predominate REA, and a negative score indicates a predominate LEA" (p. 353).

The analysis by ANOVA for repeated measures indicated that there was a significant shift to LEA during hypnosis; the means were 11.34 prehypnosis, 3.17 hypnosis, 8.93 posthypnosis. All 14 subjects demonstrated this directional shift. Heart rate decreased between prehypnosis (70.4 beats/minute) and hypnosis (67.8) and remained lower (67.9) during posthypnosis. However respiration significantly increased during hypnosis, from 13.5 breaths/minute prehypnosis to 16.2 for hypnosis and 15.2 for posthypnosis. There were no significant changes for EMG.

Self-reported depth of hypnosis remained the same for the first and second sessions. In their Discussion, the authors interpret the shift toward greater LEA during hypnosis (and return to greater REA posthypnosis) as greater right hemisphere involvement, confirming Frumkin et al. They noted that the changes were not due to increased error in the right ear, but to identification of more syllables in the left ear. Several experimental design differences could account for why this study and Frumkin obtained the shift and two other investigations did not. These investigators and Frumkin used a competing response paradigm (requiring that subjects identify which syllable is heard more clearly) and the other two studies did not.

"In evaluating the possible confound of general somatic relaxation with hypnosis per se, the physiological data provide salient information. Davidson & Schwartz (1976) have discussed the limitations in evaluating the relaxation response as a unitary concept and have recommended looking at patterns of multiple physiological measures. Failing this, the best single measure is HR (Davidson & Schwartz, 1976)" (p. 356). In this case, HR decreased over the three conditions, remaining low in posthypnosis when laterality shifted back to REA. If the cerebral shift were due to relaxation, presumably there would not have been low HR during posthypnosis.

The authors note the lack of convergence in physiological measures (EMG showing no change, RR increasing during hypnosis and remaining high, HR decreasing during hypnosis and remaining low). Lack of convergence is typical in physiological studies of the relaxation response (Davidson & Schwartz, 1976). "However, whether the three physiological measures are considered as an overall pattern in determining level of somatic relaxation or whether HR is considered alone, increased somatic relaxation due to hypnosis cannot adequately account for both the shift toward more dominant right hemisphere activity in the hypnosis condition and the shift back to more dominant left hemisphere activity during the posthypnosis condition" (p. 356).

The authors acknowledge that the absence of either a low hypnotizable subject group or a relaxation control group suggests caution in interpretation of the results.

**1987**

**Kotses, H.; Rawson, J. C.; Wigal, J. IK.; Creer, T. L. (1987). Respiratory airway changes in response to suggestion in normal individuals. Psychosomatic Medicine, 49, 536-541.**

Thirty normal individuals were told they were inhaling a substance that would either cause breathing difficulty (N - 15) or not affect breathing (N - 15). Total respiratory resistance was measured prior to and during inhalation. In reality, the subjects inhaled no substances; inhalation consisted of breathing normally into a respiratory resistance recorder. Individuals who received the former suggestion exhibited increased total respiratory resistance, whereas individuals who received the latter suggestion did not. These observations demonstrated that the ability of suggestion to affect the respiratory airway is not limited to asthmatic individuals.

**Pastorello, E. A. (1987). The role of suggestion in asthma. I. Effects of inactive solution on bronchial reactivity under bronchoconstrictor or bronchodilator suggestion. Annals of Allergy, 59, 336-338.**

Twenty-eight Ss affected by perennial asthma were selected in order to investigate the possibility of inducing or relieving an asthmatic attack by means of suggestion. 25 were positive to a methacholine challenge test, and among them, 11 reacted to an ultrasonic nebulized distilled water test. The effect of suggestion on airway response was assessed by 8 inhalations of normal saline at 32 degrees Centigrade alternately presented as a bronchoconstrictor or as a bronchodilator drug. 8 inhalations of the same diluent without any psychic stimulus were used as a control test. 7 patients reacted with bronchoconstriction to both positive and negative suggestion and to the control test. Further, this group of patients showed a lower methacholine PD10 when compared with the other Ss. In this study, the effects of suggestion on bronchial reactivity were not observed and bronchoconstriction belonged to an individual hyperactivity of the airways.

**Pastorello, E. A.; Codecasa, L. R.; Gerosa, A.; Buonocore, E.; Sillano, V.; Zanussi, C. (1987). The role of suggestion in asthma. II. Effects of a bronchoconstrictor drug on bronchial reactivity under bronchoconstrictor or bronchodilator suggestion. Annals of Allergy, 59, 339-340.**

Previous studies have shown that suggestion may modify bronchial reactivity to both inactive diluents and pharmacologically bronchoconstrictor or dilator substances. In our study, 14 patients were subjected to 2 methacholine challenge tests presented, respectively, as a bronchoconstrictor or as a bronchodilator drug. Forced expiratory volumes in one second were recorded and a PD20 was determined. No significant differences were reported in PD20 values of each patient after the 2 kinds of suggestion.

**1985**

**LaRiccia, P. J.; Katz, R. H.; Peters, J. W.; Atkinson, G. W.; Weiss, T. (1985). Biofeedback and hypnosis in weaning from mechanical ventilators. Chest, 87, 267-269.**

Weaning patients from mechanical ventilation can be hindered by both physical and psychologic factors. Biofeedback has been used successfully as an adjunct in difficult weaning problems. We have used a combination of hypnosis and biofeedback to wean a patient with neurologic disease who previously failed weaning by standard procedures. A 30-year-old woman with respiratory failure secondary to multiple sclerosis with transverse myelitis was given eight sessions of biofeedback over 12 days in which the movements of her chest wall, as monitored by magnetometers, were displayed on an oscilloscope. The patient was praised for targeted respiratory rate, amplitude, and rhythm. These sessions included hypnosis in which the patient was given suggestions of well-being and that she could breathe as she had five years earlier. In this manner the patient was successfully weaned. Respiratory biofeedback and hypnosis appear to be useful adjuncts in weaning patients from ventilators.

**Olness, Karen N.; Conroy, Mary Margaret (1985). A pilot study of voluntary control of transcutaneous PO<sub>2</sub> by children: A brief communication. International Journal of Clinical and Experimental Hypnosis, 33, 1-5.**

This pilot study took place to determine whether or not children could voluntarily change tissue oxygen as measured by a transcutaneous oxygen monitor. It tested 2 hypotheses: (a) children can voluntarily change tissue oxygen as reflected by a transcutaneous oxygen monitor and (b) children, experienced in use of self-hypnosis exercises, will be able to change tissue oxygen to a greater degree than children unfamiliar with such exercises. 11 children between the ages of 7 and 17 year were studied. 8 children were previously experienced in the use of self-hypnosis; 3 were not. A Novamatrix transcutaneous O<sub>2</sub>/CO<sub>2</sub> monitoring system provided a constant read-out of PO<sub>1</sub>, PCO<sub>1</sub> and local perfusion. After stabilization, children were asked to attempt increases of oxygen. 9 children increased tissue oxygen significantly. Of those, 8 children had previous self-hypnosis training. 1 had not. Only 2 children with no previous self-hypnosis training were unable to change oxygen values. This pilot study upholds both hypotheses; however, it does not conclude that self-hypnosis mediated the changes noted or that self-hypnosis would be essential to success in voluntary control of tissue oxygen.

**1984**

**Brown, Erick L.; Kinsman, Robert A. (1984). Resolving intractable medical problems through psychological intervention: A clinical report. Psychotherapy, 21, 452-455.**

Treatment of chronic physical illness is often complicated by psychological factors that maintain and exacerbate the illness. Hypnotic techniques, coupled with insight-oriented psychotherapy comprised an effective strategy for favorably influencing medical outcome. A clinical report illustrates how psychological intervention initiated the resolution of severe medical problems in an asthmatic patient.

Holmes, David S. (1984). Meditation and somatic arousal evidence. American Psychologist, 39 (1), 1-10.

The conceptual and methodological issues associated with research on the effects of meditation are reviewed. A summary of the research in which the somatic arousal of meditating subjects was compared to the somatic arousal of resting subjects did not reveal any consistent differences between meditating and resting subjects on measures of heart rate, electrodermal activity, respiration rate, systolic blood pressure, diastolic blood pressure, skin temperature, oxygen consumption, EMG activity, blood flow, or various biochemical factors. Similarly, a review of the research on the effects of meditation in controlling arousal in threatening situations did not reveal any consistent differences between meditating and nonmeditating (no-treatment, antimediation, or relaxation) subjects. The implications of these findings for research and practice are discussed.

Wideman, Margaret V.; Singer, Jerome E. (1984). The role of psychological mechanisms in preparation for childbirth. American Psychologist, 39, 1357-1371.

Psychoprophylactic (Lamaze) preparation for childbirth consists of six to eight classes held during the last trimester of pregnancy. These classes include instruction in the anatomy and physiology of gestation and parturition, respiration techniques, controlled neuromuscular relaxation, visual focusing, and the training of a labor coach. Although the techniques are based upon psychological principles, they have remained largely unstudied by either psychologists or physicians. This article presents a brief history of the development of the training regimen and critically examines the few empirical studies that have been conducted. Because explanations for the efficacy of the preparation, if it exists, are equivocal, literature on the explicit components of the training--that is, information, respiration techniques, conditioned relaxation, cognitive restructuring, and social support--in situations other than child delivery are reviewed and their implications for the Lamaze method discussed. However, because there exist several, more implicit factors that may affect the type of child delivery a prepared woman experiences, the literature concerning social comparison, the effects of commitment and conformity, perceived control, and endorphin secretion are also discussed as they may apply to psychoprophylactic preparation. Problems associated with the study of childbirth preparation are presented, and suggestions for the direction of future research are made.

1979

Di Piano, Frank A.; Salzberg, H. C. (1979). Clinical applications of hypnosis to three psychosomatic disorders. Psychological Bulletin, 86, 1223-1235.

Studies of hypnosis in the treatment of skin disorders, headaches, and asthma were reviewed in terms of outcomes and methodological soundness. Some studies focused on changing physiological functions, others on increasing insight in their patients, and still others on altering patients' perceptions of their symptoms. Methodological weaknesses included lack of control groups, nonrandom assignment of patients to treatment conditions, and confounding of treatment effects or lack of control for placebo effects. Additional weaknesses centered around the use of single outcome measures and the failure to assess the specific roles of mediating variables. Most of the studies reviewed showed positive treatment effects. However, there is equivocal evidence that hypnosis can directly influence autonomic functioning. Hypnosis may be valuable in facilitating one's capacity to gain insight into how one's symptoms developed and are maintained. In addition, hypnotic procedures have resulted in some success when used to indirectly alleviate symptoms by altering how individuals perceive their disorders and how these disorders affect their lives.

Jackson, J. Arthur; Gass, Gregory C.; Camp, Elizabeth M. (1979). The relationship between posthypnotic suggestion and endurance in physically trained subjects. International Journal of Clinical and Experimental Hypnosis, 27, 278-293.

55 male Ss were assigned to 5 groups: control, hypnosis alone, motivation alone, low susceptible hypnosis with motivation, or high susceptible hypnosis with motivation. Ss performed 2 runs on a treadmill to their maximum capacity, as measured by oxygen consumption, blood lactate concentration, and respiratory quotient. Groups involving hypnosis performed in the posthypnotic state. A significant increase in endurance performance was revealed in the motivation alone Ss and in high susceptible hypnosis Ss who were given motivational suggestions. Maximum ventilation was significantly increased in high susceptible hypnosis Ss when compared with control Ss and significant increases in blood lactate concentrations were revealed when the high susceptible hypnosis Ss were compared with low susceptible hypnosis and motivation alone Ss. The reasons for the changes in metabolic variables are discussed. Findings demonstrated that in achieving greater endurance performance, motivational suggestions alone are as effective as identical suggestions given to high susceptible Ss.

Parwatikar, Sadashiv D.; Brown, Marjorie S.; Stern, John A.; Ulett, George A.; Sletten, Ivan S. (1978). Acupuncture, hypnosis and experimental pain - I. Study with volunteers. Acupuncture and Electro-Therapeutic Research: International Journal, 3, 161-190.

An experiment was designed to evaluate the protective effects of different agents - acupuncture, hypnosis, Morphine, aspirin, Diazepam and placebo - upon experimentally-induced pain in humans. Twenty normal, healthy volunteers were

subjected to cold water and tourniquet- induced pain and the protective effects of 35 minutes of hypnotic suggestion, electro- stimulation of both acupuncture points and non-acupuncture points, 10 mg/kg of Morphine, 5 grains of aspirin, 10 mg of Diazepam and a mild sugar placebo were evaluated. Data was collected on subjective evaluation of pain, EKG, EEG, respiration, skin temperature, peripheral vascular activity and EMG. A special study was also done to evaluate the effects of all the above agents on the somatosensory evoked potentials and EEG. The data were further analyzed on the basis of hypnotic susceptibility of the volunteers. The results indicated: 1) Hypnosis, acupuncture at specific sites with electrical stimulation and Morphine Sulphate had about the same reduction in experimental pain. 2) Hypnosis produced different effects from those resulting from acupuncture stimulation on EEG. 3) Acupuncture stimulation in specific loci resulted in a latency increase in the early secondary response on somatosensory evoked potential. 4) Cold water pain was remarkably reduced after true acupuncture point stimulation. 5) Tourniquet (ischemic) pain was reduced by both hypnosis and true acupuncture site stimulation. 6) Skin temperature was significantly reduced on the side of acupuncture points (true) stimulation.

Thorne, D. E.; Fisher, A. G. (1978). Hypnotically suggested asthma. International Journal of Clinical and Experimental Hypnosis, 26, 92-103.

15 asthmatic and 19 non-asthmatic Ss were administered the Harvard Group Scale of Hypnotic Susceptibility, Form A (Shor & E. Orne, 1962) and accordingly assigned to one of three susceptibility groups -- low, medium, or high. Subsequently, all Ss were exposed to a hypnotically suggested asthma experience. Subjective and physiological measures of respiratory efficiency were administered before, during, and after the hypnotically suggested asthma experience. Ss did respond significantly differently in these three conditions, but the physiological measures did not reveal typical asthma physiological patterns. High and medium susceptible Ss were ostensibly convinced that they "experienced" asthma, but the low susceptible Ss were uniformly unimpressed. One of the most noteworthy findings was that Ss' ability to respond differentially (according to the asthma suggestions) was enhanced by greater susceptibility to hypnosis yet not "enhanced" by their history of previous asthma.

Collison, David R. (1975). Which asthmatic- patients should be treated by hypnotherapy?. Medical Journal of Australia, 1 (25), 776-781.

Retrospective analysis of 121 asthmatic patients who were treated by hypnotherapy. Subjects were first broken down into one of three possible groups: "light," "medium," or "deep," according to the depth of trance typically achieved. Hypnoidal states were included in the light trance group and somnambulistic state in the deep trance. All sessions concentrated on suggesting physical and mental relaxation since we know this is one of the causes of the appearance of the "asthma attack." The actual wording varied however, and this involved discussion under hypnosis, of the main personalities of the environment, fears, failures, aims, hopes

and frustrations. Post-hypnotic suggestions of continued relaxation and ability to cope with the various situations of life were given in all the cases. Auto-hypnosis was taught to enable the patient to reinforce the above suggestions and to remain in or selectively achieve a relaxed state. Results were classified into four different categories: "excellent," "good," "poor," and "nil." It was found that those patients who experienced a "high" trance depth were more likely to show excellent improvement than those who were measured as "medium" or "low" trance subjects.

**Moorefield, C. W. (1971). The use of hypnosis and behavior therapy in asthma. American Journal of Clinical Hypnosis, 13, 162-163.**

Nine patients with asthma were treated with hypnosis and behavior therapy. All of these patients showed subjective improvement to a rather marked degree, except for one patient who has had three slight attacks of asthma since the onset of her treatment. These patients have been followed from eight to approximately 24 months. The results so far have been rather encouraging and the author believes this form of treatment will prove to be of benefit in the treatment of asthma and possibly many other related conditions.

### **1970**

**Maher-Loughnan, G. P. (1970). Hypnosis and auto-hypnosis for the treatment of asthma. International Journal of Clinical and Experimental Hypnosis, 18 (1), 1-14.**

Conducted 2 controlled studies into the use of hypnosis in 252 asthma patients. Several different control procedures were used. Methods and results were summarized, and the same conclusion was reached: That hypnosis supplemented by autohypnosis was significantly more effective than control procedures. An outline is given of details of treatment methods. A current analysis of Ss involving up to 6 yr. of follow-up, is presented to provide a working guide to the regime in regular practice. To be fully effective hypnosis should be employed before steroids are started. Steroid-dependent asthma is rarely totally relieved by hypnotherapy. Describes a rationale and procedure for the use of hyperventilation as a facilitator of hypnotic trance induction. Results with 56 neurotic patients are reported. (Spanish & German summaries) (PsycINFO Database Record (c) 2002 APA, all rights reserved)

**1968**

**Summary: An investigation of hypnosis in asthma was made among patients aged 10 to 60 years with paroxysmal attacks of wheezing or tight chest capable of relief by bronchodilators. One group of patients was given hypnosis monthly and used autohypnosis daily for one year. Comparisons were made with a control group prescribed a specially devised set of breathing exercises aimed at progressive relaxation. Treatment was randomly allocated and patients were treated by physicians in nine centres. Results were assessed by daily diary recordings of wheezing and the use of bronchodilators, and by monthly recordings of F.E.V. and vital capacity. At the end of the year independent clinical assessments were made by physicians unaware of the patients' treatment.**

**There were 252 patients (127 hypnosis and 125 controls) accepted for analysis, but a number of them did not continue the prescribed treatment for the whole year: 28 hypnosis and 22 control patients failed to cooperate, left the district, or had family problems; one hypnosis and one control patient died. Seven hypnosis and 17 control patients were withdrawn as treatment failures, the difference between the two groups being statistically significant.**

**As judged by analyses based on the daily " score " of wheezing recorded in patients' diaries, by the number of times bronchodilators were used, and by independent clinical assessors, both treatment groups showed some improvement. Among men the as-sessments of wheezing score and use of bronchodilators showed similar improvement in the two treatment groups; among women, however, those treated by hypnosis showed improvement similar to that observed in the men, but**

those given breathing exercises made much less progress, the difference between the two treatment groups reaching statistical significance. Changes in F E.V. and V.C. between the control and hypnosis groups were closely similar.

Independent clinical assessors considered the asthma to be " much better " in 59% of the hypnosis group and in 43% of the control group, the difference being significant. There was little difference between the sexes. Physicians with previous experience of hypnosis obtained significantly better results than did those without such experience.

Collison, D. R. (1968). Hypnotherapy in the management of asthma. American Journal of Clinical Hypnosis, 11, 6-11.

Following a brief history of the use of hypnosis in the management of asthma, hypnotherapy with 20 ambulant non-hospitalized patients is described. Of 7 females and 13 males, 11 had an excellent response, 5 a good response, and 4 a poor response.

Rose, S. (1967). A general practitioner approach to the asthmatic patient. American Journal of Clinical Hypnosis, 10, 30-32.

NOTES

1:

"Of all the conditions which present themselves for treatment under hypnosis, the treatment of asthma, to my mind, yields the most gratifying results, particularly with children, and I believe that were hypnosis in general practice to be restricted to the treatment of the asthmatic patient alone, its use would be more than justified." [No abstract included; first paragraph from the paper.]

**1965**

Agosti, E.; Camerota, G. (1965). Some effects of hypnotic suggestion on respiratory function. International Journal of Clinical and Experimental Hypnosis, 13 (3), 149-157.

Several respiratory indices were measured in 10 Ss in 3 states: at rest, with hypnotic suggestion of relaxation, and with hypnotic instructions to imagine muscular work. The same suggestions were given to 10 control Ss in the waking state. The suggestion of relaxation produced a decrease in pulmonary ventilation in both groups, although it was substantial only in the hypnotic group which started from a higher baseline level. The imagined work produced an increase in ventilation, especially in the hypnotic group. However, in both instances because of compensatory changes in respiratory efficiency the actual uptake of oxygen remained almost unaffected. **1955**

Dorcus, Roy M.; Kirkner, Frank J. (1955). The control of hiccoughs by hypnotic therapy. Journal of Clinical and Experimental Hypnosis, 3 (2), 104-108.

## NOTES

1:

"The present paper is devoted to a discussion of 18 cases ... of hiccoughs that were treated by hypnosis at the Long Beach Veterans Hospital during the course of the past five years. Almost all of these cases had received some kind of medical therapy before hypnosis was employed. ...

"The age range of the patients (27-75 years) indicates that age is not a factor either in the onset of the spasm or in the termination of it by hypnosis. ... While there are some differences in the number of patients in the various [age] decile groups, these differences are in all probability due to sampling. The kinds of physical disorders fit into the table of causes abstracted from Samuels' article and it is evident that hiccough may be associated with a wide variety of physical diseases. With respect to the onset of the hiccoughs, the major number of the spasms seem to be initiated after the central nervous system has been depressed by an anesthetic. When the diaphragm is set in reflex action by some other cause such as vomiting, hiccoughs may be initiated and continue. The hypnotic treatment stressed two points in procedure: (a) an attempt to obtain complete muscular relaxation, and (b) an attempt to relieve the patient of anxiety concerning the spasm and his physical disorder. The number of hypnotic sessions required varied from one session to as many as 8 or 10 sessions. The number of sessions required could not be predicted in advance. No criteria of whether hypnosis would be successful have been evolved other than whether the patient is, generally speaking, a good hypnotic subject. Of the eighteen patients treated by this method fourteen were permanently relieved of their symptoms; three received no benefit and one received temporary benefit. Since other therapies had been tried on most of these patients, it is quite apparent that this form of treatment is very useful and should be applied as soon as possible after the advent of the spasm. This statement is not based on the fact that hiccoughs of shorter duration respond more readily to hypnotic therapy. However, hypnosis should be utilized early to control hiccoughs so that the hiccoughs will not add to the distress of otherwise seriously ill patients" (pp. 107-108).

## Burns

1997

Duhamel, Katherine N.; Difede, Joan; Foley, Frederick; Greenleaf, Marcia (1997, November). Hypnotizability and posttraumatic symptomatology after burn injury. [Paper] Presented at the annual meeting of the Society for Clinical and Experimental Hypnosis, Washington, D. C..

## NOTES

1:

Investigated the relationship between hypnotizability and post traumatic stress disorder (PTSD) symptoms following burn injury, in 43 hospitalized survivors. Authors found an association between these two variables and suggest that assessment of hypnotizability might help identify post-burn patients at risk for PTSD.

Hillig, Justine A.; Holroyd, Jean (1997-98). Consciousness, attention, and hypnoidal effects during firewalking. Imagination, Cognition and Personality.

Subjective experiences of individuals who walked on hot coals during a firewalking ceremony were investigated. This study extended and partially supported an investigation reported by Pekala and Ersek in this Journal [1]. Twenty-three participants completed retrospective questionnaire assessments concerning their subjective experiences while walking on hot coals. Results from twelve participants were compared with the participants' own experiences during a baseline condition. The data suggested that attention during firewalking is significantly more "one-pointed" than during a baseline condition, and that consciousness may be characterized as more "hypnoidal" than during a baseline condition. Walking on hot coals was further characterized by trends toward reporting increased altered awareness, altered experience, and absorbed attention. Participants who developed a greater degree of blistering reported significantly greater hypnoidal effects during the firewalk than those who developed a lesser degree of blistering.

Patterson, David R.; Adcock, Rebecca J.; Bombardier, Charles H. (1997). Factors predicting hypnotic analgesia in clinical burn pain. International Journal of Clinical and Experimental Hypnosis, 45 (4), 377-395.

The use of hypnosis for treating pain from severe burn injuries has received strong anecdotal support from case reports. Controlled studies provide less dramatic but empirically sound support for the use of hypnosis with this problem. The mechanisms behind hypnotic analgesia for burn pain are poorly understood with this patient population, as they are with pain in general. It is likely that, whatever the mechanisms are behind hypnotic pain analgesia, patients with burn injuries are more receptive to hypnosis than the general population. This article postulates some variables that may account for this enhanced receptivity, including motivation, hypnotizability, dissociation, and regression.

## 1996

Holroyd, Jean (1996). Hypnosis treatment of clinical pain: Understanding why hypnosis is useful. International Journal of Clinical and Experimental Hypnosis, 44 (1), 33-51.

Clinical and experimental research literature indicates hypnosis is very useful for severe and persistent pain, yet reviews suggest hypnosis is not widely used. To encourage more widespread clinical application, the author reviews recent controlled clinical studies in which hypnosis compares favorably with other interventions; links advances in understanding endogenous pain modulation to a neurophysiologic view of hypnosis and hypnoanalgesia; relates the neurophysiology of hypnoanalgesia to management of chronic pain; challenges the view that hypnotic pain control is only for the highly hypnotizable patient; and raises issues about how people learn to control pain with hypnosis. Training in hypnotic analgesia may usefully enhance nervous system inhibitory processes that attenuate pain.

## NOTES:

Hypnosis has been more effective for pain management than other cognitive behavioral interventions in studies of fibromyalgia (Haanen, Hoenderdos, Van Romunde, Hop, Malle, Terwiel, & Hekster, 1991); burn treatment (Patterson, Everett, Burns, & Marvin, 1992); and cancer bone marrow transplant procedures (Syrjala, Cummings, & Donaldson, 1992). Central nervous system gating or downward modulation of pain impulses may account for hypnotic pain control. "Hypnosis enables both amplification and attenuation of cortical response subsequent to sensory registration and prior to consciousness, depending on whether suggestions are for increasing or decreasing awareness (Blum & Barbour, 1979)" (p. 36). This type of inhibition may even be observed in the peripheral nervous system (see Hernandez-Peon, Dittborn, Borlone, & Davidovich, 1959/1960; Sharev & Tal, 1989; Kiernan, Dane, Phillips, & Price, 1995). Work by Helen Crawford (1994) suggests that frontal and limbic areas of the brain are involved in inhibitory patterns of brain activity, and that generation of theta EEG rhythms by lower centers is associated with the suppression of awareness of pain.

Some very low hypnotizable people have been able to learn to control pain with hypnosis, suggesting that it is a skill that can be learned. However, few investigations of improvement of hypnoanalgesia were located. Rather, one must generalize from the fact that other kinds of hypnosis skills have been improved using special training programs, such as the Carleton University program developed by Gorassini & Spanos, 1986). Although most research on improving hypnotic response has been based on operant learning principles, a model that incorporates respondent (classical conditioning) principles might be more useful when it comes to understanding the training of a neurophysiological response, such as inhibitory brain patterns associated with hypnoanalgesia. "Historical success with clinical pain, taken together with newer findings in the neurophysiology of hypnosis, indicate that we should be spending more energy investigating how learning may improve hypnotic analgesia" (p. 43). "We should acknowledge that there are advantages to hypnosis beyond those of relaxation, a good placebo, and psychotherapy. ... Responsible care demands that we provide training or practice in hypnotic analgesia when treating pain, and especially whenever a chronic pain patient initially appears to be nonresponsive" (p. 43).

Patterson, David; Goldberg, Myron; Ehde, Dawn (1996). Hypnosis in the treatment of patients with severe burns. American Journal of Clinical Hypnosis, 38 (3), 200-213.

Burn injuries are a frequent form of trauma, the care for which typically involves repeated, intrusive procedures and acute, excruciating levels of pain. Although research in the use of hypnosis with burn patients is largely anecdotal there is emerging evidence that the burn unit may be one of the most useful arenas for the clinical application of this technique. The acute, identifiable nature of burn care procedures and the emotional state of patients in trauma care both provide an often receptive setting for the use of this intervention.

## 1995

Ptacek, J. T.; Patterson, D. R.; Montgomery, B. K. (1995, August). Hypnosis versus Lorazepam in the treatment of burn pain. [Paper] Presented at the annual meeting of the American Psychological Association, New York.

The pain from burn dressing is substantial and is best treated with interventions that supplement opioid medication. This study compares the use of hypnosis with the benzodiazepine lorazepam (Ativan). Thirty-eight patients were randomly assigned to groups that received hypnosis or lorazepam as supplements to opioid (e.g., morphine) medication. The control group received opioid drug alone. The results indicated that relative to baseline levels with opioid drugs alone, the lorazepam group showed a significant reduction in pain ratings at post-test. The hypnosis group demonstrated a 10% reduction in pain ratings, although this change was not significant. The results suggest that hypnosis is useful, but not necessarily as powerful as a pharmacological anxiolytic. (ABSTRACT from Bulletin of Division 30, Psychological Hypnosis, Fall, 1995, Vol. 4, No. 3.)

## 1994

Holroyd, Jean (1994, January 27). Hypnosis and the mind-body relationship. [Lecture]

### NOTES:

Historically, hypnosis has been associated with mental healing (e.g. Mesmer's salon), and clinical literature has been well reviewed by T. X. Barber (1984); Di Piano & Salzberg (1979); E. Hilgard & J. Hilgard (1975); Mott (1979); Paul (1963); and Perry, Gelfand, & Marcovitch (1979). Recently psychoneuroimmunology research has provided some support for the clinical evidence of healing. Research in this area should provide for determining whether the results are due to relaxation, to suggestion (waking or hypnotic), to personality (high hypnotizability), and should lead to an understanding of the basic physiological processes.

Clinical studies are sometimes given more credence by basic laboratory studies in a closely related area. For example, irritable bowel syndrome responded better to hypnosis with direct suggestions than to a combination of psychotherapy and a placebo pill (Whorwell, Prior, and Faragher, 1984). In the laboratory, Klein and Spiegel (1989) showed that secretion of stomach acid could be controlled by hypnosis and suggestion. Chapman, Goodell, & Wolff (1959) demonstrated that hypnotic suggestions could not only decrease but could increase the inflammatory response to burns, and that the response probably was mediated by a histamine-type substance.

Warts have been removed not only by hypnotic suggestion but by waking suggestion (Spanos, Stenstrom, & Johnston, 1988; Spanos, Williams, & Gwynn, 1990), and the hypnosis was more effective than potent placebo comparison treatment conditions. The elimination of warts may be related to control of blood flow or to a change in the immunological response. Chaves, Whilden, & Roller, 1979 (and Chaves, 1980) showed that dental patients could reduce the blood loss associated with dental

surgery, using hypnosis and imagery suggestions. Bennett, Benson, & Kuiken (1986) helped back surgery patients to reduce blood loss using waking suggestions. The immune response also can be modified using hypnotic suggestion (Zachariae, Bjerring, & Arendt-Nielsen, 1989).

In the research on mind-body healing, the following considerations also apply: 1. People's psychosomatic reactivity may affect the results obtained with hypnosis. Research on the immune response has sometimes used patients with psychosomatic disorders as the research subjects, to assure reactive physiological systems. 2. Severity of the disease may affect outcome (e.g. in the Spanos studies, those with the most warts responded best to the hypnosis intervention). 3. Hypnotizability sometimes relates to outcome and sometimes does not, in these investigations. In general, among very highly hypnotizable people, some can perform one hypnotic task such as develop amnesia while others can perform other, different hypnotic tasks.

In summary, there is an extensive clinical literature on hypnosis and healing, and experimental laboratory studies can offer support and some understanding of hypnosis effects on blood flow, histamine release, acid release, immune cell function, etc. In order to establish the effect of hypnosis one needs to start with the best chances for finding an effect: use high hypnotizable subjects. But later you either need to see if results correlate with general hypnotizability or with some other ability or experience, and often waking suggestion is sufficient.

### 1993

Everett, John J.; Patterson, David R.; Burns, G. Leonard; Montgomery, Brenda; Heimbach, David (1993). Adjunctive interventions for burn pain control: Comparison of hypnosis and Ativan. Journal of Burn Care and Rehabilitation, 14, 676-683.

Thirty-two patients hospitalized for the care of major burns were randomly assigned to groups that received hypnosis, lorazepam, hypnosis with lorazepam, or placebo controls as adjuncts to opioids for the control of pain during dressing changes. Analysis of scores on the Visual Analogue Scale indicated that although pain during dressing changes decreased over consecutive days, assignment to the various treatment groups did not have a differential effect. This finding was in contrast to those of earlier studies and is likely attributable to the low baseline pain scores of subjects who participated. A larger number of subjects with low baseline pain ratings will likely be necessary to replicate earlier findings. The results are argued to support the analgesic advantages of early, aggressive opioid use via PCA or through careful staff monitoring and titration of pain drugs.

Patterson, David R. (1993, October). Managing burn pain through hypnosis. [Paper] Presented at the annual meeting of the Society for Clinical and Experimental Hypnosis, Arlington Heights, IL.

NOTES:

Since 1955 there were 13 published reports on managing burn pain through hypnosis, with generally positive results; but almost all were anecdotal, with a lack of standardized measures. Time, location, and duration of the hypnotic interventions were not specified, cost-effectiveness was hard to detect, and medications used were not reported. Publications don't even report the type of hypnotic intervention used.

Hypnosis is indicated for procedural pain more than for during resting periods. Going through dressing changes is typically more painful than the burn itself. Opioid medications don't control all the pain. In our research we use J. Barber's Rapid Induction Analgesia, which entails suggestions for: 1. Slow breathing 2. Going down 20 steps 3. Confusion and amnesia 4. Anchoring post-hypnotic suggestions 5. Touching cue for reinstating the hypnosis 6. Relaxing scenario (Patterson added this to the Barber script) 7. Returning up the steps

This intervention is good because it's replicable, and it's easy to train students to use it. The hypnosis is done the morning before the dressing change.

Instructions for nurses are: 1. Read the card 2. Have patient lie down comfortably, etc. 3. Provide post hypnotic cue (usually a touch on the shoulder)

In the first study we used patients refractory to opioids, and also used a historical control group. This was published in the American Journal of Clinical Hypnosis. Our subsequent study was published in the Journal of Consulting and Clinical Psychology (1992). We stabilized administration of opioids; then patients had hypnosis or anxiolytics or were in the control condition. There was significant reduction in pain for hypnosis.

Patterson et al (current study). Compared Benzodiazepines to hypnosis using four groups: Hypnosis plus Lorazepam Hypnosis and placebo Lorazepam Hypnosis attention control and Lorazepam Placebo hypnosis and placebo pills

Analgesia stabilized on 2 days. There was not an effect, no significant drop in pain scores for either hypnosis or Lorazepam. Perhaps we didn't get a significant drop in pain ratings because in this study we were taking all patients who applied and their initial pain ratings were not as high as in the other study. We have found no relationship or pain reduction with hypnotizability either.

Why did we not get the positive results found previously for hypnosis? There are several possibilities. There is always a trend toward a drop in pain ratings over time. People generally bottom out with a rating of 3 or 4, and it looks like a floor effect. Also, the efficacy of hypnosis may be partly contingent on baseline pain level, and motivation to cooperate with the intervention.

Could there be the same relation to baseline for benzodiazepines?

We have noted that improved application of opioids early on means pain is lower. Marks & Sacher, Annals of Internal Medicine, 1973, indicate physicians under-prescribe opiates. Also Melzack in the Scientific American states this.

We feel that we should not push hypnotherapy so much that we feed in to opioidphobia. Hypnosis is a useful adjunct to opiates. We believe that you should stabilize the patient with opioids, and if they are not responding well, then use hypnosis.

In future research we want to find out which patients do best with hypnosis.

**Pekala, Ronald J.; Ersek, Barrett (1993). Firewalking versus hypnosis: A preliminary study concerning consciousness, attention, and fire immunity. Imagination, Cognition and Personality, 12, 207-229.**

**This study assessed the subjective effects associated with firewalking, and compared them with the subjective effects associated with hypnosis and a baseline condition (eyes closed sitting quietly). Twenty-seven subjects, who walked over hot coals during a firewalk ceremony, completed questionnaires about what they subjectively experienced during the firewalk. Their experiences were subsequently compared with those of subjects (n - 246) who experienced hypnosis and a baseline condition. The data suggested that firewalking, as assessed across all subjects, is characterized by high levels of volitional control and rationality, and a very absorbed attentional style wherein the mind is one-pointed, and consciousness is characterized by strong feelings of joy and high levels of internal dialogue. Firewalking was also found to be associated with significantly more joy, one-pointedness of thought, absorption, and internal dialogue than hypnosis or the baseline condition. In addition, a cluster analysis suggested two subgroups of firewalkers based on their subjective experiences of the firewalk. Interestingly, analyzing the attentional experiences among these firewalkers who got slightly burned, versus those who did not, revealed significant differences. A one-pointed and absorbed attentional focus may be the critical variable for the fire immunity observed in firewalking.**

**NOTES:**

**About 500 people walked across coals, in 3-4 steps. At end of weekend, 71 said they would complete a questionnaire and it was mailed to them. Of those, 27 responded (25 of 26 in an average of 23 days). Hence, 5% of the population who walked responded to the questionnaire, and it was some time later. Three of 24 reported minor blisters. Those who didn't get burned reported less detachment, less of a feeling of being out of their bodies, and more thoughts than the firewalkers who got slightly burned.**

**Pekala has defined an altered state of consciousness as associated with the perception of being in an altered state of awareness (the \_subjective sense\_ of \_altered state\_ --SSAS [30]), and a change in the patterning or configuration of the subsystems or dimensions of consciousness. A discrete state of consciousness, as defined by Pekala, is associated with a significant pattern change but no perceived alteration in state of consciousness (no SSAS). An identity state of consciousness, on the other hand, is defined as having neither a significantly perceived alteration in state of awareness nor a perceived pattern change among dimensions of consciousness in reference to another state of consciousness. Since the PCI can measure both intensity and pattern effects, it can be used to assess for altered, discrete, and identity states of consciousness.**

**Using a cluster analysis they found that one group of 16 subjects reported the firewalk experience to be characterized by a significant alteration in awareness and experience (body image, time sense, etc.), and significant intensities of internal dialogue, positive and negative affect, and arousal, while a second group of six subjects reported little alteration in consciousness or experience, little losses in**

rationality or control, and less internal dialogue, positive and negative affect or arousal than the larger group.

Whereas hypnosis is usually associated with a loss in control (the classic suggestion effect), firewalking was found to be associated with increased control, a more aroused state, and more fear! Firewalking appears to be a more absorbed and one-pointed state than even hypnosis.

The nature of attentional experience is similar across firewalkers (DAQ results).

Both firewalking and hypnosis meet the criteria for altered states of consciousness (different pattern and different subjective experience), but they are not altered states in reference to each other; they are discrete states of consciousness in reference to each other, because there is a significantly different patterning of PCI dimensions between the two conditions, but no significant SSAS. This suggests that the firewalk state is qualitatively different from the hypnotic state (as induced by the induction procedure to the Harvard Scale) and probably represents a different type of state of consciousness than hypnosis. Firewalkers obtained a lower mean hypnoidal state score than hypnosis subjects, so it does not appear that the fire immunity is due to being in a "hypnotized" state.

The fact that there appears to be two groups of successful firewalkers, one of which did not report much alteration in consciousness, calls into question the theorizing concerning the importance of alteration in state of consciousness as being etiologically related to successful firewalking. Since about 25 percent of the firewalkers clustered into what appears to be a nonaltered state of awareness, this suggests a sizable percentage of subjects who did not report any significant alteration in consciousness and experience.

Hence, what may be important is not an alteration in consciousness, but rather an alteration in attention. The cluster analysis revealed a relatively unitary attentional state across all subjects suggesting that attention was deployed in a rather similar manner across all subjects, that is, with very high absorption and one-pointedness. It was also the DAQ dimensions, and not the PCI dimensions, that successfully discriminated a trend between the blistered and nonblistered firewalkers. Hence, high levels of one-pointedness and absorption, that is, how attention is deployed during firewalking may be more critical (than an alteration in consciousness in general) for the fire immunity observed during firewalking.

1992

Patterson, David R.; Everett, John J.; Burns, G. Leonard; Marvin, Janet A. (1992). Hypnosis for the treatment of burn pain. Journal of Consulting and Clinical Psychology, 60, 713-717.

The clinical utility of hypnosis for controlling pain during burn wound debridement was investigated. Thirty hospitalized burn patients and their nurses submitted visual analog scales (VAS) for pain during 2 consecutive daily wound debridements. On the 1st day, patients and nurses submitted baseline VAS ratings. Before the next day's wound debridement, Subjects received hypnosis, attention and information, or no treatment. Only hypnotized Subjects reported significant pain reductions relative to pretreatment baseline. This result was corroborated by nurse VAS ratings.

Findings indicate that hypnosis is a viable adjunct treatment for burn pain. Theoretical and practical implications and future research directions are discussed.

**NOTES:**

The treatment of burn patients involves a number of very painful procedures, including frequent removal of necrotic tissue, application of antiseptics, and bandaging. "Dressing changes often present pain so severe that the maximum dosages of opioids, even when supplemented by anxiolytics or inhalants, are often inadequate (Everett et al., 1990; Perry et al., 1981)" (p. 713). Previous research on the use of hypnosis with burn pain patients demonstrates many of the limitations found in the literature on clinical hypnosis and pain: nonrandomization of samples, nonstandardized hypnotic inductions, unreliable pain measures, inadequate control groups, unreported levels of analgesias used.

The present research controls for experimenter/therapist attention as well as 'expectancy' of both patient and hospital staff. (Both patients and their nurses were blind to group assignment.)

Patients who rated their most recent dressing change as 5 or greater (on a 1-10 scale) were invited to participate and then were randomly assigned to one of three groups: hypnosis, attention/information (pseudo hypnosis), or no treatment control. Interventions began within three days of admission to the acute burn care unit (though some had previously been on an intensive care unit). The patients were continued on opioid medication during the two days of the study, and an attempt was made to keep medication dosage constant. On Day 1 the patients received opioid medication before the dressing change, and on Day 2 they received the same medication plus their assigned treatment.

Hypnosis - Induction was administered by psychologist in patient's room before the dressing change. It was based on Barber's Rapid Induction Analgesia, modified specifically for burn wound debridement as described by Patterson, Questad, and deLateur (1989), and required 25 minutes

Attention and information (pseudo hypnosis) - The psychologist told patients they would get hypnosis, then spent 25 minutes with them, during which time the psychologist took a history of the accident and their emotional response; educated them about burn pain; encouraged them to differentiate sensations felt during dressing changes from signals of harm or danger; and informed them that their "sensation" indicated the presence of viable tissue and was a sign of healing. Toward the end of the session, patients were told "we have found that it is useful to close your eyes, count to 20, and imagine yourself in a relaxing place prior to dressing change" and were given 30 seconds to practice the "hypnosis." They were told after that brief practice session that the nurse would prompt them to begin hypnosis before their next dressing change by giving them some instructions and touch them on the shoulder.

No-treatment control condition - Patients received only the opioid medication.

"A standard set of instructions for dressing changes was given to the nurse for each S in the hypnosis and attention and information groups ... (a) having the subject sit comfortably in the tank (or lie on the table), (b) instructing the S to picture the staircase and count from 1 to 20, (c) touching the subject on the shoulder four times

during wound care, and (d) telling the subject to let the area being worked on 'become relaxed and numb'" (p. 714).

No treatment control condition - Subjects received only opioid medication for both Day 1 and Day 2 dressing changes.

A Visual Analog Scale (VAS) for rating pain was used by both the patients and the nurses, within three hours of the dressing change.

Of 87 patients who met the inclusion criteria (for age, psychiatric and language status, and length of hospital stay) only 30 were in the final group. (31 had pain rating scores below 5; 13 declined to participate; 5 were in other investigations; 5 were not able to participate because of hypnotherapist unavailability; and 3 who began the study did not complete it. Those in the final subject group averaged 34.1 years old; mean total burn surface area was 16%.

No subjects in the placebo group questioned whether they had actually been hypnotized. Nevertheless, Experimenters did a manipulation check to determine whether the pseudo hypnosis group thought they were hypnotized. Subjects rated on a scale of 1-5 the extent to which they believed the hypnotic intervention was 'effective'; means were 4.0 for hypnosis and 3.4 for placebo, a non-significant difference.

Pain medication was converted to morphine equivalents (MD) and was equivalent across the three groups.

"The hypnosis group reported a significant reduction in pain from pre- to posttreatment, whereas the attention and information and the no-treatment control groups did not change significantly ... In addition, the hypnosis group had a significantly lower posttreatment pain rating than both the attention and information and the no-treatment control groups, which did not differ significantly" (p. 715).

"Nurses' ratings of subjects in the hypnosis group showed a significant reduction in pain from pretreatment to posttreatment, whereas there were no significant pain reductions for the attention and information and the no-treatment control groups ... The three posttreatment means did not differ significantly ... [and] correlations between patient baseline and posttreatment pain ratings and those submitted by nurses were  $r(27) = .16$ ,  $p = .423$ , for baseline ratings and  $r(27) = .29$ ,  $p = .127$ , for posttreatment ratings" (p. 716).

In their Discussion, the authors note that patients' reports evidenced more treatment effect than that of nurses. Also, they observed that the treatment effects might have been stronger if they had not been following a research protocol very strictly. "We might also mention that hypnotized subjects reported lower pain scores in spite of problems that they may have had in remembering the actual amount of pain they experienced. There is an increasing body of evidence suggesting that subjects have difficulty remembering clinical pain (Carlsson, 1983). Considering these factors, we feel that the treatment effect was a robust one" (p. 716).

The low correlation between nurses' ratings and patients' ratings is consistent with earlier reports that nurses are often unable to assess patients' pain accurately (Choiniere et al., 1990; Iafrati, 1986; Walkenstein, 1982). The authors discuss why this might be, giving references. "Yet in this study, nurses [blind to group

assignment] still reported a significant pain reduction for the hypnosis group" (p. 716).

"Our findings were consistent with theoretical approaches that argue that hypnotized subjects undergo an altered state--or at least a different form of cognitive processing--as opposed to a placebo effect" (p. 716).

"The question of whether hypnosis is superior to opioid pain medication, or can be used in its stead, was never addressed in this study. All subjects received opioids throughout hospitalization, including the study period. Our bias is that opioid drugs are the primary treatment of choice for burn pain. Attempting to replace opioids with hypnosis for the purpose of satisfying the hypnotist's curiosity or convictions, while occasionally successful, may often result in unnecessary patient suffering" (p. 716).

### **1990**

**Gauld, Alan (1990). The early history of hypnotic skin marking and blistering. British Journal of Experimental and Clinical Hypnosis, 7, 139-152.**

### **NOTES:**

Reviews the history of alleged hypnotic skin marking and blistering from 1785 to 1917. Various early studies are described and brought to bear upon certain long-standing and recurrent controversies. The conclusion is drawn that, even by the end of the period surveyed, the available evidence warranted the belief that such phenomena sometimes occur. However, there were also occasional examples of their occurrence through suggestion without hypnosis, and it remained unclear to what extent hypnosis had played a special role in their production.

### **1989**

**Patterson, David R.; Questad, Kent A.; deLateur, B. J. (1989). Hypnotherapy as an adjunct to narcotic analgesia for the treatment of pain for burn debridement. American Journal of Clinical Hypnosis, 31, 156-163.**

This paper presents a hypnotherapeutic intervention for controlling pain in severely burned patients while they go through dressing changes and wound debridement. The technique is based on Barber's (1977) Rapid Induction Analgesia (RIA) and involves hypnotizing patients in their rooms and having their nurses provide posthypnotic cues for analgesia during wound cleaning. Five subjects who underwent hypnotherapy showed reductions on their pain rating scores (Visual Analogue Scale) relative to their own baselines and to the pain curves of a historical control group (N = 8) matched for initial pain rating scores. Although the lack of randomized assignment to experimental and control groups limited the validity of the results, the findings provide encouraging preliminary evidence that RIA offers an efficient and effective method for controlling severe pain from burns.

Van der Does, A. J.; Van Dyck, R. (1989). Does hypnosis contribute to the care of burn patients? Review of the evidence. General Hospital Psychiatry, 11, 119-124.

In burn treatment, hypnosis has been used for alleviation of pain, prevention and treatment of anxiety and depression, and acceleration of wound healing. Successful application of hypnosis decreases the extensive medication needed. Furthermore, it provides a tool to patients with which they may experience more control in situations that are often experienced as overwhelming. Notwithstanding these important applications and the very positive terms with which the results of studies are generally described, hypnosis has mostly been neglected as a tool to help burn patients. This article reviews the clinical and experimental evidence of the usefulness of hypnosis in the management of burns. Pain reduction and crisis intervention are promising applications. However, due to a lack of systematic and controlled research, more specific conclusions are precluded. In the controversial area of wound healing, claims for the effectiveness of hypnosis have been made on the basis of slim evidence and inconclusive studies. This hypothesis needs to be addressed in controlled experiments. In summary, systematic investigations are needed to confirm and supplement available clinical evidence. Recommendations for future research are given.

**1988**

Van der Does, A. J.; Van Dyck, R.; Spijker, R. E. (1988). Hypnosis and pain in patients with severe burns: A pilot study. Burns Including Thermal Injuries, 14, 399-404.

Presents a pilot study on the effectiveness of hypnosis in the control of pain during dressing changes of burn patients. Eight patients were treated, and all evaluated the interventions as beneficial. The treatment of four patients was more closely analyzed by obtaining pain and anxiety ratings daily. Results show a 50%-64% decrease in reported pain level for three patients and a 52% increase of pain for one patient. The mean decrease for these four patients was 30% (for overall as well as worst pain during dressing changes). A 30% reduction of anxiety level and a modest reduction of medication use were achieved concurrently. It is concluded that hypnosis is of potential value during dressing changes of burn patients. Comparison of global evaluations and daily pain ratings shows that systematic research in some cases leads to conclusions opposite from clinical observations. Follow-up recommendations for future studies are given.

Wakeman, R. J. (1988). Hypnotic desensitization of job-related heat intolerance in recovered burn victims. American Journal of Clinical Hypnosis, 31, 28-32.

The thermally injured patient who suffers extensive third-degree burns usually finds the adaptation to high temperature environments quite difficult. A 7-year study of 50 thermally injured patients with greater than 45% total body surface second- and third-degree burns was conducted to assess the usefulness of hypnosis for improved heat adaptation at the work site. There were 25 subjects in the

experimental group who received hypnotic training and 25 in a matched control group. The experimental group achieved a mean of 6.25 hours worked over 16 weeks and 63.5 days worked out of 80. They worked 4.5 to 6.5 hours per day for an average of 221 days per year for up to 3 years from baseline. The control group achieved a mean of 4.5 hours worked over 16 weeks and 54.33 days worked out of 80. The efficacy of hypnosis in heat desensitization is discussed.

**NOTES:**

Mean age was 38 for the hypnosis group, 33 for the control group; both groups had mean educational level of 8 grades. Mean percentage of total body surface burn was 50% for hypnosis and 54% for control groups.

Each patient was seen for 16 weeks, for 2 hours/week. The hypnosis group received hypnosis, were taught self hypnosis, and were given cassette tapes for use at home. The hypnosis training included a variety of techniques (e.g. progressive deep muscle relaxation, eye-fixation, eye-roll, and visual imagery techniques). They were given suggestions for lower skin temperature, lower 'inner body' temperature, less itching, gradual improvement of time spent on the job, as well as ego strengthening suggestions. The control patients received supportive psychotherapy, family consultation, and cognitive behavior therapy for the same amount of contact time with the same therapist.

The hypnosis group was to do self hypnosis every two hours at the worksite, in addition to home practice. Visual imagery suggestions were things like imagery of a cool waterfall flowing over the skin, having a tall cold glass of beer or soft drink, etc. They also had biofeedback of skin temperature during office visits, to reinforce decreases in skin temperature near the burned sites. They had exposure to heat (in a 95 degree sauna) for in gradually increased periods of time (15 to 120 minutes) before returning to the worksite.

Three years after treatment 20 of 25 control patients had quit their jobs or transferred to a cooler worksite, and all 25 had resigned from their original jobs or applied for further disability benefits. In contrast, only 2 of 25 experimental Ss were working in controlled-temperature settings, and none had applied for permanent disability benefits.

The authors note that family support was essential for the hypnosis patients to carry out their treatment program, and family consultations were essential for every patient. They also found the 'fade-in' technique using the sauna in the hospital occupational therapy area very useful for bridging the gap between practice in the office and going back to the work setting. "This procedure enabled the subject to practice self- hypnosis under controlled physical conditions while performing a work task that was more realistic than 'imagined heat' in the office setting" (p. 31).

**1987**

Dobkin de Rios, Marlene; Friedmann, Joyce K. (1987). Hypnotherapy with Hispanic burn patients. International Journal of Clinical and Experimental Hypnosis, 35 (2), 87-94.

This paper examines a culturally sensitive hypnotherapeutic intervention for Hispanic burn patients who suffer symptoms of the post-traumatic stress disorder and discusses the outcome of 27 patients seen by the authors (a medical anthropologist and a clinical psychologist), over a 3.5-year period. Given the difficulties of recent monolingual, Mexican migrants in responding to psychological interventions that are not culturally sensitive, the hypnotherapeutic interventions and procedures developed by the authors provide a plan for systematic desensitization and cultural concordance to make rehabilitation of Hispanic burn patients more effective.

**Patterson, David R.; Questad, Kent A.; Boltwood, Michael D. (1987). Hypnotherapy as a treatment for pain in patients with burns: Research and clinical considerations. Journal of Burn Care and Rehabilitation, 8 (3), 263-268.**

Hypnotherapy has increasingly been included in the management of burn patients, particularly in the area of acute pain. To better understand such issues as (1) overall efficacy of hypnotherapy to alleviate acute burn pain, (2) instances in which hypnotherapy is contraindicated, (3) interaction of hypnotherapy with medication, (4) standard induction techniques to use with various age groups, (5) role of nursing and other staff in facilitating hypnotic effects, and (6) future methodological directions, they examined the clinical and methodological merits of recent studies of hypnoanalgesia. A literature search found 17 studies in which hypnotherapy was applied to the management of burns. The literature generally supports the efficacy of this approach to reduce burn pain; however, little else can be concluded from these studies. Several recent studies have applied hypnotherapy to aspects of burn care other than pain using excellent experimental designs. It is suggested that future studies of acute pain management follow suit.

**1983**

**Spiegel, David (1983). Hypnosis with medical/surgical patients. General Hospital Psychiatry, 5, 265-277.**

The role of hypnosis as a tool in the treatment of problems commonly encountered among medical and surgical patients is examined. Hypnosis is defined as a change in state of mind far more akin to intense concentration than sleep. Diagnostic implications of differences in hypnotic responsivity are explored, and scales suitable for use in the clinic are examined. Uses of hypnosis in treating anxiety, pain, childbirth, psychosomatic symptoms, seizure disorders, neuromuscular dysfunction, and habits are described and evaluated. The phenomenon of hypnosis is presented as a means of exploring the mind-body relationship in a controlled fashion, providing information of diagnostic importance while at the same time allowing hypnotizable patients to intensify their concentration and interpersonal receptivity in the service of a therapeutic goal.

**1982**

Spanos, Nicholas P.; McNeil, Conrad; Stam, Henderikus J. (1982). Hypnotically 'reliving' a prior burn: Effects on blister formation and localized skin temperature. Journal of Abnormal Psychology, 91 (4), 303-305.

60 Ss who had previously been burned were "hypnotically age regressed" and given both suggestions to "relive" the burn experience and suggestions that a blister was forming. Although 17 Ss reported vividly imagining the burn events, none showed localized skin-coloration changes or evidence of blister formation. Moreover, skin temperature measured before, during, and after age regression indicated no overall suggestion effects. Nevertheless, 1 S did show differential skin-temperature response to the suggestion. This S had showed only moderate hypnotic susceptibility on the Harvard Group Scale of Hypnotic Susceptibility. (10 ref)

**NOTES:**

The male subject who appeared to show changes in response to the suggestion increased temperature differences between the burn site and the contralateral site from .3 degrees C before the imagining period to a maximum of 2.7 degrees C during the imagining period and decreased to 0 degrees C after the imagining period. However, temperature differences between the adjacent sites remained very small (never more than .1 degree C) throughout the session. This subject answered "no" to all seven items on the skin-sensitivity questionnaire. He testified postexperimentally to being only "slightly hypnotized" (score 1), "not at all age regressed" (score 0), and to have experienced imagery that was only 50% as vivid as the real experience. (His HGS: A score was 8.)

**1978**

Kaplan, Jerold Z.; Wakeman, John (1978). An experimental study of hypnosis in painful burns. American Journal of Clinical Hypnosis, 21, 3-12.

The present study examines the usefulness of hypnosis in the control of acute pain in thermal and electrically burned patients as an adjunctive analgesic during the routine care of burn wounds. It was hypothesized that the use of hypnosis would lead to significant reductions in the amount of drugs needed as compared to patients using medication only. Anxiety and discomfort associated with daily tanking, debridement, and dressing changes were expected to be reduced because of the introduction of hypnotic procedures. The experimental study also examined the variables of age and percent of burns. Two studies were conducted including patients with 0-20% total body burns and 31-60% burns. A variety of hypnotic techniques were used. Both studies revealed significantly lower percentages of medication used ( $p < .01$ ) by the hypnotic groups than control groups. The 7-18-year-old patients used significantly less medication ( $p < .05$ ) than the adult groups. The implications of the findings, and usefulness of hypnosis and ego strengthening techniques for improvement of self-confidence and improved body image were considered.

Vasiliev, L. (1965). Mysterious phenomena of the human psyche. New York NY: University Books. (Reviewed by Leo Wollman in American Journal of Clinical Hypnosis, 1965, 8 (2), 146-147)

NOTES

1:

AJCH Abstract by Leo Wollman: Many interesting theories about hypnosis are aired in this book. The opinions Pavlov propounded many years ago, about cortical inhibition are assiduously asserted, yet some statements made bear investigation. The mere sight of the experimenter in B.N. Birman's experiments with dogs put the dog into a hypnotic state. The appearance in the room of other people, who had not participated in the experiments, had no sleep-inducing effect. For the experimental animal, therefore, the experimenter himself had been transformed into a conditioned hypnogenous stimulus. Similarly, in group hypnotherapy, the entrance of the physician-hypnotist into the room often effects a hypnotic state in some of the subjects. The doctor has become the stimulus for the conditioned response, that of hypnotic trance state induction.

An interesting and perhaps little known fact elicited from Chapter III (Hypnotism and Suggestion) is the high percentage (12%) of those replies to questionnaires during the First International Congress on Experimental Psychology held in Paris

in 1899, which indicated that 3,000 respondents had hallucinations while in a normal state of health. The majority were visual; auditory and tactile hallucinations were less frequent.

Dr. P. P. Podyapolsky, in 1905, wrote 'I tried unsuccessfully to induce in a peasant a reddening of the skin from a mock mustard plaster not only was there no reddening, there wasn't even any appropriate sensation of burning or smarting. I surmised that this simple man had probably never experienced a mustard plaster; therefore, his mind lacked the corresponding images and the ability to reproduce them with all their consequences... And so it turned out--he had never experienced a mustard plaster. It happened that he later had occasion to put a mustard plaster on his chest, and when I hypnotized him thereafter, suggestion quickly created not only the appropriate burning sensation but also reddening of the skin where the mock mustard plaster was applied.' This phenomenon is explained by the fact that the connection between the skin and cerebral cortex by means of neural conductors may, under certain circumstances, alter the activity of different organs. The alteration operates, apparently, in the category of conditioned-reflex formation.

This book is interesting reading and from a historic point of view is worth having in one's library.

Crasilneck, Harold B.; Jenkins, M. T. (1958). Further studies in the use of hypnosis as a method of anesthesia. Journal of Clinical and Experimental Hypnosis, 6 (3), 152-158.

NOTES

1:

"At the present time it appears that there are several problems in which hypnosis is an acceptable and perhaps preferable method of anesthesia. Some of these problems include cases in which chemical analgesics and depressants are contraindicated or dangerous because of respiratory or cardiac disease. It may be indicated with patients who have demonstrated sensitivity to certain local anesthetics. Hypno-anesthesia may be used in cases in which repeated chemical anesthesia tends to have a debilitating effect on the patient with an already disturbed physiology, such as patients with thermal injuries who require multiple repeated debridements and dressings. Hypnosis may also obviate the debilitating effects of prolonged chemical anesthesia" (p. 156).

Behavior Therapy / Cognitive Therapy

**1997**

Kirsch, Irving (1996). Hypnosis in psychotherapy: Efficacy and mechanisms. Contemporary Hypnosis, 13 (2), 109-114.

Meta-analyses have established that different psychotherapies have different outcomes. Cognitive-behavioural therapies are significantly more effective than psychodynamic therapies, and their superiority increases when long-term follow-up is assessed. Hypnosis enhances the efficacy of both psychodynamic and cognitive-

behavioural psychotherapy, and this effect is especially strong in long-term outcome of treatment for obesity. The paucity of procedural differences between hypnotic and non-hypnotic treatments in many of the studies demonstrating a substantial advantage for hypnosis suggests that the effect depends on the use of the word 'hypnosis'. Hypnosis can be regarded as an empirically-validated, non-deceptive placebo, the effects of which are mediated by response expectancies.

**1996**

**Kirsch, Irving (1996). Hypnotic enhancement of cognitive-behavioral weight loss treatments--Another meta-reanalysis. Journal of Consulting and Clinical Psychology, 64 (3), 517-519.**

In a 3rd meta-analysis of the effect of adding hypnosis to cognitive-behavioral treatments for weight reduction, additional data were obtained from authors of 2 studies, and computational inaccuracies in both previous meta-analyses were corrected. Averaged across posttreatment and follow-up assessment periods, the mean weight loss was 6.00 lbs. (2.72 kg) without hypnosis and 11.83 lbs. (5.37 kg) with hypnosis. The mean effect size of this difference was 0.66 SD. At the last assessment period, the mean weight loss was 6.03 lbs. (2.74 kg) without hypnosis and 14.88 lbs. (6.75 kg) with hypnosis. The effect size for this difference was 0.98 SD. Correlational analyses indicated that the benefits of hypnosis increased substantially over time ( $r=.74$ ).

**1995**

**Kirsch, Irving; Montgomery, Guy; Sapirstein, Guy (1995). Hypnosis as an adjunct to cognitive behavioral psychotherapy: A meta-analysis. Journal of Consulting and Clinical Psychology, 63 (2), 214-220.**

A meta-analysis was performed on 18 studies in which a cognitive-behavioral therapy was compared with the same therapy supplemented by hypnosis. The results indicated that the addition of hypnosis substantially enhanced treatment outcome, so that the average client receiving cognitive-behavioral hypnotherapy showed greater improvement than at least 70% of clients receiving nonhypnotic treatment. Effects seemed particularly pronounced for treatments of obesity, especially at long-term follow-up, indicating that unlike those in nonhypnotic treatment, clients to whom hypnotic inductions had been administered continued to lose weight after treatment ended. These results were particularly striking because of the few procedural differences between the hypnotic and nonhypnotic treatments.

Miller, Mary E.; Bowers, K. S. (1993). Hypnotic analgesia: Dissociated experience or dissociated control?. Journal of Abnormal Psychology, *102*, 29-38

1994

Miller, Mary E.; Bowers, K. S. (1993). Hypnotic analgesia: Dissociated experience or dissociated control?. Journal of Abnormal Psychology, *102*, 29-38

High-hypnotizable subjects were found superior to low-hypnotizable subjects in degree of pain reduction produced by hypnotic analgesia and by a stress-inoculation (cognitive-therapy) procedure. But, stress inoculation and not hypnotic analgesia impaired performance on a cognitively demanding task that competed with pain reduction for cognitive resources. This outcome implies that hypnotic analgesia occurs with little or no cognitive effort to reduce pain, challenging the social psychological theory of hypnotic response, at least in high-hypnotizable individuals. The findings are also incompatible with the concept of dissociated experience wherein the pain and cognitive efforts to reduce it are separated from consciousness by an amnesia-like barrier. But the results do support the concept of dissociated control, which proposes that suggestions for hypnotic analgesia directly activate pain reduction and thereby avert the need for cognitive strategies to reduce pain.

Saperstein, Guy; Montgomery, Guy; Kirsch, Irving (1993, August). Cognitive-behavioral hypnotherapy: A meta-analysis. [Paper] Presented at the annual meeting of the American Psychological Association, Toronto, Canada.

Meta-analysis was used to compare the effectiveness of cognitive-behavior therapy (CBT) to that of cognitive-behavior therapy with hypnosis (CBHT). A review of the literature revealed 18 studies in which 20 hypnotic treatments were compared to similar non-hypnotic treatments and in which sufficient data were presented for the calculation of effect sizes. Effect sizes were weighted for sample size and then averaged. This resulted in a mean effect size of 1.37 standard deviation units, indicating that the average client receiving cognitive-behavioral hypnotherapy is better off than 90 percent of clients who receive the same treatment in a nonhypnotic context. Substantial variance in effect sizes was found, indicating the presence of a moderator variable. Further analyses indicated that this variance was limited to treatments in which obesity was the presenting problem. The mean effect size for the addition of hypnosis to treatments of obesity was larger ( $M = 1.98$ ) and more variable (variance = 4.10) than that for the addition of hypnosis to treatments for other presenting problems ( $M = .52$ ; variance = .06). Also, studies of clinical samples yielded larger effects ( $M = 1.72$ ) than analogue studies with college student samples ( $M = .07$ ). The effect of hypnosis was independent of whether relaxation training was included in the nonhypnotic treatment or whether the hypnotic

treatment included suggestions that were not included in the nonhypnotic treatment. Consistent with response expectancy theory, these data indicate that the substantial positive effect obtained was due to labeling the treatment 'hypnosis,' rather than to any substantive change in clinical procedure. (ABSTRACT from Bulletin of Division 30, Psychological Hypnosis, Fall 1993, Vol. 2, No. 3.)

Miller, Mary E.; Bowers, K. S. (1993). Hypnotic analgesia: Dissociated experience or dissociated control?. Journal of Abnormal Psychology, 102, 29-38.

High-hypnotizable subjects were found superior to low-hypnotizable subjects in degree of pain reduction produced by hypnotic analgesia and by a stress-inoculation (cognitive-therapy) procedure. But, stress inoculation and not hypnotic analgesia impaired performance on a cognitively demanding task that competed with pain reduction for cognitive resources. This outcome implies that hypnotic analgesia occurs with little or no cognitive effort to reduce pain, challenging the social psychological theory of hypnotic response, at least in high-hypnotizable individuals. The findings are also incompatible with the concept of dissociated experience wherein the pain and cognitive efforts to reduce it are separated from consciousness by an amnesia-like barrier. But the results do support the concept of dissociated control, which proposes that suggestions for hypnotic analgesia directly activate pain reduction and thereby avert the need for cognitive strategies to reduce pain.

1992

Kihlstrom, John F. (1992). Hypnosis: A sesquicentennial essay. International Journal of Clinical and Experimental Hypnosis, 40 (4), 301-314.

The present paper views Coe's (1992) reflections on the socio-political interests in clinical and experimental hypnosis against the background of Braid's Neurypnology of 1843. Topics considered are: the significance of the label "hypnosis"; the controversy over state; the tension between credulity and skepticism; the problem of dissociation and automaticity; current theoretical conflicts; and the relationships between practitioners and researchers.

Kirsch, Irving (1992, August). Cognitive-behavioral hypnotherapy. [Paper] Presented at the annual meeting of the American Psychological Association, Washington, DC.

The use of hypnosis to augment cognitive behavior therapy was described. Hypnotic inductions establish a context in which the effects of therapeutic interventions can be potentiated for clients with positive attitudes and expectancies toward it. Hypnosis can also provide a disinhibiting context for both clients and therapists, allowing them to behave in ways that are therapeutic, but that might seem awkward in other contexts. A meta-analysis of outcome studies in which the effects of a cognitive-behavioral treatment were compared to the effects of the same treatments supplemented by hypnosis resulted in a mean effect size of 0.87 standard deviations,

indicating the average client receiving cognitive-behavioral hypnotherapy is better off at the end of it than more than 80 percent of clients who receive the same treatment in a nonhypnotic context. (ABSTRACT from the Bulletin of Division 30, Psychological Hypnosis, Fall, 1992, Vol. 1, No. 3.)

Levitt, Eugene E. (1992, August). Hypnosis in the treatment of obesity. [Paper] Presented at the annual meeting of the American Psychological Association, Washington, DC.

The literature dealing with the hypnotherapy of overweight and weight control is comprehensively reviewed. In general, the more recent reports are methodologically more sophisticated than earlier ones. Specific techniques employed include direct and aversive suggestions, imagery, ego-enhancement, self-hypnosis and a variety of behavior modification tactics. Most hypnotherapy is carried out in groups and most subjects/patients have been female. Twenty reports providing group data summarized. All but one report weight reduction at close and at follow-up. Of eight reports using control groups, six found that the group treated by hypnotherapy lost significantly more weight than some or all of the control groups. Hypnosis with behavior modification appears to be the most effective approach. Analysis suggests that hypnosis effectuates behavioral techniques after the close of treatment. Eleven reports presenting correlations between weight loss and hypnotic susceptibility differ sharply depending upon the year of publication. Only one of seven reports published prior to 1982 found a relationship between weight loss and susceptibility. Three of four reports since 1985 found a positive relationship. It is concluded that hypnotherapy for weight control can be effective and that it is probably maximally effective with high susceptibility persons. (ABSTRACT from the Bulletin of Division 30, Psychological Hypnosis, Fall, 1992, Vol. 1, No. 3.)

Spanos, Nicholas P.; Simulates, Ann; de Faye, Barbara; Mondoux, Thomas J.; Gabora, Natalie J. (1992-93). A comparison of hypnotic and nonhypnotic treatments for smoking. Imagination, Cognition and Personality, 12, 23-43.

Three experiments administered variants of Spiegel's (1970) smoking cessation procedure to smokers in hypnotic and nonhypnotic treatments. Follow-up periods

were from twelve to twenty-four weeks depending on the experiment. Complete abstinence was an infrequent outcome in all three experiments. Greater-than-control reductions in smoking for treated subjects were obtained in two of the experiments but, in both cases treatment and control subjects failed to differ significantly before the end of the follow-up period. Hypnotic and nonhypnotic treatments produced equivalent smoking reductions in all studies, and neither hypnotizability nor questionnaire assessments of motivation to quit correlated significantly with treatment outcome. Implications are discussed.

#### NOTES:

When the experimenters compared number of treatments they simply compared two sessions of Spiegel's one-session treatment with four sessions of it. The authors make the point that perhaps they should vary the four sessions.

"In all three of the present experiments the abstinence rates associated with the Spiegel treatment were very low. Our abstinence rates were similar to those reported in one earlier study [4 - Perry et al.], but substantially lower than those reported in three other studies [2, 22, 25]. The reasons for these discrepancies between studies remains unclear, but experiment 3 suggests that these discrepancies cannot be accounted for simply in terms of whether the subjects were drawn from a university or nonuniversity population, and experiment 2 suggests that the discrepancies are unrelated to the number of treatment sessions administered to subjects.

"The finding that hypnotic and nonhypnotic subjects in all three experiments attained equivalent reductions in smoking is consistent with other comparison studies in this area which indicate that hypnotic treatments are no more effective than various nonhypnotic procedures at inducing reductions in smoking [22, 25, 30]. More generally, these findings are consistent with comparison studies on a wide variety of clinical disorders (headache pain, warts, phobias, obesity) which indicate that hypnotic treatments are no more effective than nonhypnotic ones at producing therapeutic change (see [3] for a review).

"The failure to find significant correlations between smoking reduction and hypnotizability among treated subjects is also consistent with the findings of most studies in this area [3], but the reasons why significant correlations between these variables are found in some studies and not others remains unclear. Spanos [3] suggested that significant correlations between these variables are particularly likely when hypnotizability testing is integrated into the treatment protocol. Under these circumstances subjects are likely to form strong expectations about treatment success on the basis of their self-observed responses to the hypnotizability scale. Such expectations may, in turn, influence subjects' motivations to comply with the treatment regimen, the self-statements they make concerning their likelihood of quitting, etc. In all of the present experiments hypnotizability was assessed at the end of the follow-up period and, therefore, could not influence subjects' expectations of treatment success" (pp. 40-41).

Syrjala, Karen L.; Cummings, Claudette; Donaldson, Gary W. (1992). Hypnosis or cognitive behavioral training for the reduction of pain and nausea during cancer treatment: A controlled clinical trial. Pain, 48, 137-146.

Few controlled clinical trials have tested the efficacy of psychological techniques for reducing cancer pain or post-chemotherapy nausea and emesis. In this study, 67 bone marrow transplant patients with hematological malignancies were randomly assigned to one of four groups prior to beginning transplantation conditioning: (1) hypnosis training (Hypnosis); (2) cognitive behavioral coping skills training (CB); (3) therapist contact control (TC); or (4) treatment as usual (TAU; no treatment control). Patients completed measures of physical functioning (Sickness Impact Profile; SIP) and psychological functioning (Brief Symptom Inventory; BSI), which were used as covariates in the analyses. Biodemographic variables included gender, age and a risk variable based on diagnosis and number of remissions or relapses. Patients in the Hypnosis, CB, and TC groups met with a clinical psychologist for two pre-transplant training sessions and ten in-hospital "booster" sessions during the course of transplantation. Forty-five patients completed the study and provided all covariate data, and 80% of the time series outcome data. Analyses of the principal study variables indicated that hypnosis was effective in reducing reported oral pain for patients undergoing marrow transplantation. Risk, SIP, and BSI pre-transplant were found to be effective predictors of inpatient physical symptoms. Nausea, emesis and opioid use did not differ significantly between the treatment groups. The cognitive behavioral intervention, as applied in this study, was not effective in reducing the symptoms measured.

#### NOTES:

Hypnotizability was not measured in this study.

The authors hypothesized that "(1) patients receiving hypnosis training would report the least pain, but the cognitive behavioral group would report less pain than the untreated group; and (2) both treatment groups would report less nausea and emesis than the control groups" (p. 138). The adult patients were undergoing their first marrow transplant, had survived at least 19 days post-transplant, and had participated in at least the first 8 of 10 possible inpatient sessions; five additional patients completed the study but had missing data.

Each patient in the TC (therapist contact), CB (cognitive behavioral coping skills), and Hypnosis groups participated in two 90 minute training sessions with a psychologist, 2-4 days apart, on an outpatient basis. Once admitted to hospital, twice each week they participated in a total of ten 30-minute sessions designed to reinforce use of the interventions. The TAU (treatment as usual) group had no psychologist contact. For the TC control group, the psychologist simply talked with the patients about whatever was on their minds.

The CB group received multiple interventions: training in relaxation (2 techniques-progressive muscle relaxation and abbreviated autogenic relaxation) with tapes provided; cognitive restructuring (Turk et al., 1983) which included training in attention redirection and restructuring self-defeating cognitions; preparing coping self-statements or affirmations, by focusing attention on neutral or pleasant events

or objects, or by occupying their attention through mental repetition of affirmations, songs or prayer; encouragement to think of negative events as time limited; provision of information, especially the beneficial effects of reducing physiological arousal and attention to pain and nausea; assistance in setting short-term progress-related goals for self-care such as exercise, caloric intake, and mouth care; exploration of the meaning of their illness and of bone marrow transplant.

For the Hypnosis group, individually tailored Ericksonian inductions (Lankton & Lankton, 1983) with relaxation and multi-sensory imagery were taped and given to the patient to use in daily practice, in between sessions. The suggestions were directed at reducing pain, nausea, and the emotional reactions to those symptoms; there also were suggestions about health, well-being, self-control and enhanced coping capabilities.

The results were analyzed by ANCOVA (except where non-parametric analysis was required with the opioid data). Due to gender differences in reported pain (men experiencing more) and the fact that the TAU group had an over-representation of men, the TAU group could not be used in the pain analyses. However, there were no gender differences in nausea reports, so that all four groups could be used for nausea outcome analyses.

The Hypnosis group evidenced the lowest amount of post-transplant pain, and used (nonsignificantly) less opioids than the other groups. No significant treatment effects were observed for either nausea or emesis.

In their discussion, the authors noted that "The hypnosis group's peak pain was lower and of a shorter duration than the other three groups. Opioid use closely followed the course of pain intensity. ... The gender effect may be characteristic of this particular sample [since it was unexpected].

"Nausea and emesis followed a less predictable course than pain. ... nausea fluctuated dramatically from day to day within treatment groups. As nausea moderated after completion of conditioning, the day to day fluctuations remained striking. This lack of symptom predictability may have contributed to the difficulty patients had in using the interventions effectively" (p. 143).

"The lack of significant differences between treatment groups in opioid use indicates that lower pain report in the hypnosis group cannot be explained by increased opioid use. Results do not support the second hypothesis that both hypnosis and cognitive behavioral training would reduce chemotherapy or radiation-induced nausea and emesis.

"In MT patients, several factors may limit the impact of either cognitive behavioral training or hypnosis on nausea and emesis. First, MT patients receive higher doses of emetogenic agents than are given to most other cancer patients. Second, patients in this study had only two sessions in which to learn relaxation techniques; this may not have provided adequate training. Third, the most severe emetic challenge began immediately with the first dose of chemotherapy rather than having a gradual onset. This did not permit patients to master the techniques with milder symptoms before applying training to intense symptoms. Fourth, for all patients, psychological interventions were provided as adjuncts to medications rather than as substitutes for antiemetics or opioids. Both antiemetics and opioids have substantial cognitive side effects which, in high doses, may impact patients' abilities to implement

interventions which are in essence cognitive. This combination of factors may have provided too severe a challenge to a newly learned skill. In contrast to nausea, oral pain developed over a number of days, permitting practice while symptoms were mild and before administration of opioids.

"Results suggest that the imagery component of the hypnosis intervention was central to its efficacy. Not only was the cognitive behavioral intervention without imagery not effective in reducing the symptoms measured, but we found in clinical practice that patients intermittently began to refuse sessions with relaxation alone. Even hypnosis patients, when under the physical stresses of treatment, had shortened attention spans that necessitated briefer inductions, less time spent on relaxation, and more active, engaging imagery.

"... Since, in clinical practice, imagery is frequently a component of cognitive behavioral treatment, these results would not generalize to those settings where imagery is combined with other skill training.

"Several other possible limitations of the cognitive behavioral intervention merit consideration. Our experience indicates that the number of components used in the two training sessions were more than patients could competently learn in a short time. ... A further possibility is that maladaptive cognitions, which are the targets of cognitive restructuring, may be the exception rather than the rule among MT patients who tend to focus, with their families, on positive, hopeful attitudes toward their treatment" (pp. 144- 145).

The authors note that the relatively small sample size may have provided inadequate statistical power to demonstrate effects with some of the outcome variables

Tosi, D. J.; Rudy, D. R.; Lewis, J.; Murphy, M. A. (1992). The psychobiological effects of cognitive experiential therapy, hypnosis, cognitive restructuring, and attention placebo control in the treatment of essential hypertension. Psychotherapy, 29, 274-284

Evaluated the effects of cognitive experiential hypnotherapy (CEH), which includes hypnosis, cognitive restructuring, and developmental staging, on essential hypertension. CEH, Hypnosis alone, cognitive restructuring, and attention-placebo control conditions were randomly assigned to 39 subjects. There was a significant interaction effect with the nine psychobiological outcome measures. Discriminant analysis found a stronger overall effect over time for CEH when compared with its components.

Grossarth-Maticek, R.; Eysenck, H. J. (1991). Creative novation behaviour therapy as a prophylactic treatment for cancer and coronary heart disease: Part II - Effects of treatment. Behaviour Research and Therapy, 29, 17-31.

NOTES:

Reports on what they call creative novation behavior therapy or "autonomy training" to prevent cancer and coronary heart disease in prone individuals. This individually tailored cognitive-behavioral program includes the use of hypnosis and of imagery. When administered individually (20-30 hours) in a group (6-15 sessions of up to several hours) or via bibliotherapy with 4-6 hours of individual therapy, the outcome was better than that of control subjects. After 13 years, 45 of 50 cancer-prone subjects in individual treatment were still alive (and none of the 5 deaths were from cancer), while among 50 control subjects, 31 died, 16 from cancer. This study along with Spiegel et al. (1989) article in *Lancet* have important implications for health care.

Mauer, D. R. (1991, October). A comparison of cognitive-behavioral and hypnotic techniques in the management of electromyography pain (Dissertation, University of Iowa). Dissertation Abstracts International, 53 (4), 1070-B. (Order No. DA 9217180)

"Compared a cognitive behavioral technique that included providing specific sensory and procedural information combined with relaxation with a hypnotic technique (relaxation with guided imagery) and a control group for management of acute EMG pain and anxiety. Pain and anxiety ratings were gathered from 45 EMG patients and observers for both nerve conduction and needle electrode components of the EMG exam. It was found that only the hypnosis group significantly reduced pain and anxiety during the needle electrode portion of the procedure. Patients with unexplained or functional symptoms reported more EMG pain and anxiety than patients who had an organically based disease. Because having had a prior EMG seemed to have an effect on the efficacy of treatment, the data were reexamined. Results determined that inexperienced EMG patients who were treated had less pain and anxiety than patients who experienced EMG before, but inexperienced control patients had an increase in pain and anxiety over experienced patients" (p. 1070).

#### NOTES

This is a commentary on two papers by Grossarth-Maticek and Eysenck, in which they report on 'creative novation behaviour therapy' to prevent cancer and heart disease in people with personalities associated with the development of those diseases. Therapy may involve hypnosis and/or relaxation, with suggestions that facilitate modification of unhealthy expectancies. The papers are:

Grossarth-Maticek, R. & Eysenck, H.J. (1991). Creative novation behaviour therapy as a prophylactic treatment for cancer and coronary heart disease: Part I - Description of treatment. *Behaviour Research and Therapy* 29, 1-16.

Eysenck, H.J. & Grossarth-Maticek, R. (1991). Creative novation behaviour therapy as a prophylactic treatment for cancer and coronary heart disease: Part II - Effects of treatment. *Behaviour Research and Therapy* 29, 1, 17-31.

Oettingen, Gabriele; Wadden, Thomas A. (1991). Expectation, fantasy, and weight loss: Is the impact of positive thinking always positive?. Cognitive Therapy and Research, 15 (2), 167-175.

Investigated the impact of expectation and fantasy on the weight losses of 25 obese women participating in a behavioral weight reduction program. Both expectations of reaching one's goal weight and spontaneous weight-related fantasies were measured at pretreatment before Ss began 1 year of weekly group treatment. Consistent with the hypothesis that expectation and fantasy are different in quality, these variables predicted weight change in opposite directions. Optimistic expectations but negative fantasies favored weight loss. Ss who displayed pessimistic expectations combined with positive fantasies had the poorest treatment outcome. Expectation but not fantasy predicted program attendance. The effects of fantasy are discussed with regard to their potential impact on weight reduction therapy.

Rapee, Ronald M. (1991). The conceptual overlap between cognition and conditioning in clinical psychology. Clinical Psychology Review, 11, 193-203.

Given the fact that contemporary theories of conditioning regularly utilize information processing concepts such as memory and expectancies, classifying clinical theories as either cognitive or conditioned appears to be outdated. Yet, this dichotomy is still upheld in many clinical writings. Such a false dichotomy seems to serve more of a political function than a theoretical one and thus is likely to interfere with a complete understanding of psychopathology. While the terms conditioning and cognition are often used to imply unconscious learning on the one hand versus conscious, rational learning on the other, this usage is not consistent. A more empirically useful way to describe pathological behavior may be in terms of the amount of attentional resources utilized.

Salkovskis, Paul M.; Clark, David M.; Hackmann, Ann (1991). Treatment of panic attacks using cognitive therapy without exposure or breathing retraining. Behaviour Research and Therapy, 29 (2), 161-166.

Used a multiple baseline design among 7 panic patients to determine whether a modified form of treatment involving cognitive procedures reduces panic attack frequency. Ss received both focal and nonfocal treatment. Focal therapy concentrated on bringing about reattribution of bodily sensations. Six of the 7 Ss showed a marked reduction in panic frequency following focal cognitive treatment, while nonfocal treatment did not reduce panic frequency. Results provide preliminary evidence that cognitive procedures that exclude breathing retraining and exposure to feared situations or sensations can reduce panic attack frequency, and that cognitive procedures that do not target misinterpretations of bodily sensations may not reduce panic.

Schwarz, Shirley P.; Blanchard, Edward B. (1991). Evaluation of a psychological treatment for inflammatory bowel disease. Behaviour Research and Therapy, 29 (2), 167-177.

Compared the effectiveness of a multicomponent behavioral treatment package, which included inflammatory bowel disease (IBD) education, progressive muscle relaxation, thermal biofeedback, and training in use of cognitive coping strategies, with the effectiveness of symptom-monitoring as a control condition. The treatment group consisted of 11 IBD patients (aged 25-62 yrs); 8 of 10 persons (aged 25-71 yrs) in the control group completed treatment. At posttreatment, the treatment group showed fewer reductions in symptoms (5) than the symptom-monitoring controls (8). However, treated Ss perceived themselves as coping better with IBD and as feeling less IBD-related stress. It is hypothesized that the differences in treatment responses may be related to differences between Ss with ulcerative colitis and Ss with Crohn's disease.

1990

Clark, Duncan B.; Agras, W. Stewart (1990). The assessment and treatment of performance anxiety in musicians. American Journal of Psychiatry, 148 (5), 598-605.

94 adults with a performance anxiety problem were recruited by mass media announcements and were seen in a university-based outpatient psychiatric clinic. Assessments were questionnaires for all 94 ss, diagnostic interview of 50 ss, and laboratory performance of 34 ss. Treatment conditions were 6 weeks of buspirone, 6 weeks of placebo, a five-session group cognitive-behavior therapy program (CBTP) with buspirone, or the CBTP with placebo. All Ss fulfilled criteria for Diagnostic and Statistical Manual of Mental Disorders-III-Revised (DSM-III-R) social phobia. Of the 15 full-time professional musicians, 10 had tried propranolol and 3 had stopped performing. Most Ss had substantial anxiety and heart rate increases during lab speech and musical performances. CBTP resulted in significant reductions in subjective anxiety, improved quality of musical performance, and improved performance confidence.

Harmon, Teresa M.; Hynan, Michael T.; Tyre, Timothy E. (1990). Improved obstetric outcomes using hypnotic analgesia and skill mastery combined with childbirth education. Journal of Consulting and Clinical Psychology, 58, 525-530.

Studied the benefits of hypnotic analgesia as an adjunct to childbirth in 60 nulliparous women. Subjects were divided into high- and low-susceptibility groups before receiving six sessions of childbirth education and skill mastery using an ischemic pain task. Half of the subjects in each group received a hypnotic induction at the beginning of each session; the remaining control subjects received relaxation and breathing exercises typically used in childbirth education. Both hypnotic subjects and highly susceptible subjects reported reduced pain. Hypnotically prepared births had shorter Stage 1 labors, less medication, higher Apgar scores,

and more frequent spontaneous deliveries than control subjects' births. Highly susceptible, hypnotically treated women had lower depression scores after birth than women in the other three groups. The authors believe that repeated skill mastery facilitated the effectiveness of hypnosis in the study.

Kaye, J. M.; Schindler, B. A. (1990). Hypnosis on a consultation-liaison service. General Hospital Psychiatry, 12, 379-383.

Studied the use of hypnosis on a consultation-liaison service with a broad spectrum of medically hospitalized patients. Autohypnosis tapes were used for reinforcement. Twenty-nine women and eight men from 24-75 years of age were hypnotized for relief of depression, pain, anxiety, or side effects of chemotherapy. Results were excellent (total to almost total relief of symptoms) in 68%, fair in 22%, and poor in 11%, with no differences among the results with the various conditions. This demonstrates that hypnotherapy is an extremely useful tool in medical management of patients in consultation-liaison psychiatry.

Kirsch, Irving (1990). Changing expectations: A key to effective psychotherapy. Pacific Grove, CA: Brooks/Cole. (Reviewed in American Journal of Clinical Hypnosis, 34, 138)

**NOTES:**

This is a clinical hypnosis textbook written from the perspective of a cognitive therapist, and based on response-expectancy theory. The author discusses how expectancy theory can account for results obtained with hypnosis, cognitive behavioral, and psychodynamic psychotherapy, as well as with psychopharmacology. The book draws heavily upon psychological research in psychotherapy as well as hypnosis, and discusses how therapists can mobilize patient positive expectations for change. Hypnotic responses are viewed as 'genuine' responses that subjectively are not perceived to be under voluntary control (similar to other classes of response behavior).

Newshan, Gayle; Balamuth, Ron (1990-91). Use of imagery in a chronic pain outpatient group. Imagination, Cognition and Personality, 10, 25-38.

Reports treatment of chronic pain, integrating relaxation, cognitive therapy, and imagery techniques for 3 groups of chronic pain patients. Imagery and visualization were the most important components of the treatment.

**NOTES:**

Chronic nonmalignant pain is defined as pain that exists beyond the normal and expected healing time, usually six months or more after the initial injury or trauma. Patients used daily journal to monitor level of pain using a color scale 4 times/day (blue - little or no pain, green mild pain, yellow moderate, orange severe, and red pain so intense it could kill or render the patient unconscious).

Used two types of imagery: mental rehearsal of actually doing and reaching a goal, or symbolic representation of the pain as a creature, alive, within their bodies. They dialog with the creature, asking Why are you here? What do you need from me? What can I do to live with you? What is the message you have for me? patients are asked to listen very closely for the response.

Cognitive restructuring is introduced later to identify dysfunctional thought patterns and correct them. They are taught, 1) thoughts influence behavior and emotions, 2) thoughts can be changed, and therefore 3) behavior can be changed. However, not all patients benefit from cognitive restructuring (because resistant to self monitoring or frightened or critical of own negative thoughts).

Relaxation is especially beneficial in breaking the pain/anxiety cycle, reducing fear associated with pain, improving sleep patterns, promoting a general feeling of well-being and facilitating mental imagery. Mental imagery, on the other hand, provides a means of self-discovery. It is defined by Achterberg and Lawlis (1980) as the internal experience of a perceptual event in the absence of the actual external stimuli; although usually thought of as visual, it may well involve any other sensory modality associated with the image.

Imagery is a proverbial process, eliciting the rich symbolism of knowledge of a person's unconscious and providing powerful insights indirectly. It provides an opportunity for one to reorganize a problem or experience, such as pain, towards a more positive resolution. Imagery can increase the patient's self-esteem and self-control and seems to facilitate well behavior. It is also a vivid method of communication from the patient to the therapist and the rest of the group. The group members had a healthy respect for these images and were able to appreciate the impact they had in their recovery, even if the process is not completely understood.

In each of their cases, "it is important to emphasize that the pain was never 'cured,' the pain persisted throughout treatment. Again, the program does not take away the patients' pain but changes the pain experience and enables patients to participate more fully in their lives despite the pain. As suggested by the 'big person, small person' concept, the pain would probably always be part of their lives, but through the program it could be a smaller, more manageable part. Imagery proved to be a valuable tool in helping clients achieve this goal.

Schwarz, Shirley P.; Taylor, Ann E.; Scharff, Lisa; Blanchard, Edward B. (1990). Behaviorally treated irritable bowel syndrome patients: A four-year follow-up. Behaviour Research and Therapy, 28 (4), 331-335.

A 4-yr longitudinal study evaluated 19 patients (aged 23-60 yrs) suffering from Irritable Bowel Syndrome (IBS) who had completed a multicomponent treatment involving progressive muscle relaxation, thermal biofeedback, cognitive therapy, and IBS education at baseline. 17 Ss rated themselves as more than 50% improved. Six of the 12 Ss who submitted symptom monitoring diaries met the criteria for clinical improvement, (i.e., achieving at least a 50% reduction in primary IBS symptom scores). The means on all measures at long-term follow-up were lower than those obtained prior to treatment. When follow-up symptom means were

compared with pretreatment means, significant reductions were obtained on abdominal pain/tenderness, diarrhea, nausea, and flatulence.

Stanton, Harry E. (1990). Using ego-enhancement to increase assertiveness. British Journal of Experimental and Clinical Hypnosis, 7, 133-137.

An ego-enhancement technique embodying three metaphors designed to help elderly people become more assertive is described. These metaphors: (1) the cloud - a symbol for 'getting rid of things'; (2) the snowball - a symbol for determination; and (3) the pyramid - a symbol for confidence, are linked together to achieve both general ego- enhancement and increased assertiveness.

Turner, Judith A.; Clancy, Steve; McQuade, Kevin J.; Cardenas, Diana D. (1990). Effectiveness of behavioral therapy for chronic low back pain: A component analysis. Journal of Consulting and Clinical Psychology, 58 (5), 573-579.

The effects of outpatient group behavioral therapy including aerobic exercise (BE), behavioral therapy only (B), and aerobic (E) on pain and physical and psychosocial disability were evaluated and compared in a group of mildly disabled chronic low-back-pain patients. Ninety-six Ss were randomly assigned to the 3 treatments and a waiting-list control (WL) condition and assessed on a variety of patient self-report, spouse-rated, and direct observational measures at pretreatment, posttreatment, and 6- and 12-month follow-ups. Patients in the BE condition, but not the B or E conditions, improved significantly more pretreatment to posttreatment than did WL patients on the patient self-report and observer-rated measures. At both follow-ups, all 3 treatment groups remained significantly improved from pretreatment, with no significant differences among treatments.

Vanderlindin, Johan; Vandereycken, Walter (1990). The use of hypnosis in the treatment of bulimia nervosa. International Journal of Clinical and Experimental Hypnosis, 38 (2), 101-111.

**NOTES:**

25 people who were highly hypnotizable were treated. Treatment consisted of three phases: introduction to hypnosis, addressing core issues, and ensuring long term results. The induction included focus on breathing, relaxation, and arm levitation. Subject was told to imagine that she is eating a meal, while concentrating and tasting her food. She is then told to imagine a recent binge and to exaggerate all the negative consequences of bingeing (weight gain, low self-esteem) and all the positive consequences of binge-free life.

To address Subject's core issues of why bingeing started, the Subject is told to separate her ego from her bulimic past, and the therapist then tries to find out why the bulimic past entered the patients' life. The therapist then tries to 'negotiate' with the bulimic past and tries to help the patient find other ways to deal with the problems. Cognitive restructuring and hypnosis techniques are used.

The final phase, which entails a year of followup care, involves helping the patients to become independent from their past. Many bulimic patients are still dependent on their parents, and this may have caused their dependency on food. Therefore, the goal of hypnosis is to allow herself to become emotionally independent and to control her life.

It was estimated that 50% of patients completely recovered and 30% showed great improvement but 20% did not change at all.

Wells, Adrian (1990). Panic disorder in association with relaxation induced anxiety: An attentional training approach to treatment. Behavior Therapy, 21 (3), 273-280.

Trained a 40-yr-old woman with panic disorder without agoraphobic avoidance in the use of an attentional training procedure that was effective in eliminating panic and facilitated tension reduction without producing anxiety. A 2-treatment design revealed that a procedure evoking external attentional focus eliminated panic attacks, whereas autogenic training increased the frequency of panic attacks and the intensity of anxiety. Possible roles of self-focus in mediating panic and the effects of relaxation are discussed.

1989

Cooper, Nancy A.; Clum, George A. (1989). Imaginal flooding as a supplementary treatment for PTSD in combat veterans: A controlled study. Behavior Therapy, 20 (3), 381-391.

14 Vietnam veterans suffering from posttraumatic stress disorder (PTSD) were assigned either to standard treatment (control group), or standard treatment plus imaginal flooding (experimental group). The 2 groups were closely matched on medications and combat roles and tours of duty were comparable. Experimental Ss received up to 14 sessions of flooding for a maximum of one and one-half hours per session. Self-report measures were administered at pre-treatment, post-treatment, and at 3-mo follow-up. These measures included the Behavioral Avoidance Test, the Beck Depression Inventory, and a Modified Vietnam Experiences Questionnaire. Results indicate that flooding increased the effectiveness of usual treatment, particularly in such areas as re-experiencing symptoms and sleep disturbances. However, flooding had no effect on level of depression, trait anxiety, and violence-proneness.

Edelson, Jeffrey; Fitzpatrick, Jody L. (1989). A comparison of cognitive-behavioral and hypnotic treatments of chronic pain. Journal of Clinical Psychology, 45, 316-323.

27 male chronic pain patients were assigned to 1 of 3 treatment groups: hypnosis, cognitive-behavioral, and attention control. Hypnosis and cognitive-behavioral treatments were identical, with the exception of the hypnotic induction. Scores on the McGill Pain Questionnaire (MPQ) and a measure of the overt motor behavior element of chronic pain were collected at pretreatment, posttreatment, and follow-

up intervals. Analyses showed significant increases in activity and decreases in pain intensity for the cognitive-behavioral treatment. Changes for the hypnosis treatment were noted only on the MPQ. Changes for both groups were sustained on the 1-mo follow-up. Findings generally support the superiority of the cognitive-behavioral treatment on behavior measures and its equivalence to hypnosis on subjective measures.

Heap, Michael (1989). Antecedent imagery in a case of Gilles de la Tourette syndrome. British Journal of Experimental and Clinical Hypnosis, 6 (1), 55-56.

#### NOTES

1:

Author presents a male teenager diagnosed with Gilles de la Tourette syndrome, who was treated without noticeable success using a variety of techniques (relaxation, suggestion, hypnoanalysis, video-feedback, paradoxical injunction).

Stanton, Harry E. (1989). Hypnotic relaxation and the reduction of sleep onset insomnia. International Journal of Psychosomatics, 36, 64-68.

A hypnotic relaxation technique was compared to stimulus control and placebo conditions as a means of reducing sleep onset latency (SOL). Forty-five subjects were matched on their baseline SOL as measured through sleep diaries. They were randomly assigned to one of the three groups and experienced four weekly sessions of 30- minutes' duration, with demand effects being controlled through the use of counter- demand instructions. Data generated by the study suggested that the particular hypnotic relaxation treatment used was effective in helping Ss sleep more quickly. Neither stimulus control nor placebo groups recorded similar improvement.

Tosi, D. J.; Judah, S. M.; Murphy, M. A. (1989). The effects of a cognitive experiential therapy utilizing hypnosis, cognitive restructuring, and developmental staging in psychological factors associated with duodenal ulcer disease: A multivariate experimental study. Journal of Cognitive Psychotherapy, 3, 273-290.

This study evaluated the effects of a Cognitive Experiential Therapy (CET)--in the past referred to as Rational Stage Directed Hypnotherapy--Cognitive Restructuring (CR), Hypnosis Only (HO), and a no-treatment control condition on the duodenal ulcer syndrome. CET is a systematic, stage-directed therapy that employs hypnosis and the cognitive restructuring of self-defeating cognitive, emotional, physiological, and behavioral tendencies. Seven criterion variables were assessed using two standardized instruments and questionnaire data. The standardized instruments included the Millon Behavioral Health Inventory (MBHI) and the Common Beliefs Survey III (CBS). Twenty-five volunteer duodenal ulcer patients were subjects in a 4 x 3 factorial design with repeated measures consisting of the four treatments and pretest, posttest, and follow-up. There was a significant treatment effect, and effects were observed on personality coping styles, beliefs and locus of control scales, and

on gastrointestinal disturbance. CET appeared to have an ameliorative effect on psychological factors associated with duodenal ulcer.

Van den Bergh, Omer; Eelen, Paul; Baeyens, Frank (1989). Brief exposure to fear stimuli: Imagery ability as a condition of fear enhancement and fear decrease. Behavior Therapy, *20*, 563-572.

Examined fear enhancement and fear decrease during brief exposure to fear stimuli. 140 good and poor imagery Subjects (aged 14-18 years) with medium fear levels toward spiders were exposed to a live spider, either by looking at it or by thinking of an invisible, but present spider during either 60, 180, or 360 sec. Control Subjects were given a distraction task. Subjective fear and behavioral approach were measured. Brief exposure hindered fear decrease compared to the control condition. Good imagers showed more fear decrease and were less affected by the mode of exposure. Fear enhancement occurred only in poor imagers at the longer exposure duration (360 sec) during thinking. In that condition, good imagers showed their greatest fear decrease.

1988

Malone, M.; Strube, M. (1988). Meta-analysis of non-medical treatment for chronic pain. Pain, *34*, 231-234.

Conducted a meta-analysis of 109 published studies which assessed the outcome of various nonmedical treatments for chronic pain, 48 of which had sufficient information to calculate effect sizes. The remainder were examined according to proportion of patients rated as improved. Mood and number of subjective symptoms consistently showed greater responses to treatment than did pain intensity, pain duration, or frequency of pain, indicating the importance of using a multidimensional framework for pain assessment. Effect sizes for treatments were 2.74 for autogenic training, 2.67 for hypnosis, 2.23 for pill placebo, 1.33 for package treatments that allowed patients to choose from diverse pain management strategies, .95 for biofeedback, .76 for cognitive therapy, .67 for relaxation, .55 for operant conditioning, and .46 for TENS units. However, the largest numbers of studies were in the area of biofeedback, a treatment package, and relaxation, and we must be cautious in interpreting the effect sizes due to the small number of studies in the sample.

Tsushima, W. T. (1988). Current psychological treatments for stress-related skin disorders. Cutis, *42*, 402-404.

Surveys current methods used by psychologists in the management of stress-related skin disorders, including hypnosis, relaxation training, biofeedback, operant conditioning, and cognitive behavioral therapy. These techniques offer promise in the treatment of certain dermatologic conditions, but the limited amount of well-controlled and replicated studies of their use suggests that caution be taken in their application.

Wakeman, R. J. (1988). Hypnotic desensitization of job-related heat intolerance in recovered burn victims. American Journal of Clinical Hypnosis, 31, 28-32.

The thermally injured patient who suffers extensive third-degree burns usually finds the adaptation to high temperature environments quite difficult. A 7-year study of 50 thermally injured patients with greater than 45% total body surface second- and third-degree burns was conducted to assess the usefulness of hypnosis for improved heat adaptation at the work site. There were 25 subjects in the experimental group who received hypnotic training and 25 in a matched control group. The experimental group achieved a mean of 6.25 hours worked over 16 weeks and 63.5 days worked out of 80. They worked 4.5 to 6.5 hours per day for an average of 221 days per year for up to 3 years from baseline. The control group achieved a mean of 4.5 hours worked over 16 weeks and 54.33 days worked out of 80. The efficacy of hypnosis in heat desensitization is discussed.

**NOTES:**

Mean age was 38 for the hypnosis group, 33 for the control group; both groups had mean educational level of 8 grades. Mean percentage of total body surface burn was 50% for hypnosis and 54% for control groups.

Each patient was seen for 16 weeks, for 2 hours/week. The hypnosis group received hypnosis, were taught self hypnosis, and were given cassette tapes for use at home. The hypnosis training included a variety of techniques (e.g. progressive deep muscle relaxation, eye-fixation, eye-roll, and visual imagery techniques). They were given suggestions for lower skin temperature, lower 'inner body' temperature, less itching, gradual improvement of time spent on the job, as well as ego strengthening suggestions. The control patients received supportive psychotherapy, family consultation, and cognitive behavior therapy for the same amount of contact time with the same therapist.

The hypnosis group was to do self hypnosis every two hours at the worksite, in addition to home practice. Visual imagery suggestions were things like imagery of a cool waterfall flowing over the skin, having a tall cold glass of beer or soft drink, etc. They also had biofeedback of skin temperature during office visits, to reinforce decreases in skin temperature near the burned sites. They had exposure to heat (in a 95 degree sauna) for in gradually increased periods of time (15 to 120 minutes) before returning to the worksite.

Three years after treatment 20 of 25 control patients had quit their jobs or transferred to a cooler worksite, and all 25 had resigned from their original jobs or applied for further disability benefits. In contrast, only 2 of 25 experimental Ss were working in controlled-temperature settings, and none had applied for permanent disability benefits.

The authors note that family support was essential for the hypnosis patients to carry out their treatment program, and family consultations were essential for every patient. They also found the 'fade-in' technique using the sauna in the hospital occupational therapy area very useful for bridging the gap between practice in the office and going back to the work setting. "This procedure enabled the subject to

practice self- hypnosis under controlled physical conditions while performing a work task that was more realistic than 'imagined heat' in the office setting" (p. 31).

Crist, Dwayne Anderson (1987). The effect of suggestibility on the efficacy of relaxation training instruction: A multisession evaluation (Dissertation, University of Alabama). Dissertation Abstracts International, 47 (n9-B), 3950.

"Progressive relaxation is a well established procedure used in the treatment of anxiety related disorders. Research has suggested that the muscle tension-release component of progressive relaxation is the critical variable in producing relaxation effects. However, other techniques which do not employ muscle-tension release have proven effective. It has been suggested that treatment type may interact with personality characteristics to produce greater effects. Suggestibility was selected as a personality characteristic that may facilitate or inhibit relaxation effects. Fifty high and 50 low suggestible individuals were selected to participate based on scores from the Creative Imagination Scale. Half of each group was randomly assigned to either a progressive relaxation or imagery relaxation treatment. Subjects received four weekly sessions of relaxation training. The Relaxation Scale was administered before and after each session to assess effects of training. The results indicated that high suggestible individuals had significantly greater increases in relaxation within session on each of the three scales of the Relaxation Scale, but this appeared to be a result of lower pre-test scores. Only the Physical Assessment scale also demonstrated higher post-test scores for the high suggestible participants. A ceiling effect appeared to be operating for both the Physiological Tension and Cognitive Tension scales. There were no significant differences between the progressive relaxation and imagery relaxation treatments. It appears that muscle tension release may not be a critical variable in relaxation effects" (p. ).

Jay, Susan (1987, October). Hypnotic susceptibility and response to psychological intervention for distress related to painful procedures in leukemic children. [Paper] Presented at the annual meeting of the Society for Clinical and Experimental Hypnosis, Los Angeles.

#### NOTES:

Presented children with a cognitive behavioral intervention package that involved five elements 1. Filmed Modeling (child modeling and talking about it with good coping skills) 2. Positive Reinforcement - trophy 'for doing the best you can,' to change aversive situation to a positive situation 3. Breathing Exercises - 'puff yourself up like a tire' 4. Emotive Imagery/Distraction - super hero image (Superman), or being in a favorite place 5. Behavioral Rehearsal - dollplay, reviewing the procedure with medical equipment.

For Numbers 4 and 5 the therapist would actively guide the procedures; numbers 3, 4 & 5 are hypnotic elements.

Valium had lowered children's distress prior to procedures but not during the procedures. This study involved Valium plus cognitive behavior therapy.

25 Subjects ages 6-12, were measured for hypnotizability

**2 groups: (1) Cognitive Behavior Therapy + Valium given just before intervention started, after film ended; (2) Cognitive Behavior Therapy alone.**

**Dependent Measures: 1. Observation Scale of Behavioral Distress coded every 15 seconds. 2. Faces Scale for Fear (self report) before procedure**

**Faces Scale for Pain (self report) after procedure 3. Blood pressure**

**RESULTS. No Significant Differences were found between the two groups (CBT vs CBT + Valium). Pre-Post Analyses: Post intervention scores were significant lower than Pretest on [missed notes]**

**Jay, Susan M.; Elliott, Charles H.; Katz, Ernest; Siegel, Stuart E. (1987). Cognitive-behavioral and pharmacologic interventions for children's' distress during painful medical procedures. Journal of Consulting and Clinical Psychology, 55, 860-865.**

**This study evaluated the efficacy of a cognitive-behavioral intervention package and a low-risk pharmacologic intervention (oral Valium), as compared with a minimal treatment-attention control condition, in reducing children's distress during bone marrow aspirations. The subjects were 56 leukemia patients who ranged in age from 3 years to 13 years. The three intervention conditions were delivered in a randomized sequence within a repeated-measures counterbalanced design. Dependent outcome measures included observed behavioral distress scores, self-reported pain scores, pulse rate, and blood pressure scores. Repeated-measures analyses of variance indicated that children in the cognitive-behavior therapy condition had significantly lower behavioral distress, lower pain ratings, and lower pulse rates than when they were in the attention- control condition. When children were in the Valium condition, they exhibited no significant differences from the attention control condition except that they had lower diastolic blood pressure scores.**

**Diamond, Michael Jay (1986). Hypnotically augmented psychotherapy: The unique contributions of the hypnotically trained clinician. American Journal of Clinical Hypnosis, 28 (4), 238-247.**

**In the last century, psychotherapists trained in clinical hypnosis have made a number of unique contributions to the psychotherapeutic endeavor, particularly in the areas of psychotherapeutic theory, technique, and practice. Nine factors indexing the contribution of hypnotherapists are discussed. They are: 1) communication focus; 2) maximizing expectation and belief; 3) mind-body emphasis; 4) handling of resistance; 5) employing trance phenomena; 6) using archaic levels of relationship; 7) stressing healthy, adaptive ego functions; 8) using therapist trance; and 9) permitting responsible creativity. Each factor is considered as it pertains to hypnotic technique and phenomena as well as how it is manifested in clinical treatment.**

David (Ed.), Consciousness and self regulation: Advances in research and theory (4, ). New York: Plenum Press.

**NOTES:**

Reviews changes that have occurred in progressive relaxation training and their effects. The authors conclude:

"Jacobson's original progressive relaxation technique differs from the types of progressive relaxation used by many current practitioners in a number of fundamental respects. Jacobson emphasized relaxation as a method of learning to control one's excess muscle tension 24 hours per day. In his mind, progressive relaxation was not a method by which something is done\_ to\_ a person. Rather, it is a method by which the individual learns to control his or her own body. Jacobson, therefore, rejected the use of suggestion and of various biofeedback instruments and conditioning techniques that may induce relaxation during a training session. Empirical evaluations of most elements of the two progressive relaxation techniques have not yet been done. Thus, although many studies have compared progressive relaxation with a number of hypnotic, cognitive, and combined somatic-cognitive techniques, no one has dismantled the progressive relaxation technique Jacobson's or modified versions, in order to study the exact contribution of suggestion or cognitive interventions to the modified progressive relaxation technique, or of teaching one muscle at a time. The evidence reviewed above, however, does lead us to hypothesize that Jacobson's original technique would be relatively more effective in producing lasting somatic changes, whereas the revised technique might be more effective in producing cognitive changes or even short-term somatic changes. If these hypotheses are borne out, we predict that for many applications in behavioral medicine Jacobson's original technique will be found to be preferable. This will be especially true for those disorders which cannot be assessed by asking the patient how he or she feels but must be evaluated physiologically (e.g., hypertension and various cardiac arrhythmias, where the patient may sometimes even feel worse when the problem is controlled than when it is not).

"In the 'big picture' of therapy, of course, the distinctions between the two techniques may be overshadowed by such overriding issues as whether relaxation therapy is even \_relevant\_ for the individual. We have extensively discussed this issue elsewhere (Woolfolk & Lehrer, 1984b) but we reemphasize here that we see relaxation training as a specific method for overcoming definable problems and not as a panacea nor as a way of life. Nevertheless, we believe that the various approaches to the progressive relaxation technique are sufficiently different, both in practice and in philosophy, that we would do well to evaluate these differences in a rigorous fashion" (Lehrer, Woolfolk, Goldman 209- 210).

Miller, Mary E.; Bowers, Kenneth S. (1986). Hypnotic analgesia and stress inoculation in the reduction of pain. Journal of Abnormal Psychology, 95, 6-14.

Investigated the influence of hypnotic ability on 3 methods of reducing cold-pressor pain. Following a baseline immersion, 30 high- and 30 low-hypnotizable undergraduates were randomly assigned to 1 of 3 treatment groups: stress

inoculation training, stress inoculation training defined as hypnosis, or hypnotic analgesia. Analysis of pain reports indicated a significant hypnotic ability x treatment interaction. Among Ss receiving hypnotic analgesia, high-hypnotizables reported significantly less intense pain than lows. There was no differential response for high- and low-hypnotizable Ss receiving stress inoculation training, whether or not it was defined as hypnotic. Moreover, Ss in the stress inoculation condition (whether or not defined as hypnosis) reported using cognitive strategies to reduce pain, whereas this was not the case for Ss in the hypnotic analgesia condition. The present findings seem inconsistent with the social psychological account of hypnosis and are discussed from a dissociation perspective, which views hypnosis as involving changes in the way information is processed.

1985

Bolocofsky, David N.; Spinler, Dwayne; Coulthard-Morris, Linda (1985). Effectiveness of hypnosis as an adjunct to behavioral weight management. Journal of Clinical Psychology, 41 (1), 35-41.

109 17-67 year olds completed a behavioral treatment for weight management either with or without the addition of hypnosis. Results show that, at the end of the 9-week program, both interventions resulted in significant weight reduction. However, at 8-month and 2-year follow-ups, the hypnosis Ss showed significant additional weight loss, while those in the behavioral-treatment-only group exhibited little further change. More Ss who used hypnosis also achieved and maintained their personal weight goals. It is suggested that hypnosis may have been an effective motivator for Ss to continue practicing the more adaptive eating behaviors acquired during treatment. Findings support the utility of employing hypnosis as an adjunct to a behavioral weight management program. (25 ref)

Spanos, Nicholas P.; Ollerhead, Virginia Gail; Gwynn, Maxwell I. (1985-86). The effects of three instructional treatments on pain magnitude and pain tolerance: Implications for theories of hypnotic analgesia. Imagination, Cognition and Personality, 5, 321-337.

Between baseline and posttesting on the cold pressor test, subjects were assigned to four treatments: a) hypnotic analgesia, b) brief instructions to "Do whatever you can to reduce pain," c) stress inoculation, and d) no instruction control. Participants in the three instructional treatments showed significantly greater baseline to posttest decrements in pain magnitude and significantly greater increments in pain tolerance than controls. However, the instructional treatments did not differ significantly from one another in these regards. Pretested hypnotic susceptibility correlated significantly with degree of pain reduction in the hypnotic analgesia treatment but not in the "Do whatever" or stress inoculation treatments. Theoretical implications are discussed.

1984

Billotti, Thomas J. (1984, August). The effects of rational emotive imagery and rational emotive imagery plus hypnosis in reduced public speaking anxiety (Dissertation). Dissertation Abstracts International, 46 (2), 633-634-B.

"Previous investigations have demonstrated the effectiveness of rational emotive therapy in reducing public speaking anxiety and the increased benefit derived by combining rational emotive procedures with hypnosis. The present study examined the effectiveness of rational emotive imagery and rational emotive imagery plus hypnosis in reducing public speaking anxiety in subjects with high and low levels of imaginative ability. The dependent measures employed included self report, behavioral and physiological measures of anxiety. "47 undergraduate students who reported anxiety while speaking in public served as subjects in the study. The subjects were divided into high and low levels of imaginative ability and randomly assigned to one of three experimental groups as follows: rational emotive imagery, rational emotive imagery plus hypnosis, and an instructional control group. It was hypothesized that subjects in the rational emotive imagery plus hypnosis group would evidence significantly less anxiety than subjects in the rational emotive imagery and instructional control group, and that subjects with high pre-treatment levels of imaginative ability would evidence significantly less anxiety than subjects with low pre-treatment levels of imaginative ability. "The results of this study provided some support for the efficacy of combining rational emotive imagery with hypnosis. Subjects in the rational emotive imagery plus hypnosis group evidenced significantly less anxiety than subjects in the rational emotive imagery and instructional control group on the two self-report measures. There were no significant differences as between subjects in the rational emotive imagery group and instructional control group or between subjects with high and low imaginative ability on post-treatment assessments. Subjects tended to have their highest pulse rates at the start of the speeches, their lowest pulse rate just after the speeches, and moderate pulse rates just before and during the speeches. "Factors contributing to these results and interpretations of the data were discussed. Suggestions regarding the direction of future research were offered" (p. 633- 634).

Morrow, Gary R. (1984). Appropriateness of taped versus live relaxation in the systematic desensitization of anticipatory nausea and vomiting in cancer patients. Journal of Consulting and Clinical Psychology, 52 (6), 1098-1099.

Investigated the suggestion that the relaxation part of systematic desensitization--an effective treatment for the nausea and vomiting experienced by approximately 25% of cancer patients in anticipation of chemotherapeutic treatments-- could be learned from a prerecorded audiotape prior to meeting a psychologist for treatment. 10 cancer patients who had developed anticipatory nausea or vomiting were assigned to either a live-relaxation or a tape-relaxation group. Results show that 4 of 5 Ss assigned to the tape-relaxation group experienced nausea while listening to the prerecorded audiotape, while none of the patients in the live-relaxation group reported nausea when subsequently listening to an audiotape made during the live presentation of relaxation.

Newton, Bernauer (1984, October). The use of imagery in the treatment of cancer patients. [Paper] Presented at the annual meeting of the Society for Clinical and Experimental Hypnosis, San Antonio, TX.

Several hundred cancer patients were treated with the Simonton visualization method, with the additional factor that they were hypnotized for the visualization. In a long term follow-up study, those patients who were treated for at least 6 months and are still alive had imagery that was vivid, persistent, positive, and passive ("passive" here meaning an underlying sense of calm). Those who died had the opposite kind of images, and retrospective review of clinical notes indicates their aggressive images reflected desperation. Of the patients who were treated less than six months, a few lived. Their images also were vivid, persistent, and positive.

Stam, Henderikus J.; McGrath, Patricia A.; Brooke, Ralph I. (1984). The effects of a cognitive-behavioral treatment program on temporo-mandibular pain and dysfunction syndrome. Psychosomatic Medicine, 46, 534-545.

Sixty-one patients, clearly diagnosed as suffering from temporo-mandibular pain and dysfunction syndrome (TMPDS), were randomly assigned to one of three groups, (1) hypnosis and cognitive coping skills, (2) relaxation and cognitive coping skills, or (3) a no-treatment control group. All patients were evaluated with a standard hypnotic susceptibility scale prior to treatment. The two treatment groups received four weekly sessions of their respective treatments. Patients in the hypnosis and relaxation groups reported equivalent decrements in pain, abnormal sounds in the temporomandibular joint, and limitations of jaw mobility. Hypnotic susceptibility was significantly correlated with reductions in reported pain for the treatment groups. Patients' age and the duration of pain prior to treatment were not related to treatment outcome. Patients who dropped out of treatment had fewer limitations in jaw movement but did not differ on any other variable from patients who remained in treatment. These findings are discussed in relation to the hypothesis that TMPDS is a stress related muscular pain and dysfunction.

Wideman, Margaret V.; Singer, Jerome E. (1984). The role of psychological mechanisms in preparation for childbirth. American Psychologist, 39, 1357-1371.

Psychoprophylactic (Lamaze) preparation for childbirth consists of six to eight classes held during the last trimester of pregnancy. These classes include instruction in the anatomy and physiology of gestation and parturition, respiration techniques, controlled neuromuscular relaxation, visual focusing, and the training of a labor coach. Although the techniques are based upon psychological principles, they have remained largely unstudied by either psychologists or physicians. This article presents a brief history of the development of the training regimen and critically examines the few empirical studies that have been conducted. Because explanations for the efficacy of the preparation, if it exists, are equivocal, literature on the explicit components of the training--that is, information, respiration techniques,

conditioned relaxation, cognitive restructuring, and social support--in situations other than child delivery are reviewed and their implications for the Lamaze method discussed. However, because there exist several, more implicit factors that may affect the type of child delivery a prepared woman experiences, the literature concerning social comparison, the effects of commitment and conformity, perceived control, and endorphin secretion are also discussed as they may apply to psychoprophylactic preparation. Problems associated with the study of childbirth preparation are presented, and suggestions for the direction of future research are made.

Boutin, Gerald E.; Tosi, Donald J. (1983). Modification of irrational ideas and test anxiety through rational stage directed hypnotherapy (RSDH). Journal of Clinical Psychology, 39 (3), 382-391.

Examined the effects of four treatment conditions on the modification of Irrational Ideas and test anxiety in female nursing students. The treatments were Rational Stage Directed Hypnotherapy, a cognitive behavioral approach that utilized hypnosis, and vivid emotive imagery, a hypnosis-only treatment, a placebo condition, and a no-treatment control. The 48 Ss were assigned randomly to one of these treatment groups, which met for 1 hour per week for 6 consecutive weeks with in-vivo homework assignments also utilized. Statistically, significant treatment effects on cognitive, affective, behavioral, and physiological measures were noted for both the RSDH and hypnosis group at the posttest and at a 2-month follow-up. Post-hoc analyses revealed the RSDH treatment group to be significantly more effective than the hypnosis only group on both the post- and follow-up tests. The placebo and control groups showed no significant effects either at posttreatment or at follow-up.

Flatt, Jennifer R. (1983). What makes therapy work? Thoughts provoked by a case study. Australian Journal of Clinical and Experimental Hypnosis, 11 (2), 63-72.

The case described is offered as illustrating the doubt common to introspective therapists: what did cure the patient? "Francesca's" presenting problem and the object of the short-term psychological intervention described here, was a fairly circumscribed set of fears related to enclosed spaces. The therapeutic approach adopted was primarily hypnobehavioural, with hypnotically-assisted systematic desensitization and "in vivo" exposure being the main components of the planned programme. However, at the client's suggestion, one hypnotic session with content planned by the therapist as age regression produced rather dramatic and unexpected results claimed by the patient to effect complete cure.

## NOTES

The therapist suggested that "her mind would take her back to a time that was important in understanding her fears and that she would be able to stay calm and relaxed while this past event was revealed to her" (p. 69). She subsequently imagined being in a cave, peaceful and calm. "On being roused from hypnosis, Francesca eagerly described her cave image. She was enthusiastic about the significance of this

experience, claiming that it was evidence that in a \_previous life\_ she had died from being locked into a cave as some sort of punishment and that this pexperience made her fear of enclosed places rational and comprehensible to her" (p. 69).

Myles, (1983, April). Cognition, hypnotic susceptibility, and laboratory induced pain (Dissertation, University of Waterloo). Dissertation Abstracts International, 43 (10), 3360-B.

"Individuals' experiences of pain, and responses to pain treatments vary greatly. This study attempted to relate two areas of research concerned with this variation: (a) cognitions and pain (thoughts, images, etc.), in particular, catastrophizing versus coping; and (b) hypnotic susceptibility and analgesia. "Subjects were preselected for high or low hypnotic susceptibility. Susceptibility assessment was divorced from the laboratory study to minimize the potential bias of expectancies concerning hypnosis. High hypnotic susceptibility was expected to potentiate therapeutic effects of hypnotic-like treatment that did not involve a hypnotic induction. "Ten high and ten low-susceptible subjects were assigned to each of three groups: (a) a cognitive treatment, encouraging subjects to reduce spontaneous catastrophizing and increase self-generated coping cognitions; (b) a dissociative imagery treatment, encouraging subjects to engage in self-generated engrossing images; (c) an attention- placebo manipulation. "Pre and post-treatment assessments involved tolerance and pain-report measures during the cold-pressor task, and interview and questionnaire information concerning cognitions. "No treatment effects were evident on measures of pain. Cognitive data indicated less catastrophizing and more coping during the post-treatment stressor across all groups. Subjects in the dissociative imagery group did report more imagery during the post- treatment assessment than subjects in the other groups, but this increased use of imagery was not associated with a decrease in pain. "Interview and questionnaire data supported prior reports that catastrophizing is related to increased pain. Low catastrophizing was associated with a high sense of control, high use of a variety of coping strategies, and lower pain reports. These relationships were altered following treatment, however, leading to a caution in generalizing about such variables. "High susceptibility did not potentiate therapeutic effects for either experimental treatment. Nor was susceptibility related in any other consistent way to pain, although high susceptibility was associated with more extensive use of post-treatment imagery. "Methodological inconsistencies and problems in laboratory pain research were discussed, and suggestions made for future work in the area" (p. 3360).

Polk, W. M. (1983). Treatment of exhibitionism in a 38-year-old male by hypnotically assisted covert sensitization. International Journal of Clinical and Experimental Hypnosis, 31 (3), 132-138.

This case study reports the successful treatment of a 38-year-old male with a 14 year history of exhibitionism. A multifaceted treatment program was used, involving hypnotically assisted covert sensitization and brief marital therapy. Hypnosis was used to develop psychic aversive and reinforcing stimuli from the patient's past

experience. The value of hypnosis in enhancing imagery in cognitive treatment approaches and the need for only experienced clinicians to utilize the present intervention strategy is discussed.

Schandler, Steven L.; Dana, Edward R. (1983). Cognitive imagery and physiological feedback relaxation protocols applied to clinically tense young adults: A comparison of state, trait, and physiological effects. Journal of Clinical Psychology, 39, 672-681.

Examined changes in targeted and general tension behaviors as well as reductions in physiological tension associated with cognitive imagery and electromyographic biofeedback relaxation procedures. Three groups of 15 female college students participated. During three weekly sessions each person received either guided cognitive imagery relaxation, frontalis muscle feedback relaxation, or a self-rest control procedure. The Anxiety Differential was administered before and after each session, while frontalis EMG, heart rate, and skin temperature were monitored continuously. A second Temperament Analysis was administered after the final session. The imagery procedure was associated with moderate reductions in physiological tension and significant reductions in state anxiety and three tension-related personality dimensions. Self-rest persons displayed lesser reductions in general tension with little physiological change. While biofeedback persons showed the largest reductions in physiological tension, they displayed only small and variable changes in state anxiety and personality dimensions. The data raise continued questions about the application of physiologically based operant relaxation procedures and support the use of cognitively mediated protocols for the treatment of specific or general anxiety behaviors.

1982

Cognitive therapies have, for the most part, proceeded in ignorance of recent work in hypnosis. The present article attempts to summarize some of the findings in hypnosis that are relevant for clinicians and investigators in the tradition of cognitive behavioral modification. Especially important is the concept of suggestion, and the fact of individual differences in hypnotic ability. It is argued that at least some of the therapeutic effectiveness of non-hypnotic therapies may be due to such individual differences. The importance of suggestion appears to be especially important in the treatment of psychosomatic disorders, and numerous illustrations are given showing that therapeutic outcome with such disorders is correlated with hypnotic ability, even when specific hypnotic procedures are not employed.

Howard, L.; Reardon, J. P.; Tosi, D. (1982). Modifying migraine headache through rational stage directed hypnotherapy: A cognitive-experiential perspective. International Journal of Clinical and Experimental Hypnosis, 30 (3), 257-269.

Recent techniques designed to modify migraine headache have emphasized physiological modification via hypnosis only or biofeedback. Psychological factors, however, have been identified as causal in many psychophysiological disorders such

as migraine. The present case study describes the results of utilizing Rational Stage Directed Hypnotherapy (RSDH) of Tosi (1974), Tosi and Marzella (1975), and Tosi (1980a) in the treatment of an individual suffering from severe migraine headaches. RSDH, designed to attend to both physiological and psychological factors, is a cognitive-experientially based, stage directed, systematic psychotherapeutic regimen which utilizes hypnosis and hypnotic imagery to enhance the rational restructuring of negative cognitive/emotional/physiological/behavioral states.

In the present case study, RSDH demonstrated superior effects over the hypnosis only treatment and baseline in reducing migraine headaches. The client demonstrated improvement on both self-report measurement (frequency of migraine headaches) and objective test results (MPI, Hathaway & McKinley, 1951; Tennessee Self-Concept Scale, Fitts, 1979). In describing this case, particular attention was given to analyzing cognitive distortions via hypnotic imagery in a temporal framework. Analysis and restructuring of past traumatic events which were symbolically affecting the client's current behavior were particularly significant aspects of the treatment process.

LeBaron, Samuel; Zeltzer, Lonnie (1982, October). The effectiveness of behavioral intervention for reducing chemotherapy related nausea and vomiting in children with cancer. [Paper] Presented at the annual meeting of the Society for Clinical and Experimental Hypnosis, Indianapolis, IN.

Eight children (nine to seventeen years, Mean age 12.1) with cancer received behavioral intervention for chemotherapy related nausea and vomiting. Within three to five days after the administration of each course of chemotherapy, patients rated (1-10 scale; 1 = none, 10 = all the time or maximal amount) their nausea and vomiting and the extent to which chemotherapy bothered them and disrupted their daily routine. After a pre-intervention assessment of 2.5 courses of chemotherapy, patients received intervention (Mean = 2.6 courses). Significant reductions following intervention (Wilcoxon matched-pairs signed ranks test) were found in nausea ( $Z = 2.37, p$

Lyles, Jeanne Naramore; Burish, Thomas G.; Krozely, Mary G.; Oldham, Robert K. (1982). Efficacy of relaxation training and guided imagery in reducing the aversiveness of cancer chemotherapy. Journal of Consulting and Clinical Psychology, 50, 509-524.

Fifty cancer patients receiving chemotherapy, 25 by push injection and 25 by drip infusion, were assigned to one of three conditions for their chemotherapy treatments: (a) progressive muscle-relaxation training plus guided-relaxation imagery; (b) therapist control, in which a therapist was present to provide support and encouragement but did not provide systematic relaxation training; and (c) no-treatment control. Patients participated in one pretraining, three training, and one follow-up session. Results indicated that during the training sessions, patients who received relaxation training, relative to patients in either of the other two conditions, (a) reported feeling significantly less anxious and nauseated during chemotherapy,

(b) showed significantly less physiological arousal (as measured by pulse rate and systolic blood pressure) and reported less anxiety and depression immediately after chemotherapy, and (c) reported significantly less severe and less protracted nausea at home following chemotherapy. The attending nurses' observations during chemotherapy confirmed patient reports. In general, patients in the therapist control condition and the no-treatment control condition did not differ significantly from each other. The differences among conditions generally remained significant during the follow-up session. The data suggest that relaxation training may be an effective procedure for helping cancer patients cope with the adverse effects of their chemotherapy.

**Oliver, George W. (1982-83). A cancer patient and her family: A case study. American Journal of Clinical Hypnosis, 25 (2-3), 156-160.**

In recent years, increasing numbers of mental health workers have been attempting to use techniques of psychotherapy to influence the course of malignant disease. This paper reviews in detail the course of treatment of one female patient with an inoperable malignancy and conveys a sense of the clinical experience of working intensively with a cancer patient and her family. It shows the complex levels of interaction within the patient herself, between the patient and her family, and between the therapist and her family and within the therapist himself during different phases of the therapeutic journey.

**Redd, William H.; Andrykowski, Michael A. (1982). Behavioral intervention in cancer treatment: Controlling aversion reactions to chemotherapy. Journal of Consulting and Clinical Psychology, 50 (6), 1018-1029.**

During the protracted course of cancer chemotherapy, approximately 25% of patients develop aversion reactions to treatment by becoming nauseated and/or vomiting before their chemotherapy treatments. This phenomenon has been conceptualized as a result of respondent conditioning. Since commonly used antiemetic drugs do not reliably control anticipatory nausea/emesis, behavioral techniques of control have been studied. They include hypnosis used in conjunction with guided-relaxation imagery, progressive muscle relaxation with guided imagery, and systematic desensitization. (67 ref)

**Redd, William H.; Andresen, Graciela V.; Minagawa, Rahn Y. (1982). Hypnotic control of anticipatory emesis in patients receiving cancer chemotherapy. Journal of Consulting and Clinical Psychology, 50 (1), 14-19.**

**NOTES: Deep muscle relaxation hypnosis controlled nausea, gagging, retching in all cases. Anticipatory emesis recurred when hypnosis was not used. During subsequent sessions in which hypnosis was reinstated, anticipatory emesis was again controlled.**

Redd, William H.; Rosenberger, Patricia H.; Hendler, Cobie S. (1982-83). Controlling chemotherapy side effects. American Journal of Clinical Hypnosis, 25 (2-3), 161-172.

Severe nausea and vomiting are commonly experienced by cancer patients after receiving chemotherapy treatments. Moreover, approximately 25% of these patients develop conditioned aversions to treatment and become nauseated before they receive their chemotherapy injections. The use of deep muscle relaxation hypnosis in conjunction with guided imagery to control pre- and post-chemotherapy nausea and emesis is discussed. Theoretical and clinical issues raised by this application of hypnosis in cancer treatment are also addressed.

Shapiro, Arnold (1982-83). Psychotherapy as adjunct treatment for cancer patients. American Journal of Clinical Hypnosis, 25 (2-3), 150-155.

During the past ten years psychotherapy as adjunct treatment for cancer patients has become increasingly common. The use of hypnosis as an integral part of that treatment has also burgeoned. This report will follow the progress of two cancer patients in psychotherapy. While each is highly individual, the commonalities which allow treatment to be systematic will be quite apparent. The ability to minimize pain and discomfort, the ability to keep the white cell count high despite ongoing chemotherapy, and augmenting the ability of the body's immune system to fight the disease are utilized by both of the patients. All of the above are accomplished through the use of visual imagery in the trance state. Visual imagery is also used to reach feelings which patients are often unable to verbalize, and of which they often claim to be unaware. Other aspects of therapy such as the gradual shift from despair to hope and even confidence, and the development of more assertive behavior are discussed.

Stoyva, J. M.; Anderson, C. (1982). A coping-rest model of relaxation and stress management. In Goldberger, L.; Breznitz, S. (Ed.), Handbook of stress: Theoretical and clinical aspects (pp. 745-763). New York: The Free Press.

#### NOTES:

"Patients with psychosomatic or stress linked disorders are likely to show signs of high physiological arousal, and they are likely, under stress, to react strongly in the symptomatic system and to show evidence of being deficient in the ability to shift from the coping to the rest mode (e.g., slowness of habituation to, and recovery from, stressful stimulation). A corollary inference is that such patients ... show activity in the symptomatic system for a higher percentage of the time that [sic] do normal subjects. We suggest that this defect in the capacity to shift to a rest condition is the principal reason that various relaxation procedures have so often proved successful in the alleviation of stress related symptoms" (p. 748).

The authors refer to a number of different stress management procedures. Among those associated with primary focus on the rest phase they include: Relaxation training (progressive relaxation, autogenic training, EMG feedback, meditation

[Zen, TM]), Specific biofeedback (hand temperature, electrodermal response [EDR], EMG from particular muscle group), and Systematic desensitization. Among those associated with primary focus on coping phase are: Assertiveness training, Social skills retraining and motor skills retraining, Self-statements, Imagery (Guided waking imagery, autogenic abreaction, covert reinforcement and covert sensitization, behavior rehearsal). These various procedures may reflect three dimensions or aspects of the stress response, with some addressing physiology and others addressing cognition or behavior change.

"Rachman (1978) ... found it useful to divide the phenomenon of fear into physiological, cognitive, and behavioral components. Similarly, Davidson and Schwartz (1976) conceptualized relaxation as consisting of somatic, cognitive, and attentional components. Phillips (1977) argued that pain, such as headache pain, can be viewed as consisting of cognitive, behavioral, and physiological aspects (and that, consequently, we should not expect high correlations between headache pain and a particular physiological measure such as forehead EMG level). ...

"... In discussing contemporary studies of dreaming, they [Stoyva and Kamiya (1968)] proposed that there is no single, totally valid indicator of dreaming as a mental experience. Instead, there are several imperfect indicators of the dream experience--verbal report, rapid eye movements, and certain electroencephalographic (EEG) stages. ... Discrepancies among the indicators can serve to generate hypotheses" (p. 749).

The authors discuss different ways of retraining the capacity to rest: relaxation training (including biofeedback, etc.), systematic desensitization; and of reshaping the coping response: assertiveness training, social skills and motor skills retraining, self-statements, imagery techniques; and discuss controllability. These notes cover only a very small part of their extensive review, the material most relevant to hypnosis and suggestion.

"Although imagery techniques are often employed by stress management therapists, one approaches this area with ambivalence. In part, this uneasiness springs from the unsettling awareness that imagery techniques have been embraced by a freewheeling assortment of lay psychologists such as Emil Coue, Dale Carnegie, and Norman Vincent Peale, not to mention a diverse throng of contemporary 'mind controllers' and self-styled healers. A more serious source of uneasiness is ignorance of the specific processes at work. What are the mechanisms by which imagery affects the stress response?" (p. 756).

"There is intriguing recent evidence that simply the illusion of control may exert beneficial effects. Stern, Miller, Ewy, and Grant (1980) noted that subjects who were led to believe by means of bogus information feedback that they were successfully lowering their heart rates showed a reduction in stress type symptoms, especially those of a cardiovascular nature. It seems possible that the feeling of control may be an important part of what we have called 'placebo responding.' Stoyva (1979b) suggested that this phenomenon is probably not a unitary entity but, rather, a cluster of processes, of which the feeling of developing control over factors affecting one's disorder is an important and potentially manipulable component of therapeutic interventions" (p. 758).

1981

Araoz, Daniel L. (1981). Negative self-hypnosis. Journal of Contemporary Psychotherapy, 12, 45-52.

A review of recent developments in psychotherapeutic methods of cognitive behavior therapy leads to the conclusion that negative self-hypnosis (NSH) is operative in problematic behavior. NSH is elucidated, and a counteractive, five-stage approach of self-hypnosis is proposed to effectively deal with NSH.

Kellerman, J. (1981). Hypnosis as an adjunct to thought stopping and covert reinforcement in the treatment of homicidal obsessions in a twelve-year-old boy. International Journal of Clinical and Experimental Hypnosis, 29 (2), 128-135.

A combined cognitive behavioral approach was used to successfully treat matricidal obsessions in an otherwise psychologically well-adjusted 12-year-old boy. The primary problem was conceptualized as anxiety over loss of control. Therapeutic techniques included re-defining of symptoms, thought-stopping, hypnotic enhancement of imagery in order to facilitate cognitive restructuring, covert reinforcement, home practice, and paradoxical instructions to produce the symptom. A decline in obsessions began after 3 sessions and total remission was observed after 6 sessions (10 weeks). 2-year follow-up revealed no recurrence of symptoms. The value of hypnosis as an adjunct to behavior therapy with children is discussed.

O'Brien, Richard M.; Cooley, Lewis E.; Ciotti, Joseph; Henninger, Kathleen M. (1981). Augmentation of systematic desensitization of snake phobia through posthypnotic dream suggestion. American Journal of Clinical Hypnosis, 23, 231-238.

Nine snake phobics who had scored above eight on the SHSS (Form A) were given four desensitization sessions and five sessions in which a pleasant posthypnotic dream of the phobic object was suggested. These subjects were significantly superior to a desensitization-only control group on a behavioral avoidance test. Seven of the nine hypnosis subjects were able to touch a real snake. The two subjects who did not touch the snake reported dreams in which the snake was either absent or threatening. Although conclusions are limited by differential attention and susceptibility, the technique seems promising.

Scrignar, C. B. (1981). Rapid treatment of contamination phobia with hand-washing compulsion by flooding with hypnosis. American Journal of Clinical Hypnosis, 23, 252-257.

Two obsessive-compulsive patients with contamination phobias and hand-washing compulsions are presented. Psychoanalytic psychotherapy had resulted in little change. Behavior therapy techniques of thought-stopping, systematic desensitization, progressive muscle relaxation, cognitive restructuring and self-imposed response prevention were first used, resulting in some subjective

improvement, but no change in the hand-washing rate. Hypnosis, emphasizing relaxation, positive suggestion and corrective information provided further temporary subjective improvement but little change in compulsive rituals. Hypnosis, combined with the behavioral technique of flooding, produced rapid improvement. The patients maintained improvement at seven years and two years. Flooding under hypnosis may afford obsessive-compulsive patients a rapid and economical therapeutic procedure.

Worthington, Everett L.; Shumate, Michael (1981). Imagery and verbal counseling methods in stress inoculation training for pain control. Journal of Counseling Psychology, 28 (1), 1-6.

Investigated 3 elements of stress inoculation training, a therapeutic package for helping clients control anxiety, anger or pain. 96 undergraduate females were tested twice for ice water tolerance. In a 3 design, the independent variables were the presence or absence of (a) pleasant imagery, (b) a conceptualization of pain as a multistage process, and (c) planned, explicit self-instructions. A multivariate analysis of covariance using the (transformed) pretest tolerance rating and 2 self-ratings of pain. Imagery users (Is) controlled their pain better than nonimagery users (NIs). There was a significant interaction of Imagery and Conceptualization. NIs had longer tolerance and less self-reported pain at withdrawal when they heard no conceptualization. The Is did not derive additional benefit from hearing the conceptualization. Self-instruction did not affect pain control. Results suggest that pleasant imagery effectively relieves pain and may account for much of the effectiveness of stress inoculation training. (23 ref)

1980

Bornstein, Philip H.; Devine, David A. (1980). Covert modeling-hypnosis in the treatment of obesity. Psychotherapy: Theory, Research and Practice, 17 (3), 272-276.

Investigated the efficacy of a covert modeling/hypnosis treatment package in the control of obesity. 48 overweight female volunteers (who had been administered the Harvard Group Scale of Hypnotic Susceptibility, Eating Patterns Questionnaire, and Rotter's Internal-External Locus of Control Scale) were randomly assigned to 1 of the following groups: (a) covert modeling/hypnosis, (b) covert modeling, (c) no-model scene control, and (d) minimal treatment (where Ss received a shortened version of the covert modeling/hypnosis procedure following an 8-wk no-treatment period.) Results indicate a significant effect for weight loss from pretreatment to follow-up across all groups combined. Proportion weight loss measures indicated significantly greater weight loss only for the covert modeling/hypnosis group as compared to the no-model controls. Implications for combining behavior therapy and hypnotic techniques are discussed. (30 ref).

Bornstein, P. H.; Rychtarik, R. G.; McFall, M. E.; Winegardner, J.; Winnett, R. L.; Paris, D. A. (1980). Hypnbehavioral treatment of chronic nailbiting: A multiple

baseline analysis. International Journal of Clinical and Experimental Hypnosis, 28 (3), 208-217.

3 highly hypnotizable Ss were administered a hypnbehavioral treatment package in an attempt to alleviate chronic nailbiting behavior. The combined hypnotic and behavioral procedures included standard induction and deepening techniques, motivation enhancement, time-projection, self-reinforcement, aversion-relief, coping self-instructions, and posthypnotic suggestion. A multiple baseline design across Ss was employed as a means of evaluating the treatment intervention. Results for all Ss indicated immediate and dramatic increase in fingernail lengths concomitant with the introduction of treatment. At 3-month follow-up, 1 S demonstrated a moderate reversal effect while the remaining 2 Ss continued to indicate substantial progress. These findings were discussed with regard to the efficacy of hypnbehavioral treatment strategies and utilization of single-case experimental designs in future hypnotherapy research.

Powell, Douglas H. (1980). Helping habitual smokers using flooding and hypnotic desensitization techniques: A brief communication. International Journal of Clinical and Experimental Hypnosis, 28 (3), 192-196.

A subgroup of individuals who were helped to stop smoking by hypnosis or other means returned to consuming a few cigarettes a day. A flooding and hypnotic desensitization technique assisted 4 of 7 individuals who resumed smoking in becoming and remaining abstinent for a 6- to 9-month follow-up period.

Puente, Antonio E.; Beiman, Irving (1980). The effects of behavior therapy, self-relaxation, and transcendental meditation on cardiovascular stress response. Journal of Clinical Psychology, 26 (1), 291-295.

#### NOTES

1:

Compared Behavior Therapy (BT), self-relaxation (SR), transcendental meditation (TM), and a waiting-list control group (WL) on measures of cardiovascular and subjective stress response. Male and female respondents (N = 60) to an ad for therapy were evaluated in assessment sessions before and after treatment. The results indicate that BT and SR were more effective than either TM or WL in reducing cardiovascular stress response. These data were interpreted as resulting from therapeutic suggestion and positively reinforced client progress.

1979

Beers, Thomas M.; Karoly, Paul (1979). Cognitive strategies, expectancy, and coping style in the control of pain. Journal of Consulting and Clinical Psychology, 47, 179-180

Measures of tolerance, self-reported pain threshold, and overall discomfort of cold-pressor pain were obtained from 114 male subjects in a pretest-training-posttest experiment. Training consisted of brief practice in one of four cognitive strategies:

rational thinking, compatible imagery, incompatible imagery, and task-irrelevant cognition. Analyses of covariance indicated (a) that cognitive-imaginal strategies facilitated endurance of pain and raised self-reported threshold, (b) that rational thinking and compatible imagery were generally the most effective treatments, (c) that expectancy alone was not a significant pain-attenuating factor, (d) that treatments did not affect discomfort ratings, and (e) that individual differences in imaginal ability and coping style did not correlation with changes in any of the dependent measures.

Katz, Norman W. (1979). Comparative efficacy of behavioral training, training plus relaxation, and a sleep/trance hypnotic induction in increasing hypnotic susceptibility. Journal of Consulting and Clinical Psychology, 47, 119-127.

A social-learning-based behavioral training procedure and the same procedure with the addition of progressive relaxation instructions were compared with a traditional sleep/trance eye-fixation hypnotic induction. As predicted, the hypothesis that a social-learning training procedure would be more effective than a sleep/trance induction was supported. The hypothesis that the addition of relaxation instructions would further potentiate the social-learning treatment was not supported. The results suggest that for subjects of low and medium hypnotic susceptibility, social-learning procedures are a more effective way of increasing suggestibility than a sleep/trance induction. Changes in subjects' conceptions of hypnosis, particularly in terms of moving toward a self-control viewpoint, were hypothesized to be an intervening variable.

Perry, Campbell; Gelfand, Robert; Marcovitch, Phillip (1979). The relevance of hypnotic susceptibility in the clinical context. Journal of Abnormal Psychology, 88 (5), 592-603.

Despite experimental evidence that hypnotic susceptibility is a relatively stable characteristic of the individual, and one that is very difficult to modify, clinical investigators tend to see susceptibility as irrelevant to therapeutic outcome. Such investigators view motivational and interpersonal variables as more essential to the therapeutic change. The evidence for the clinical relevance of hypnotizability is sparse and contradictory. Most existing studies stem from medical hypnosis and indicate that susceptibility plays an important role in the successful treatment of such conditions as clinical pain, warts, and asthma. Two studies are reported that seek to pursue a contrary finding reported by Perry and Mullen, who found that susceptibility was unrelated to the successful treatment of a socially learned behavior (cigarette smoking). Both studies confirmed the earlier finding of a lack of relation. In Study 1, however, stepwise multiple regression analysis located three inventory items concerning the motivation of cigarette smokers. The combination of items was found to predict outcome for 67.39% of 46 clients treated either by hypnosis or by rapid smoking. The finding was replicated in Study 2, which utilized a combined hypnosis - rapid smoking technique and employed a different therapist.

The outcome for 9 of the 13 quitters and 37 of the 62 nonquitters across the two studies could be predicted by the three motivational questionnaire variables.

Spanos, Nicholas P.; Radtke-Bodorik, H. Lorraine; Ferguson, John D.; Jones, Bill (1979). The effects of hypnotic susceptibility, suggestions for analgesia, and the utilization of cognitive strategies on the reduction of pain. Journal of Abnormal Psychology, 88, 282-292.

Subjects previously stratified in terms of hypnotic susceptibility had an arm immersed in ice water for a 60-sec pretest and, afterward, were assigned to one of four treatments: (a) hypnosis plus analgesia suggestion, (b) hypnosis alone, (c) suggestion alone, or (d) no hypnosis - no suggestion. Next, the subjects were retested in ice water and then interviewed about their experiences during the retest. High susceptibles reported the use of more cognitive strategies during the retest and showed greater pretest-to-retest pain magnitude reductions than did low susceptibles. Similar effects occurred for subjects given, as opposed to not given, a suggestion. The hypnosis variable, however, failed to affect either strategy use or pain magnitude. Strategy use facilitated pain reduction only for subjects who did not worry about, and did not exaggerate, the unpleasantness of the situation (i.e., noncatastrophizers). The very few subjects who showed dramatic pretest- to-retest reductions in pain magnitude (50% reduction or more) were all high-susceptible noncatastrophizers who used one or more cognitive strategies.

Turner, Ralph M.; Ascher, L. Michael (1979). Controlled comparison of progressive relaxation, stimulus control, and paradoxical intention therapies for insomnia. Journal of Consulting and Clinical Psychology, 47 (3), 500-508.

Assessed the effectiveness of treatment programs based on progressive relaxation, stimulus control, and paradoxical intention in the context of sleep difficulties for 50 volunteer Ss. The results indicate that each of the therapeutic procedures significantly reduced sleep complaints in contrast to placebo and waiting list control groups. No differences were observed among the 3 active techniques. (1 1/2 p ref).

1978

Brown, Jude M.; Chaves, John F., Ph.D (1978, August). Hypnosis in the treatment of sexual dysfunction. [Paper] Presented at the annual meeting of the American Psychological Association, Toronto, Canada.

Recent reports suggest that hypnosis may be a useful technique for the treatment of sexual dysfunction. Five distinct strategies for the utilization of hypnosis in sex therapy can be identified: (1) as a diagnostic tool, (2) to improve self-confidence, (3) as an adjunct to behavior therapy, (4) for the direct removal of symptoms, and (5) to facilitate the resolution of neurotic conflicts. Case reports documenting these applications of hypnotic procedures typically fail to include significant information regarding patient variables, symptomatology, the nature of the therapeutic intervention, and criteria for improvement. Although the conclusions provided by

these case studies are encouraging, it is essential that the efficacy of hypnotic techniques in sex therapy be evaluated by controlled studies.

Dempsey, George L.; Granich, Marina (1978). Hypno-behavioral therapy in the case of a traumatic stutterer: A case study. International Journal of Clinical and Experimental Hypnosis, 26 (3), 125-133.

Hypnotherapy was used to treat a 41-year-old veteran for a severe stuttering problem, which began suddenly following a traumatic accident while serving during the Korean War and persisted for an ensuing 19-year period. A detailed clinical report illustrates how hypnotherapy was integrated with other treatment modalities to treat a rather distressing, and in this case incapacitating, speech disorder. Various strategies for treatment are discussed.

Porter, J. W. (1978). Suggestions and success imagery for study problems. International Journal of Clinical and Experimental Hypnosis, 26, 63-75.

A procedure is presented for dealing with study problems in cases where patients come with an expectancy of help through hypnosis. Specific suggestions directly related to the study difficulty are given. "Success imagery" is outlined for use under hypnosis and by the student himself in his daily life. Two self-management techniques associated with the relaxation induced by exhalation are given further strength by being made posthypnotic suggestions. A direct posthypnotic suggestion for "concentration and recall" is combined with contingency management to effect more efficient performance when the decision is made to study. Four sessions are shown by clinical experience to be generally adequate to allow a transition from therapy to self-management of the problem aided by the student's own use of self-hypnosis. A general outline of how this is achieved for the first three sessions incorporates both Wolberg's (19656) suggestions to remove barriers preventing progress and Stanton's (1977) Rational-Emotive Therapy suggestions to strengthen the person's belief in himself.

1977

Ascher, L. M. (1977). The role of hypnosis in behavior therapy. In Edmonston, William E., Jr. (Ed.), Conceptual and investigative approaches to hypnosis and hypnotic phenomena (296, ). New York: New York Academy of Sciences.

NOTES:

He does not differentiate physical and mental relaxation (Davidson & Schwartz). Insists that hypnosis treatment not include desensitization operations.

"Two studies (Gibbins et al., and Woody and Schaube) presented data that seemed to indicate that desensitization plus a hypnotic induction procedure resulted in greater fear reduction than desensitization alone. However, an analysis of the procedures employed suggests that the conclusion may be unwarranted, or at least

premature. Both studies confound the hypnotic induction with added elaboration of desensitization scenes, as well as additional direct fear-reduction suggestions. In addition, Gibbons et al. further confounded their study by placing good hypnosis subjects into the hypnotic-induction group as opposed to the desensitization or control groups. Barber has pointed out that the type of method that Gibbins et al. employed in subject assignment, as opposed to random assignment, results in the inability to control for such things as previous experience, the relationship of the subject with the experimenter, and the differential effects of these factors on the subject's attitudes, expectancies, and motivation" (p. 256).

"Finally, some individuals writing from the context of hypnotherapy, have suggested that the effects of specific imaginal behavioral techniques may be due to the possible existence of hypnosis or the trance state unwittingly incorporated into these behavioral procedures. The difficulties of such a position have been addressed by Barber, Cautela, Johnston and Donaghue, Spanos, Spanos, et al., Spanos and Barber, and Weitzenhoffer, among others. The following, as a group, have pointed out the difficulties inherent in the position that certain procedures, not otherwise associated with hypnosis, may nevertheless result in the production of a 'trance state' in susceptible subjects (Barber, Chaves, and Spanos) have delineated the differences between hypnosis and various behavioral procedures (Cautela, Spanos et al., and Spanos and Barber); and have presented strong arguments for suggesting that the effectiveness of hypnotherapeutic techniques are due to the inclusion of components of desensitization in the procedure rather than to the induction of a 'trance'" (pp. 257-258).

Barkley, R. A.; Hastings, J. E.; Jackson, T. L., Jr. (1977). The effects of rapid smoking and hypnosis in the treatment of smoking behavior. International Journal of Clinical and Experimental Hypnosis, 25 (1), 7-17.

29 Ss were assigned to one of 3 treatment conditions and treated for their cigarette smoking over a 2-week period. These conditions were: group rapid smoking, group hypnosis, and an attention-placebo control group. All treatments produced significant reductions in average daily smoking rates during the treatment phase but all Ss returned to near baseline levels of smoking by the 6-week follow-up. The rapid smoking and hypnosis groups did not differ from the control group in smoking rates at treatment termination or at the 6-week follow-up. They also did not differ from the control group in the number of Ss abstaining from smoking by treatment termination but did differ at follow-up. Eventually, at the 9-month follow-up, only Ss from the group rapid smoking condition had significantly more abstainers than the control group. The results suggested that rapid smoking can work as effectively in group procedures as previous individualized approaches had demonstrated. Group hypnosis, while less effective than some previous individualized approaches had indicated, was nevertheless only marginally less effective than the group rapid smoking procedure. The use of abstinence rates as opposed to average rates of smoking was strongly recommended as the best measure of treatment effectiveness for future research in this area.

Novaco, Raymond W. (1977). Stress inoculation: A cognitive therapy for anger and its application to a case of depression. Journal of Consulting and Clinical Psychology, 45 (4), 600-8.

Clinical interventions for anger disorders have been scarcely addressed in both theory and research in psychotherapy. The continued development of a cognitive behavior therapy approach to anger management is presented along with the results of its application to a hospitalized depressive with severe anger problems. The treatment approach follows a procedure called "stress inoculation," which consists of three basic stages: cognitive preparation, skill acquisition and rehearsal, and application practice. The relationship between anger and depression is discussed.

Scott, D. S.; Barber, T. X. (1977). Cognitive control of pain: Four serendipitous results. Perceptual and Motor Skills, 44, 569-570.

The experiment was designed to determine whether specific cognitive strategies are effective in reducing pain. Subjects were tested either on cold pain or pressure pain. Although the cognitive strategies did not significantly alter pain tolerance or pain intensity, the following four findings emerged: (a) males and females responded in a similar manner to the painful stimuli, (b) both the experimental subjects and the controls had surprisingly high tolerance of pain, (c) subjects typically generated their own thoughts and images to control pain, and (d) subjects responded to cold pain and to pressure pain in a similar manner.

#### NOTES:

80 subjects were randomly assigned to 4 groups, in the following conditions: 1. detailed instructions on how to interpret pain sensations as non-painful 2. a condensed version of the same instructions 3. instructions to imagine pleasant events during the pain stimulation 4. no instructions (controls)

Half were tested on cold pain, half on pressure pain.

Pain tolerance and also ratings of pain severity were not significantly different under any one of the four treatments. [A subsequent experiment (Scott & Barber, 1976) included somewhat similar experimental treatments but extended maximum allowable tolerance time from 3 min to 10 min. In this case, marked differences in pain tolerance were produced by the experimental treatments. It appears that results obtained in experiments on pain tolerance may depend on whether the ceiling for tolerance is set low or high.]

Post experimental interviews indicated that the typical subject used his assigned cognitive strategy part of the time during his exposure to the pain stimulation. During the remaining part of the pain period, the typical subject did not use any strategy or used a strategy for pain control derived from his own previous experience.

In general, the subjects tolerated the cold pain for the same length of time they tolerated the pressure pain and they rated the two kinds of pain as equally severe.

Stanton, Harry E. (1977). The utilization of suggestions derived from rational-emotive therapy. International Journal of Clinical and Experimental Hypnosis, 25 (1), 18-26.

A series of positive suggestions derived from Ellis' rational-emotive therapy were compared with Hartland's "ego-strengthening" technique in terms of patients' belief in their efficacy. Both pre- and post-treatment ratings were collected. Patients tended to approach treatment with a positive feeling that the treatment would help them with their problem and this belief was strengthened after the 10 therapy sessions had been completed. Further ratings taken 6 months later indicated that patients' belief in the value of the suggestive therapy had not decreased over time.

1974

Chaves, John F.; Barber, Theodore Xenophon (1974). Cognitive strategies, experimenter modeling, and expectation in attenuation of pain. Journal of Abnormal Psychology, 83 (4), 356-363.

Verbal reports of pain were obtained from 120 subjects during a base-level pretest and also during a posttest conducted under one of several experimental treatments. The pain stimulus was a heavy weight applied to a finger for two minutes. During the posttest, subjects who had been asked to utilize cognitive strategies for reducing pain (to imagine pleasant events or to imagine the finger as insensitive) showed a reduction in pain as compared to uninstructed control subjects. Subjects led to expect a reduction in pain, but not provided with cognitive strategies, also showed reduced pain during the posttest as compared to control subjects, but the reduction was smaller than for subjects using cognitive strategies. An experimenter modeling procedure, used with one half of the subjects under each experimental treatment, was effective in reducing verbal reports of pain only for subjects with high pretest levels who were asked to imagine pleasant events.

Russell, Elbert W. (1974). The power of behavior control: A critique of behavior modification methods. Journal of Clinical Psychology, 30 (2), 111-136.

NOTES

1:

In summarizing the effectiveness of behavior therapy the author states, "At this point there does not appear to be sufficient evidence to demonstrate that all of the effectiveness of various types of behavior therapy is produced by non-specific, especially placebo, effects. In fact, it is more probable that many of these techniques will be found to have elements that are not due to non-specific effects and, as such, they will be the treatment of choice for certain limited problems, such as aversive therapy for autistic children or training of the mentally retarded. Nevertheless, concerning the central issue in this monograph, it is increasingly apparent that a very large proportion of the 'power' of behavior methods is due to non-specific, suggestion or placebo effects.

"As such, this 'power' is neither behavioristic, new, nor particularly threatening. It is not new since it has been known to medicine for many decades. As Shapiro states,

'the history of both physiologic and psychologic treatment is largely the history of the placebo effect; those who forget it are destined to repeat it'. In support of the age of this problem, Shapiro also quotes from the compiler of the remedies of the Paris Pharmacologia, a century ago, 'What pledge can be afforded that the boasted remedies of the present-day will not, like their predecessors, fall into disrepute, and in their turn serve only as a humiliating memorial to the credulity and infatuation of the physicians who recommended and prescribed them'" (p. 120-121).

"The large amount of suggestion or placebo effect in behavior therapy does raise at least two vital problems. The first problem involves the ethics of using suggestion or a placebo. Is it ethical to give the patient a false or questionable explanation for the source of the effectiveness of behavior procedures? Such an explanation would be that they are based on proven scientific behavior principles when major people in the field do not believe this and evidence is mounting that the primary source of effect is suggestion. Secondly, what will be the effect on the attitude of the general public toward professional psychology when they realize that the effectiveness of psychological behavior therapy methods is primarily a matter of suggestion? Will they not consider it a modern patent medicine? The damage that could be done to the prestige of psychology might take decades to repair. JH

1973

Tori, Christopher; Worell, Leonard (1973). Reduction of human avoidant behavior: A comparison of counterconditioning, expectancy, and cognitive information approaches. Journal of Consulting and Clinical Psychology, 41 (2), 269-278.

This study was designed to compare the fear-reducing efficacy of procedures based on three major theories that have been proposed to account for the success of systematic desensitization therapy: (a) cognitive information storage and retrieval, (b) cognitive expectancy, and (c) counterconditioning. Predictions were confirmed in that the outcome measures of the high-expectancy placebo group and the two cognitive-coping groups were significantly superior to those of the counterconditioning and no-treatment groups. Thus, this experiment supports the supposition that changes in human avoidant behavior may be attributed to demand and expectancy variables rather than the conditioning of "antagonistic responses" as has been previously suggested.

1971

Moorefield, C. W. (1971). The use of hypnosis and behavior therapy in asthma. American Journal of Clinical Hypnosis, 13, 162-163.

Nine patients with asthma were treated with hypnosis and behavior therapy. All of these patients showed subjective improvement to a rather marked degree, except for one patient who has had three slight attacks of asthma since the onset of her treatment. These patients have been followed from eight to approximately 24 months. The results so far have been rather encouraging and the author believes this form of treatment will prove to be of benefit in the treatment of asthma and possibly many other related conditions.

1970

Davis, Daniel; McLemore, Clinton W.; London, Perry (1970). The role of visual imagery in desensitization. Behaviour Research and Therapy, 8 (1), 11-13.

NOTES

1:

Summary: a measure of visual imagery ability was obtained for 33 females who and participated in desensitization therapy for snake phobia. Visual imagery was positively related to pretherapy performance (closeness of approach to a live snake), but not to improvement. On the basis of these results and the results of two other studies, it was hypothesized that the fear of good imagers tends to be based on imagination while that of poor imagers tends to be based on sensory experience. Most psychologists now recognize behavior therapy as effective in alleviating a wide variety of fears, but the nature of the processes underlying the various methods remains an open issue. Imagery has been of particular interest as a possible common denominator among various desensitization techniques. Lazarus (1961), for example, asserts that a "prerequisite for effective application of desensitization is the ability to conjure up reasonably vivid images," and Wolpe (1961) claims, "it is essential for visualizing to be at least moderately clear." London suggests that theoretically opposed treatments such as reciprocal inhibition (Wolpe, 1958) and implosion (Stampfl and Levis, 1967) may both be facilitated by repeated imagery which "produces a discrimination set such that the patient learns to distinguish between the imaginative, cognitive, affective aspects of experience, and the sensory and overt muscular aspects" (1964, p. 130). However, no systematic studies linking visual imagery to desensitization have been reported. This study examined the relationship between visual imagery and success in desensitization therapy.

1969

Meyer, Robert G.; Tilker, Harvey (1969). The clinical use of direct hypnotic suggestion: A traditional technique in the light of current approaches. International Journal of Clinical and Experimental Hypnosis, 17 (2), 81-88.

Described a psychotherapeutic procedure which utilized hypnosis and aspects from the behavior therapies. Direct manipulation of behavior in an efficient, effective, and replicable procedure was the goal. Posthypnotic suggestions for the manifestation of desired behaviors were combined with attempts to induce S to reinforce his own behavioral changes. The 2 cases presented are of male prison inmates diagnosed as having character disorders. Positive and substantiated changes in physiological, behavioral, and attitudinal areas occurred. These continued without decrease over 6 mo. (with some indication of healthy adjustment at 1 yr.) for 1 S, and for 15 mo. with some continuous improvements for the 2nd S. (Spanish & German summaries) (PsycINFO Database Record (c) 2002 APA, all rights reserved)

**1994**

**Kennedy, James; Coe, William C. (1994). Nonverbal signs of deception during posthypnotic amnesia: A brief communication. International Journal of Clinical and Experimental Hypnosis, 42 (1), 13-19.**

The question of hypnotic subjects complying with instructions, perhaps even purposely deceiving the hypnotist or deceiving themselves, has arisen from the state-nonstate (skeptical-credulous) theoretical controversy. However, experimental testing of competing hypotheses has been difficult. The current report offers methodological procedures that may prove useful. Subjects who were given posthypnotic amnesia instructions were tested on free recall and implicit recall of a 20-word list. To detect the possibility of deception, videotapes of real subjects and simulating subjects during and after posthypnotic amnesia were rated for nonverbal signs of deception, signs taken from the works of Ekman, Ekman and Friesen, and Zuckerman et al. Preliminary results were gathered on a small pilot sample, and recommendations for procedural improvements are proposed.

**Ader, Robert; Felton, David; Cohen, Nicholas (1990). Interactions between the brain and the immune system. In Cho, Arthur K.; George, Robert; Blaschke, Terrence (Ed.), null (30, pp. 561-602). Palo Alto, CA: Annual Reviews Inc..**

**NOTES:**

Without attempting to cover all the literature, we have used stress effects and conditioning phenomena as illustrations to point out that behavior can influence immune function. We have also described data indicating that the immune system can receive and respond to neural and endocrine signals. Conversely, behavioral, neural, and endocrine responses seem to be influenced by an activated immune system. Thus, a traditional view of immune function that is confined to cellular interactions occurring within lymphoid tissues is insufficient to account for changes in immunity observed in subhuman animals and man under real world conditions.

"These data question seriously the notion of an autonomous immune system. ... The immune system is, indeed, capable of considerable self-regulation, and immune responses can be made to take place in vitro. The functions of that component of adaptive processes known as the immune system that are of ultimate concern, however, are those that take place in vivo. There are now compelling reasons to believe that in vivo immunoregulatory processes influence and are influenced by the neuroendocrine environment in which such processes actually take place ... . The immune system appears to be modulated, not only by feedback mechanisms mediated through neural and endocrine processes, but by feedforward mechanisms as well. The immunologic effects of learning, an essential feedforward mechanism, suggest that, like direct neural and endocrine processes, behavior can, under appropriate circumstances, serve an immunoregulatory function in vivo. Conceptually, the capacity to suppress or enhance immune responses by conditioning has raised innumerable questions about the normal operation and modifiability of the immune system via neural and endocrine processes.

**"We do not yet know the nature of all the channels of communication between the brain and the immune system or the functional significance of the neural and endocrine interrelationships that have been established....**

**"This integrated circuitry has extensive ascending and descending connections among the regions cited. These regions also share many similarities. They are sites intimately involved in visceral, autonomic, and neuroendocrine regulation. The cortical and limbic forebrain regions mediate both affective and cognitive processes and may be involved in the response to stressors, in affective states and disorders such as depression, in aversive conditioning, and in the emotional context of sensory inputs from the outside as well as the inside world. From an immunologic perspective, these regions are the sites in which lesions result in altered responses of cells of the immune system; they are the regions that respond to immunization or cytokines by altered neuronal activity or altered monoamine metabolism; and they are the regions that possess the highest concentration of glucocorticoid receptors and link some endocrine systems with neuronal outflow to the autonomic and neuroendocrine systems. Thus, this circuitry is the major system of the CNS suspected to play a key role in responding to immune signals and regulating CNS outflow to the immune system" (pp. 587-589).**

**Pereira, Robert Peter (1986, July). The role of organismic involvement in hypnotic emotional behavior (Dissertation, Wayne State University). Dissertation Abstracts International, 47 (1), 385-B. (Order No. DA8605027)**

**"Two hundred college undergraduates were pretested via the Harvard Group Scale of Hypnotic Susceptibility: Form A. Fifty subjects scoring in the range 7-12 were designated as Reals, while 25 subjects scoring in the range 0-4 were designated as Simulators. Reals and Simulators were given differential instructions before the administration of a second hypnotic induction procedure, which was accompanied by a task in which subjects were asked to relive each of three emotional experiences, i.e., fear, anger, and happiness. Reals were given instructions encouraging cooperation, while Simulators were instructed to try to convince a group of experienced hypnotists that they were deeply hypnotized, when, in fact, they would not be. "Physiological, overt-behavioral, and cognitive measures taken either during or following the relived-emotions task served as indices of Sarbin's organismic involvement construct. A post-experimental measure of the realness of subjects' relived emotional experience was regressed on these organismic indices in order to test Sarbin's assumption of a positive linear relationship between organismic involvement and belief-in imaginings, using data from the Real group only. Results indicated that, across all three emotions, the linear composite of organismic indices shared statistically significant amounts of variance with the criterion of experiential realness. Obtained amounts of shared variance ranged from 22% (during anger) to 55% (during happiness). These findings were interpreted as offering clear and robust support for Sarbin's theory of hypnosis. Suggestions for further research were offered. "The question of Real-Simulator differences was explored through several multivariate analyses of variance and covariance, using the organismic**

indices as dependent variables. These analyses were performed on the original sample of Reals and Simulators, and on two subsamples of Reals/Highs and Simulators/Lows which were created through the use of pre- and/or post-experimental exclusion criteria. Reals/Highs showed statistically higher levels of effort than did Simulators/Lows during all three emotions, as well as higher levels of skin conductance and finger temperature during anger. These findings were interpreted as being of theoretical and practical significance. Multiple replications of the physiological findings were recommended in order to assess the extent to which the skin conductance and finger temperature variables might be used in practical, i.e., forensic contexts" (p. 385-B).

Sands, Steven (1986, August). The use of hypnosis in establishing a holding environment to facilitate affect tolerance and integration in impulsive patients. Psychiatry, 49.

This paper is concerned with the use of hypnosis in establishing a facilitating and holding environment in the treatment of impulsive behavior across a range of diagnoses. The reason for this cross-diagnostic viewpoint is to underscore the common sources of such action and the needs to be met in its treatment. Illustrations from work with two patients are presented: One was a hypomanic and bulimic woman who was successful in her profession; the other was an underemployed and sometimes unemployed schizophrenic man. Both were inclined to self-defeating impulsive action---bulimia in the woman, assault in the man.

## 1985

Kirsch, Irving (1985, November). Response expectancy as a determinant of experience and behavior. American Psychologist, 40 (11), 1189-1202.

Response expectancies, defined as expectancies of the occurrence of nonvolitional responses, have generally been ignored in theories of learning. Research on placebos, hypnosis, and fear reduction indicates that response expectancies generate corresponding subjective experiences. In many cases, the genuineness of these self-reported effects has been substantiated by corresponding changes in behavior and physiological function. The means by which response expectancies affect experience, physiology, and behavior are hypothesized to vary as a function of response mode. The generation of changes in subjective experience by corresponding response expectancies is hypothesized to be a basic psychological mechanism. Physiological effects are accounted for by the mindbody identity assumption that is common to all nondualist philosophies of psychology. The effects of response expectancies on volitional behavior are due to the reinforcing properties of many nonvolitional responses. Classical conditioning appears to be one method by which response expectancies are acquired, but response expectancy effects that are inconsistent with a conditioning hypothesis are also documented.

Vickery, Anne R.; Kirsch, Irving; Council, James R.; Sirkin, Mark I. (1985). Cognitive skill and traditional trance hypnotic inductions: A within-subjects comparison. Journal of Consulting and Clinical Psychology, 53 (1), 131-133

Comparison of a traditional trance hypnotic induction and a cognitive skill induction in a within-Ss design with 40 undergraduates showed that the cognitive skill induction enhanced subjective responses to suggestions and produced significant increments in behavioral responses when it was preceded by the trance induction. The trance procedure led to greater self-reported alterations in consciousness. Findings suggest that skill induction teaches cognitive strategies that enhance responsivity to suggestions in subsequent hypnotic experiences, independent of alterations in consciousness elicited by trance induction.

### 1981

Tellegen, Auke (1981). Practicing the two disciplines for relaxation and enlightenment: Comment on 'Role of the feedback signal in electromyograph biofeedback: the relevance of attention' by Qualls and Sheehan. Journal of Experimental Psychology: General, 110, 217-226.

High and Low Absorption Ss differ in set rather than in capability for attending to external or internal stimuli, as Qualls and Sheehan suggest. Trait x Treatment interaction for Absorption illustrates concept of personality dispositions being inherently interactive functional units. Provides a content analysis of Absorption scale (subscales) and relates absorption to other constructs in psychology. "It is not the internal versus external focus per se that play a decisive role but the subject's experiential versus instrumental set. For example, with two treatment levels, one would expect to obtain an Absorption x Treatment interaction even if both treatment conditions required an external attentional focus, as long as they contrasted an experiential and an instrumental set" (pp 223-224).

Gerschman, Jack; Burrows, Graham D.; Reade, Peter; Foenander, George (1979). Hypnotizability and the treatment of dental phobic behavior. In Burrows, Graham D.; Collison, David R.; Dennerstein, Lorraine (Ed.), Hypnosis 1979: Proceedings of the 8th International Congress of Hypnosis and Psychosomatic Medicine, Melbourne, Australia (pp. 33-39). New York: Elsevier/North Holland Biomedical Press.

### NOTES:

Found significant relationship between hypnotizability scores on the Diagnostic Rating Scale (O'Connell, D. N., Orne, M. T., & Shor, R. D., 1966) and responsivity to treatment employing hypnosis for dental phobia.

### 1975

Lick, John R. (1975). Expectancy, false galvanic skin response feedback, and systematic desensitization in the modification of phobic behavior. Journal of Consulting and Clinical Psychology, 43 (4), 557-567.

This study compared systematic desensitization and two pseudotherapy manipulations with and without false galvanic skin response feedback after every session suggesting improvement in the modification of intense snake and spider fear. The results indicated no consistent differences between the three treatment groups, although all treatments were significantly more effective than no treatment in modifying physiological, behavioral, and self-report measures of fear. A 4-month follow-up showed stability in fear reduction on self-report measures for the three treatment groups. Overall, the results of this experiment were interpreted as contradicting a traditional conditioning explanation of systematic desensitization. An alternate explanation for the operation of systematic desensitization emphasizing the motivational as opposed to conditioning aspects of the procedure is discussed.

**1974**

**Bloom, Richard F. (1974). Validation of suggestion-induced stress.**

**NOTES**

**1:**

**Technical Memorandum 23-74 (October 1974), US Army Human Engineering Laboratory, Aberdeen Proving Ground, Maryland 21005, AMCMS Code 5910.21.68629, Contract No. DAAD05-73-C-0243, Dunlap and Associates, Inc. (now Stamford, CT), AD002557.**

Sixty college men, divided into three equal groups, each attended two induced stress sessions in which their physiological, psychological and performance reactions were measured. Their responses were compared to determine if valid stress reactions could be induced through suggestion in an altered state (in this case, hypnosis), and also to determine the validity of such reactions if the subject had never before experienced that stress situation. It was demonstrated that valid stress reactions can be induced in an individual with the aid of suggestions, especially if the real stress situation has been experienced before. If no previous experience with that real situation exists, the subject still exhibits stressful reactions; however, the closest resemblance to real stress is found in the subjective or psychological measures, less similarity is found in the physiological measures, and the least similarity is found in the performance measures.

**1961**

**Sutcliffe, J. P. (1961). 'Credulous' and 'Skeptical' views of hypnotic phenomena: Experiments on anesthesia, hallucination, and delusion. Journal of Abnormal and Social Psychology, 62, 189-200.**

The author distinguishes between 2 interpretations of hypnotic phenomena: the credulous (S does or does not experience what the hypnotist suggests) and the skeptical (S reports what is suggested regardless of the "reality" of his experience). 2 groups of Ss (distinguished with respect to the presence or not of genuine hypnotic behavior and posthypnotic amnesia) were placed in a 3 [control (not under hypnotic trance), hypnotic trance, nontrance acting (S asked to act as if conditions were as suggested)] by 2 (stimulus present or not) design involving paraesthesias,

hallucinations, and delusional thinking. Evidence (such as GSR, interference in thinking due to feedback, test measures of delusion) suggests that S does not misperceive the real situation, but misreports it. **1958**

Barber, Theodore Xenophon (1958). Hypnosis as perceptual-cognitive restructuring: II. "Post"-hypnotic behavior. Journal of Clinical and Experimental Hypnosis, 6 (1), 10-20.

NOTES

1:

The author presents "experimental evidence indicating that there is no essential difference between 'hypnotic' behavior and 'post-hypnotic' behavior" (p. 11).

"Summary and Conclusions

"When 'somnambulistic' subjects were told to 'wake up' after they were given a 'post-hypnotic suggestion' and 'amnesia for the suggestion' they behaved as follows:

1. They opened their eyes and became relatively more aware of their surroundings.
2. They were aware that the signal for the 'post-hypnotic- behavior had special significance for them.
3. They were 'set' to 'obey the hypnotist's suggestions' from the moment they were told to 'wake up,' until they were convinced that their interpersonal relationship with the operator was no longer that of subject and hypnotist.
4. When the 'post-hypnotic suggestion' was uncomplicated and fitted into the normal pattern of behavior, the subjects carried it out without 'going deeper into trance,' i.e., without becoming relatively more 'detached' from their surroundings. However, when the 'post-hypnotic suggestion' was of such a nature that it was necessary for the subjects to 'go deeper into trance' to properly carry it out, the subjects did 'go deeper into trance.'

"Whether the subjects did or did not have amnesia for the 'post-hypnotic suggestion' was not important. 'Amnesic' and 'non-amnesic' subjects carried out the 'post-hypnotic' behavior in essentially the same way.

"These experiments indicate that:

1. If the operator properly manipulates the situation, the 'good' hypnotic subject is 'set' to carry out the operator's commands in the 'post-hypnotic' period in the same way as during 'hypnosis.'
2. If, in order to properly carry out the 'post-hypnotic suggestions,' it is necessary for the subject to 'go deeper into trance' -- i.e., to become relatively inattentive to stimuli not emanating from the operator -- the good subject will do so.
3. There is no essential- difference between the subject's behavior in the 'hypnotic' period and in the 'post-hypnotic' period.
4. If we are to continue speaking of 'suggestions' to be carried out in the post-hypnotic period we should term them 'post'-hypnotic 'suggestions'" (pp. 19-20).

Bibliography

**2002**

Gravitz, Melvin (2002). Hypnosis as a counter-measure against the polygraph test of deception.. Polygraph Journal, 31, 293-297.

This article presents a bibliography of experimental and applied studies for reference by those interested in the use of hypnosis as a counter-measure in the "lie detector" test.

### **1988**

**Nash, Michael R.; Minton, Ann; Baldrige, Jeffrey (1988). Twenty years of scientific hypnosis in dentistry, medicine, and psychology: A brief communication. International Journal of Clinical and Experimental Hypnosis, 36, 198-205.**

This paper examines the number of hypnosis articles appearing over the past 20 years in the scientific literature. A comprehensive index of all hypnosis articles published from 1966 to 1985 was obtained by using 5 computer reference data bases (Psychological Abstracts, Index Medicus, Psych Info, Psych Alert, Medline, and Index to Dental Literature). Over 3,500 scientific articles on hypnosis were categorized as to year published (1966 to 1985); journal title; and journal discipline (dental, medical, psychological, core hypnosis specialty journals, and interdisciplinary journals). The period 1966-1969 witnessed a relative prominence of hypnosis articles. For the next 12 years, the number of articles modestly declined. During the most recent 4-year period (1982-1985) there has been a sharp increase, with more articles published in this period than any other. The authors conclude: (a) that there is a stable level of acceptance and interest in hypnosis methodologies across years and disciplines and (b) that this stability, along with the growth of hypnosis specialty journals, signals maturation of the field. A list of dental, medical, psychological, and interdisciplinary journals which publish hypnosis articles is included.

### **1987**

**Gravitz, Melvin A. (1987). Two centuries of hypnosis specialty journals. International Journal of Clinical and Experimental Hypnosis, 35 (4), 265-276.**

Hypnosis under a variety of names has been utilized in clinical practice and scientific research for more than 2 centuries. During that time, there have been numerous periodicals which functioned as specialized outlets for publications related to the modality. In addition, there have been hundreds more which contained hypnosis articles within more general contexts. A comprehensive compilation of these specialized journals has not been available, however, and the present research presents the most complete listing to date. A total of 139 different titles was located through a search of the literature. The largest single group of these was published in French, while English was the second most frequent language used. The oldest hypnosis periodical was the *Annales de la Societe Harmonique des Amis-Reunis de Strasbourg* which was published in Strasbourg, France, in 1786, under the possible editorship of A. M. J. Chastenot de Puysegur. The first English language journal was published in London in 1816 with Francis Corbax as editor and was entitled the *Magnetiser's Magazine and Annals of Animal Magnetism*. In

the United States, 1842 was the initial year for the publication of the first 3 hypnosis journals.

**Hollender, M. H. (1987). The Albert Moll hypnosis collection. International Journal of Clinical and Experimental Hypnosis, 35 (1), 1-7.**

An outstanding collection on hypnosis and related subjects -- about 800 items -- is housed at Vanderbilt University. It was assembled by Albert Moll, an eminent practitioner, who himself contributed many scholarly works to the field. Information about Moll and his unique collection is called to the attention of scholars who have a special interest in the history of hypnosis.

## **Biofeedback**

### **2002**

**Hammond, D. C. (2002). Treatment of chronic fatigue with neurofeedback and self-hypnosis.. NeuroRehabilitation, 16, 1-6..**

A 21 year old patient reported a relatively rapid onset of serious chronic fatigue syndrome (CFS), with her worst symptoms being cognitive impairments. Congruent with research on rapid onset CFS, she had no psychiatric history and specialized testing did not suggest that somatization was likely. Neuroimaging and EEG research has documented brain dysfunction in cases of CFS. Therefore, a quantitative EEG was done, comparing her to a normative data base. This revealed excessive left frontal theta brainwave activity in an area previously implicated in SPECT research. Therefore, a novel treatment approach was utilized consisting of a combination of EEG neurofeedback and self-hypnosis training, both of which seemed very beneficial. She experienced considerable improvement in fatigue, vigor, and confusion as measured pre-post with the Profile of Mood States and through collaborative interviews with both parents. Most of the changes were maintained at 5, 7, and 9 month follow-up testing.

**Shenefelt, Philip (2002). Complementary psychotherapy in dermatology: Hypnosis and biofeedback. Clinics in Dermatology, 20 (5), 595-601.**

Hypnosis has been used for millenia to treat medical and dermatologic problems. The use of biofeedback is more recent, being dependent on instrumentation to measure such parameters as galvanic skin resistance (GSR) and skin temperature. Numerous dermatological disorders may be improved or cured using hypnosis as an alternative or complementary therapy. Examples include acne excoriee, alopecia areata, atopic dermatitis, congenital ichthyosiform erythroderma, dyshidrotic dermatitis, erythromelalgia, furuncles, glossodynia, herpes simplex, hyperhidrosis, ichthyosis vulgaris, lichen planus, neurodermatitis, postherpetic neuralgia, pruritus, psoriasis, rosacea, trichotillomania, urticaria, verruca vulgaris, and vitiligo. Dermatologic procedure anxiety can also be reduced using hypnosis.

Skin problems that have an autonomic nervous system component can be assisted by biofeedback with or without hypnosis. Examples include biofeedback of GSR for hyperhidrosis and biofeedback of skin temperature for Raynaud's syndrome. Hypnosis may enhance the effects obtained by biofeedback.

**1999**

**Kirsch, Irving; Lynn, Steven Jay (1999). Automaticity in clinical psychology. American Psychologist, 54 (7), 504-515.**

The authors provide an overview of the literature on the ability of response expectancies to elicit automatic responses in the form of self-fulfilling prophecies and link it to the broader psychological investigation of automatic processes. The authors review 3 areas of research in which response expectancies have been shown to affect experience, behavior, and physiology: placebo effects, the effects of false biofeedback on sexual arousal, and the alteration of perceptual and cognitive functions by hypnotic and nonhypnotic suggestion. Also reviewed are data suggesting that all behavior, including novel and intentional behavior, is initiated automatically. Following this review, the authors summarize some of the ways in which knowledge of response expectancy effects and other automatic processes that influence experience and behavior can enhance clinical practice.

**NOTES**

**1:**

Although expectancy accounts for some variance in the development of classical hypnosis effects, it is also true that "experimental data suggest that faking accounts for relatively few of these effects" (p. 507). "The best predictors of hypnotic suggestibility are waking suggestibility and response expectancy, and expectancy remains a significant predictor of hypnotic response even with waking suggestibility controlled (Braffman & Kirsch, in press; Kirsch, 1997)" (p. 508). The authors theorize that automatisms (like Chevreul pendulum) are "responses that are primed for automatic activation by two response sets: an intention and an expectancy for their occurrence" (p. 508). They suggest that most behavior is routine, virtually automatic, because cognitive structures like schemas, scripts, or plans that are outside immediate awareness trigger the behavior. They cite research by Libet (1985) and hypotheses developed by Nisbett & Wilson (1977) and Dennett (1991), concluding that "the feeling of will is a judgment, rather than an introspected content" (p. 509). The authors discuss the Chevreul pendulum phenomenon in terms of expectancy theory and explore how their theory would apply to psychotherapy.

**Wickramasekera, Ian (1999). How does biofeedback reduce clinical symptoms and do memories and beliefs have biological consequences? Toward a model of mind-body healing. Applied Psychophysiology and Biofeedback, 24 (2), 91-105.**

Changes in the magnitude and direction of physiological measures (EMG, EEG, temperature, etc.) are not strongly related to the reduction of clinical symptoms in biofeedback therapy. Previously, nonspecified perceptual, cognitive, and emotional

factors related to threat perception (Wickramasekera, 1979, 1988, 1998) may account for the bulk of the variance in the reduction of clinical symptoms. The mean magnitude of these previously nonspecified or placebo factors is closer to 70% when both the therapist and patient believe in the efficacy of the therapy. This powerful placebo effect is hypothesized to be an elicited conditioned response (Wickramasekera, 1977a, 1977c, 1980, 1985) based on the memory of prior healing. These memories of healing are more resistant to extinction if originally acquired on a partial rather than continuous reinforcement schedule. High and low hypnotic ability in interaction with threat perception (negative affect) is hypothesized to contribute to both the production and reduction of clinical symptoms. High and low hypnotic ability respectively are hypothesized to be related to dysregulation of the sympathetic and parasympathetic arms of the autonomic nervous system. Biofeedback is hypothesized to be the most effective for reducing clinical symptoms in people of low to moderate hypnotic ability. For people high in trait hypnotic ability, training in self-hypnosis or other instructional procedures (e.g., autogenic training, progressive muscle relaxation, meditation, CBT, etc.) will produce the most rapid reduction in clinical symptoms.

**1998**

**Eimer, Bruce; Freeman, Arthur (1998). Pain management psychotherapy: A practical guide. New York NY: John Wiley & Sons, Inc**

**NOTES**

**1:**

"Pain Management Psychotherapy" (PMP) provides a clear and methodical look at pain management psychotherapy beginning with the initial consultation and work-up of the patient and continuing through termination of treatment. It is a thoughtful and thorough presentation that covers methods for psychologically assessing the chronic pain patient (structured interviews, pain assessment tests and rating scales, instruments for evaluating beliefs, attitudes, pain behavior, disability, depression, anxiety, anger and alienation), treatment planning, cognitive-behavioral therapy techniques, and a range of hypnotic approaches to pain management. The book covers both traditional (cognitive and behavior therapy, biofeedback, assessing hypnotizability, choice of inductions, designing an individualized self-hypnosis exercise) as well as newer innovative techniques (e.g., EMDR, pain-relief imagery, hypno-projective methods, hypno-analytic reprocessing of pain-related negative experiences). An extensive appendix reproduces in their entirety numerous forms, rating scale, inventories, assessment instruments, and scripts.

The senior author, Bruce Eimer, states in his online comments on Amazon.com that "most therapists hold the belief that 'real' chronic pain patients are quite impossible to help. This book attempts to dispel these misguided beliefs by providing a body of knowledge, theory, and techniques that have proven value in understanding and relieving chronic physical pain." He also states that "the challenge for the therapist is to persuade the would-ne patient/client that he or she has something to offer that can help take way pain and bring back more pleasure. This challenge is negotiated through the therapeutic relationship. However, the therapist just can't be 'warm, accepting, non-judgmental and empathic'. The therapist must also have knowledge

and skills relevant to relieving pain. Only then can the therapist impart such knowledge, and in teaching these skills to the pain patient, help the patient become something of a 'self-therapist'. . . I dedicate this book to everyone who wants to find ways to make living with pain more comfortable, and to the ongoing search for better ways to relieve pain."

**DeBenedittis, Giuseppe De (1996). Hypnosis and spasmodic torticollis -- report of four cases: A brief communication. International Journal of Clinical and Experimental Hypnosis, 44 (4), 292-306.**

Dystonia and particularly spasmodic torticollis are neuromuscular disorders that are extremely resistant to most therapies (physical, medical, or surgical). Torticollis is a unilateral spasm of the neck muscles, particularly of the sternocleidomastoid, that produces violent, tonic turning of the head to one side. The etiology remains uncertain, although the role of psychogenic factors has been emphasized. This article reviews the literature and reports four cases of spasmodic torticollis treated successfully with hypnosis. In all four cases, psychogenic causes were involved. Postural hypnosis (i.e., hypnosis in the standing position) was employed to counteract and minimize muscle spasms due to postural reflexes. A hypnobehavioral approach was adopted along with hypnotic strategies that included hierarchical desensitization, sensory-imaging conditioning, ego-boosting suggestions, and hypnosis-facilitated differential muscle retraining. In two cases, a combined hypnosis and electromyographic-biofeedback approach was used to equilibrate and retrain affected neck muscles. Although the hypnotherapeutic process took several months to induce and stabilize significant changes, outcome results were good to excellent in all cases, with marked reduction of the torticollis and the hypertrophy of the neck muscles as well as a reduced interference of symptoms in daily living. -- Journal Abstract

## **1995**

**Capafons, A.; Amigs, S. (1995). Emotional self-regulation therapy for smoking reduction: Description and initial empirical data.. International Journal of Clinical and Experimental Hypnosis, 43 (1), 7-19.**

Self-regulation therapy (Amigs, 1992) is a set of procedures derived from cognitive skill training programs for increasing hypnotizability. First, experiences are generated by actual stimuli. Clients are then asked to associate those experiences with various cues. They are then requested to generate the experiences in response to the cues, but without the actual stimuli. When they are able to do so quickly and easily, therapeutic suggestions are given. Studies of self-regulation therapy indicate that it can be used successfully to treat smoking.

## **1994**

Culbert, Timothy P.; Reany, Judson B.; Kohen, Daniel P. (1994). Cyberphysiologic strategies for children: The clinical hypnosis/biofeedback interface. International Journal of Clinical and Experimental Hypnosis, 42 (2), 97-117.

This article presents an in-depth discussion of the integrated use of self-hypnosis and biofeedback in the treatment of pediatric biobehavioral disorders. The rationale for integrating these techniques and their similarities and differences are discussed. The concepts of children's imaginative abilities, mastery, and self-regulation are examined as they pertain to these therapeutic strategies. Three case studies are presented that illustrate the integrated use of self-hypnosis and biofeedback in the treatment of children with psychophysiological disorders. The authors speculate on the specific aspects of these self-regulation or "cyberphysiologic" techniques that appear particularly relevant to positive therapeutic outcomes.

**1993**

Wickramasekera, Ian (1993). Observations, speculations and an experimentally testable hypothesis on the mechanism of the presumed efficacy of the Peniston and Kulkosky procedure. Biofeedback, 21, 17-20.

Raises the speculation that alpha/theta EEG brainwave training procedures that have shown preliminary effectiveness with alcoholics and PTSD war veterans may be effective, at least in part, because of an enhancement of hypnotizability resulting from such training. Research to evaluate this is suggested.

Bindler, Paul R. (1992, October). Biofeedback-assisted hypnosis: Theoretical and clinical perspectives. [Paper] Presented at the annual meeting of the Society for Clinical and Experimental Hypnosis, Arlington, VA.

**NOTES:**

Relates personality trait of absorption to biofeedback literature. Surprisingly, low absorption ability Ss do better than high absorption Ss on biofeedback (Qualls & Sheehan). All but one study that compared biofeedback and hypnosis found no difference in effectiveness. However recently Miller & Cross found high hypnotizables reduce EMG better with hypnosis and lows did better with biofeedback.

Our findings also supported notion that highs perform better with sensory imagery instructions and lows do better with biofeedback. Critical in determining the outcome is the way Ss deploy attention. Qualls & Sheehan, and we, find highs don't like attention drawn away from internal cognitive strategies by the biofeedback signal. However lows find the signal to keep their attention focused. Author developed model combining biofeedback and hypnosis to capitalize on the attentional characteristics of patients, the specific cognitive and affective characteristics of the pt. Highs start with using altered state of consciousness to help them to alter their cognition patterns. Some do not relax during hypnosis and biofeedback can be used. Hypnotic suggestions can be added to biofeedback to

emphasize attention to internal discrimination. Attention to stimuli is poor when arousal is too low or too high. Both biofeedback and hypnosis can be used to create a moderate level of attention.

With low hypnotizables, they need to increase awareness of contingencies between cognitions and physiological states; to verbalize and express their feelings. Initially they learn to recognize, label, and express their feelings through biofeedback, which amplifies the physiol. state/body sensations. It provides a means of relaxation. Begin with brief trials of biofeedback to train low arousal states. Duration of training is gradually lengthened to 15 minutes. Patient should be continually questioned about feelings etc. (physical) during exercise, and their response correlated with the feedback signal.

Many lows have difficulty expressing feelings in words. Biofeedback allows the correlation to emerge initially by the instruments. Crystal's "preparatory" treatment: helping patient with affect tolerance prepares them for next stage of verbalizing emotions. Biofeedback facilitates this by deintensifying the effect of discharged affect.

**Zitman, Frans G.; Van Dyck, Richard; Spinhoven, Philip; Linszen, A. Corrie G. (1992). Hypnosis and autogenic training in the treatment of tension headaches: A two-phase constructive design study with follow-up. Journal of Psychosomatic Research, 36, 219-228.**

Tension headaches can form a chronic (very long duration) condition. EMG biofeedback, relaxation training and analgesia by hypnotic suggestion can reduce the pain. So far, no differences have been demonstrated between the effects of various psychological treatments. In a constructively designed study, we firstly compared an abbreviated form of autogenic training to a form of hypnotherapy (future oriented hypnotic imagery) which was not presented as hypnosis and secondly we compared both treatments to the same future oriented hypnotic imagery, but this time explicitly presented as hypnosis. The three treatments were equally effective at post-treatment, but after a 6- month follow-up period, the future oriented hypnotic imagery which had been explicitly presented as hypnosis was superior to autogenic training. Contrary to common belief, it could be demonstrated that the therapists were as effective with the treatment modality they preferred as with the treatment modality they felt to be less remedial.

#### NOTES

1:

An earlier review by these authors found that EMG biofeedback and relaxation training were equally effective with headache [Zitman, 1983, Biofeedback and chronic pain, In *Advances in Pain Research and Therapy* (Edit by Bonica, Lindblom, Iggo) V. 5, pp 794-809. N. Y.: Raven Press]. Other authors also found that hypnotic suggestion, EMG biofeedback and EMG biofeedback plus progressive relaxation training were equally effective [Schlutter, Golden, Blume, 1980, A comparison of treatments for prefrontal muscle contraction headache. *Br J. Med Psychol*, 53, 47-52.]. The authors raise the question whether any treatment element

or perhaps combination of elements can enhance a basic relaxation training procedure, with respect to chronic headache.

The first phase of this research compared autogenic training (AT) and future oriented hypnotic imagery (FI) which was not labeled as hypnosis. Results were the same for both groups, and were reported earlier [van Dyck, Zitman, Linssen et al. *International Journal of Clinical and Experimental Hypnosis*, 1991, 39, 6-23]. The current study added a third group which received future oriented hypnotic imagery but also was told that they were getting hypnosis (FI-H). Thus the AT and FI groups were 'historical' comparison groups for the FI-H group in this study.

Patients were described as having headache complaints of at least 6 months (76% had been suffering for >2 years), were over 18 years old, had no drug dependence and no psychiatric disorder, and no previous therapy with autogenic training or hypnosis; no other treatment during the project; fluent in Dutch.

The autogenic training consisted of six exercises learned in a fixed order. The FI method, in which the hypnotized patient imagines himself in a future, pain-free, situation, had been described by Milton Erickson [1954, *Pseudo-orientation in time as a hypnotherapeutic procedure*. *JCEH*, 2, 261-283]. For that future situation the investigators used descriptions that the patients provided. Both kinds of intervention taught patients muscular and mental relaxation. Both methods required home practice of the technique, using audio cassettes.

In order to substantiate the labeling of the hypnotic procedure as hypnotic future oriented imagery (FI-H) "hand levitation induction was employed during session two with the purpose of inducing positive expectancies concerning hypnosis as a procedure capable of changing ordinary experiences in an unexpected way [17]. This hand levitation procedure, however, was not presented on tape. Except for the labeling as hypnosis and the hand levitation induction, the hypnotic future oriented imagery procedure was identical to the future oriented imagery procedure in the first phase" (p. 221).

Treatment lasted for 8 weeks and provided 2 12 hours of therapist and 24 1/2 hours of home training with taped instructions. The outcome measures included: 1. Budzinsky-type headache index (mean daily sum of intensity rating for each hour of headache activity recorded during 3 separate days of the week of an assessment session) 2. State Anxiety 3. Zung-type Self-rating Depression Scale 4. Perceived credibility of treatment (4 Question's developed by Borkovec & Nau using a visual analogue scale) 5. Neuroticism from the CPI

**RESULTS.** Of 96 patients who agreed to participate, 17 dropped out before the post-treatment assessment. Of the remaining 79, 28 completed AT treatment, 27 FI, and 24 FI-H. Sixty-six attended the follow-up assessment; there were no dropouts from the FI-H, and the drop-outs were equally divided between the AT and FI condition. The headache index scores were logarithmically transformed because the distribution was positively skewed.

Using ANOVA, in terms of post-treatment scores, there were no significant main effects for therapist or treatment, nor were there any significant interaction effects when analyzing headache index, state anxiety, and depression. There was a significant main effect for Time for three outcome measures: headache index score, state anxiety, and depression.

Post-treatment, neither amount of medication used nor subjective estimates of headaches differed by treatment or by therapist. However, over time there were beneficial results for both treatment groups. "Patients rated their headaches as significantly reduced compared to pre-treatment (a mean pain reduction of 40%). ...they had significantly reduced their use of analgesic medication (a mean decrease of 14%)" (p. 224).

Using ANOVA, in terms of follow-up scores, again there were no significant main effects for Treatment or Therapist on the outcome measures of headache index, state anxiety, or depression. There now were three time periods (pre-, post-, and follow-up), and once again there was significant main effect for Time for headache index (though not for state anxiety). That is, people benefitted over the time of the treatment and follow-up. Moreover, there was a significant interaction effect between Therapy and Time on the headache index measure. "A posteriori contrasts revealed that the patients from the FI-H condition showed a greater reduction in their headaches between pre-treatment and follow-up than patients from the AT condition" (p. 225).

The authors write in their Discussion, "Our data indicate that at least in tension headache patients, defining a procedure explicitly as hypnotherapy may not lead to greater effects at post-treatment, but does lead to longer lasting effects" (p. 226).

"The paucity of differences between the three conditions may be a consequence of the study design: the small number of patients and the large SD may have prevented the detection of more differences in effect between the three conditions" (p. 226).

"Other critical remarks are related to the difference in headache reduction at follow-up between AT and FI-H. Firstly, the differences at follow-up were found only with respect to the headache index and not with respect to the subjective estimate of the pain. Secondly, in defining future oriented hypnotic imagery explicitly as hypnosis, we hoped to enhance the efficacy via increased credibility. We found increased efficacy, but we did not find enhanced credibility. Therefore, the differences in effect at follow-up must have another cause. The different effects at follow-up could be linked to the fact that the FI-H condition was the only one without drop-outs. This absence of drop-outs was due to a new research assistant who tried extraordinarily hard to make the patients return for follow-up. By doing so, she may have prevented the patients who gained much from the treatment from dropping out as well as those who gained little" (p. 226-227).

"In this study, despite the differences in therapists' preferences, both therapists were equally effective with all three treatments. This is an intriguing finding which goes against the belief commonly held by clinicians that therapists are more effective with the type of therapy they prefer" (p. 227).

"The effects were modest, but it must be kept in mind that most of our patients referred by a neurologist were chronic headache sufferers (76% had been suffering for > 2 yr). In such a group of patients even small effects are important, especially when these effects are long-lasting" (p. 227).

Acosta-Austan, Frank (1991). Tolerance of chronic dyspnea using a hypnoeducational approach: A case report. American Journal of Clinical Hypnosis, 33, 272-277.

A 48-year-old woman with severe, chronic obstructive pulmonary disease was instructed in the use of peak-flow feedback and hypnotically induced relaxation to reduce the intensity of dyspnea during periods of anxiety. Peak-flow information provided physiologic feedback as well as a safety feature in the event that subjective improvement did not correspond with objective physiologic improvement. I used a progressive relaxation method for inducing hypnosis and gave her suggestions of well-being and muscle relaxation. Peak-flow feedback was useful in enhancing the patient's confidence that hypnotic relaxation was successful in improving respiratory function.

Russell, Christine; Davey, Graham C. (1991). The effects of false response feedback on human 'fear' conditioning. Behaviour Research and Therapy, 29 (2), 191-196.

Describes a human electrodermal conditioning experiment in which 28 students (aged 19-30 yrs) were given false skin conductance feedback during conditioned stimulus/stimuli (CS) presentation. In comparison with attentional control groups, Ss who believed they were exhibiting a strong conditioned response (CR) did actually emit a greater magnitude CR, while Ss who believed they were exhibiting a weak CR emitted a lower magnitude CR. When both self-report and behavioral measures of unconditioned stimulus/stimuli (UCS) evaluation were taken after conditioning, response feedback (RFB) had not differentially affected Ss' evaluation of the aversiveness of the UCS. The response modulating effects of RFB may not be caused by RFB influencing evaluation of the UCS, but they are consistent with the hypothesis that beliefs about the nature of RFB influence the strength of the UCS representation itself.

Schwarz, Shirley P.; Blanchard, Edward B. (1991). Evaluation of a psychological treatment for inflammatory bowel disease. Behaviour Research and Therapy, 29 (2), 167-177.

Compared the effectiveness of a multicomponent behavioral treatment package, which included inflammatory bowel disease (IBD) education, progressive muscle relaxation, thermal biofeedback, and training in use of cognitive coping strategies, with the effectiveness of symptom-monitoring as a control condition. The treatment group consisted of 11 IBD patients (aged 25-62 yrs); 8 of 10 persons (aged 25-71 yrs) in the control group completed treatment. At posttreatment, the treatment group showed fewer reductions in symptoms (5) than the symptom-monitoring controls (8). However, treated Ss perceived themselves as coping better with IBD and as feeling less IBD-related stress. It is hypothesized that the differences in treatment responses may be related to differences between Ss with ulcerative colitis and Ss with Crohn's disease.

Weisz, G. (1991, December). Meta-analysis of hypnosis and biofeedback pain control with children, adolescents and young adults (Dissertation, Pace University). Dissertation Abstracts International, 52 (6), 3321-B. (Order No. DA 9132945)

**NOTES:**

This study used meta-analysis to investigate the issues related to treatment efficacy with hypnosis and biofeedback in anxiety management and in child, adolescent, and young adult pain. Analysis revealed that hypnosis and biofeedback were effective in pain and anxiety reduction and appeared equally effective. This contrasts with metaanalysis results by Malone & Strube (1988) showing almost triple superiority of hypnosis and autogenic training over biofeedback. The study notes methodologic variables that may distort or reduce the size of obtained effects.

**1990**

Schwarz, Shirley P.; Taylor, Ann E.; Scharff, Lisa; Blanchard, Edward B. (1990). Behaviorally treated irritable bowel syndrome patients: A four-year follow-up. Behaviour Research and Therapy, 28 (4), 331-335.

A 4-yr longitudinal study evaluated 19 patients (aged 23-60 yrs) suffering from Irritable Bowel Syndrome (IBS) who had completed a multicomponent treatment involving progressive muscle relaxation, thermal biofeedback, cognitive therapy, and IBS education at baseline. 17 Ss rated themselves as more than 50% improved. Six of the 12 Ss who submitted symptom monitoring diaries met the criteria for clinical improvement, (i.e., achieving at least a 50% reduction in primary IBS symptom scores). The means on all measures at long-term follow-up were lower than those obtained prior to treatment. When follow-up symptom means were compared with pretreatment means, significant reductions were obtained on abdominal pain/tenderness, diarrhea, nausea, and flatulence.

**1989**

Wickramasekera, Ian (1989). Enabling the somatizing patient to exit the somatic closet: A high-risk model. Psychotherapy: Theory, Research and Practice, 26 (4), 530-544.

Problems in establishing a therapeutic alliance make somatizing patients poor candidates for psychotherapy. A logical analysis is presented of the conspiracy of silence between the somatizing patient, the medical doctor, and the health insurance industry regarding the psychosocial factors contributing to somatization. Alternatives are sought to repeated biomedical tests and therapies that are clinically unproductive and iatrogenic. Two psychophysiological pathways are proposed that are promising to reduce the distance between the medical doctors' and the psychologists' procedures. The new profile of illness has produced a paradigm shift with implications for an expansion of the definition of the word "physician".

**1988**

Malone, M.; Strube, M. (1988). Meta-analysis of non-medical treatment for chronic pain. Pain, 34, 231-234.

Conducted a meta-analysis of 109 published studies which assessed the outcome of various nonmedical treatments for chronic pain, 48 of which had sufficient information to calculate effect sizes. The remainder were examined according to proportion of patients rated as improved. Mood and number of subjective symptoms consistently showed greater responses to treatment than did pain intensity, pain duration, or frequency of pain, indicating the importance of using a multidimensional framework for pain assessment. Effect sizes for treatments were 2.74 for autogenic training, 2.67 for hypnosis, 2.23 for pill placebo, 1.33 for package treatments that allowed patients to choose from diverse pain management strategies, .95 for biofeedback, .76 for cognitive therapy, .67 for relaxation, .55 for operant conditioning, and .46 for TENS units. However, the largest numbers of studies were in the area of biofeedback, a treatment package, and relaxation, and we must be cautious in interpreting the effect sizes due to the small number of studies in the sample.

Spinhoven, Philip (1988). Similarities and dissimilarities in hypnotic and nonhypnotic procedures for headache control: A review. American Journal of Clinical Hypnosis, 30 (3), 183-194.

Similarities and differences between hypnosis and similar psychological procedures in the treatment of headache are reviewed. A brief outline of various hypnotic and nonhypnotic interventions for headache reduction shows that none of these procedures has consistently proved to produce superior results. Possible common denominators such as control of physiological processes, placebo factors, and the alteration of cognitive factors are discussed. The positive relationship between hypnotic susceptibility and hypnotic pain reduction indicates that the value of hypnosis seems to be less a matter of therapeutic procedure per se than of which context activates a patient's hypnotic potential for pain reduction.

#### NOTES:

The author summarizes literature on biofeedback and relaxation: "(a) biofeedback with home practice of relaxation is, at least in some cases, effective in reducing migraine and tension headache; (b) relaxation training alone has also produced some success in reducing migraine and tension headaches; and (c) there is not sufficient evidence that biofeedback in the treatment of these pain problems yields results superior to relaxation training" (p. 184). Hypnotherapy for headache is not reviewed in detail, but he provides a table showing various controlled studies and their results. "With the exception of the methodologically problematic study of Anderson, Basker, and Dalton (1975), no differences in effect are found between hypnosis and biofeedback (Andreychuck & Skriver, 1975; Schlutter, Golden, & Blume, 1980; Friedman & Taub, 1984) and hypnosis and relaxation (Friedman & Taub, 1984; Spinhoven, Van Dyck, Zitman, & Linsen, 1985)" (p. 184). He notes

that there are no studies that directly compare hypnosis and nonhypnotic relaxation interventions for headache.

"In all the studies in which hypnotizability was related to outcome, irrespective of patient selection method of measurement, and hypnotic procedure used, a significant positive relationship between hypnotizability and therapy results was found in more than 350 patients (Andreychuck & Skriver, 1975; Cedercreutz, Lahteenmaki, & Tulikoura, 1976; Cedercreutz, 1978; Friedman & Taub, 1984; Spinhoven et al., 1985). If we consider the level of hypnotizability rather than the details of the hypnotic procedure, it seems that headache patients who are highly hypnotizable benefit more from hypnosis in the reduction of headache.

"However, little reliable information is available concerning the underlying dimensions of hypnotic susceptibility relevant for pain reduction. In the neodissociation theory of Hilgard it is suggested that highly hypnotizable patients register pain covertly outside conscious awareness (Hilgard, 1977, 1979). In the social learning model of Spanos and his coworkers (Spanos, Radtke-Bodorik, Ferguson, & Jones, 1979; Spanos, Kennedy, & Gwynn, 1984), it is assumed that high susceptibles show a relatively greater preference for focusing attention on internal thoughts and images as a way of attenuating pain than low susceptibles.

"A recent experimental study of Miller and Bowers (1986), which directly compared hypnotic analgesia, cognitive-behavior therapy, and cognitive-behavior therapy defined as hypnosis in high and low susceptibles, suggests that pain reduction achieved by highly hypnotizable subjects during hypnosis is not mediated by the deliberate use of cognitive strategies (such as imaginative inattention). Cognitive strategy use resulted in pain reduction only during behavior therapy. Clinical studies about the experiential aspects of high and low susceptible headache patients during hypnosis, biofeedback, relaxation training, and cognitive-behavior therapy are urgently needed. If process research in a clinical setting validates that hypnotic analgesia involves the activation of a subsystem of pain control temporarily dissociated from conscious executive control, a therapy component specific for hypnosis will have been identified" (pp. 189-190).

Tsushima, W. T. (1988). Current psychological treatments for stress-related skin disorders. Cutis, *42*, 402-404.

Surveys current methods used by psychologists in the management of stress-related skin disorders, including hypnosis, relaxation training, biofeedback, operant conditioning, and cognitive behavioral therapy. These techniques offer promise in the treatment of certain dermatologic conditions, but the limited amount of well-controlled and replicated studies of their use suggests that caution be taken in their application.

Wakeman, R. J. (1988). Hypnotic desensitization of job-related heat intolerance in recovered burn victims. American Journal of Clinical Hypnosis, *31*, 28-32.

The thermally injured patient who suffers extensive third-degree burns usually finds the adaptation to high temperature environments quite difficult. A 7-year

study of 50 thermally injured patients with greater than 45% total body surface second- and third-degree burns was conducted to assess the usefulness of hypnosis for improved heat adaptation at the work site. There were 25 subjects in the experimental group who received hypnotic training and 25 in a matched control group. The experimental group achieved a mean of 6.25 hours worked over 16 weeks and 63.5 days worked out of 80. They worked 4.5 to 6.5 hours per day for an average of 221 days per year for up to 3 years from baseline. The control group achieved a mean of 4.5 hours worked over 16 weeks and 54.33 days worked out of 80. The efficacy of hypnosis in heat desensitization is discussed.

#### **NOTES:**

Mean age was 38 for the hypnosis group, 33 for the control group; both groups had mean educational level of 8 grades. Mean percentage of total body surface burn was 50% for hypnosis and 54% for control groups.

Each patient was seen for 16 weeks, for 2 hours/week. The hypnosis group received hypnosis, were taught self hypnosis, and were given cassette tapes for use at home. The hypnosis training included a variety of techniques (e.g. progressive deep muscle relaxation, eye-fixation, eye-roll, and visual imagery techniques). They were given suggestions for lower skin temperature, lower 'inner body' temperature, less itching, gradual improvement of time spent on the job, as well as ego strengthening suggestions. The control patients received supportive psychotherapy, family consultation, and cognitive behavior therapy for the same amount of contact time with the same therapist.

The hypnosis group was to do self hypnosis every two hours at the worksite, in addition to home practice. Visual imagery suggestions were things like imagery of a cool waterfall flowing over the skin, having a tall cold glass of beer or soft drink, etc. They also had biofeedback of skin temperature during office visits, to reinforce decreases in skin temperature near the burned sites. They had exposure to heat (in a 95 degree sauna) for in gradually increased periods of time (15 to 120 minutes) before returning to the worksite.

Three years after treatment 20 of 25 control patients had quit their jobs or transferred to a cooler worksite, and all 25 had resigned from their original jobs or applied for further disability benefits. In contrast, only 2 of 25 experimental Ss were working in controlled-temperature settings, and none had applied for permanent disability benefits.

The authors note that family support was essential for the hypnosis patients to carry out their treatment program, and family consultations were essential for every patient. They also found the 'fade-in' technique using the sauna in the hospital occupational therapy area very useful for bridging the gap between practice in the office and going back to the work setting. "This procedure enabled the subject to practice self- hypnosis under controlled physical conditions while performing a work task that was more realistic than 'imagined heat' in the office setting" (p. 31).

#### **1986**

Sargent, Joseph; Solbach, Patricia; Coyne, Lolafaye; Spohn, Herbert; Segerson, John (1986). Results of a controlled, experimental, outcome study of nondrug

treatments for the control of migraine headaches. Journal of Behavioral Medicine, 9, 291-323.

Headache variables were examined for 136 subjects who participated for 36 weeks in one of four groups: No Treatment, Autogenic Phrases, EMG Biofeedback, Thermal Biofeedback. All subjects kept daily records of headache activity and medication usage and participated in 22 laboratory sessions during which frontalis EMG and hand temperature measurements were taken; those in the 3 treatment groups practiced at home. There was a substantial reduction in headache variables in all groups. The No- Treatment Group differed significantly from the treatment groups combined, with the least reduction in headache variables. The thermal biofeedback group vs EMG biofeedback and autogenic phrases groups showed a suggestive trend toward improvement in the frequency and intensity of total headache.

1985

LaRiccia, P. J.; Katz, R. H.; Peters, J. W.; Atkinson, G. W.; Weiss, T. (1985). Biofeedback and hypnosis in weaning from mechanical ventilators. Chest, 87, 267-269.

Weaning patients from mechanical ventilation can be hindered by both physical and psychologic factors. Biofeedback has been used successfully as an adjunct in difficult weaning problems. We have used a combination of hypnosis and biofeedback to wean a patient with neurologic disease who previously failed weaning by standard procedures. A 30-year-old woman with respiratory failure secondary to multiple sclerosis with transverse myelitis was given eight sessions of biofeedback over 12 days in which the movements of her chest wall, as monitored by magnetometers, were displayed on an oscilloscope. The patient was praised for targeted respiratory rate, amplitude, and rhythm. These sessions included hypnosis in which the patient was given suggestions of well-being and that she could breathe as she had five years earlier. In this manner the patient was successfully weaned. Respiratory biofeedback and hypnosis appear to be useful adjuncts in weaning patients from ventilators.

Miller, Lorence S.; Cross, Herbert J. (1985). Hypnotic susceptibility, hypnosis, and EMG biofeedback in the reduction of frontalis muscle tension. International Journal of Clinical and Experimental Hypnosis, 33, 258-272.

Biofeedback and hypnosis have been used in the treatment of similar disorders. While each has been useful, it is unclear whether they involve similar or conflicting processes. Bowers & Kelly (1979) have hypothesized that high hypnotizable Ss are more likely to benefit from hypnosis and similar procedures, than moderate and low hypnotizable individuals. In contrast, Qualls & Sheehan (1979, 1981 a, b, c) have argued that hypnosis and biofeedback involve antithetical abilities. In the present

study, high, moderate, and low hypnotizable individuals (N = 60) were randomly assigned to either EMG biofeedback or hypnosis conditions and instructed to relax. It was found that the mean percent reduction in frontalis muscle tension over the last 5 trials was significantly greater for the high hypnotizable Ss during hypnosis than the moderate and low hypnotizable Ss. The moderate and low hypnotizable Ss demonstrated greater reductions in frontalis muscle tension during EMG biofeedback than during hypnosis. These findings are partly supportive of the predictions of Qualls and Sheehan that hypnosis and biofeedback involve antithetical processes.

#### NOTES:

Qualls and Sheehan (1979, 1981a) "have hypothesized that biofeedback and hypnosis abilities involve antithetical or antagonistic cognitive processes. Specifically, they argued that the biofeedback signal interferes with the natural ability of high absorption Ss to 'direct their attention in an effortless manner toward subjective, imaginal experience [1981a, p. 33],' by forcing them to attend to the external environment. In contrast, low absorption Ss, as well as moderate hypnotizable Ss, possess inadequate abilities to direct their attention in such an effortless and absorbing manner towards inner, subjective experiences, and therefore, the biofeedback signal better enables them to focus their attention. While the pattern of EMG results among the high, moderate, and low hypnotizable Ss ... was somewhat consistent with these predictions, the self-report data did not reveal differences in Ss' awareness of the biofeedback signal or hypnotic suggestions. In addition, there was only a trend for the high hypnotizable Subjects to report less effort in attempting to relax. It is, therefore, unclear whether the explanations postulated by Qualls and Sheehan (1979, 1981a) for the differences found in this study are valid" (p. 269).

Subjective relaxation response results were complex. Ss were asked how relaxed they were during the experimental session in comparison to the previous hypnosis sessions (screening tests). Biofeedback Ss rated the experimental session less favorably than hypnosis Ss. Ss were asked to what degree the feedback (or hypnotic suggestions) helped them to relax; there were significant main effects for treatment and trait, as well as a significant trait x sex interaction. Hypnosis Ss reported that this procedure was more helpful than was reported by the biofeedback Ss. Newman-Keuls comparison revealed that the main effect for trait was due to the high hypnotizable Ss reporting more help from the procedures than the low hypnotizable Ss, and moderate hypnotizable Ss. The Trait x Sex interaction was the result of the high hypnotizable female Ss indicating more help from either relaxation procedure, than was reported by the low hypnotizable male Ss and moderate hypnotizable female Ss and the high hypnotizable male Ss indicated that the procedures were significantly more helpful than was reported by the low hypnotizable male Ss.

Schlesinger, Jay Lawrence (1985). Hypnotizability in relation to success in learning biofeedback training: Attentional involvement (Dissertation, Adelphi University). Dissertation Abstracts International, 45 (n8-B), 2701. (Order No. DA 8424937)

#### **NOTES:**

**"This study investigated the role of attentional focus in the relationship between hypnotizability and success in learning two types of biofeedback training. 40 female college students, aged 18-25, were measured for hypnotic responsiveness, and given one session of EMG biofeedback and one session of temperature biofeedback. For the biofeedback training, 20 Ss received written instructions designed to establish a passive, non-volitional attentional focus on the feedback signal, and 20 received written instructions intended to establish an active, volitional attentional focus on the feedback signal.**

**"It was hypothesized that level of hypnotizability would be positively related to success in learning EMG and temperature biofeedback training for the Ss given passive, non-volitional attentional instructions, while level of hypnotizability would be negatively related to success in learning biofeedback training for the Ss given active, volitional attentional instructions. It was also hypothesized that higher hypnotizables would perform better with temperature biofeedback than with EMG biofeedback, and that lower hypnotizables would perform better with EMG biofeedback than with temperature biofeedback.**

**"The hypotheses were not supported, nor was any overall relationship between level of hypnotizability and success in learning biofeedback demonstrated. There was support to suggest that an active, volitional attentional focus on the biofeedback signal was most adequately maintained by the 20 Ss given the active volitional instructions. Clinical implications of these findings and directions for future research were discussed"**

#### **1984**

**Funch, Donna P.; Gale, Elliot N. (1984). Biofeedback and relaxation therapy for chronic temporomandibular joint pain: Predicting successful outcomes. Journal of Consulting and Clinical Psychology, 52 (6), 928-935.**

**Fifty-seven patients with chronic temporomandibular joint (TMJ) pain were randomly assigned to receive either relaxation or biofeedback therapy. Therapy efficacy was assessed (immediate posttreatment and 2-year follow-up), and pretherapy factors (demographic, clinical, personality) were used to predict successful outcomes for each therapy group. Although there were no significant differences in outcomes, characteristics of patients with successful outcomes were not similar for the two therapies. Successful patients in the relaxation condition tended to be younger, had experienced TMJ pain for a shorter period of time, and had reported problems with other psychophysiological disorders. Successful patients in the biofeedback group tended to be older, married, had experienced TMJ pain for a longer period of time, and had not received prior equilibration treatment. Only two of these factors, equilibration and presence of other disorders, were related to both short- and long-term outcomes, suggesting that they may be particularly useful as predictors of outcome. These findings do suggest that knowledge of pretherapy factors, particularly clinical, may allow for more optimal assignment to therapy conditions.**

Murphy, Joseph K.; Fuller, A. Kenneth (1984). Hypnosis and biofeedback as adjunctive therapy in blepharospasm: A case report. American Journal of Clinical Hypnosis, 27, 31-37.

The efficacy of ophthalmologic, hypnotic, and biofeedback treatment procedures in a case of blepharospasm was evaluated. Manual eye rubbing and eye opening served as dependent measures which were assessed by the patient during treatment and a three month follow-up. Results indicated that ophthalmologic treatment had a limited effect. In contrast, brief hypnosis had a dramatic but short-lived effect and biofeedback had a moderate but sustained effect. Results are discussed in terms of the efficacy of psychological intervention, the limitations of the report, and the need for future research.

### 1983

Radtke, H. Lorraine.; Spanos, Nicholas P.; Armstrong, L. A.; Dillman, N.; Boisvenue, M. E. (1983). Effects of electromyographic feedback and progressive relaxation training on hypnotic susceptibility: Disconfirming results. International Journal of Clinical and Experimental Hypnosis, 31 (2), 98-106.

The efficacy of relaxation training in modifying hypnotic susceptibility was investigated. Following 2 pretests of hypnotic susceptibility, 24 Ss who scored 7 or below on both tests were randomly assigned to 1 of 2 relaxation training groups (EMG-biofeedback or progressive relaxation) or a no-treatment control group. Relaxation training was conducted over 10 20-minute sessions and was monitored by measurement of frontalis EMG. All Ss were then administered a posttest of hypnotic susceptibility. Hypnotic susceptibility did not increase significantly from pretest to posttest. Moreover, change in frontalis EMG was unrelated to change in susceptibility. These results fail to confirm earlier work conducted by Wickramasekera (1972, 1973, 1977).

Schandler, Steven L.; Dana, Edward R. (1983). Cognitive imagery and physiological feedback relaxation protocols applied to clinically tense young adults: A comparison of state, trait, and physiological effects. Journal of Clinical Psychology, 39, 672-681.

Examined changes in targeted and general tension behaviors as well as reductions in physiological tension associated with cognitive imagery and electromyographic biofeedback relaxation procedures. Three groups of 15 female college students participated. During three weekly sessions each person received either guided cognitive imagery relaxation, frontalis muscle feedback relaxation, or a self-rest control procedure. The Anxiety Differential was administered before and after each session, while frontalis EMG, heart rate, and skin temperature were monitored continuously. A second Temperament Analysis was administered after the final session. The imagery procedure was associated with moderate reductions in physiological tension and significant reductions in state anxiety and three tension-related personality dimensions. Self-rest persons displayed lesser reductions in general tension with little physiological change. While biofeedback persons showed

the largest reductions in physiological tension, they displayed only small and variable changes in state anxiety and personality dimensions. The data raise continued questions about the application of physiologically based operant relaxation procedures and support the use of cognitively mediated protocols for the treatment of specific or general anxiety behaviors.

**1982**

**Credidio, Steven G. (1982). Comparative effectiveness of patterned biofeedback vs meditation training on EMG and skin temperature changes. Behaviour Research and Therapy, 20, 233-241.**

Examined whether a low arousal, relaxation pattern of frontalis EMG decreases and peripheral skin temperature increases could be attained more effectively through biofeedback or meditation training. 30 21-59 yr old females were randomly assigned to 1 of 3 groups: patterned biofeedback, clinically standardized meditation, or control. Prior to training, Ss were administered the Eysenck Personality Inventory. Each S was seen weekly for 7 sessions. Subjective experiences and time spent practicing at home were also recorded. Results indicate that the meditation group showed significantly lower EMG levels at the end of treatment than did the control group. The biofeedback group had difficulty in patterning the 2 feedback signals simultaneously. Extraverts in the control group had the highest EMG levels. The most positive subjective reports came from Ss in the meditation group. It is suggested that meditation offers a viable alternative as a relaxation procedure, requiring little time to learn and devoid of any performance criteria levels.

**Holroyd, Jean; Nuechterlein, Keith; Shapiro, David; Ward, Frederick (1982). Individual differences in hypnotizability and effectiveness of hypnosis or biofeedback. International Journal of Clinical and Experimental Hypnosis, 30 (4), 45-65.**

8 high and 8 low hypnotizable Ss used biofeedback and hypnosis to lower blood pressure in one session and forehead EMG activity in another session. Results were analyzed by repeated measures analyses of covariance using baseline physiological level on the dependent variable as the covariate. Electromyographic level was reduced more immediately by biofeedback than by hypnosis. When the task was to lower blood pressure, blood pressure and skin conductance were more effectively reduced by hypnosis than by biofeedback, considering only the first half of each session to eliminate within-session transfer effects. Hypnotizability did not predict overall outcome. Factors which may have prevented demonstrating a clearer relationship between hypnotizability and success using biofeedback or hypnosis are discussed. State and trait anxiety, cognitive strategies used during the tasks, and self-reported hypnotic depth are examined for correlates of successful performance.

**Lehrer, Paul M. (1982). How to relax and how not to relax: A re-evaluation of the work of Edmund Jacobson: I. Behaviour Research and Therapy, 20 (5), 417-428.**

Contrasts E. Jacobson's (1928-1970) method of progressive relaxation with modified techniques that emphasize suggestion, brevity, and the feeling of large differences between tension and relaxation. The literature suggests that the modifications may have been premature. The psychophysiological effects of suggestion are weaker than those of progressive relaxation. Tape-recorded instruction appears to be completely ineffective as a method for teaching relaxation as a skill that can be used across situations. Live training contributes more than simple feedback; its effectiveness may lie in individualized adaptation of training technique. EMG biofeedback makes taped training more effective but contributes nothing to intensive live training. Despite its greater length, Jacobson's original technique is preferred to the modified techniques, particularly when psychophysiological effects are important. Length of training does not appear to be a critical factor. (116 ref)

Shapiro, Deane H. (1982). Overview: Clinical and physiological comparison of meditation with other self-control strategies. American Journal of Psychiatry, 139 (3), 267-274.

In 1977, the American Psychiatric Association called for a critical examination of the clinical effectiveness of meditation. The present author reviews the pertinent literature and defines meditation as a family of techniques that attempt to focus attention in a nonanalytical way and attempt not to dwell on discursive, ruminating thought. Meditation is then compared with such self-regulation strategies as biofeedback, hypnosis, and progressive relaxation. Particular attention is given to the "uniqueness" of meditation as a clinical intervention strategy as well as the adverse effects of meditation. Future research should deal with the context of meditation, a component analysis, refinement of the dependent variable, S variables, and the phenomenology of meditation.

Stern, T. E. (1982). The effects of Ericksonian hypnosis and biofeedback on self-reported measures of pain (Dissertation). Dissertation Abstracts International, 43, 3744-B.

**NOTES:**

Conducted a 6-subject case study comparing the effectiveness of so-called Ericksonian hypnosis and biofeedback on chronic pain. Two subjects improved more on subjective and behavioral pain measures using biofeedback, three improved more using hypnosis, and one did not improve in either condition.

Stoyva, J. M.; Anderson, C. (1982). A coping-rest model of relaxation and stress management. In Goldberger, L.; Breznitz, S. (Ed.), Handbook of stress: Theoretical and clinical aspects (pp. 745-763). New York: The Free Press.

**NOTES:**

"Patients with psychosomatic or stress linked disorders are likely to show signs of high physiological arousal, and they are likely, under stress, to react strongly in the symptomatic system and to show evidence of being deficient in the ability to shift

from the coping to the rest mode (e.g., slowness of habituation to, and recovery from, stressful stimulation). A corollary inference is that such patients ... show activity in the symptomatic system for a higher percentage of the time that [sic] do normal subjects. We suggest that this defect in the capacity to shift to a rest condition is the principal reason that various relaxation procedures have so often proved successful in the alleviation of stress related symptoms" (p. 748).

The authors refer to a number of different stress management procedures. Among those associated with primary focus on the rest phase they include: Relaxation training (progressive relaxation, autogenic training, EMG feedback, meditation [Zen, TM]), Specific biofeedback (hand temperature, electrodermal response [EDR], EMG from particular muscle group), and Systematic desensitization. Among those associated with primary focus on coping phase are: Assertiveness training, Social skills retraining and motor skills retraining, Self-statements, Imagery (Guided waking imagery, autogenic abreaction, covert reinforcement and covert sensitization, behavior rehearsal). These various procedures may reflect three dimensions or aspects of the stress response, with some addressing physiology and others addressing cognition or behavior change.

"Rachman (1978) ... found it useful to divide the phenomenon of fear into physiological, cognitive, and behavioral components. Similarly, Davidson and Schwartz (1976) conceptualized relaxation as consisting of somatic, cognitive, and attentional components. Phillips (1977) argued that pain, such as headache pain, can be viewed as consisting of cognitive, behavioral, and physiological aspects (and that, consequently, we should not expect high correlations between headache pain and a particular physiological measure such as forehead EMG level). ...

"... In discussing contemporary studies of dreaming, they [Stoyva and Kamiya (1968)] proposed that there is no single, totally valid indicator of dreaming as a mental experience. Instead, there are several imperfect indicators of the dream experience--verbal report, rapid eye movements, and certain electroencephalographic (EEG) stages. ... Discrepancies among the indicators can serve to generate hypotheses" (p. 749).

The authors discuss different ways of retraining the capacity to rest: relaxation training (including biofeedback, etc.), systematic desensitization; and of reshaping the coping response: assertiveness training, social skills and motor skills retraining, self-statements, imagery techniques; and discuss controllability. These notes cover only a very small part of their extensive review, the material most relevant to hypnosis and suggestion.

"Although imagery techniques are often employed by stress management therapists, one approaches this area with ambivalence. In part, this uneasiness springs from the unsettling awareness that imagery techniques have been embraced by a freewheeling assortment of lay psychologists such as Emil Coue, Dale Carnegie, and Norman Vincent Peale, not to mention a diverse throng of contemporary 'mind controllers' and self-styled healers. A more serious source of uneasiness is ignorance of the specific processes at work. What are the mechanisms by which imagery affects the stress response?" (p. 756).

"There is intriguing recent evidence that simply the illusion of control may exert beneficial effects. Stern, Miller, Ewy, and Grant (1980) noted that subjects who were

led to believe by means of bogus information feedback that they were successfully lowering their heart rates showed a reduction in stress type symptoms, especially those of a cardiovascular nature. It seems possible that the feeling of control may be an important part of what we have called 'placebo responding.' Stoyva (1979b) suggested that this phenomenon is probably not a unitary entity but, rather, a cluster of processes, of which the feeling of developing control over factors affecting one's disorder is an important and potentially manipulable component of therapeutic interventions" (p. 758).

## 1981

Claghorn, James L.; Mathew, Roy J.; Largen, John W.; Meyer, John S. (1981). Directional effects of skin temperature self-regulation on regional cerebral blood flow in normal subjects and migraine patients. American Journal of Psychiatry, 138, 1182-1187.

Vascular headache of the migraine type is associated with vasomotor changes in cerebral arteries. The authors studied whether skin temperature training (biofeedback) reduced the frequency, severity, and duration of these headaches by measuring the regional cerebral blood flow (CBF) in 11 female migraine patients (27-52 years) and 9 female volunteers (22-37 years), using the noninvasive 133 Xe inhalation technique. Half of each group was randomly assigned to a hand-warming or a hand-cooling group. CBF increased in several regions of the left hemisphere to a significant degree only for the migraineurs who were in the hand-warming group. The pattern of vasomotor regulation apparently differed between migraine and normal Ss. The migraineurs' headache symptoms were affected by both warming and cooling, but warming produced more salutary effects.

Cott, A.; et al. (1981). The long-term therapeutic significance of the addition of electromyographic biofeedback to relaxation training in the treatment of tension headaches. Behavior Therapy, 12, 556-559.

**ABSTRACT:** Eight tension headache sufferers seeking traditional medical treatment from a neurologist participated in either a therapist-delivered relaxation training (RT) condition or an RT plus EMG feedback condition. Mean hours of pain/day, headache severity, and medication ingestion were significantly lower in both groups following treatment. Results were maintained at a 1-year follow-up for hours of pain/day and medication ingestion. Findings thus indicate no benefit of adding EMG feedback to relaxation training.

Piedmont, Ralph L. (1981). Effects of hypnosis and biofeedback upon the regulation of peripheral skin treatment. Perceptual and Motor Skills, 53, 855-862.

The purpose of this study was to examine the influence of hypnosis on the regulation of peripheral skin temperature. The independent variables were the presence of a hypnotic trance during the session on thermal regulation and the number of trials received. A two-factor mixed-design analysis of variance with repeated measures on one factor showed a significant main effect for trials and a significant interaction between hypnosis and trials. It may be concluded that hypnosis, in conjunction with

thermal regulation techniques, exerts a significant influence over performance. The cognitive characteristics influenced by hypnosis may account for this finding.

## 1980

Adams, Henry E.; Feuerstein, Michael; Fowler, Joanne L. (1980). Migraine headache: Review of parameters, etiology, and intervention. Psychological Bulletin, 87 (2), 217-237.

The migraine headache is a disorder of much interest to clinicians and researchers in the areas of psychology and medicine. Research that has investigated various characteristics of this disorder and the factors contributing to its etiology and a variety of treatment techniques have appeared in both the medical and the psychological literature. The present article provides a comprehensive critical appraisal of this literature, with particular emphasis on psychological intervention. Theoretical issues involving biological and psychological factors in migraine etiology are discussed, and a psychobiological model for the migraine disorder is proposed. Areas requiring further basic and clinical research are identified. Major conclusions include (a) that etiological factors of migraine remain unclear; (b) that pharmacological intervention does not constitute an adequate treatment method in terms of headache elimination; (c) that although a number of psychological treatment approaches have been reported in the literature, there are few well-controlled evaluations, and definitive conclusions regarding differential effectiveness of the various techniques are difficult; and (d) that a biofeedback approach directed at modifying the peripheral pain mechanism in migraine appears to be a promising treatment technique for this disorder.

Crosson, B. (1980). Control of skin temperature through biofeedback and suggestion with hypnotized college women. International Journal of Clinical and Experimental Hypnosis, 28 (1), 75-87.

4 groups of 9 college women attempted to raise finger temperature relative to forehead temperature during hypnosis. After a hypnotic induction, each group of Ss received 1 of the following treatments for temperature control: (a) biofeedback, (b) suggestion and imagery, (c) biofeedback plus suggestion and imagery, and (d) a relaxation, false-feedback control. Groups were initially balanced for hypnotic susceptibility. Between-subject differences in baseline temperatures were statistically controlled. After 4 training sessions, only Ss in the groups receiving biofeedback and biofeedback plus suggestion and imagery demonstrated evidence of learned temperature control, and only Ss in the biofeedback group demonstrated a significantly greater ability to control skin temperature than Ss in the control group. Changes in temperature during hypnotic induction did not appear to affect changes during the subsequent treatment. There was no significant correlation between hypnotic susceptibility and temperature control for Ss in any group, contrary to popular assumption. Future research should attempt to ascertain if combined use of biofeedback and hypnosis offers any advantages to the use of biofeedback alone.

**Dumas, R. A. (1980). Cognitive control in hypnosis and biofeedback. International Journal of Clinical and Experimental Hypnosis, 28 (1), 53-62.**

The relation between biofeedback and hypnotic self-control abilities was examined in the EEG alpha biofeedback situation. 17 Ss, selected on the basis of group hypnotic susceptibility tests, completed 4 EEG alpha training sessions, with enhance, suppress, and unreinforced baseline conditions. The 5 Ss who scored high on the hypnotic susceptibility test did not gain significant control over their EEG alpha, whereas those Ss who scored moderate or low on the test did gain control over their alpha. "Control" in this experiment was gained by learning contingent alpha suppression. There were no differences between the hypnotizability groups in baseline EEG alpha production.

NOTES

1:

"In summary, the results of the present study in combination with the results of the Friedman and Taub (1977) study should lead to the treatment of biofeedback and hypnosis as potentially different processes involving different, possibly antagonistic, cognitive processes. The treatment of hypnosis and hypnotic ability as different phenomena from biofeedback self-control should lead to experimental designs which do not automatically assume additivity of effects. Such enlightened designs will then shed more light on the mechanisms of each and the relation of these two cognitive control techniques" (0. 60).

**Hurley, John D. (1980). Differential effects of hypnosis, biofeedback training, and trophotropic responses on anxiety, ego strength, and locus of control. Journal of Clinical Psychology, 36 (2), 503-507.**

Pretested 60 college students on three scales: the IPAT Anxiety Scale, the Barron Ego-strength scale, and the Rotter I-E scale. The Ss then were assigned randomly to one of four treatment groups designated: hypnotic treatment, biofeedback treatment, trophotropic treatment, and control. Three of these groups met separately for 60 minutes once a week for 8 weeks. The control group did not meet during this time. During the sessions, each group was trained in a different technique for self-regulation. At the end of the 8-week period the scales were readministered to all groups. A series of covariance analyses indicated that hypnosis was a more effective self-regulatory technique for lowering anxiety levels when compared to biofeedback or trophotropic response procedures. With regard to increasing ego strength, both the hypnotic training group and the biofeedback training group proved to be significant. No significant difference was found between the experimental and control groups on the I-E scores.

**1979**

**Quall, Penelope J.; Sheehan, Peter W. (1979). Capacity for absorption and relaxation during electromyograph biofeedback and no-feedback conditions. Journal of Abnormal Psychology, 88 (6), 652-662.**

The present research examined the relation between absorption capacity and relaxation during electromyograph biofeedback and no-feedback (instructions only) conditions. Sixteen high absorption and 16 low absorption female subjects

underwent a biofeedback and no-feedback session with the order of conditions counterbalanced. For high absorption subjects in the first session, EMG reductions were greater during no- feedback than during biofeedback, although the performance of biofeedback subjects improved in the second session. For low absorption subjects, no differences in EMG reductions were apparent across experimental conditions. Postexperimental self-report data demonstrated differences between absorption groups in subjects' state of arousal and quality of consciousness. It was concluded that for subjects with high capacity for absorbed attention, experimental conditions that allow for a withdrawal from the external environment are most conducive to relaxation, whereas for subjects with limited capacity for absorbed attention, conditions such as biofeedback that place an attentional demand on subjects may be preferable.

Turk, Dennis C.; Meichenbaum, Donald H.; Berman, William H. (1979). Application of biofeedback for the regulation of pain: A critical review. Psychological Bulletin, 86 (6), 132

The biofeedback literature for the regulation of pain is reviewed and found wanting on both conceptual and methodological grounds. In particular, studies on the use of biofeedback for the treatment of tension and migraine headaches and chronic pain indicate that biofeedback was not found to be superior to less expensive, less instrument- oriented treatments such as relaxation and coping skills training. The relative absence of needed control comparisons was noted, and the need for caution in promoting biofeedback was stressed. Suggestions for future research are offered.2-1338.

## 1978

Acosta, Frank X.; Yamamoto, Joe; Wilcox, Stuart A. (1978). Application of electromyographic biofeedback to the relaxation training of schizophrenic, neurotic, and tension headache patients. Journal of Consulting and Clinical Psychology, 46 (2), 383-384.

This study examined the effects of electromyographic (EMG) biofeedback on tension reduction by schizophrenic, neurotic, and tension headache patients. Fourteen patients participated voluntarily in at least 10 weekly EMG biofeedback sessions at a public outpatient clinic. All had complained of chronic tension. Patients showed significant decreases in their muscle tension levels with successive biofeedback training sessions. No significant differences were found between the schizophrenic, neurotic, and tension headache groups. A further contribution was the finding that patients with diverse socioeconomic and educational levels benefitted similarly from EMG biofeedback training.

Counts, D. Kenneth; Hollandsworth, James G., Jr.; Alcorn, John D. (1978). Use of electromyographic biofeedback and cue-controlled relaxation in the treatment of test anxiety. Journal of Consulting and Clinical Psychology, 46 (5), 990-996.

The effect of using electromyographic (EMG) biofeedback to increase the efficacy of cue-controlled relaxation training in the treatment of test anxiety was studied. Forty

college undergraduates scoring in the upper third on a self-report measure of test anxiety were randomly assigned to one of four treatment conditions - EMG-assisted cue- controlled relaxation, cue-controlled relaxation alone, attention-placebo relaxation, and no-treatment control. Pre-post self-report measures of test anxiety, state anxiety, and trait anxiety were obtained. In addition, a performance measure in the form of a mental abilities test was administered. Subjects from the three relaxation groups received six 45- minute individual sessions over a period of 2 weeks. All treatments were conducted using audiotape recordings. The results indicate that cue-controlled relaxation is effective in increasing test performance for test anxious subjects, that EMG biofeedback does not contribute to the effectiveness of this procedure, and that self-report measures of anxiety are susceptible to a placebo effect.

Lehrer, Paul M. (1978). Psychophysiological effects of progressive relaxation in anxiety neurotic patients and of progressive relaxation and alpha feedback in nonpatients. Journal of Consulting and Clinical Psychology, 46 (3), 389-404.

Gave 10 anxiety neurotic patients 4 sessions of individual instruction in progressive relaxation; 10 patients served as waiting list controls. 10 nonpatients were assigned to each of the same conditions, and an additional 10 nonpatients were given 4 sessions of alpha feedback. Nonpatients showed more psychophysiological habituation over sessions than patients in response to hearing 5 very loud tones and to a reaction time task. Patients, however, showed greater physiological response to relaxation than did nonpatients. After relaxation, the autonomic responses of the patients resembled those of the nonpatients. The effects of relaxation were more pronounced in measures of physiological reactivity than in measures of physiological activity. Defensive reflexes yielded to orienting reflexes more readily in nonpatients than in patients. There was also a tendency for progressive relaxation to generalize to autonomic functions more than alpha feedback.

**1977**

Ansel, Edward Leslie (1977). A simple exercise to enhance response to hypnotherapy for migraine headache. International Journal of Clinical and Experimental Hypnosis, 25 (2), 68-71.

A common method of hypnotherapy for migraine headache utilizes suggestions of warmth for the hands and coldness for the head. This procedure reverses the abnormal pattern of vasodilation and excess supply of blood in the head and decreased supply in the extremities associated with this type of headache, thereby relieving the pain. A simple exercise, utilizing centrifugal force to dramatically increase blood flow to the hands, is described. It promotes relief in itself and provides a vivid background experience to enhance productivity of this effect in hypnosis. It appears to be especially useful in patients exhibiting lesser degrees of trance capacity.

Friedman, Howard; Taub, Harvey A. (1977). The use of hypnosis and biofeedback procedures for essential hypertension. International Journal of Clinical and Experimental Hypnosis, 25, 335-347.

In an attempt to evaluate a procedure combining 2 techniques, hypnosis and biofeedback, which might effect significant changes in diastolic blood pressure in essential hypertensives, Ss were placed in 1 of 4 groups: hypnosis only, biofeedback only, hypnosis and biofeedback combined, or measurement only. The first phase -- training sessions and brief follow-ups (1 week and 1 month) -- of the long-term study with 6 monthly follow-up periods, was evaluated. Hypnosis only and biofeedback only procedures were both capable of providing significant lowering of diastolic pressure. However, in intergroup comparisons, the hypnosis only procedure showed the most impressive effect. Unexpectedly, the procedure of combining hypnosis and biofeedback into one technique was as ineffective as the measurement only procedure.

#### NOTES

1:

In their discussion of the finding that hypnosis + biofeedback did not yield more positive results, the authors state, "it is possible that two opposing sets were established that negated each other: the biofeedback instructions wherein S was enjoined to direct his attention externally and to attempt to change the displayed number which reflected diastolic pressure, versus the more passive, relaxed attitude implied in hypnotic induction. It is interesting to note that Benson et al. (1974b) have similarly suggested that the set involved in biofeedback training may interfere with the elicitation of the 'relaxation response.' Also, Orne [personal communication] has indicated that, although anticipating a synergistic effect as a result of combining hypnotic and biofeedback procedures, some difficulty may lie in requiring Ss to be hypnotized during [emphasis on 'during' in original] the biofeedback training procedure"

Pelletier, K. R.; Peper, E. (1977). Developing a biofeedback model: Alpha EEG feedback as a means for pain control. International Journal of Clinical and Experimental Hypnosis, 25, 361-371.

3 adept meditators voluntarily inserted steel needles into their bodies while physiological measures (EEG, EMG, GSR, EKG, and respiration) were recorded. Although each adept used a different passive attention technique, none reported pain. During the insertion, 2 of the 3 Ss increased their alpha EEG activity. The role of alpha EEG and its relationship to pain control is discussed.

#### NOTES

1:

The three adepts studied were: (1) RCT, a 34 yr old Ecuadorian who had "demonstrated control over pain by placing bicycle spokes through his body, being suspended from hooks inserted under his shoulder blades, and walking through fire -- all without reported pain or observed damage to his skin;" (2) JSL, a 31 yr old Korean karate expert, who "suspended a 25-pound bucket of water from a sharpened spoke placed through a fold of skin on his forearm;" and (3) JS, a 50-yr

old Dutch meditator who had "demonstrated pain and bleeding control" (pp. 363-365). "RCT, JSL, and JS each remarked that pain is principally fear of and attention to pain, and they maintained that anyone can learn to control pain through relaxation and passive attention" (p. 367). Both JS and RCT had increased alpha EEG activity during piercing, whereas JSL showed no increase. The authors suggest that "the karate expert practiced a very focused meditation, during which he mentally saw and felt the ki energy as a point, while RCT and JS employed passive attention and did not attend to the body stimuli. Thus, it is possible for physiological measurements to reflect strategies used in dissociation of pain perception, and that the quality of pain perception is altered if S is at either extreme of focused or unfocused conscious attention" (p. 368). "We hypothesize that, for nonadepts, alpha EEG training without alpha blocking to stimuli could become a distraction technique whereby S again could learn self-control and competence as he becomes more successful in controlling his EEG" (p. 369).

Wickramasekera, Ian (1977). The placebo effect and medical instruments in biofeedback. Journal of Clinical Engineering, 2 (3), 227-230.

This article defines a "placebo effect" and identifies some of its parameters in pain control and in other areas of medicine. It proposes a new model of the placebo effect and advances the hypothesis that biomedical instruments used in biofeedback studies, like drugs, can acquire and generate placebo effects. Such placebo effects can complicate the interpretation of specific experimental treatments in human clinical research in which biomedical instruments are used.

1976

Dugan, Michelle; Sheridan, Charles (1976). Effects of instructed imagery on temperature of hands. Perceptual and Motor Skills, 42, 14.

NOTES:

Sixteen college student volunteers were involved in the research. Subjects were randomly assigned to two groups, either to warm or to cool their hands. All 10 subjects attempting to cool their hands were able to cool at least one hand, and six people cooled both hands. For those trying to warm their hands, five warmed at least one hand and one was able to warm both hands. Four people were able to cool their hands without hypnosis, conditioning, or feedback.

Schaudler, S. L.; Grings, W. W. (1976). An examination of methods for producing relaxation during short-term laboratory sessions. Behaviour Research and Therapy, 14, 419-426.

NOTES:

Subjects were 100 undergraduate students, average age 22.3, distributed into two experiments as follows.

Experiment 1 20 had progressive relaxation (Jacobsonian, abbreviated as done by Paul, 1969) = PR 20 had visual feedback (from forearm extensor) = VFB 20 had

tactile feedback (from forearm extensor) = TFB 20 had relaxation control (music) = CT

Experiment 2 10 had auditory feedback (from forearm extensor) = AFB 10 had tactile feedback (from forearm extensor) = TFB

The results obtained for the various measures were as follows. Anxiety was significantly reduced by PR and TFB; perhaps by AFB. Blood pressure was significantly reduced by AFB, TFB, VFB and PR. Heart rate was significantly reduced by VFB, AFB, TFB, but not PR or CT Extensor EMG was significantly reduced by VFB, TFB, PR, and AFB Frontalis EMG was significantly reduced by TFB, PR and AFB Skin conductance was significantly reduced by TFR and PR

In their Discussion the authors noted that tactile biofeedback was especially beneficial and achieved lower levels of response than the other feedback techniques. Visual feedback was somewhat poorer than progressive relaxation and tactile feedback approaches. Also, the progressive relaxation heart rate and respiratory rate changes were not as impressive as the biofeedback group effects.

## 1975

Alexander, A. Barney (1975). An experimental test of assumptions relating to the use of electromyographic biofeedback as a general relaxation technique. Psychophysiology, 656-662.

Twenty-eight normal adults participated in an experimental test of two assumptions underlying the use of electromyographic (EMG) biofeedback as a general relaxation training technique: 1) that trained EMG reduction in one muscle generalizes to untrained muscles; and 2) that subjective feelings of relaxation are related to EMG reduction. An experimental group received 5 sessions, during the middle 3 of which EMG biofeedback training was offered on the frontalis muscle. Throughout all sessions, EMG recordings were also taken from the forearm and lower leg, and rating of subjective relaxation feelings were obtained at regular intervals. A control group, matched with the experimental group on baseline frontalis EMG, received 5 similar sessions without feedback. Employing a maximum p of .05, the results revealed no evidence of generalization of EMG reduction from the frontalis to the untrained sites, nor any tendency for successful frontalis EMG reduction to result in increased feelings of relaxation beyond what was obtainable from relaxing without the benefit of training. The results were interpreted as suggesting the EMG biofeedback cannot yet be accepted as a viable general relaxation training technique.

Andrews, Reagan H., Jr. (1975). Placebo effects in EMG biofeedback (Dissertation). Dissertation Abstracts International, 36, 1424.

"Differential instructions were employed in a negative placebo model to alter expectancies of success in achieving criterion frontalis EMG voltage levels in 30 female subjects. The negative placebo model dictated that all subjects receive true feedback during both of two 10-minute experimental trials. On one of the two trials they were informed that feedback would be accurate, and on the other trial, that feedback would be accurate only 50% of the trial period. Data was collected for 20

subjects in a 2 X 2 Latin Square design, while 10 subjects were designated control subjects and received high-success expectancy instructions on both experimental trials. Pre-trial measures included administration of a standard hypnotic susceptibility scale and a pre-test subjective questionnaire. Dependent variable was the time from onset of feedback to 70% reduction of resting EMG levels of the frontalis. Significant differences were found between high and low-expectancy trials for experimental subjects. Effects were strongest on the first experimental trial and tended to diminish on the following trial. Correlation of hypnotic susceptibility scores with response latencies was not significant, but subjects' impression of their degree of relaxation during susceptibility scale administration was significantly correlated with criterion latencies. Importance of subject expectancies, instrumentation standards and implications for future studies in the biofeedback area were discussed" (p. 1424).

Andreychuk, Theodore; Skriver, Christian (1975). Hypnosis and biofeedback in the treatment of migraine headache. International Journal of Clinical and Experimental Hypnosis, 23 (3), 172-183.

A study was made to explore the effects of subject hypnotizability in response to 3 treatment procedures applied to 33 migraine headache sufferers. These treatment procedures included biofeedback training for hand-warming, biofeedback training for alpha enhancement and training for self-hypnosis. The Hypnotic Induction Profile (HIP) of Spiegel & Bridger (1970) was given to each S to determine degree of hypnotizability and the MMPI was administered to all Ss. All 3 treatment groups showed significant reductions in headache rates and there were no significant differences between groups. Cutting across treatment groups, high hypnotizable Ss (N - 15) showed significant reductions in headache rates when compared with low hypnotizable Ss (N - 13). There was no correlation between HIP scores and the hysteria scale of the MMPI.

Cowings, Patricia S. (1975, September). Observed differences in learning ability of heart rate self-regulation as a function of hypnotic susceptibility. [Paper] Presented at the 3rd Congress of the International College of Psychosomatic Medicine, Rome.

Three groups of eight men and women were given personality tests and were taught to control their own heart rates. Experimental group I and the control group had low hypnotic susceptibility (Stanford Hypnotic Susceptibility Scale), and subjects in experimental group II had high hypnotic susceptibility. The experimental groups received autogenic therapy and biofeedback, while the control group was given biofeedback only. Subjects who received autogenic therapy and biofeedback performed better than the control group. Significant differences, however, were found in all psychological test scores between high and low hypnotic susceptibles.

Lick, John R. (1975). Expectancy, false galvanic skin response feedback, and systematic desensitization in the modification of phobic behavior. Journal of Consulting and Clinical Psychology, 43 (4), 557-567.

This study compared systematic desensitization and two pseudotherapy manipulations with and without false galvanic skin response feedback after every session suggesting improvement in the modification of intense snake and spider fear. The results indicated no consistent differences between the three treatment groups, although all treatments were significantly more effective than no treatment in modifying physiological, behavioral, and self-report measures of fear. A 4-month follow-up showed stability in fear reduction on self-report measures for the three treatment groups. Overall, the results of this experiment were interpreted as contradicting a traditional conditioning explanation of systematic desensitization. An alternate explanation for the operation of systematic desensitization emphasizing the motivational as opposed to conditioning aspects of the procedure is discussed.

Melzack, Ronald; Perry, Campbell (1975). Self-regulation of pain: The use of alpha-feedback and hypnotic training for the control of chronic pain. Experimental Neurology, 46, 452-469.

Patients suffering chronic pain of pathological origin received alpha- feedback training methods in association with prior hypnotic training. Changes in the intensity and quality of pain were measured with the McGill Pain Questionnaire. The combined procedures produced a substantial decrease in pain (by 33% or greater) in 58% of the patients during the training sessions. Both the sensory and affective dimensions of the pain were diminished. The EEG records indicated that the majority of patients learned to increase their alpha output during the training sessions. In contrast, patients who received the alpha training alone reported no decreases in pain even though they showed increases in alpha output. Patients who received hypnotic training alone also produced increased EEG alpha during the training sessions and showed substantial (though not statistically significant) decreases in pain. The results demonstrate that chronic, pathological pain can be reduced in a significant number of patients by means of a combination of alpha-feedback training, hypnotic training, and placebo effects. It is concluded, however, that the contribution of the alpha training procedure to pain relief is not due to increased EEG alpha as such but, rather, to the distraction of attention, suggestion, relaxation, and sense of control over pain which are an integral part of the procedure.

1974

London, Perry; Cooper, Leslie M.; Engstrom, D. R. (1974). Increasing hypnotic susceptibility by brain wave feedback. Journal of Abnormal Psychology, 83 (5), 554-560.

Presents a reanalysis of earlier studies by D. R. Engstrom et al (1970) as well as additional findings which show that successful training to increase alpha rhythm duration raises people's hypnotic susceptibility. Ss in the previous studies were 30 volunteers who had low to moderate hypnotic susceptibility and low alpha production. It was found, subsequent to publication, that some Ss had had previous

exposure to alpha training. When they were eliminated in reanalysis, the previous findings were still confirmed; alpha training was more effective for experimental than for control Ss, and hypnotic susceptibility accordingly increased more among experimentals than among controls. In addition, base-rate alpha production in each training session was correlated with feedback alpha output among experimental Ss but not among controls. **1973**

**Roberts, Alan H.; Kewman, Donald G.; Macdonald, Hugh (1973). Voluntary control of skin temperature: Unilateral changes using hypnosis and feedback. Journal of Abnormal Psychology, 82 (1), 163-168.**

To demonstrate the ability of human Ss to achieve control over specific autonomic functions, hypnosis and auditory feedback were used to train a select group of hypnotically talented subjects to produce a difference in skin temperature in one hand relative to the other in a direction specified by the experimenter. Large and reliable effects were shown demonstrating that some individuals are capable of achieving a high degree of voluntary control over the autonomic processes involved in peripheral skin temperature regulation. Individual differences between subjects were noted, and variables that might account for these are discussed.

**Wickramasekera, Ian (1973). Effects of electromyograph feedback on hypnotic susceptibility: More preliminary data. Journal of Abnormal Psychology, 82 (1), 74-77.**

The purpose of this double-blind study was to determine if taped verbal relaxation instructions and response-contingent electromyographic feedback training would increase suggestibility or hypnotic susceptibility over that obtained with instructions and false or noncontingent feedback, The present data appear to confirm the hypothesis

## **Biological Rhythm**

**1995**

**Wallace, Benjamin; Kokoska, Andrzej (1995). Fluctuations in hypnotic susceptibility and imaging ability over a 16-hour period. International Journal of Clinical and Experimental Hypnosis, 43 (1), 20-33.**

Within-subject variability for hypnotic susceptibility as measured by the Harvard Group Scale of Hypnotic Susceptibility, Form A and for imaging ability as measured by the Vividness of Visual Imagery Questionnaire was determined over a 16-hour period. Half of the subjects were day persons, those most alert during daytime hours (as determined by the Alertness Questionnaire); the remaining subjects were night persons. For day persons, hypnotic susceptibility was greatest at 10:00 a.m. and 2:00 p.m.; for night persons, susceptibility was greatest at 1:00 p.m. and between 6:00 p.m. and 9:00 p.m. Imaging ability also varied as a function of time of administration. However, these peak periods occurred before and after

hypnotic susceptibility peaks. Such a pattern was interpreted as indicating the possible existence of an ultradian cycle for imaging ability.

**1993**

Wallace, Benjamin; Kokoszka, Andrzej (1993, October). Within-subject variability in hypnotic susceptibility and imaging ability: Same or different?. [Paper] Presented at the annual meeting of the Society for Clinical and Experimental Hypnosis, Arlington Heights, IL.

**NOTES:**

Subjects were given the Harvard scale of hypnotizability and an imagery questionnaire (VVIQ) repeatedly. They had been asked, "when are you the most alert during the day?" and classified as Day People and Night People. People had higher scores on the Harvard for Day People at 10 a.m. and 2 p.m., for Night People at 1 p.m. and at 6, 7, 8, and 9 .m. This replicates my 1993 study. VVIQ scores do not show that pattern; they are zig-zag. What is the relationship between peaks on the two scales? They don't peak at the same time. This may be why in the literature we don't find a strong relationship between hypnotizability and imagery ability. VVIQ scores peak before hypnotizability scores on the same people. This might mean an ultradian cycle for imaging ability. So these abilities are not stable throughout 24 hours, despite the fact that hypnotizability scores are stable over 25 years!

**1992**

Lippincott, Brian (1992). Owls and larks in hypnosis: Individual differences in hypnotic susceptibility relating to biological rhythms. American Journal of Clinical Hypnosis, 34, 185-192.

In 1986 Coleman developed the Owl and Lark Questionnaire to differentiate morning people from evening people, with owl individuals being more alert during the evening phase and lark individuals being more alert during the morning phase. Rossi has hypothesized that the bimodal peaks of hypnotizability found by Aldrich and Bernstein in 1987 were caused by alterations in owl and lark circadian rhythms. In the current study I used the Harvard Group Scale of Hypnotic Susceptibility, Form A to test compliance with hypnotic suggestions among 42 graduate students at three times of the day: in the morning, in the evening, and, as a control, in the middle of the night. Owls were more hypnotizable than larks in the morning, and larks were also significantly more hypnotizable in the evening than owls. There was no difference between the two groups in the middle of the night. A possible implication of this study is that one fundamental mechanism of therapeutic hypnosis is the entrainment of psychobiological rhythms.

**NOTES:**

The author tested Subjects at 8-10 a.m., 4-6 p.m., and midnight to 2 a.m. because they were the times when owls and larks could be most easily differentiated (morning and late afternoon) or were most equal (night). The goal was "to determine if individuals differentiated by the Owl and Lark Questionnaire have

different peaks of hypnotizability associated with the rest phases of their biological rhythms." (P. 187).

"To control for practice effects (Cooper, Banford, Schubot, & Tart, 1967), one third of the subjects started rotating at each of the three test times and proceeded in clockwise order (morning-evening-night; evening-night-morning; night-morning-evening).

"There were at least 24 hours between tests to assure that boredom from the testing was not a factor" (p. 188).

**DISCUSSION.** "Rossi has extended Erickson's naturalistic approach and has hypothesized the entrainment of the ultradian biological rhythms as a possible factor in therapeutic hypnosis. ... Rossi states: 'The ultradian theory of hypnotherapeutic healing proposes that (1) the source of psychosomatic reactions is in stress-induced distortions of the normal periodicity of ultradian cycles and, (2) the naturalistic approach to hypnotherapy facilitates healing by permitting a normalization of these ultradian processes.' (Rossi, 1982, p. 23)" (pp. 189-190).

"If owls and larks were not separated, the results of this study would show no differences in hypnosis. Perhaps this is why Hollander et al. (1988) found no change in hypnotizability using a direct-suggestion measure after a 2-day training in Ericksonian techniques" (p. 190).

**Brown, Peter (1991). The hypnotic brain: Hypnotherapy and social communication. New Haven, CT: Yale University Press.**

**NOTES:**

Notes are taken from a review of this book: Diamond, Michael (1993). Book review. *Bulletin of the Menninger Clinic*, 57 (Winter), 120-121.

Brown "posits that because the fundamental matrix of the human brain is metaphoric, hypnosis results from skillful matching of metaphorical communication with the brain's biological, rhythmic alterations. The most significant feature of trance experience is thereby located in the hypnotist-subject interaction" (p. 120).

"The middle section [of the book is comprised largely of] literature reviews in support of Rossi's (1986) ultradian rhythm theory of hypnosis and Lakoff and Johnson's (Johnson, 1987; Lakoff & Johnson, 1980) experientialist theory of conceptual thought" (p. 120). The final section includes "research evidence on medical uses of hypnosis, a theory of dissociation and multiple personality disorders, and an uncritical discussion of Milton Erickson's naturalistic hypnotherapeutic approach ... [and also] a brief discussion of the social-cultural functions of possession states among the Mayotte culture" (p. 120).

**Brown, Peter (1991). Ultradian rhythms of cerebral function and hypnosis. Contemporary Hypnosis, 8, 17-24.**

As a consequence of his observations of the clinical work of Milton Erickson, Ernest Rossi has proposed an 'ultradian rhythm theory of hypnosis'. Rossi demonstrated that the spontaneous changes in cognition, affect and behaviour which occur as part

of the ultradian cycle (which Erickson referred to as 'the common everyday trance') are similar to the changes which occur during hypnosis. A review of studies of the phasic changes in hemispheric function suggests that ultradian changes do parallel the changes found in hypnosis.

#### **NOTES:**

Falling asleep and waking up are regulated by two separate mechanisms rather than being opposite poles of one mechanism (Winfrey, 1980). Kleitman (1961) suggested a 90-min cycle, the basic rest-activity cycle (BRAC). In addition to physiological alterations, there are alterations in cognition, mood and behavior (Rossi & Cheek, 1988); vigilance (Okawa, Matousek & Petersen 1984); peripheral blood flow (Ramano & Gizdulich, 1980); respiratory amplitude (Horne & Whitehead, 1976); visual evoked potentials (Zimmerman, Gortelmeyer & Wiemann, 1983); pupillary diameter, stability and reactivity to light, and saccadic eye movements (Lavie & Kripke, 1981).

These diurnal variations may relate to hypnotic behavior. There is a recurring increase in daydream and fantasy, as well as visual imagery (Kripke & Sonnenschein, 1978). "There is evidence for a parallel recurring cognitive and emotional cycle with increased emotional responsiveness and a more subjective cognitive processing of information (Evans, 1972; Holloway, 1978; Overton, 1978; Thayer, 1987). Subjects appear to repeat the cycle approximately 16 times per day, with a range of 70-120 minutes. Kripke and Sonnenschein (1978) noted that the subjects were personally unaware of any repeating cycle in their mental lives" (p. 19).

The brainstem arousal mechanisms seem to be implicated in periodic changes in the EEG. Ultradian rhythms are "more easily detected under conditions of increased sleep need, reduced external performance demand and lowered motivation to focus externally (Broughton, 1985)" (p. 20). Sterman (1985) observed that the rhythm was most marked in resting state and disappears during complex visuomotor tasks. Relationship of EEG patterns to attentional patterns indicate there may be two different forms of attention, one for focused awareness (often thought to be associated with trance state) and the other a generalized vigilance (which would be reduced in hypnosis). Ultradian changes in consciousness reflected in the EEG may suggest increased internal absorption associated with visual imagery, a feature of the trance state.

"There has recently been a partial direct confirmation of Rossi's hypothesis. Aldrich and Bernstein (1987 [International Journal of Clinical and Experimental Hypnosis]) reported a bimodal distribution of Harvard Group Scale Hypnotic Susceptibility (HGSHS) scores when they are done at different times throughout the day. They note the parallel of the changes in HGSHS scores and the circadian variations in body temperature which suggest changes in hypnotic responsiveness coinciding with the fluctuations of physiological rhythms.

"Other support comes from some highly original work involving breathing rhythms. There are cyclic alterations in relative air flow between the left and right nostrils with an average period of 2-3 hours (Hasegawa & Kern, 1977). This nasal ultradian rhythm is correlated with an increase in contralateral cerebral

hemispheric activity (Werntz, Bickford, Bloom & Shannahoff-Khalsa, 1981, 1983; Klein, Pilon, Prosser & Shannahoff-Khalsa, 1986). The alterations in hemispheric function do appear to be related to changes both in the style of cognition, particularly in an increase in vivid visual imagery, and in performance on specific tasks (Klein et al., 1986). Thus these studies support the notion of an ultradian rhythm of cerebral function which is associated with characteristic physical manifestations mediated by the autonomic nervous system. Whether or not these changes are directly related to the findings reported by Aldrich and Bernstein has yet to be established" (p. 21).

The authors conclude that "the most consistent evidence for ultradian rhythms is demonstrated by the mechanisms of the hypothalamic-limbic system and by brain-stem mechanisms that regulate arousal and attention processes (Parmeggiani, 1987); neuroendocrine regulatory mechanisms (Follenius, Simon, Brandenberger & Lenzi, 1987) and autonomic nervous system function (Bossom, Natelson, Levin & Stokes, 1983; Gordon & Lavie, 1986). These studies also suggest an ongoing dynamic interaction between cortical and subcortical structures throughout the ultradian cycle (Parmeggiani, 1987), and suggest that these interactions may be of great significance in hypnosis" (p. 21).

## 1987

Aldrich, Kevin J.; Bernstein, Douglas A. (1987). The effect of time of day on hypnotizability: A brief communication. International Journal of Clinical and Experimental Hypnosis, 35, 141-145.

Hypnotizability has been shown to be very stable for long periods of time in a person's adult life when no attempts at modification are made (Morgan, Johnson, & Hilgard, 1974). Even though it can be improved by several different means, attempts to modify individual hypnotizability may only allow people to reach a 'plateau' level of hypnotizability that is predetermined for each person. The present experiment addressed the question of whether hypnotizability like body temperature, reflex response intensity, and performance on various mental and motor tasks, fluctuates in a circadian rhythm. The Harvard Group Scale of Hypnotic Susceptibility, Form A (HGSHS:A) of Shor and E. Orne (1962) was used to test compliance with hypnotic suggestions among several large groups of Ss at different hours of the day. A plot of the mean HGSHS:A scores obtained at each time of day showed a bimodal distribution, with the highest mean score significantly different from 2 of the 3 minima. Although the second peak did not differ significantly from the minima, its occurrence was consistent with the bimodal distributions which sometimes occur in other circadian rhythms, such as body temperature and complex mental and motor skill performance. One possible implication for the results of this study is that they suggest that hypnotherapy could be more effective for individuals at different times of the day, as they approach their 'plateau' level of suggestibility. Average Harvard score was greatest at noon, least at 8 pm; mid-range at 8 am, 2 pm; and medium high at 10 am, 4 pm, and 6 pm. "The general plot of hypnotizability approximately conforms to plots of average body temperature obtained in other studies (e.g., Horne & Ostberg, 1976; Kleitman,

1963). The dips, however, also appear after times when Ss were likely to have eaten lunch and dinner, suggesting that food consumption may have an effect on hypnotizability. Further research controlling for this possible effect and measuring body temperature, as well as testing Ss in the absence of 'zeitgeber' ('time-givers' such as clocks, natural light, and other devices to give Ss information about the time of day) will be necessary to determine the diurnal function of hypnotizability and whether it follows a true circadian rhythm" (p. 144).

## Bleeding

### 1995

Enqvist, Bjorn; von Konow, L.; Bystedt, H. (1995). Pre- and perioperative suggestion in maxillofacial surgery: Effects on blood loss and recovery. International Journal of Clinical and Experimental Hypnosis, 43 (3), 284-294.

The basic assumption underlying the present study was that emotional factors may influence not only recovery but also blood loss and blood pressure in maxillofacial surgery patients, where the surgery was performed under general anesthesia. Eighteen patients were administered a hypnosis tape containing preoperative therapeutic suggestions, 18 patients were administered hypnosis tapes containing pre- and perioperative suggestions, and 24 patients were administered a hypnosis tape containing perioperative suggestions only. The patients who received taped suggestions were compared to a group of matched control patients. The patients who received preoperative suggestions exhibited a 30% reduction in blood loss. A 26% reduction in blood loss was shown in the group of patients receiving pre- and perioperative suggestions, and the group of patients receiving perioperative suggestions only showed a 9% reduction in blood loss. Lower blood pressure was found in the groups that received pre- and perioperative and perioperative suggestions only. Rehabilitation was facilitated in the group of patients receiving perioperative suggestions only.

### 1991

Hopkins, Mildred B.; Jordan, Jeanette M.; Lundy, Richard M. (1991). The effects of hypnosis and of imagery on bleeding time: A brief communication. International Journal of Clinical and Experimental Hypnosis, 39, 134-139.

2 studies are reported, one using hypnotized Ss selected on hypnotizability and one using Ss selected on imagery vividness, whose purpose is to examine whether non-patient Ss can control their bleeding in a laboratory setting. All Ss were cut on both arms with the "Surgicutt" device, an instrument that automatically makes a cut that will bleed from 2 to 10 minutes. Results suggest that Ss, who are instructed to reduce the bleeding time in one arm and to let the other arm bleed normally, are not able to control bleeding time.

Madrid, Antonio D.; Barnes, Susan v.d.H. (1991). A hypnotic protocol for eliciting physical changes through suggestions of biochemical responses. American Journal of Clinical Hypnosis, 122-128.

We employed brief hypnotherapy to effect physical changes in patients suffering from medical disorders including allergies, rectal bleeding, systemic lupus, hyperemesis, headache, asthma, and chronic pain. We present, in language appropriate to the individual patient, considerations and suggestions to effect the release of healing biochemicals. Ideomotor signals indicated the patient's awareness of the healing. We hypothesize that the technique triggered novel state-dependent memory, learning, and behavior.

**NOTES:**

They hypothesize that the technique they use triggers novel state-dependent memory, learning, and behavior (See for example Rossi, 1987, and Rossi & Cheek, 1988).

Hypnotic Protocol: "1. Tell the patient that he can heal himself by allowing his body to supply its own biochemicals needed to make him well. If a specific biochemical is known, such as cortisone or endorphins, name it. "2. Hypnotize the patient. Resistant or hard to hypnotize patients need not be deeply hypnotized because the patients, using this protocol, will automatically go into trance while accomplishing the next task of accessing and using ideomotor signals (Erickson, 1980; Rossi & Cheek, 1988). "3. Tell the patient that his index finger will automatically and involuntarily twitch and float when his body releases the biochemicals he needs. This ideomotor response (Rossi & Cheek, 1988) is the sole physical response required of the patient. Rossi hypothesizes that the ideomotor response correlates with biochemical changes (Rossi & Cheek, 1988). "4. Next, ask the patient to consider some things (as described below). Present the considerations one after another until one of them triggers the ideomotor response. "5. In some instances, ask the patient to practice on his own. Many patients who have dramatic emotional reactions during or at the completion of the task may not need to practice on their own" (p. 123).

They present several 'considerations' to the patient, one after the other, tailored to the patient's specific case, until his finger twitches or floats, indicating a biochemical response. For example, the following 'considerations' have been used: "1. Psychodynamic: 'Consider that you are not blamed for anything; that you are in fact perfect just the way you are; that you are loved by those you care about.' 'Consider that you can forgive whoever needs forgiving for hurting you.' 'Consider that there are no longer any threats; everything is better; everything is as it used to be.' "2. Autosuggestion: 'Tell your body to heal. It knows what to do; so ask it to do it.' 'Tell your adrenal glands to produce the steroids that your body needs.' 'Allow a glowing light to permeate that injured back, filling it with healing energy.' "3. Incompatible responses: 'Cover yourself with a cool breeze, cooling the injured leg.' 'Imagine your back getting slack and limp and relaxed.' 'Imagine your stomach lining becoming smooth and moving with easy, ocean-like waves.' "4. Emotion calling: 'Consider yourself feeling very happy with everything, for no reason at all.'

'Consider yourself getting angry at someone--your mother, your wife (husband), your boss, your lawyer.' "5. Bargaining: 'Tell yourself that you will heal if you agree to stay away from that job.' 'Tell yourself you will heal by allowing your right arm to begin to hurt when you are over- exerting yourself.' 'Tell yourself that you will heal in exchange for something else, not so serious, to replace this disease and to serve the same function'" (pp. 123-124).

They present seven cases involving, respectively, allergies, rectal bleeding, systemic lupus, hyperemesis of pregnancy, adult onset asthma, chronic pain, and cluster headaches. Two cases were particularly interesting because they represented patients who did not respond initially.

Their procedure involves reframing the state or emotion originally associated with the onset of disease using considerations, and then giving a suggestion that it is within the power of the person, rather than factors outside, to heal the body. First they instruct the patient that the body can heal itself; then they give the list of suggestions for the patient to consider, persisting with different considerations until they get an ideomotor response. Incorporation of the patient's psychodynamic issues appears to be very important.

The authors regard it as unimportant if the patient cannot be hypnotized; "As Cheek (Cheek & LeCron, 1968; Rossi & Cheek, 1988) points out, the patient's inability to be hypnotized may be synonymous with his disease. It is actually beneficial if the patient cannot achieve ideomotor responses at first because both he and the therapist then trust the validity of the response when it does occur after the appropriate consideration" (p. 127).

Palan, Bhupendra M.; Lakhani, Jitendra D. (1991). Converting a 'threat' into a 'challenge': A case of stress-related hemoptysis managed with hypnosis. American Journal of Clinical Hypnosis, 33 (4), 241-247.

A 24-year-old patient was treated using hypnosis for chronic repeated episodes of hemoptysis. The symptom episodes were related to academic examinations (perceived as a threat by the patient). Clinical examinations and laboratory investigations failed to indicate an organic cause for hemoptysis. He did not respond to empirical treatment trials. These negative findings suggested the psychosomatic nature of the illness. We used hypnotherapeutic ego-strengthening and guided-imagery approaches. This reduced his acute anxiety but failed to check hemoptysis. Use of explorative hypnotic dreaming revealed an emotional trauma as the possible cause of origin of the symptoms. We restructured the trauma experience during hypnotic regression. We advised him to skip the upcoming examination and conducted a total of six therapeutic sessions. The patient continued using self-hypnosis throughout the follow-up period of 3 years during which he remained symptom free and achieved remarkable academic progress. He now perceives an examination as a challenge.

## 1988

Azuma, Nagato; Stevenson, Ian (1988). 'Psychic surgery' in the Philippines as a form of group hypnosis. American Journal of Clinical Hypnosis, 31, 61-67.

Psychic surgeons and their patients were observed in the Philippines during a variety of procedures of 'minor surgery.' In six cases, subcutaneous tissues (cysts and benign tumors) were removed. Histological examination confirmed the gross diagnoses and left no doubt that the skin had been penetrated. Although the psychic surgeons used no analgesics or anesthetics, the patients appeared to experience little or no pain and only slight bleeding. The authors believe that a supportive group 'atmosphere' enables the patients to enter a quasi-hypnotic state that reduces pain and facilitates healing.

## 1986

Swirsky-Sacchetti, Thomas; Margolis, Clorinda G. (1986). The effects of a comprehensive self-hypnosis training program on the use of factor VIII in severe hemophilia. International Journal of Clinical and Experimental Hypnosis, 34, 71-83.

Hemophilia, the bleeder's disease, is characterized by internal bleeding episodes which have been associated anecdotally with psychological stress. The focus of the present investigation was to study the potential utility of a comprehensive self-hypnosis training program to decrease stress and to assess the amount of clotting factor used for bleeding by those individuals trained in self-hypnosis compared to a control group. 30 severe hemophiliacs on home therapy were randomly assigned to a treatment or to a waiting list control group. The treatment group received a comprehensive 6-week training program including support, education, deep relaxation, and self-hypnosis. Over the 18-week follow-up, the treatment group significantly reduced the amount of factor concentrate used to control bleeding in comparison to controls. The treatment group also significantly reduced general distress level as measured by a symptom checklist. The training was extremely cost effective, and the results support the efficacy of this comprehensive training program to augment the medical management of severe hemophiliacs on a home therapy regimen.

## NOTES:

The authors begin with a discussion of the importance of being able to reduce the amount of blood factor concentrate required by hemophiliacs, including the problems of obtaining uncontaminated blood in an era of HTLV-III and LAV contamination and the fact that some patients with Hemophilia A have developed antibodies to Factor VIII (so-called inhibitor patients). When an inhibitor patient hemorrhages, it is potentially life-threatening. Earlier controlled clinical research by LaBaw (1975) indicated that hypnosis might be useful for decreasing blood usage. The current study builds upon that research and adds further control procedures.

The hypotheses of this study were: "(a) hemophiliacs who received the comprehensive training program including self-hypnosis along with education, support, and relaxation for stress management would significantly reduce the amount of factor concentrate used to control spontaneous bleeding in comparison to randomly assigned waiting list controls; (b) the general distress level, as measured by the SCL-90 (Derogatis, 1977), would significantly decrease for the treatment

group from pretraining to follow-up; and (c) hypnotizability as measured by the Harvard Group Scale of Hypnotic Susceptibility, Form A (HGSHS:A) of Shor and E. C. Orne (1962) would show a positive correlation with the treatment effect" (p. 74).

The Subjects were patients of a hematologically severe status (less than 1% clotting factor present in the blood); ages 11-50, mean age 30; normally distributed on socioeconomic variables; and prescreened to rule out serious psychological dysfunction. The treatment and control groups did not differ in SES or pretest bleeding severity. Control Ss were informed that they would receive the same training after the initial follow-up period. Three Ss were lost from the treatment group because they did not complete the 6 weekly self-hypnosis training sessions, and three from the control group due to geographic move or decision to obtain treatment elsewhere.

Patients recorded their factor usage on log sheets, and their reports were checked with distribution records kept at the clinic. (Factor received during hospital stays was not included. Also 3 "inhibitor" patients--2 treatment, 1 control--were removed from some analyses because they must infuse Factor IX at a level that far exceeds the amount appropriate for body were an inhibitor not present.)

The Ss, in groups of 3-4 people, were educated about the effects of stress on bleeding, physiological signals of overstress, and then trained as a group in self hypnosis. Each training session began with a group hypnosis induction followed by various suggestions and imagery. They were given a cassette tape with suggestions for decreased bleeding, ego-strengthening, relaxation, and sensations of floating. In addition to listening to the tape at least once each day, they were taught rapid (1-2 minute) inductions to combat stress, and were to develop their own self-hypnosis procedure.

In terms of results, 9 of 11 (82%) treatment Ss and 4 of 10 (40%) control Ss decreased in blood factor usage ( $p < .05$ ). There was a great deal of variability between Subjects. While the treatment group demonstrated an overall decrease in factor usage, the control group actually had an overall increase in usage. The authors speculate that possibly a change in season caused the increase, because several Ss reported that a change in season ordinarily caused an increase due to their arthritic joints. Also, a change to warmer weather might have led to increased physical activity. General distress, measured by General Severity Index of the SCL-90, was reduced significantly for the treatment group. (Results of SCL-90 aren't reported for control group.)

The third hypothesis was not supported. In fact, the correlation between HGSHS:A and treatment effect was in the opposite direction from what was expected ( $- .25$ , n.s.). However, "there was a significant correlation ( $\rho = .56$ ,  $p < .025$ ) between Ss' self-reported trance usage and change scores, indicating that those Ss who practiced self-hypnosis more were more likely to have decreased factor usage. There was also a trend ( $\rho = .44$ ,  $p < .10$ ) between treatment Ss' change scores and their initial distress levels (GSI), suggesting that those Ss who were initially more distressed tended to profit more from treatment" (pp. 78-79).

In their Discussion, the authors suggest that the fact that the treatment effect of decreased factor usage was consistent throughout the follow-up period suggests that

reduced usage was not due to a placebo effect. They note that placebo responses are usually brief, and situation-specific (Frank, 1976). They see the need for further research to clarify which component(s) of the treatment program are effective (self-hypnosis, relaxation, education, social support), and to extend the length of follow-up period. Since hypnotizability did not correlate with outcome, the results might be due to some other component. Since outcome did correlate with amount of self hypnosis practice, motivation may be an important determiner of effect. Decreased stress was not only reported by Ss but also reflected in changes on the test scores (SCL-90). Also, several Ss spontaneously used the self hypnosis for school and occupational performance, and to relieve headaches. In terms of financial benefits, "the one patient who had the most significant decrease in factor usage noted an average monthly savings of \$850. For the entire treatment group (including those few Ss whose factor usage increased), the training resulted in savings of \$1240 per month over the follow-up period" (p. 81).

### 1985

Lichstein, Kenneth L.; Eakin, Terry L. (1985). Progressive versus self-control relaxation to reduce spontaneous bleeding in hemophiliacs. Journal of Behavioral Medicine, 8 (2), 149-162.

Investigated the effects of progressive and self-control relaxation on spontaneous bleeding and collateral symptoms with 7 hemophiliacs (average age 32.6 years) in a combined multiple-baseline partial-crossover design. Following 6 or 12 weeks of training in either or both relaxation methods, there was no strong evidence that the treatment affected bleeding or perceived pain in these Ss. Results failed to replicate findings of W. L. LaBow (1975) or J. W. Varni (see PA, Vol 65:13289) (20 ref)

### 1984

Bishay, Emil; Stevens, Grant; Lee, Chingmuh (1984). Hypnotic control of upper gastrointestinal hemorrhage: A case report. American Journal of Clinical Hypnosis, 27, 22-25.

The use of hypnosis for control of bleeding during and after surgical procedures is common practice. It has also been a useful tool for control of bleeding in hemophiliac children, especially during dental procedures, and in traffic accidents. This paper presents the successful treatment with hypnosis of a patient with upper gastrointestinal tract bleeding. After treatment, the patient was discharged from the hospital without the need for surgical intervention.

### NOTES:

The physician explained to the patient that nothing would hurt her and that nobody would do anything against her will, that if she could "relax," then her unconscious mind would help her control her bleeding. [Gives script used in the hypnosis.] Trance terminated after 20 minutes. "One hour later, endoscopy performed under local anesthesia revealed 'non-bleeding gastritis, no ulcers seen.' She had no bleeding following the hypnotherapy" (p. 23).

**LeBaron, Samuel; Zeltzer, Lonnie K. (1984). Research on hypnosis in hemophilia--preliminary success and problems: A brief communication. International Journal of Clinical and Experimental Hypnosis, 32, 290-295.**

Although little is known about physiological effects of hypnosis on hemophilia, hypnosis for reduction of pain and/or bleeding in hemophilia has attracted increasing attention. Literature on this topic is reviewed, and important problems in conducting clinical research on hypnosis for hemophilia are discussed.

**NOTES:** Reviews literature on physiological effects of hypnosis on hemophilia (for reduction of pain and/or bleeding). Discusses problems in conducting clinical research on same.

### **1983**

**Fung, E. H.; Lazar, B. S. (1983). Hypnosis as an adjunct in the treatment of von Willebrand's disease. International Journal of Clinical and Experimental Hypnosis, 31 (4), 256-265.**

Hypnosis has been used to control bleeding, both in normals and hemophiliacs. Case material is presented to demonstrate how hypnosis was used as an adjunct to standard medical treatment of a boy and his mother with von Willebrand's disease, initially to reduce anxiety and improve self-esteem and the parent-child relationship, and later, to reduce bleeding. This use of hypnosis illustrates the relationship between hemostatic control and psychological adaptation.

### **1957**

**Crasilneck, Harold B.; Fogelman, Morris J. (1957). The effects of hypnosis on blood coagulation. Journal of Clinical and Experimental Hypnosis, 5 (3), 132-137.**

A series of hematologic methods designed to determine the coagulative function of the blood were performed on eight healthy individuals who had previously been conditioned to enter somnambulistic states of hypnotic sleep. Rigorous and quantitative experimental conditions and controls were followed throughout the four phases of the study. The results of the present study indicate that hypnosis and simple hypnotic suggestion are not correlated with any alterations of bleeding or blood clotting factors in normal man" (pp. 135-136).

**Solovey, Galina; Milechnin, Anatol (1957). Concerning the nature of hypnotic phenomena. Journal of Clinical and Experimental Hypnosis, 5 (2), 67-76.**

### **NOTES**

**1:**  
The authors write about the place of the hypnotic state in general psychology: "the study of the psychological mechanisms that make the appearance of the phenomenon possible, which need not be different from the normal and current psychological mechanisms in everyday life\_" (p. 67). They classify hypnotic phenomena into three groups:

**"I. Phenomena \_ which are a function of the state of psychological\_ retrogression (hypnotic depth), appearing in spontaneously [sic] or when proposed by the operator.**

**II. Phenomena which appear without any specific suggestion, as \_ a side issue of other suggestions,\_ capable of originating emotional states in the subject.**

**III. Phenomena \_ which are independent of all suggestion,\_ being a constituent part of the hypnotic state itself, in its 'positive' or 'negative' forms" (p. 68).**

Using this framework, the authors describe several aspects of hypnosis: catalepsy, anesthesia, retrogression, the taking of a role, negativism and resistance, visceral changes, emotional stabilization, psychotherapeutic benefits (indirect). They observe that direct suggestions are often not necessary for therapeutic benefit, and give as an example the tendency for less bleeding when dentists suggest that patients will not feel less pain.

"For the elucidation of this point, the authors carried out an experiment in a dental clinic, taking six easily hypnotizable subjects in whom dental extractions were to be performed. They were given only the suggestions that they would feel the doctor working, but not experience pain ... that they would pay no attention to it ... or even if they felt a little pain, this would not trouble them and they would bear it perfectly ... Nothing was said about the loss of blood. As a result, in all the cases the loss of blood was slight, practically insignificant, though technically difficult extractions of roots were included" (p. 74).

"The explanation of hypnotic phenomena as natural and normal consequences of the hypnotic emotional state, and of the state of psychological retrogression, eliminates the supposed mysterious powers of suggestion. \_ Suggestion is thus relegated to the modest role of a litmus paper which reveals the psychological functioning of the individual\_ in an experimental environment. On the other hand, in everyday-life hypnosis, in the principal hypnotic relationships of parents with their children, of teachers with their pupils, etc. (11), suggestibility plays an important role in education or re-education" (p. 75).

**1956**

**NOTES**

**1:**

The authors report on a demonstration of dental extractions with two patients (of five patients with whom hypnosis was attempted). They describe successful results despite 3-minute inductions in people not pre-trained, a terse and abrupt approach by the dentist (who uses only hypnosis and refers non-responding patients elsewhere). "While the hypnotist demonstrated effectively what could be done with hypnosis, his theoretical orientaton as to why this had occurred can only be described as unfortunate. In response to questioning he stated and quite flatly: that in hypnosis there are no dangers (1); that hypnosis is essentially cardiovascular in nature; that drugs had no place along with hypnosis--despite the advice of Moss (2) that dentists should use hypnosis along with drugs routinely unless the latter is contraindicated. He expressed his attitude toward the use of local anesthetics by indicating that the package he had had was thrown away because it had become spoiled from disuse. Hypnosis was presented in effect as an all or nothing technique" (p. 3).

**NOTES**

**1:**

**The patient was a 14 year old male with an impacted mandibular left first molar. A series of surgical interventions were required to remove granulation tissue, overlying bone, and fibrotic tissue prior to orthodontic procedures. Hypnoanesthesia and suggestions to stop bleeding and salivating were successfully employed. In fact "It was noticeable with the last two procedures that spontaneous dryness occurred without any suggestion by the operator" (p. 26).**

**1953**

**Kroger, William S. (1953). Hypnotherapy in obstetrics and gynecology. Journal of Clinical and Experimental Hypnosis, 1 (2), 61-70.**

**Author's Summary - "A high percentage of gynecologic complains [sic] are due to psychic factors. Therapeutic efforts, therefore, must be directed primarily toward the psychologic component. Until recently, the principal weapon of the dynamically oriented physician was orthodox psychoanalysis. However, the increased interest for a relatively rapid approach has demonstrated the diagnostic and therapeutic value of hypnoanalysis. This development has been concomitant with the psychoanalyst's [sic] interest in 'brief psychotherapy' and narcosynthesis.**

**"In many functional gynecologic disorders, hypnoanalysis has supplanted the parent therapy even though this form of treatment utilizes the concepts of dynamic psychiatry.**

**"The relevant literature on the use of hypnotherapy in functional obstetrical and gynecological disorders has been reviewed.**

**"Significant areas for research have been pointed out.**

**"This review emphasizes that hypnosis per se is only of value in obtaining symptomatic relief. On the other hand, hypnoanalysis elicits the responsible dynamics behind the symptom, and is effective in reaching all aspects of the personality.**

**"Hypnoanalysis will be more applicable in obstetrics and gynecology when there is a wider acceptance of its techniques" (p. 68).**

**Blindness**

**1992**

**Spanos, Nicholas P.; Burgess, C. A.; Cross, P. A.; MacLeod, G. (1992). Hypnosis, reporting bias, and suggested negative hallucinations. Journal of Abnormal Psychology, 101, 192-199.**

Examined the role of reporting bias in hypnotic negative hallucinations by using a paradigm in which reporting bias was assessed independently of perceptual change. In Experiment 1, highly hypnotizable subjects reported significant loudness reductions when tested for hypnotic deafness. Later, however, these subjects biased their reported loudness reductions in the absence of perceptual change, and their reporting bias scores were almost as large as their hypnotic deafness reports. Subjects also biased their ratings of strategy use. In Experiment 2, ratings of blindness given in response to a hypnotic negative visual hallucination suggestion were significantly correlated with reporting bias scores obtained in this paradigm. Although hypnotic blindness and hypnotic deafness correlated significantly, the partial correlation between these variables was nonsignificant when reporting bias scores were statistically controlled. Results are used to support a skeptical view of hypnotic response as being based on compliance.

Bryant, Richard A.; McConkey, Kevin M. (1989). Hypnotic blindness: A behavioral and experiential analysis. Journal of Abnormal Psychology, 98, 71-77.

**NOTES:**

"This research examined the influence of visual information on a decision task that subjects were administered during hypnotically suggested blindness. Real, hypnotizable subjects and simulating, un hypnotizable subjects were tested in two experiments. Experiment 1 focused on behavioral responses, and Exper. 2 focused on experiential reactions. In both experiments, the findings indicated that the behavioral responses of reals were influenced by visual info. despite their reported blindness. The behavioral responses of reals and simulators were essentially similar. The experiential data in Experiment 2 provided information about the phenomenal nature of subjects' reported blindness. The experiential reactions of reals and simulators were essentially different. The research is discussed in terms of the issues that need to be considered in the development of a model of hypnotic blindness" (p. 71).

Bryant, Richard A.; McConkey, Kevin M. (1989). Visual conversion disorder: A case analysis of the influence of visual information. Journal of Abnormal Psychology, 98, 326-329.

**NOTES:**

"Examined the influence of visual information on a decision task that was administered to an individual with monocular visual conversion disorder. Findings indicated that his performance was influenced by the visual information and by motivation instructions. The findings are discussed in terms of a model of hysterical blindness that recognizes the interplay of cognitive and motivational processes" (p. 326).

Blum, Gerald S.; Nash, John; Jansen, Robert D.; Barbour, John S. (1981, June). Posthypnotic attenuation of a visual illusion as reflected in perceptual reports and cortical event-related potentials. Academic Psychology Bulletin, 3, 251-271.

Highly selected and trained hypnotic subjects, capable of ablating portions of visual stimuli from conscious awareness, showed varying degrees of ability to attenuate the Titchener-Ebbinghaus circles illusion post-hypnotically under a negative visual hallucination instruction. The presence or absence of such inhibitory skill, inferred from perceptual reports, was differentially reflected in changes in cortical event-related potentials not typically associated with shifts in selective attention. These findings point to the cognitive operation of a distinctive mechanism of selective inattention.

#### NOTES:

Blum et al. postulate an inhibitory mechanism of the central nervous system with stages of amplification and attenuation. They suggest that individual differences in inhibitory skill may be improved with practice even for very skilled Subjects. They studied this type of inhibition using a visual illusion (the Titchener-Ebbinghaus circles) because the neural locus of such illusions is thought to be more central in the nervous system rather than at the level of the retina.

Experiment 1. Three Ss trained in using hypnosis viewed stimuli in waking and posthypnotic negative visual hallucination (NVH) conditions. All three had previously passed a negative hallucination item (not seeing a playing card of three such cards placed on a table). Training included practice sessions applying NVH to the experimental stimuli. S1 reported immediate success; S2 experienced some initial difficulty ("I have a feeling something's there") but then reported success; S3 required a couple of long practice sessions.

The classic Titchener-Ebbinghaus illusion stimuli were used. Stimuli were ten slides with drawings of a standard 17-mm-diameter black circle on the left and a comparison black circle on the right. The black circle on the right was either 14, 15, 16, 17, or 18 mm in diameter, skewed intentionally around 17, to compensate for the proportion of smaller and larger judgments applied to the comparison figure in relation to the standard. One black comparison figure was surrounded by seven 15-mm diameter white circles; the other by seven 10 mm diameter white circles. The key drawings were both black circles of 17 mm. The second set of five drawings, used as a control, contained the same black circles but lacked outer rings of white circles.

The Subject was to state whether the black circle on the right appeared larger, smaller, or the same as the standard black circle on the left. Slides were shown for 4 seconds each, with 6 seconds in between slides.

Alternating blocks of trials were given under baseline (B) condition and a posthypnotically programmed negative hallucination condition (NVH). In the NVH condition, "the rings of white circles surrounding the standard and comparison black inner circles were 'ablated' from consciousness. The observers were amnesic in the waking state for their prior hypnotic instructions and were cued in advance of a block of trials simply by the phrases 'This will be a mixed series' (referring to B, in

which the stimuli appeared as they really were, some with outer rings of white circles present and others not), or 'This will be a black only series' (referring to NVH, in which all stimuli appeared to the observer as black circles only, whether the outer rings were physically present or not)" (pp. 254- 255). Sessions were spread out over 8-12 months for each observer, interspersed with a variety of other experiments.

In one session the Experimenters used a selective attention instruction, with Ss given posthypnotic suggestions to regulate their cognitive arousal to a peak of mental alertness and concentration (+AA) and focus on the inner black circles but not to negatively hallucinate the outer white circles.

Although all three Ss showed the illusion effect, they varied in ability to attenuate the illusion when negative visual hallucination suggestions were given. "S1 showed a very greatly reduced frequency of reports in the illusory direction under the NVH condition, a less marked reduction under +AA concentration, and no reduction at all under a waking instruction to ignore the outer circles; S2 revealed a moderate but significant reduction under NVH but not under +AA; S3 gave no evidence of attenuation in either condition" (p. 258). The response times for the two more successful Ss (1 and 2) with the 17 mm stimuli under NVH conditions were not different when the outer circles were either present or absent.

Experiment 2. The next year S1 and S2 returned but S3 was no longer available as a Subject; S4 and S5 were added and trained in hypnosis skills. EEG evoked response potentials (ERPs) were recorded while Ss made size judgments as in Experiment 1. Averaged ERPs for each block of 100 stimulus presentations were obtained for the first 500 milliseconds following stimulus onset. Judges blind to the experimental conditions evaluated the ERP records.

All Subjects experienced the Titchener-Ebbinghaus illusion, but again there were individual differences in ability to attenuate the illusion: S1 was the most successful; S2 gave significantly fewer responses in the larger category under NVH than B conditions; and both S1 and S2 improved attenuation performance over the previous year. S4 fell between S1 and S2 in ability; S5 was unable to attenuate the illusion in the NVH condition.

Results. "All three observers whose perceptual reports indicated some attenuation of the visual illusion during the NVH condition also showed a consistent reduction of the P2-N2 amplitude during NVH" (p. 262) at the Occipital sites. Median amplitude reduction was 36%, 40%, and 36% for S1, S2, and S4; only 7% for S5. There were no similar reductions for the other electrode sites, though "enhancement of P2-N2 amplitudes occurred in the lateral prefrontal and frontal areas in the two most successful individuals, S1 and S4" (p. 263). There was also a lag in N2 peak latencies for the three best subjects. The Experimenters noted that the N2 peak occurred 50 msec later in the frontal and prefrontal areas than in the occipital area.

In their Discussion, the authors express the view that it is not likely that faking could have occurred, for several reasons: 1. The Subjects were trained to report honestly, and they often had reported failures to experience hypnotic phenomena suggested during training sessions. 2. The task elicited rapid responses, usually in less than 2 seconds, to 10 different slides in randomized blocks of 100 trials, which would make self monitoring of responses extremely difficult. 3. Subjects exhibited a

consistency of responses over experimental sessions that were widely separated in time, making conscious or unconscious deception unlikely. 4. The finding of no difference in latency between 17 mm stimuli with and without outer rings of white circles supports an interpretation of reliable reporting. 5. Differences in ERP data between the B and NVH conditions were obtained only for those Ss who successfully attenuated the illusion.

The authors also state, "In terms of our conceptual model of the mind, inhibitory skill is attributable to the capacity for invoking inhibitory action earlier in the sequence as signals are processed through stages of amplification and attenuation en route to consciousness (Blum & Barbour, 1979). In the NVH condition of the present task, first- stage attenuation ... [Subject 1] ... occurs in time to negate the illusion as well as preventing conscious awareness of the outer white circles, second-stage attenuation takes place too late to disrupt the illusion but still in time to keep the outer circles from consciousness" (p. 265). Note that the unsuccessful Subject 5 had the highest score on the screening hypnotizability tests. The variation among very high hypnotizables casts doubt on the practice of grouping Ss who score between 9 and 12 on the SHSS. "It is perhaps not surprising that many previous hypnotic studies involving alterations in such subtle phenomena as visual illusions have yielded negative results." p. 266.

N.B. None of the Ss was able to eliminate the illusion under a strong waking instruction to ignore the outer circles while judging the inner black ones. "These different results for AA and NVH instructions pinpoint the contrast between selective attention (+AA) and selective inattention (NVH)" (p. 266).

The ERP changes seen in occipital and frontal areas were in opposite directions. Thus "the data suggest an effect which seems to parallel both investment of attention (increases in late components over frontal cortex) and withdrawal of attention (relative decreases in late components over occipital cortex). This parallel leads us to speculate that our occipital decreases may have been due to active inhibition of information-processing in the occipital regions, and that the late component enhancement over frontal areas may have been due to the mobilization of resources in these areas necessary to accomplish the tonic inhibition of visual input. ... Activity in the frontal cortex apparently 'programs' inhibition on the specific sensory nuclei of the thalamus, in a modality specific and topographical way, accomplishing gating of sensory information to primary sensory cortex" (p. 268).

## 1965

Barber, Theodore Xenophon (1965). Physiological effects of 'hypnotic suggestions': A critical review of recent research (1960-64). Psychological Bulletin, 201-222.

Recent studies are reviewed which were concerned with the effectiveness of suggestions given under "hypnosis" and "waking" experimental treatments in alleviating allergies, ichthyosis, myopia, and other conditions and in eliciting deafness, blindness, hallucinations, analgesia, cardiac acceleration and deceleration, emotional responses, urine secretion to sham water ingestion, narcotic-like drug effects, and other phenomena. The review indicates that a wide variety of

physiological functions can be influenced by suggestions administered under either hypnosis or waking experimental treatments, and direct and indirect suggestions to show the particular physiological manifestations are crucial variables in producing the effects.

**1960**

Sukhakarn, Khun Vichit (1960/1962). Extra ocular vision [Letter]. British Journal of Medical Hypnotism, 14 (2), 41-47

**NOTES:**

The article is in the original form of a letter to Herbert Spiegel, M.D. The author describes experiences training subjects, both blind and with normal vision, to 'see' through the skin of their cheeks. Training involved concentrative meditation (Buddhist) and hypnosis. Simple tests were performed, apparently independently, by two other scientists.

"From information available from our subjects, the Extra Ocular Vision gained through the cheek-skin is different from those through the eyes as best explained here below:-- (1) The vision through the cheek-skin first takes a form of a series of spots somewhat like the image of coarse gain prints. Only after further training the spots are transformed into a clear object, so clear that needle threading is possible. (2) Objects seen through the cheek-skin are as clear as through the eyes. Distant objects can be magnified by the subject's wish, just like looking through an opera glass. (3) The vision gained through the cheek-skin is first 'seen' in black and white, and the 'colour picture' is achieved only after further training. But the colour 'seen' through the cheek is more intense than those through the eyes. (4) The field of vision 'seen' through each side of the cheek is more narrow than those seen through each eye. (5) There is a sign indicating that the vision through the cheek is only two-dimensional, the subjects find it difficult at first to stand the finger to another finger test" (p. 42).

**1954**

Erickson, Milton H. (1954). The development of an acute limited obsessional hysterical state in a normal hypnotic subject. Journal of Clinical and Experimental Hypnosis, 2, 27-41.

**NOTES**

**1:**

The 25 year old female graduate student in psychology had often been used in hypnosis experiments and as a demonstration subject, and had witnessed induction of hypnotic deafness, blindness, and color-blindness though she had not been given those suggestions herself. Scientific curiosity appeared to be the motivation for volunteering to experience hypnotic blindness, but she was skeptical about her ability to experience it. The author gave a series of "exceedingly tedious" suggestions to develop somnambulism (passively responsive and receptive) followed by suggestions leading gradually to development of "blindness" with the intention of concealing it from the hypnotist, with attendant strong and mixed emotions.

The initial attempts failed because the subject ostensibly was deceiving herself into thinking she had developed hypnotic blindness, but the author also was of the opinion that she was seeking to meet unconscious personality needs. The author then covertly changed the goal of the experiment "to develop in the subject an acute hysterical obsessional compulsive mental state which would be accompanied by hypnotic blindness and which would parallel or resemble the obsessive compulsive hysterical mental disturbances encountered in psychiatric practice" (p. 32). The author developed a monologue of suggestions based in part on the utterances of hospitalized obsessive patients and in part on trauma relating to traumatic blindness in a kitten and a friend of the subject. In a slow but directed manner the author built up a double-bind situation which eventually led to the experience of hypnotic blindness as well as heightened emotional reactivity, crying etc.

## **Blood Hematology**

### **2003**

Wood, Gary J.; Bughi, Stefan; Morrison, John; Tanavoli, Sara; Tanavoli, Sohrab; Zadeh, Homayoun H. (2003). Hypnosis, differential expression of cytokines by T-cell subsets, and the hypothalamo-pituitary-adrenal axis. American Journal of Clinical Hypnosis, 45 (3), 179-196.

Tested the hypothesis that hypnosis can differentially modulate T-cell subsets, and that this effect is mediated by changes in hypothalamo-pituitary-adrenal (HPA) mediators. Seven healthy, highly hypnotizable volunteers (aged 24-42 yrs) participated in 3 1-day sessions, a baseline and 2 intervention sessions. Hypnosis intervention entailed a standardized induction, suggestions for ego strengthening and optimally balanced functioning of the immune and neuroendocrine systems, and post-hypnotic suggestions for stress management and continued optimal balance of bodily systems. Blood samples were analyzed for T-cell activation and intracellular cytokine expression (Interferon [IFN]-gamma, Interleukin-2 [IL-2], Interleukin-4,) and HPA axis mediators (ACTH, cortisol, and beta-endorphin). The proportion of T-cells expressing IFN-gamma and IL-2 were lower after hypnosis. T-cell activation response to polyclonal stimulation was positively correlated with ACTH and beta-endorphin, while IFN-gamma expression was correlated with levels of cortisol. Further controlled studies utilizing hypnosis with patients in treatment are warranted in order to examine whether an altered T-cell response can be replicated in the presence of disease. ### **1997**

Dinges, David F.; Whitehouse, Wayne G.; Orne, Emily Carota; Bloom, Peter B.; Carlin, Michele M.; Bauer, Nancy K.; Gillen, Kelly A.; Shapiro, Barbara S.; Ohene-Frempong, Kwaku; Dampier, Carlton; Orne, Martin T. (1997). Self-hypnosis training as an adjunctive treatment in the management of pain associated with

sickle cell disease. International Journal of Clinical and Experimental Hypnosis, 45 (4), 417-432.

A cohort of patients with sickle cell disease, consisting of children, adolescents, and adults, who reported experiencing three or more episodes of vaso-occlusive pain the preceding year, were enrolled in a prospective two-period treatment protocol. Following a 4-month conventional treatment baseline phase, a supplemental cognitive-behavioral pain management program that centered on self-hypnosis was implemented over the next 18 months. Frequency of self-hypnosis group training sessions began at once per week for the first 6 months, became biweekly for the next 6 months, and finally occurred once every third week for the next 6 months, and finally occurred once every third week for the remaining 6 months. Results indicate that the self-hypnosis intervention was associated with a significant reduction in pain days. Both the proportion of "bad sleep" nights and the use of pain medications also decreased significantly during the self-hypnosis treatment phase. However, participants continued to report disturbed sleep and to require medications on those days during which they did experience pain. Findings further suggest that the overall reduction in pain frequency was due to the elimination of less severe episodes of pain. Non-specific factors may have contributed to the efficacy of treatment. Nevertheless, the program clearly demonstrates that an adjunctive behavioral treatment for sickle cell pain, involving patient self-management and regular contact with a medical self-hypnosis team, can be beneficial in reducing recurrent, unpredictable episodes of pain in a patient population for whom few safe, cost-effective medical alternatives exist.

## 1996

Hall, Howard; Papas, Angela; Tosi, Michael; Olness, Karen N. (1996). Directional changes in neutrophil adherence following passive resting versus active imagery. International Journal of Neuroscience, 85, 185-194.

This study was designed to determine whether increases or decreases in neutrophil adherence could be achieved following a self-regulation (relaxation/imagery) intervention. Fifteen subjects were randomly assigned to one of three conditions. Two experimental groups employed imagery focused on either increasing or decreasing neutrophil adherence. Subjects had two weeks of self-regulation practice (4 total training sessions) prior to blood drawings. A third group of control subjects had the same number of resting sessions without imagery training. All subjects had blood samples collected before and after either 30 minutes of self-regulation or resting practice for two sessions. Pulse and peripheral finger temperature measures were taken before and after the blood samples. Both experimental groups demonstrated decreases in neutrophil adherence, and the control group showed a tendency toward increases in this measure. The psychophysiologic data for the control group was suggestive of a relaxation response. The experimental group that attempted to increase neutrophil adherence demonstrated psychophysiologic responses that were contrary to relaxation. We concluded that an active cognitive exercise or process is associated with decreases in neutrophil adherence irrespective

of the intent of the exercise. In contrast, relaxation without an active imagery exercise was associated with increases in neutrophil adherence. The results of this study are discussed in terms of behavioral engineering of directional immune changes.

### **1993**

**Crawford, Helen J.; Gur, Ruben C.; Skolnick, Brett; Gur, Raquel E.; Benson, Deborah M. (1993). Effects of hypnosis on regional cerebral blood flow during ischemic pain with and without suggested hypnotic analgesia. International Journal of Psychophysiology, 15, 181-195.**

Using <sup>133</sup>Xe regional cerebral blood flow (CBF) imaging, two male groups having high and low hypnotic susceptibility were compared in waking and after hypnotic induction, while at rest and while experiencing ischemic pain to both arms under two conditions: attend to pain and suggested analgesia. Differences between low and highly-hypnotizable persons were observed during all hypnosis conditions: only highly-hypnotizable persons showed a significant increase in overall CBF, suggesting that hypnosis requires cognitive effort. As anticipated, ischemic pain produced CBF increases in the somatosensory region. Of major theoretical interest is a highly-significant bilateral CBF activation of the orbito-frontal cortex in the highly-hypnotizable group only during hypnotic analgesia. During hypnotic analgesia, highly-hypnotizable persons showed CBF increase over the somatosensory cortex, while low-hypnotizable persons showed decreases. Research is supportive of a neuropsychophysiological model of hypnosis (Crawford, 1991; Crawford and Gruzelier, 1992) and suggests that hypnotic analgesia involves the supervisory, attentional control system of the far-frontal cortex in a topographically specific inhibitory feedback circuit that cooperates in the regulation of thalamocortical activities.

**Hall, Howard; Minnes, Luke; Olness, Karen (1993). The psychophysiology of voluntary immunomodulation. International Journal of Neuroscience, 69, 221-234.**

In twenty-two studies of intentional efforts of humans to change immune measures, only four monitored psychophysiological parameters. One study reported physiologic alterations associated with immune changes. In this current study we examined changes in pulse rate and peripheral temperature associated with intentional changes in neutrophil adherence. Subjects had blood, pulse and temperature recordings collected before and after either a rest condition (Group A), or a self-regulation exercise (Groups B and C) for two sessions. Group C had four prior training sessions before participating in the experimental sessions. This study found no association between psychophysiological alterations and neutrophil changes. The control group (A) demonstrated no significant neutrophil changes but showed physiologic alterations, whereas, the experimental group (C) that showed increases in neutrophil adherence demonstrated no significant physiologic changes. It was speculated that intentional changes on neutrophil adherence and the pattern of the psychophysiological measures were associated with and reflective of cognitive activity.

**1992**

**Hall, Howard; Minnes, Luke; Tosi, Michael; Olness, Karen (1992). Voluntary modulation of neutrophil adhesiveness using a cyberphysiologic strategy. International Journal of Neuroscience, 63, 287-297.**

In a study of voluntary immunomodulation, 45 subjects were assigned either to a control group or one of two experimental groups. All groups had blood and saliva samples collected before and after either a 30 minute rest condition (Control group) or a 30 minute cyberphysiologic strategy (Experimental groups) to increase neutrophil adherence. These samples were analyzed on a range of immunologic measurements including neutrophil adherence. The second experimental group practiced a cyberphysiologic strategy two weeks prior to the experimental session. Subjects in each group returned to repeat their exercise in a second session the following week. Analysis of all immune measurements revealed statistical significance for changes in neutrophil adherence. These studies suggest that such strategies may be used to effect changes in immune cell functions. Analysis further revealed that those subjects with prior cyberphysiologic training were able, by the second session, to induce a significant increase in neutrophil adherence.

**1991**

**Rapkin, David A.; Straubing, Marsha; Holroyd, Jean (1991). Guided imagery, hypnosis and recovery from head and neck cancer surgery. International Journal of Clinical and Experimental Hypnosis, 39, 215-226.**

The value of a brief, preoperative hypnosis experience was explored with a sample of 36 head and neck cancer surgery patients. 15 patients volunteered for the experimental hypnosis intervention. 21 patients who received usual care (no hypnosis) were followed through their hospital charts and were used as a comparison group. Hypnotic intervention and usual care groups were comparable in terms of relevant demographic variables. Postoperative hospitalizations for the hypnotic intervention group were significantly shorter than for the usual care group. Within the hypnotic intervention group, hypnotizability was negatively correlated with surgical complications and there was a trend toward a negative correlation between hypnotizability and blood loss during surgery. Findings suggest that imagery-hypnosis may be prophylactic, benefitting patients by reducing the probability of postoperative complications and thereby keeping hospital stay within the expected range. Recommendations are presented for a controlled, randomized, clinical trial with a sufficiently large sample to provide the opportunity for statistical analysis with appropriate power.

**1990**

**Gil, Karen M.; Williams, David A.; Keefe, Francis J.; Beckham, Jean C. (1990). The relationship of negative thoughts to pain and psychological distress. Behavior Therapy, 21 (3), 349-362.**

Examined the degree to which negative thoughts during flare-ups of pain are related to pain and psychological distress in 3 pain populations: sickle cell disease, rheumatoid arthritis, and chronic pain. 185 adults completed the Inventory of Negative Thoughts in Response to Pain (INTRP), a pain rating scale, the SCL-90 (revised), and a coping strategies questionnaire. Factor analysis of the INTRP revealed 3 factors: Negative Self-Statements, Negative Social Cognitions, and Self-Blame. High scorers on Negative Self-Statement and Negative Social Cognitions reported more severe pain and psychological distress. Ss with chronic daily pain had more frequent negative thoughts during flare-ups than those having intermittent pain secondary to sickle cell disease or rheumatoid arthritis. The INTRP appears to have adequate internal consistency and construct validity.

Sletvold, H.; Jensen, G. M.; Gotestam, K. G. (1990). The effect of specific hypnotic suggestions on blood pressure in normotensive subjects. Pavlovian Journal of Biological Science, 26, 20-24.

Twenty normotensive subjects participated in a study of the effects of specific suggestions on blood pressure (BP). After an induction, the experimental group received suggestions presumed to be relatively nonactivating, although capable of lowering or raising BP. A control group was used to record the BP changes over time. All subjects met for one session. Eight subjects from the experimental group met for a second session. Both adaptation and induction resulted in significant BP decreases. A specific suggestion to increase BP gave a significant result when compared to the induction point. There was no significant change from induction to the BP-decrease suggestion. Both systolic and diastolic BP behaved in the same way. A second experimental session resulted in no significant change compared with the first session. Also, no significant difference was found in suggestibility scores from the first to the second session. The results are in line with previously published studies.

1989

DeBenedittis, Giuseppe; Panerai, Alberto A.; Villamira, Marco A. (1989). Effects of hypnotic analgesia and hypnotizability on experimental ischemic pain. International Journal of Clinical and Experimental Hypnosis, 37 (1), 55-69.

Mechanisms of hypnotic analgesia are still poorly understood and conflicting data are reported regarding the underlying neurochemical correlates. The present study was designed to investigate the effects of hypnotically induced analgesia and hypnotizability on experimental ischemic pain, taking into account pain and distress tolerance as well as the neurochemical correlates. 11 high hypnotizable Ss and 10 low hypnotizable Ss, as determined by scores on the Stanford Hypnotic Susceptibility Scale, Form C (Weitzenhoffer & E. R. Hilgard, 1962), were administered an ischemic pain test in both waking and hypnotic conditions. The following variables were measured: (a) pain and distress tolerance, (b) anxiety levels, and (c) plasma concentrations of beta-endorphin and adrenocorticotrophic hormone (ACTH). Results confirmed significant increases of pain and distress

tolerance during hypnosis as compared to the waking state, with positive correlations between pain and distress relief and hypnotizability. Moreover, a hypnotically induced dissociation between the sensory-discriminative and the affective-motivational dimensions of pain experience was found, but only in high hypnotizable Ss. Hypnotic analgesia was unrelated to anxiety reduction and was not mediated either by endorphins or by ACTH.

Meyer, H. K.; Diehl, B. J.; Ulrich, P. T.; Meinig, G. (1989). Changes in regional cortical blood flow in hypnosis. Zeitschrift für Psychosomatische Medizin und Psychoanalyse, 35, 48-58.

#### NOTES:

Regional cerebral blood flow (rCBF) was measured by means of the 133-Xenon inhalation method in 12 healthy male volunteers who had several months of experience in doing self-hypnosis (autogenic training). During hypnotically suggested right arm levitation, as compared to resting conditions, they found an increase in cortical blood flow and an activation of temporal areas; the latter finding was considered to reflect acoustical attention. In addition, a so-far-unexplained deactivation of inferior temporal areas was observed during successful self hypnosis and hypnosis. While there was a global absolute increase of cortical blood flow bilaterally, they could not observe a relative increase of the right as compared to the left hemisphere during hypnosis. Several subjects successfully performed the levitation of the right arm, despite a relative left hemispheric activation, provided the absolute right hemispheric activation remained dominant.

Jay, Susan M.; Elliott, Charles H.; Katz, Ernest; Siegel, Stuart E. (1987). Cognitive-behavioral and pharmacologic interventions for children's' distress during painful medical procedures. Journal of Consulting and Clinical Psychology, 55, 860-865.

This study evaluated the efficacy of a cognitive-behavioral intervention package and a low-risk pharmacologic intervention (oral Valium), as compared with a minimal treatment-attention control condition, in reducing children's distress during bone marrow aspirations. The subjects were 56 leukemia patients who ranged in age from 3 years to 13 years. The three intervention conditions were delivered in a randomized sequence within a repeated-measures counterbalanced design. Dependent outcome measures included observed behavioral distress scores, self-reported pain scores, pulse rate, and blood pressure scores. Repeated-measures analyses of variance indicated that children in the cognitive-behavior therapy condition had significantly lower behavioral distress, lower pain ratings, and lower pulse rates than when they were in the attention- control condition. When children were in the Valium condition, they exhibited no significant differences from the attention control condition except that they had lower diastolic blood pressure scores.

Meyer, von H. K.; Diehl, B. J. M.; Ulrich, P.; Meinig, G. (1987). Kurz- und langfristige Änderungen der kortikalen Durchblutung bei Autogenem Training[Short and long-term changes in cortical circulation caused by autogenic training]. Zeitschrift für Psychosomatische Medizin und Psychoanalyse, 33 (1), 52-62.

English Summary. The well-known hyperfrontal pattern of hemispheric blood flow measured with 133-Xenon is not found in 12 healthy resting men who have been practicing Autogenic Training at least six months. This might indicate a long-term decrease in the level of activation. Successfully practiced exercises of Autogenic Training lead to an increased blood flow in the Rolandic area representing the body scem (sic) and to a decreased blood flow in regions related to acoustical attention and to autonomic functions. Left hemispheric cerebral blood flow is lower in rest. The relative activation of the left hemisphere during Autogenic Training is discussed.

Ulrich, P.; Meyer, H. J.; Diehl, B.; Meinig, G. (1987). Cerebral blood flow in autogenic training and hypnosis. Neurosurgery Review, 10, 305-307. (Abstracted in American Journal of Clinical Hypnosis, 1989)

In 12 healthy volunteers with at least an experience of 6 months in autogenic training (AT), the cerebral blood flow (CBF) was measured at rest, in AT, and in hypnosis (H). The results were correlated with individual test profiles. The cortical flow pattern at rest of our AT-trained volunteers did not show the hyperfrontality which is described in the literature. This may be interpreted as an effect of better and habitualized relaxation in long-trained AT practitioners. This flow pattern corresponds to the low grades of neuroticism and aggressivity found in the tests. Furthermore, an activation in central cortical areas and a deactivation in regions which are associated with acoustic and autonomous functions occur. Possible explanations for these phenomena as well as for the relatively low perfusion of the left hemisphere at rest and activation in AT are discussed. The global rise of CBF in Hypnosis may be an activation effect caused by resistance against the hypnotizer: the deeper the trance, the smaller the catalepsy of the right arm and in temporal cortical fields processing acoustic inputs.

## 1986

Suls, Jerry; Sanders, Glenn S.; Labrecque, Mark S. (1986). Attempting to control blood pressure without systematic instruction: When advice is counterproductive. Journal of Behavioral Medicine, 9 (6), 567-577.

Hypothesized that, without assistance, Ss' attempts to keep their blood pressure low would produce increases in blood pressure, compared to Ss asked to respond naturally to an arousing stimulus. 50 male undergraduates watched a videotape containing a neutral (nonarousing) section and an erotic section while their blood pressure was recorded by an automated blood-pressure monitoring device. 22 Ss were asked to relax and keep their blood pressure low during the erotic parts of the

videotape, and 28 Ss were asked to respond naturally. Results confirm the hypothesis, suggesting that urging people to relax can be counterproductive if they do not also receive systematic instruction on how to relax or control blood pressure.

**1984**

**Bishay, Emil; Stevens, Grant; Lee, Chingmuh (1984). Hypnotic control of upper gastrointestinal hemorrhage: A case report. American Journal of Clinical Hypnosis, 27, 22-25.**

The use of hypnosis for control of bleeding during and after surgical procedures is common practice. It has also been a useful tool for control of bleeding in hemophiliac children, especially during dental procedures, and in traffic accidents. This paper presents the successful treatment with hypnosis of a patient with upper gastrointestinal tract bleeding. After treatment, the patient was discharged from the hospital without the need for surgical intervention.

**NOTES:**

The physician explained to the patient that nothing would hurt her and that nobody would do anything against her will, that if she could "relax," then her unconscious mind would help her control her bleeding. [Gives script used in the hypnosis.] Trance terminated after 20 minutes. "One hour later, endoscopy performed under local anesthesia revealed 'non-bleeding gastritis, no ulcers seen.' She had no bleeding following the hypnotherapy" (p. 23).

**Conn, Lois; Mott, Thurman, Jr. (1984). Plethysmographic demonstration of rapid vasodilation by direct suggestions: A case of Raynaud's Disease treated by hypnosis. American Journal of Clinical Hypnosis, 26, 166-170.**

Raynaud's Disease is a painful vasospastic disorder of the fingers and toes precipitated by cold or emotional stimuli. Treatment has usually included protection from cold stimuli and vasodilators. Biofeedback, imagery, relaxation, and hypnosis have also been used. The relationship between response to treatment and hypnotizability has been inconclusive. A case of Raynaud's Disease was treated using hypnosis. The patient was highly hypnotizable and responded rapidly to direct suggestion with a fourfold increase in her blood volume. The implications of this rapid response and its relationship to hypnotizability are discussed with suggestions for further studies.

**NOTES:**

The authors review experimental literature on the usefulness of hypnosis in modifying peripheral circulation, finding both positive (Barabasz and McGeorge, 1978, Roberts, Kewman, and MacDonald, 1973) and negative (Peters, Lundy, and Stern, 1973; Black, Edholm, Fox, and Kidd, 1963) outcomes. Experiments relating outcome to hypnotizability also have positive (Block, Levitsky, Teitelbaum, and Valletta, 1977) and negative (Crosson, 1980; Roberts et al, 1973) results.

Clinical literature found that peripheral circulation could be influenced (Crasilneck & Hall, 1975; Norris & Huston, 1956; Jacobson et al., 1973) but none of those studies reported the hypnotizability of the patients. In the Crasilneck and Hall (1975) investigation, 60% of their 48 Raynaud's patients experienced marked improvement in symptoms or remission.

Hypnotizability has been investigated with respect to biofeedback results, finding both no relationship (Holroyd et al., 1982) and a positive relationship (Andreychuk and Skriver, 1975).

In this investigation, the highly hypnotizable (Stanford Hypnotic Susceptibility Scale, Form A, score = 11) female patient was treated with hypnosis when the blood vessels in her hands were constricted. Either she had arrived at the office with poor circulation, or a Raynaud's attack was induced with ice water. Hypnosis involved progressive relaxation followed by suggestions to visualize the blood vessels in her hand opening up, the blood warming and nourishing her hands. "With each beat of your pulse your hand becomes warmer as more blood reaches your fingers. It is as though you are lying in the warm sun. Try to visualize the blood vessels in your hand opening up...." (P. 168).

The patient was asked to use self hypnosis and a cassette of the office session twice a week between sessions, but in fact she either failed to practice or did the exercise once between weekly sessions.

With neutral hypnosis (no specific suggestions about circulation) there was little change in pulse volume; with suggestions to open up her blood vessels, there was an increase in blood volume that began within 20 seconds, reaching four times the baseline in 45 seconds. This increase was reproduced in later sessions, and a somewhat lesser degree of change could be produced with self hypnosis.

In their Discussion, the authors question whether the positive results depend on someone who is high in hypnotizability, and/or on someone with a labile vascular system. They refer to a model of biological information processing to explain how suggestions might have been incorporated by the patient. "Bowers (1977) has speculated that hypnotized patients process information in a way different from when they are not hypnotized. He presents a number of different studies which have shown a significant relationship between hypnotizability and treatment response in patients with illnesses with a clear cut physiological component, including asthma, warts, and ichthyosis. He then speculates that 'suggestions delivered to deeply hypnotized subjects can be transduced into information that is somatically encodable, thereby producing a selective and specific impact on body function and structure.' This kind of processing of information could explain the very rapid response described in the patient presented here.

"In reviewing the cases in which blistering has been produced by hypnotic suggestion, Chertok (1981) states, 'It therefore clearly emerges that these experiments have all been conducted with highly hypnotizable subjects, including a very large proportion of true somnambulists. Inversely, there is not a single known case where a blister has been produced without the subject having been deeply hypnotized beforehand'" (p. 169).

Hall, Howard R. (1984, October). Hypnosis, imagery, and the immune system. [Paper] Presented at the annual meeting of the Society for Clinical and Experimental Hypnosis, San Antonio, TX.

**NOTES:**

Studied the relationship of hypnosis to immune functions, using imagery methods like the Simontons did with their cancer patients. Twenty normal volunteers were hypnotized and asked to imagine their white blood cells (WBCs) attacking weak germs like strong sharks would attack something, and they were told that the sharks would continue working after they came out of hypnosis (a post-hypnotic suggestion). They were asked to "feel it and experience it any way you can," to avoid emphasizing visual imagery too much. Then they were taught self hypnosis and sent home to practice twice a day for a week.

Three blood measures increased after hypnosis: --B-cells increased with pokeweed stimuli (an allergen) for younger Ss, not older Ss --WBC's increased for highly hypnotizable Ss who were young, not for poor hypnotizable Ss or for any older Ss (Age range was 22-80.) --Lymphocyte count increased, approaching significance for highly hypnotizable Ss who were young but not for poor hypnotizable Ss or for older Ss. A personality test administered before the hypnosis, the SLC-90, suggested that the higher the distress level, the lower the lymphocyte count before hypnosis training. Two scores that summed up the distress level correlated -.49 and -.53, respectively. The psychological distress measured by the personality test decreased after the week of self-hypnosis practice. Of the two scores that summed up distress, one decreased for everyone (General Severity Index) and the other decreased only for highly hypnotizable Ss (Positive Symptom Total). Thus, a week of self hypnosis with imagining one's WBC's eating up weak germs in the blood led to both an increase in immune response indicators and a decrease in psychological distress. Psychological distress decreased as lymphocytes increased.

Dr. Hall repeated these procedures with a small number of Ss who were told just to "lie down and rest" rather than being hypnotized and given instructions to imagine their WBC's increasing. None of the above changes occurred. However, he cautions that his research doesn't indicate whether the positive effects are due to relaxation, imagery, or hypnosis since all three were involved

Holmes, David S. (1984). Meditation and somatic arousal evidence. American Psychologist, 39 (1), 1-10.

The conceptual and methodological issues associated with research on the effects of meditation are reviewed. A summary of the research in which the somatic arousal of meditating subjects was compared to the somatic arousal of resting subjects did not reveal any consistent differences between meditating and resting subjects on measures of heart rate, electrodermal activity, respiration rate, systolic blood pressure, diastolic blood pressure, skin temperature, oxygen consumption, EMG activity, blood flow, or various biochemical factors. Similarly, a review of the research on the effects of meditation in controlling arousal in threatening situations did not reveal any consistent differences between meditating and nonmeditating (no-

treatment, antimeditation, or relaxation) subjects. The implications of these findings for research and practice are discussed.

Fung, E. H.; Lazar, B. S. (1983). Hypnosis as an adjunct in the treatment of von Willebrand's disease. International Journal of Clinical and Experimental Hypnosis, **31** (4), 256-265.

Hypnosis has been used to control bleeding, both in normals and hemophiliacs. Case material is presented to demonstrate how hypnosis was used as an adjunct to standard medical treatment of a boy and his mother with von Willebrand's disease, initially to reduce anxiety and improve self-esteem and the parent-child relationship, and later, to reduce bleeding. This use of hypnosis illustrates the relationship between hemostatic control and psychological adaptation

**1981**

Claghorn, James L.; Mathew, Roy J.; Largen, John W.; Meyer, John S. (1981). Directional effects of skin temperature self-regulation on regional cerebral blood flow in normal subjects and migraine patients. American Journal of Psychiatry, **138**, 1182-1187.

Vascular headache of the migraine type is associated with vasomotor changes in cerebral arteries. The authors studied whether skin temperature training (biofeedback) reduced the frequency, severity, and duration of these headaches by measuring the regional cerebral blood flow (CBF) in 11 female migraine patients (27-52 years) and 9 female volunteers (22-37 years), using the noninvasive <sup>133</sup>Xe inhalation technique. Half of each group was randomly assigned to a hand-warming or a hand-cooling group. CBF increased in several regions of the left hemisphere to a significant degree only for the migraineurs who were in the hand-warming group. The pattern of vasomotor regulation apparently differed between migraine and normal Ss. The migraineurs' headache symptoms were affected by both warming and cooling, but warming produced more salutary effects.

**1980**

Case, David B.; Fogel, David H.; Pollack, Albert A. (1980). Intrahypnotic and long-term effects of self-hypnosis on blood pressure in mild hypertension. International Journal of Clinical and Experimental Hypnosis, **28**, 27-38.

Self-hypnosis using the method of Spiegel (1974) was evaluated in 15 patients with labile or mild essential hypertension who were equally hypnotizable and adhered to a regimen of 6-10 daily exercises for a 4-month period. During the hypnotic state, there were consistent rises in both systolic and diastolic pressures in hypnotizable patients, but not in non-hypnotizable controls. Similar but smaller changes were also observed in normotensive subjects. Pressure rose immediately with hypnosis and subsided gradually over 15 minutes. However, the long-term effects of the daily practice of self-hypnosis were variable: ambulatory diastolic pressure fell in 5

patients, was unchanged in 7 patients, and rose in 3 patients. The changes in blood pressure could not be specifically attributed to the daily practice of self-hypnosis; however, all patients experienced improvement in well-being, mood, and behavior patterns during the 4-month period. The study indicates that self-hypnosis can produce changes in behavior and mood which may be beneficial to cardiovascular health, although paradoxically, the act of hypnosis by this technique is pressor. Aside from its therapeutic potential, self-hypnosis may provide useful information about central mechanisms of blood pressure regulation.

## **1978**

**Parker, Jerry C.; Gilbert, Gary S.; Thoreson, Richard W. (1978). Reduction of autonomic arousal in alcoholics: A comparison of relaxation and meditation techniques. Journal of Consulting and Clinical Psychology, 46 (5), 879-886.**

To investigate and compare the effects of progressive relaxation training and meditation training on autonomic arousal in alcoholics, 30 subjects were selected from a population of alcoholics in a Veterans Administration hospital substance-abuse program. The subjects were randomly assigned to one of the following three experimental conditions: (a) progressive relaxation training group, (b) meditation training group, or (c) quiet rest control group. All groups met for 3 weeks during which state anxiety, blood pressure, heart rate, and spontaneous galvanic skin responses were measured. The measures were designed to assess the treatment effects following the first training session and at the end of the total training period. The results indicate that both progressive relaxation training and meditation training are useful for reducing blood pressure in alcoholics. In addition, significant differences between the groups in the effectiveness of the relaxation procedures were found. Meditation training induced blood pressure decreases at an earlier point in the 3-week training period and affected decreases in systolic blood pressure that progressive relaxation training did not. These results support the idea of considerable specificity of response to relaxation techniques.

## **1974**

**Redmond, Daniel P.; Gaylor, Michael S.; McDonald, Robert H.; Shapiro, Alvin P. (1974). Blood pressure and heart-rate response to verbal instruction and relaxation in hypertension. Psychosomatic Medicine, 36 (4), 285-297.**

Recent data have suggested that instructional set and task awareness may play a substantial role in the achievement of directional changes in blood pressure associated with "operant conditioning" techniques. Six hypertensive patients were instructed alternately to raise (UP) and lower (DOWN) their blood pressure by concentrating on changing "heart rate, force of contraction, and blood vessel resistance to flow." Paired 10 min periods were separated by the experimenter's entry and exit. Five of the subjects were taught progressive muscular relaxation (PMR), and the protocol repeated, with PMR induced throughout this session. The immediate cardiovascular response to PMR, induced in both the presence and absence of the experimenter, was studied. Systolic (SBP) and diastolic (DBP) blood

pressure and heart rate (HR) were measured every 30 sec in all sessions. Direction of changes in BP and HR for UP and DOWN periods was appropriate and significant in both instruction sessions, and these differences for BP frequently reached significant levels of magnitude. In general, interactions for HR did not reach significant levels. Comparison of the two sessions yielded little difference between them. PMR uniformly lowered BP and HR, but was of significant magnitude only when induction of PMR involved the active participation of the experimenter. Interview data revealed considerable dramatic mental imagery associated with directional shifts in BP. The results indicate that directional instruction may result in appropriate changes in BP and HR of a magnitude comparable to those reported in studies using "external biofeedback." PMR did not alter the response. This study adds to other data which point to the potential for nonspecific or "placebo" effects to be operative in conditioning studies.

#### **NOTES:**

The authors reviewed literature suggesting that blood pressure changes have been brought about by hypnotic suggestions of attitudes, progressive muscular relaxation, autogenic training (a form of self hypnosis), yogi, transcendental meditation, and hypnotically suggested relaxation.

The instructions to raise and lower blood pressure by concentrating on changing heart rate, force of contraction, and blood vessel resistance to flow were a repetitive monologue with a monotonous emphasis on "rate and force of heart beat and resistance of vessels to flow." Most subjects spontaneously introduced imagery appropriate to the desired change. The authors expressed the opinion that task awareness (to change the blood pressure) influenced the results, and the changes were accomplished more by associative imagery than by responding to the literal meaning of instructions.

Duncan, Irma W.; Dressler, Robert L.; Lyon-James, Sara; Sears, Alden B. (1958). The search for an index of hypnosis. Journal of Clinical and Experimental Hypnosis, 6 (2), 95-108.

#### **NOTES**

1:

"Summary

"Blood and urine samples were obtained from 18 university students at the beginning and end of two experimental sessions, one with and one without hypnosis. Some of the subjects relaxed during the sessions; others imagined or hallucinated a traumatic experience.

"Of a variety of measurements made, urinary volumes and 17-ketosteroids, the eosinophil count and psychogalvanometer recordings appear to give useful information about any changes due to the hypnosis. The biochemical changes caused by the experimentally produced emotions seem to depend on the individual and his past experience rather than the hypnosis. The data suggest that if the

experience hallucinated is known to the subject, the biochemical changes indicate a relaxed state during the hypnosis. The psycho-galvanometer recordings may indicate an agitated state while the biochemical indices suggest a relaxed state" (pp. 106-107).

## C RESEARCH

### CANCER

2002

Edser, Stuart J (2002, March). Hypnotically-facilitated counter-conditioning of anticipatory nausea and vomiting associated with chemotherapy: A case study.. *Australian Journal of Clinical Hypnotherapy and Hypnosis*, 23 (1), 18-30.

Presents an account of a cancer patient who suffers from severe anticipatory nausea and vomiting in the lead-up to chemotherapy treatment. The paper briefly contextualises the symptomatology of the presenting problem in the behavioural and hypnotic literature and recounts the rationale and methods that the writer used in assisting the patient to overcome the problem. Counter-conditioning was used to desensitise the patient to the aversive stimuli and hypnosis used to enhance this effect and to facilitate the final outcome.

Harper, Gary W. (1999). A developmentally sensitive approach to clinical hypnosis for chronically and terminally ill adolescents. *American Journal of Clinical Hypnosis*, 42 (1), 50-60.

Adolescents who suffer from terminal and/or chronic medical illnesses must face difficult developmental issues coupled with increased burdens of physical discomfort and uncertainty about survival. Clinical hypnosis is one technique that can be used to help these individuals gain a sense of comfort and control over their lives. I describe the use of a developmentally sensitive hypnotherapeutic intervention for chronically and terminally ill adolescents. I have used the technique for the reduction of various types of physical and psychological discomfort secondary to a range of medical problems such as cancer, end-stage renal disease, organ transplant, and HIV disease. The treatment focuses on the use of personalized procedures that attempt to increase perceptions of control through interactive formats. Movement through a personally intriguing journey is used as a metaphor for controlling and moving away from discomfort. I also present three case examples as well as general treatment recommendations for clinical use.

Lioffi, Christina; Hatira, Popi (1999). Clinical hypnosis versus cognitive behavioural training for pain management with pediatric patients undergoing bone marrow aspirations. *International Journal of Clinical and Experimental Hypnosis*, 47 (2), 104-116.

A randomized controlled trial was conducted to compare the efficacy of clinical hypnosis versus cognitive behavioral (CB) coping skills training in alleviating the pain and distress of 30 pediatric cancer patients (age 5 to 15 years) undergoing bone marrow aspirations. Patients were randomized to one of three groups: hypnosis, a package of CB coping skills, and no intervention. Patients who received either hypnosis or CB reported less pain and pain-related anxiety than did control patients and less pain and anxiety than at their own baseline. Hypnosis and CB were similarly effective in the relief of pain. Results also indicated that children reported more anxiety and exhibited more behavioral distress in the CB group than in the hypnosis group. It is concluded that hypnosis and CB coping skills are effective in preparing pediatric oncology patients for bone marrow aspiration.

Eimer, Bruce; Freeman, Arthur (1998). *Pain management psychotherapy: A practical guide*. New York NY: John Wiley & Sons, Inc..

#### NOTES

"Pain Management Psychotherapy" (PMP) provides a clear and methodical look at pain management psychotherapy beginning with the initial consultation and work-up of the patient and continuing through termination of treatment. It is a thoughtful and thorough presentation that covers methods for psychologically assessing the chronic pain patient (structured interviews, pain assessment tests and rating scales, instruments for evaluating beliefs, attitudes, pain behavior, disability, depression, anxiety, anger and alienation), treatment planning, cognitive-behavioral therapy techniques, and a range of hypnotic approaches to pain management. The book covers both traditional (cognitive and behavior therapy, biofeedback, assessing hypnotizability, choice of inductions, designing an individualized self-hypnosis exercise) as well as newer innovative techniques (e.g., EMDR, pain-relief imagery, hypno-projective methods, hypno-analytic reprocessing of pain-related negative experiences). An extensive appendix reproduces in their entirety numerous forms, rating scale, inventories, assessment instruments, and scripts.

The senior author, Bruce Eimer, states in his online comments on Amazon.com that "most therapists hold the belief that 'real' chronic pain patients are quite impossible to help. This book attempts to dispel these misguided beliefs by providing a body of knowledge, theory, and techniques that have proven value in understanding and relieving chronic physical pain." He also states that "the challenge for the therapist is to persuade the would-ne patient/client that he or she has something to offer that can help take way pain and bring back more pleasure. This challenge is negotiated through the therapeutic relationship. However, the therapist just can't be 'warm, accepting, non-judgmental and empathic'. The therapist must also have knowledge and skills relevant to relieving pain. Only then can the therapist impart such knowledge, and in teaching these skills to the pain patient, help the patient become something of a 'self-therapist'. . . I dedicate this book to everyone who wants to find ways to make living with pain more comfortable, and to the ongoing search for better ways to relieve pain."

Bayot, A.; Capafons, A.; Cardeqa, E. (1997). Emotional self-regulation therapy: A new and efficacious treatment for smoking.. *American Journal of Clinical Hypnosis*, 40 (2), 146-156.

We described emotional self-regulation therapy, a recently-developed suggestion technique for the treatment of smoking, and present data attesting to its efficacy. Of the 38 individuals who completed treatment, 82% (47% of the initial sample) stopped smoking altogether and 13% (8% of the initial sample) reduced their smoking. A follow-up at 6 months showed that 66% (38% of the initial sample) of those who had completed the treatment remained abstinent and reported minimal withdrawal symptoms or weight gain. In a no-treatment comparison group, only 8% reduced their smoking or became abstinent.

Holroyd, Jean (1996). Hypnosis treatment of clinical pain: Understanding why hypnosis is useful. *International Journal of Clinical and Experimental Hypnosis*, 44 (1), 33-51.

Clinical and experimental research literature indicates hypnosis is very useful for severe and persistent pain, yet reviews suggest hypnosis is not widely used. To encourage more widespread clinical application, the author reviews recent controlled clinical studies in which hypnosis compares favorably with other interventions; links advances in understanding endogenous pain modulation to a neurophysiologic view of hypnosis and hypnoanalgesia; relates the neurophysiology of hypnoanalgesia to management of chronic pain; challenges the view that hypnotic pain control is only for the highly hypnotizable patient; and raises issues about how people learn to control pain with hypnosis. Training in hypnotic analgesia may usefully enhance nervous system inhibitory processes that attenuate pain.

#### NOTES

Hypnosis has been more effective for pain management than other cognitive behavioral interventions in studies of fibromyalgia (Haanen, Hoenderdos, Van Romunde, Hop, Malle, Terwiel, & Hekster, 1991); burn treatment (Patterson, Everett, Burns, & Marvin, 1992); and cancer bone marrow transplant procedures (Syrjala, Cummings, & Donaldson, 1992). Central nervous system gating or downward modulation of pain impulses may account for hypnotic pain control. "Hypnosis enables both amplification and attenuation of cortical response subsequent to sensory registration and prior to consciousness, depending on whether suggestions are for increasing or decreasing awareness (Blum & Barbour, 1979)" (p. 36). This type of inhibition may even be observed in the peripheral nervous system (see Hernandez-Peon, Dittborn, Borlone, & Davidovich, 1959/1960; Sharev & Tal, 1989; Kiernan, Dane, Phillips, & Price, 1995). Work by Helen Crawford (1994) suggests that frontal and limbic areas of the brain are involved in inhibitory patterns of brain activity, and that generation of theta EEG rhythms by lower centers is associated with the suppression of awareness of pain.

Some very low hypnotizable people have been able to learn to control pain with hypnosis, suggesting that it is a skill that can be learned. However, few investigations of improvement of hypnoanalgesia were located. Rather, one must generalize from the fact that other kinds of hypnosis skills have been improved using special training programs, such as the Carleton University program developed by Gorassini & Spanos, 1986). Although most research on improving hypnotic response has been based on operant learning principles, a model that incorporates respondent (classical conditioning) principles might be more useful when it comes to understanding the training of a neurophysiological response, such as inhibitory brain patterns associated with hypnoanalgesia. "Historical success with clinical pain, taken together with newer findings in the neurophysiology of hypnosis, indicate that we should be spending more energy investigating how learning may improve hypnotic analgesia" (p. 43). "We should acknowledge that there are advantages to hypnosis beyond those of relaxation, a good placebo, and psychotherapy. ... Responsible care demands that we provide training or practice in hypnotic analgesia when treating pain, and especially whenever a chronic pain patient initially appears to be nonresponsive" (p. 43).

Jones, M. M. (1994). Apnea in postsurgical hypnotherapy of an esophageal cancer patient: A brief communication. *International Journal of Clinical and Experimental Hypnosis*, 42 (3), 179-183.

Use of clinical hypnosis in the postsurgical psychotherapy of an esophageal cancer patient who could not swallow involved reenactment of the successful surgery and producing hallucinations of taste and smell, as well as working through emotions relating to the surgery and her disease. An apnea that occurred in a late phase of the treatment was addressed with the familiar arm pumping technique that had been used as a deepening technique, resulting in the patient's resuming normal breathing. The experience reminds the practitioner of the possible unexpected professional demands when working in a medical environment. It also provides clues as to the underlying psychological mechanisms and their role in successful symptom removal. A 6-year follow-up confirmed the lasting effect of this brief psychotherapy.

Kraft, Tom (1993). Using hypnosis with cancer patients: Six case studies. *Contemporary Hypnosis*, 10, 43-48.

Hypnosis can be used in a number of different ways for helping patients suffering from cancer. As well as pain relief, hypnosis may be used to correct insomnia that does not respond to sleeping tablets; for the reduction in skin irritation and dyspnoea when these are due to organic causes, and for treatment-related over-eating. Some patients will use hypnosis in a symbolic way. When this occurs, just as in dream interpretation, it is important to ask the patient for associations, so that these symbols can be understood. Hypnosis can be an extremely useful addition to the medical armamentarium, and should be employed as an adjunct to standard forms of cancer treatment. This paper reports six case studies in which hypnosis was used to help cancer patients.

**Barinaga, Marcia (1992). Giving personal magnetism a whole new meaning. Science, 256, 967.**

**NOTES:**

**Cited in Noetic Sciences Review, Autumn, 1992. This geobiologist has discovered that the human brain contains billions of tiny magnets--some 7 billion of them, each so small that their total weight is only one/millionth of an ounce. In magnetite-containing bacteria, the crystals are used as a compass needle which orients the bacteria with respect to the Earth's magnetic field. In birds, bees, and fish, where concentration of the mineral is a few orders of magnitude higher than he found in the human brain, it is used as a navigational aid. He plays down the possible connection to weak electromagnetic fields that supposedly cause cancer (unless fields could induce very weak electrical fields inside the cells, disrupting cellular function). Other possible interpretations: a means for cells to store excess iron, or part of a magnetic sensing system, or a vestigial system left over in evolution from when we were more directly connected with the earth's magnetic field and may have relied on it for navigation or migratory movement.**

**Kraft, Tom (1992). Counteracting pain in malignant disease by hypnotic techniques: Five case studies. Contemporary Hypnosis, 9, 123-129.**

**Five cases of patients suffering from cancer are described in which hypnotic visualization techniques were successfully employed to relieve pain and anxiety. This study supports the view that hypnosis can be an effective tool for pain relief in malignant disease, particularly when traditional methods have been exhausted.**

**Levitan, Alexander A. (1992). The use of hypnosis with cancer patients. Psychiatric Medicine, 10, 119-131.**

**Hypnosis has proven to be extremely valuable in the treatment of cancer patients. Specific applications include: establishing rapport between the patient and members of the medical health team; control of pain with self-regulation of pain perception through the use of glove anesthesia, time distortion, amnesia, transference of pain to a different body part, or dissociation of the painful part from the rest of the body; controlling symptoms, such as, nausea, anticipatory emesis, learned food aversions, etc.; psychotherapy for anxiety, depression, guilt, anger, hostility, frustration, isolation, and a diminished sense of self-esteem; visualization for health improvement; and, dealing with death anxiety and other related issues. Hypnosis has unique advantages for patients including improvement of self-esteem, involvement in self-care, return of locus of control, lack of unpleasant side effects, and continued efficacy despite continued use.**

**Spiegel, David (1992, October). Hypnotizability. [Paper] Presented at the annual meeting of the Society for Clinical and Experimental Hypnosis, Arlington, VA.**

**NOTES**

Dr. Spiegel announced that this was a last minute substitution for Fred Frankel's presentation on Hypnotizability.

We have ongoing a major replication of the study that we published on group therapy with terminally ill breast cancer patients. The matched control patients get educational materials but not psychotherapy. We are looking at NKC cytotoxicity and delayed hypersensitivity.

Tasks: spend 15 minutes discussing list of problems; 15 minutes discussing things like, "What is your spouse doing that doesn't help; what can we do to help it?" We get drop in NKC cytotoxicity immediately afterward, returning after 24 hrs to usual levels. Controls don't drop in NKC cytotoxicity. This measure of stress may be a predictor of survival time.

In Fawzy's study of group therapy with melanoma patients, they noted a significant difference at 6 months in interferon augmented activity of NK, which didn't hold up at a year. But at 6 years there were 10 of 40 deaths in control group vs 3 of 40 deaths in treated group. This is a vigorous effect.

Cohen's study of colds in New England J. of Med is another good clinical study.

There are two broad areas of relevance of hypnotizability to healing: 1. Hypnotizability as a trait: do highs differ in way they regulate body or mind? 2. Is there something you do when in hypnotized state that is different? Studies of treatment of warts with hypnosis are important 3. Transition between states, e.g. circadian rhythms; is there a shift in wakefulness between trance and nontrance states that affects health?

Psychiatric Diagnosis and self regulation. High hypnotizability is associated with certain psychiatric disorders (dissociative reaction, PTSD, MPD, etc.). Schizophrenics score much lower than normals (av. = 4 vs 7; replicated with the Hypnotic Induction Profile (HIP). Stanford Hypnotizability Scales show no difference in means, but do show a difference in range). I don't know what this means. But schizophrenics can falsely pass some Stanford Scale items, e.g. amnesia which they don't however reverse; so schizophrenics' hypnotizability scores may be inflated on Stanford scales. We don't see extremely high scores in schizophrenics.

Psychoactive medication doesn't affect scores of schizophrenics, but improves scores of anxiety neurotics (by reducing anxiety). Frischholz has an article coming out in a psychiatry journal that confirms this.

There is a lot of evidence that patients with dissociative disorders are more hypnotizable than other groups. Frischholz et al couldn't replicate Frankel's finding of higher scores in phobics. Pettinati et al found higher scores in bulimia and I haven't seen anything to counter that. Another idea is that high hypnotizables are very good at internal regulation

Spiegel & Ken Kline selected Ss who could regulate gastric activity. They got an 80% increase in gastric acid output while imagining eating; got 40% decrease in output when imagining something pleasant that wasn't imagining eating. Injected with pentagastrin, which induces gastric output, they still got a decrease in gastric acid output in the relaxation condition.

This suggests that hypnotizability should be a selection criterion for some research. See also Katz et al. 1974 (?) with acupuncture; and McGlashan, Evans & Orne on the placebo response.

Herbert Spiegel found that 2/3 of highs but 1/3 of lows were cured of phobia. Eye roll sign on the HIP, living with spouse/lover, rating self as hypnotizable, and giving a postcard follow-up response at one week post treatment were associated with 89% rate abstinence at 2 years follow-up, when only 23% overall of 223 were abstinent. Absence of those positive predictors was associated with only a 4% rate of abstinence.

Spira, James L.; Spiegel, David (1992). Hypnosis and related techniques in pain management. *Hospice Journal*, 8, 89-119.

Hypnosis has been used successfully in treating cancer patients at all stages of disease and for degrees of pain. The experience of pain is influenced not only by physiological factors stemming from disease progression and oncological treatment, but also from psychosocial factors including social support and mood. Each of these influences must be considered in the successful treatment of pain. The successful use of hypnosis also depends upon the hypnotizability of patients, their particular cognitive style, their specific motivation, and level of cognitive functioning. While most patients can benefit from the use of hypnosis, less hypnotizable patients or patients with low cognitive functioning need to receive special consideration. The exercises described in this chapter can be successfully used in groups, individual sessions, and for hospice patients confined to bed. Both self-hypnosis and therapist guided hypnosis exercises are offered.

Syrjala, Karen L.; Cummings, Claudette; Donaldson, Gary W. (1992). Hypnosis or cognitive behavioral training for the reduction of pain and nausea during cancer treatment: A controlled clinical trial. *Pain*, 48, 137-146.

Few controlled clinical trials have tested the efficacy of psychological techniques for reducing cancer pain or post-chemotherapy nausea and emesis. In this study, 67 bone marrow transplant patients with hematological malignancies were randomly assigned to one of four groups prior to beginning transplantation conditioning: (1) hypnosis training (Hypnosis); (2) cognitive behavioral coping skills training (CB); (3) therapist contact control (TC); or (4) treatment as usual (TAU; no treatment control). Patients completed measures of physical functioning (Sickness Impact Profile; SIP) and psychological functioning (Brief Symptom Inventory; BSI), which were used as covariates in the analyses. Biodemographic variables included gender, age and a risk variable based on diagnosis and number of remissions or relapses. Patients in the Hypnosis, CB, and TC groups met with a clinical psychologist for two pre-transplant training sessions and ten in-hospital "booster" sessions during the course of transplantation. Forty-five patients completed the study and provided all covariate data, and 80% of the time series outcome data. Analyses of the principal study variables indicated that hypnosis was effective in reducing reported oral pain for patients undergoing marrow transplantation. Risk, SIP, and BSI pre-transplant were found to be effective predictors of inpatient physical symptoms. Nausea, emesis and opioid use did not differ significantly between the treatment

groups. The cognitive behavioral intervention, as applied in this study, was not effective in reducing the symptoms measured.

## NOTES

Hypnotizability was not measured in this study.

The authors hypothesized that "(1) patients receiving hypnosis training would report the least pain, but the cognitive behavioral group would report less pain than the untreated group; and (2) both treatment groups would report less nausea and emesis than the control groups" (p. 138). The adult patients were undergoing their first marrow transplant, had survived at least 19 days post-transplant, and had participated in at least the first 8 of 10 possible inpatient sessions; five additional patients completed the study but had missing data.

Each patient in the TC (therapist contact), CB (cognitive behavioral coping skills), and Hypnosis groups participated in two 90 minute training sessions with a psychologist, 2-4 days apart, on an outpatient basis. Once admitted to hospital, twice each week they participated in a total of ten 30-minute sessions designed to reinforce use of the interventions. The TAU (treatment as usual) group had no psychologist contact. For the TC control group, the psychologist simply talked with the patients about whatever was on their minds.

The CB group received multiple interventions: training in relaxation (2 techniques-progressive muscle relaxation and abbreviated autogenic relaxation) with tapes provided; cognitive restructuring (Turk et al., 1983) which included training in attention redirection and restructuring self-defeating cognitions; preparing coping self-statements or affirmations, by focusing attention on neutral or pleasant events or objects, or by occupying their attention through mental repetition of affirmations, songs or prayer; encouragement to think of negative events as time limited; provision of information, especially the beneficial effects of reducing physiological arousal and attention to pain and nausea; assistance in setting short-term progress-related goals for self-care such as exercise, caloric intake, and mouth care; exploration of the meaning of their illness and of bone marrow transplant.

For the Hypnosis group, individually tailored Ericksonian inductions (Lankton & Lankton, 1983) with relaxation and multi-sensory imagery were taped and given to the patient to use in daily practice, in between sessions. The suggestions were directed at reducing pain, nausea, and the emotional reactions to those symptoms; there also were suggestions about health, well-being, self-control and enhanced coping capabilities.

The results were analyzed by ANCOVA (except where non-parametric analysis was required with the opioid data). Due to gender differences in reported pain (men experiencing more) and the fact that the TAU group had an over-representation of men, the TAU group could not be used in the pain analyses. However, there were no gender differences in nausea reports, so that all four groups could be used for nausea outcome analyses.

The Hypnosis group evidenced the lowest amount of post-transplant pain, and used (nonsignificantly) less opioids than the other groups. No significant treatment effects were observed for either nausea or emesis.

In their discussion, the authors noted that "The hypnosis group's peak pain was lower and of a shorter duration than the other three groups. Opioid use closely followed the course of pain intensity. ... The gender effect may be characteristic of this particular sample [since it was unexpected].

"Nausea and emesis followed a less predictable course than pain. ... nausea fluctuated dramatically from day to day within treatment groups. As nausea moderated after completion of conditioning, the day to day fluctuations remained striking. This lack of symptom predictability may have contributed to the difficulty patients had in using the interventions effectively" (p. 143).

"The lack of significant differences between treatment groups in opioid use indicates that lower pain report in the hypnosis group cannot be explained by increased opioid use. Results do not support the second hypothesis that both hypnosis and cognitive behavioral training would reduce chemotherapy or radiation-induced nausea and emesis.

"In MT patients, several factors may limit the impact of either cognitive behavioral training or hypnosis on nausea and emesis. First, MT patients receive higher doses of emetogenic agents than are given to most other cancer patients. Second, patients in this study had only two sessions in which to learn relaxation techniques; this may not have provided adequate training. Third, the most severe emetic challenge began immediately with the first dose of chemotherapy rather than having a gradual onset. This did not permit patients to master the techniques with milder symptoms before applying training to intense symptoms. Fourth, for all patients, psychological interventions were provided as adjuncts to medications rather than as substitutes for antiemetics or opioids. Both antiemetics and opioids have substantial cognitive side effects which, in high doses, may impact patients' abilities to implement interventions which are in essence cognitive. This combination of factors may have provided too severe a challenge to a newly learned skill. In contrast to nausea, oral pain developed over a number of days, permitting practice while symptoms were mild and before administration of opioids.

"Results suggest that the imagery component of the hypnosis intervention was central to its efficacy. Not only was the cognitive behavioral intervention without imagery not effective in reducing the symptoms measured, but we found in clinical practice that patients intermittently began to refuse sessions with relaxation alone. Even hypnosis patients, when under the physical stresses of treatment, had shortened attention spans that necessitated briefer inductions, less time spent on relaxation, and more active, engaging imagery.

"... Since, in clinical practice, imagery is frequently a component of cognitive behavioral treatment, these results would not generalize to those settings where imagery is combined with other skill training.

"Several other possible limitations of the cognitive behavioral intervention merit consideration. Our experience indicates that the number of components used in the two training sessions were more than patients could competently learn in a short time. ... A further possibility is that maladaptive cognitions, which are the targets of cognitive restructuring, may be the exception rather than the rule among MT patients who tend to focus, with their families, on positive, hopeful attitudes toward their treatment" (pp. 144- 145).

The authors note that the relatively small sample size may have provided inadequate statistical power to demonstrate effects with some of the outcome variables.

Burish, Thomas G.; Snyder, Susan L.; Jenkins, Richard A. (1991). Preparing patients for cancer chemotherapy: Effect of coping preparation and relaxation interventions. *Journal of Consulting and Clinical Psychology*, 59 (4), 518-525.

60 cancer chemotherapy patients were randomly assigned to 1 of 4 treatments: (a) relaxation training with guided relaxation imagery (RT), (b) general coping preparation package (PREP), (c) both RT and PREP, or (d) routine clinic treatment only. All patients were assessed on self-report, nurse observation, family observation, and physiological measures and were followed for 5 sequential chemotherapy treatments. Results indicate that the PREP intervention increased patients' knowledge of the disease and its treatment, reduced anticipatory side effects, reduced negative affect, and improved general coping. RT patients showed some decrease in negative affect and vomiting, but not as great as in past studies. The data suggest that relatively simple, 1-session coping preparation intervention can reduce many different types of distress associated with cancer chemotherapy and may be more effective than often-used behavioral relaxation procedures.

Grossarth-Maticek, R.; Eysenck, H. J. (1991). Creative novation behaviour therapy as a prophylactic treatment for cancer and coronary heart disease: Part II - Effects of treatment. *Behaviour Research and Therapy*, 29, 17-31.

#### NOTES

Reports on what they call creative novation behavior therapy or "autonomy training" to prevent cancer and coronary heart disease in prone individuals. This individually tailored cognitive-behavioral program includes the use of hypnosis and of imagery. When administered individually (20-30 hours) in a group (6-15 sessions of up to several hours) or via bibliotherapy with 4-6 hours of individual therapy, the outcome was better than that of control subjects. After 13 years, 45 of 50 cancer-prone subjects in individual treatment were still alive (and none of the 5 deaths were from cancer), while among 50 control subjects, 31 died, 16 from cancer. This study along with Spiegel et al. (1989) article in *Lancet* have important implications for health care.

McCue, Peter A. (1991). Key Paper Review: Prophylactic therapy for cancer and coronary heart disease. [Comment/Discussion]

#### NOTES

This is a commentary on two papers by Grossarth-Maticek and Eysenck, in which they report on 'creative novation behaviour therapy' to prevent cancer and heart disease in people with personalities associated with the development of those diseases. Therapy may involve hypnosis and/or relaxation, with suggestions that facilitate modification of unhealthy expectancies. The papers are:

Grossarth-Maticek, R. & Eysenck, H.J. (1991). Creative novation behaviour therapy as a prophylactic treatment for cancer and coronary heart disease: Part I - Description of treatment. *Behaviour Research and Therapy* 29, 1-16.

Eysenck, H.J. & Grossarth-Maticek, R. (1991). Creative novation behaviour therapy as a prophylactic treatment for cancer and coronary heart disease: Part II - Effects of treatment. *Behaviour Research and Therapy* 29, 1, 17-31.

Rapkin, David A.; Straubing, Marsha; Holroyd, Jean (1991). Guided imagery, hypnosis and recovery from head and neck cancer surgery. *International Journal of Clinical and Experimental Hypnosis*, 39, 215-226.

The value of a brief, preoperative hypnosis experience was explored with a sample of 36 head and neck cancer surgery patients. 15 patients volunteered for the experimental hypnosis intervention. 21 patients who received usual care (no hypnosis) were followed through their hospital charts and were used as a comparison group. Hypnotic intervention and usual care groups were comparable in terms of relevant demographic variables. Postoperative hospitalizations for the hypnotic intervention group were significantly shorter than for the usual care group. Within the hypnotic intervention group, hypnotizability was negatively correlated with surgical complications and there was a trend toward a negative correlation between hypnotizability and blood loss during surgery. Findings suggest that imagery-hypnosis may be prophylactic, benefitting patients by reducing the probability of postoperative complications and thereby keeping hospital stay within the expected range. Recommendations are presented for a controlled, randomized, clinical trial with a sufficiently large sample to provide the opportunity for statistical analysis with appropriate power.

#### NOTES

Actual stay in hospital, post-surgery, was 8.7 days (SD = 3.7) for the Hypnosis group and 13.9 days (SD = 9.7) for the Usual Care group; the range was 3-17 days for the Hypnosis group and 5-42 days for the usual care group.

The hypnosis script included an indirect, permissive induction; positive suggestions for relaxation and healing imagery; images of calm situations that would lead to expectation for healing (e.g. a 'healing pool'); suggestions for patients to develop their own images of pleasurable, comforting situations. The only direct suggestions were for minimal blood loss during surgery, modeled after those given in the waking situation by Bennett, Benson, and Kuiken (1986).

As measured by the Stanford Hypnotic Clinical Scale, there were five highly hypnotizable patients (scores 4-5), six mediums (scores 2-3), and four lows (scores 0-1). "Hypnotizability correlated negatively with complications ( $r = -.54$ ,  $p < .04$ , two-tailed test). There was a trend toward a negative correlation with length-of-stay ( $r = -.37$ ,  $p < .18$ , two-tailed test) and estimated blood loss ( $r = -.40$ ,  $p < .15$ , two-tailed test). Note that these correlations represent moderate to large effects, and the significance levels are due in part to low power associated with a small N (Cohen, 1988). The means for blood lost during surgery for the three hypnotizability groups were: highs = 904 cc, mediums = 1465 cc, and lows = 2056 cc" (p. 222).

Data on cost could not be published in this article but later was published in a letter to the Editor of the Newsletter of the Society of Clinical and Experimental Hypnosis (February 1994, Vol. 35, No. 1, p.8). "The average savings for the intervention group was \$6,725. While this difference fell short of statistical significance on the Wilcoxon test ( $Z = -1.5402$ ,  $p < .10$ ), it is rather striking on its face. The range actually was \$7849 to \$27,782 for Intervention Group patients and \$9,390 to \$53,627 for Usual Care group patients.

"In 1990 a semi-private room at UCLA Center for the Health Sciences cost \$405 to \$529 per day, depending on quality; standard ICU care (one nurse for two patients) was \$1236 per day, and more intensive care (one nurse for one patient) was \$2471/day. Head and neck surgery patients may remain in the ICU, driving up costs, solely because they have not learned to suction their own tracheostomies, usually a motivational factor that might be affected by hypnosis. UCLA is a tertiary care hospital in a high-cost area (and is therefore reimbursed at higher rates than many other hospitals), and costs may be driven up by the many additional procedures required for long-stay patients. Therefore the cost savings could not be expected to be as great where expected length of stay is brief, ICU use is limited, and community costs are lower" (p. 8).

Zeltzer, Lonnie K.; Dolgin, M. J.; LeBaron, Samuel; LeBaron, C. (1991). A randomized, controlled study of behavioral intervention for chemotherapy distress in children with cancer. *Pediatrics*, 88, 34-42.

Subjects were randomly assigned to hypnosis, nonhypnotic distraction/relaxation, or attention placebo control. children in the hypnosis group reported the greatest reduction in both anticipatory and postchemotherapy symptoms. Distraction/relaxation kept symptoms from getting worse, but they did not get better, and the control children's symptoms became much worse.

Kaye, J. M.; Schindler, B. A. (1990). Hypnosis on a consultation-liaison service. *General Hospital Psychiatry*, 12, 379-383.

Studied the use of hypnosis on a consultation-liaison service with a broad spectrum of medically hospitalized patients. Autohypnosis tapes were used for reinforcement. Twenty-nine women and eight men from 24-75 years of age were hypnotized for relief of depression, pain, anxiety, or side effects of chemotherapy. Results were excellent (total to almost total relief of symptoms) in 68%, fair in 22%, and poor in 11%, with no differences among the results with the various conditions. This demonstrates that hypnotherapy is an extremely useful tool in medical management of patients in consultation-liaison psychiatry.

LaClave, Linda J.; Blix, Susanne (1989). Hypnosis in the management of symptoms in a young girl with malignant astrocytoma: A challenge to the therapist. *International Journal of Clinical and Experimental Hypnosis*, 37 (1), 6-14.

This paper presents the case of a 6.5-year-old girl with malignant astrocytoma of the left brain hemisphere. During the course of her chemotherapy treatment, severe

vomiting developed to the degree that on several occasions she became dehydrated. Discontinuation of chemotherapy was being considered when she was referred for hypnotherapy. Despite severe neurological impairments which excluded many traditional techniques, hypnosis was successful in eliminating emesis. Hypnosis was also utilized to decrease pain and to improve sleep patterns. Drawings are presented to help show how this child resolved anxiety associated with treatment and fears surrounding the knowledge of her impending death.

Spiegel, David; Bloom, J. R.; Kraemer, H. C.; Gottheil, E. (1989, October 14). The beneficial effect of psychosocial treatment on survival of metastatic breast cancer patients: A randomized prospective outcome study. *Lancet*, 888-891.

The effect of psychosocial intervention on time of survival of 86 metastatic breast cancer patients was studied using randomized prospective design. The one-year treatment consisted of weekly supportive group therapy with training in self-hypnosis for pain management, and resulted in significant reductions in mood disturbance and pain. Both the treatment and control groups had routine oncologic care. At ten-year follow-up, only three of the original 86 patients were still alive, and death records were obtained for the other 83. Survival from the time of randomization and onset of intervention was 36.6 (sd = 37.6) months for the treatment group, compared with 18.9 (sd = 10.8) months for the control group, and this difference was highly significant ( $Z = 3.94$ ,  $p < .0001$ ) using the Cox life table regression model. Kaplan-Meier survival analysis indicated that the divergence in survival began at 20 months after entry into the study, or 8 months after the treatment intervention ended. These unexpected findings suggest that intensive psychosocial support affects the course of the illness, although the mechanism by which it does so is not clear.

Jay, Susan (1987, October). Hypnotic susceptibility and response to psychological intervention for distress related to painful procedures in leukemic children. [Paper] Presented at the annual meeting of the Society for Clinical and Experimental Hypnosis, Los Angeles.

#### NOTES

Presented children with a cognitive behavioral intervention package that involved five elements 1. Filmed Modeling (child modeling and talking about it with good coping skills) 2. Positive Reinforcement - trophy 'for doing the best you can,' to change aversive situation to a positive situation 3. Breathing Exercises - 'puff yourself up like a tire' 4. Emotive Imagery/Distraction - super hero image (Superman), or being in a favorite place 5. Behavioral Rehearsal - dollplay, reviewing the procedure with medical equipment.

For Numbers 4 and 5 the therapist would actively guide the procedures; numbers 3, 4 & 5 are hypnotic elements.

Valium had lowered children's distress prior to procedures but not during the procedures. This study involved Valium plus cognitive behavior therapy.

25 Subjects ages 6-12, were measured for hypnotizability

**2 groups: (1) Cognitive Behavior Therapy + Valium given just before intervention started, after film ended; (2) Cognitive Behavior Therapy alone.**

**Dependent Measures: 1. Observation Scale of Behavioral Distress coded every 15 seconds. 2. Faces Scale for Fear (self report) before procedure**

**Faces Scale for Pain (self report) after procedure 3. Blood pressure**

**RESULTS. No Significant Differences were found between the two groups (CBT vs CBT + Valium). Pre-Post Analyses: Post intervention scores were significant lower than Pretest on [missed notes]**

**Jay, Susan M.; Elliott, Charles H.; Katz, Ernest; Siegel, Stuart E. (1987). Cognitive-behavioral and pharmacologic interventions for children's' distress during painful medical procedures. Journal of Consulting and Clinical Psychology, 55, 860-865.**

**This study evaluated the efficacy of a cognitive-behavioral intervention package and a low-risk pharmacologic intervention (oral Valium), as compared with a minimal treatment-attention control condition, in reducing children's distress during bone marrow aspirations. The subjects were 56 leukemia patients who ranged in age from 3 years to 13 years. The three intervention conditions were delivered in a randomized sequence within a repeated-measures counterbalanced design. Dependent outcome measures included observed behavioral distress scores, self-reported pain scores, pulse rate, and blood pressure scores. Repeated-measures analyses of variance indicated that children in the cognitive-behavior therapy condition had significantly lower behavioral distress, lower pain ratings, and lower pulse rates than when they were in the attention- control condition. When children were in the Valium condition, they exhibited no significant differences from the attention control condition except that they had lower diastolic blood pressure scores.**

#### **NOTES**

**Lonnie Zelzer, M.D., in a UCLA Hypnosis Seminar lecture in 1992, stated that in pre-treatment with Valium the patients did worse during the procedure, vs no pretreatment with Valium, because the medicated patients didn't have clarity of attention during the cognitive behavioral learning.**

**Katz, Ernest R.; Kellerman, Jonathan; Ellenberg, Leah (1987). Hypnosis in the reduction of acute pain and distress in children with cancer. Journal of Pediatric Psychology, 12, 379-394.**

**Hypnosis has been used as a behavioral approach to help children tolerate aversive medical procedures more effectively, but empirical longitudinal research evaluating the outcome of such interventions has been limited. In the present study, 36 children with acute lymphoblastic leukemia between the ages of 6 and 12 years of age undergoing repeated bone marrow aspirations (BMAs) were randomized to hypnosis or play comparison groups. Subjects were selected on their behavioral performance on baseline procedures and received interventions prior to their next three BMA procedures. Major results indicated an improvement in self-reported distress over baseline with both interventions, with no differences between them.**

Girls exhibited more distress behavior than boys on three of four dependent measures used. Suggestions of an interaction effect between sex and treatment group were noted. The role of rapport between patient and therapist in therapeutic outcome was also evaluated. Results are discussed in terms of potential individual differences in responding to stress and intervention that warrant further research.

Hendler, Cobie S.; Redd, William H. (1986). Fear of hypnosis: The role of labeling in patients' acceptance of behavioral interventions. *Behavior Therapy*, 17, 2-13.

One hundred and five outpatient cancer chemotherapy patients were interviewed to assess their attitudes toward hypnosis and relaxation as well as to determine their beliefs in and willingness to try a behavioral procedure. Patients were randomly assigned to groups receiving identical descriptions labeled "hypnosis," "relaxation," or "passive relaxation with guided imagery." The description stressed the behavioral components of hypnosis and relaxation rather than the nonbehavioral techniques often associated with hypnosis such as age regression and posthypnotic suggestion. Patients believed hypnosis to be a powerful process that involved loss of control and altered states of consciousness. When compared with a group of college students, patients held significantly more fearful, conservative views about hypnosis. Patients who received a description of an intervention labeled "hypnosis" were significantly less likely to believe the procedure would effectively control their nausea and vomiting and were significantly less likely to state they would try the procedure than patients in the other two label conditions. This reaction to the label occurred independently of patients' degree of nausea, vomiting, and pain due to their chemotherapy treatments.

Achterberg, J. (1984, October). Cancer, immunology, psychological factors, and imagery. [Paper] Presented at the annual meeting of the Society for Clinical and Experimental Hypnosis, San Antonio, TX.

#### NOTES

Author developed a way of scoring imagery (which will be published in *Imagery and Disease*). In terms of predicting who will die and who will survive, the content of the images doesn't seem to be as important as the quality (strength, vividness, etc.), which supports Bernauer Newton's (1984) findings. "The image seems to be a basic pre-verbal component of our species that has survival value."

Margolis, Clorinda G. (1984). Hypnosis and cancer: An overview of the field. [Unpublished manuscript]

#### NOTES

This paper apparently was presented either at American Psychological Association or the Society for Clinical and Experimental Hypnosis. The author has two tables summarizing types of cancer associated with pain, and pain syndromes in patients with cancer.

Table 3 is a list of Erickson's procedures for Controlling Pain: --Direct hypnotic suggestion for total abolition of pain --Permissive indirect hypnotic abolition of pain

--Amnesia --Hypnotic analgesia --Hypnotic anesthesia --Hypnotic replacement or substitution of sensations --Hypnotic displacement of pain --Hypnotic dissociation  
Time and body disorientation --Hypnotic reinterpretation of pain experience --  
Hypnotic time distortion --Hypnotic suggestions effecting a diminution of pain  
(from Rossi, Ed., *Innovative Hypnotherapy*, Vol. IV of the Collected Papers of  
Milton H. Erickson on Hypnosis, 1980)

Table 4 is a list of Sacerdote's Procedures for Controlling Pain: --Teleological  
approach --Reinterpretation of signals --Associating and conditioning --Dissociation  
--Simile of electric wiring --Development of amnesia --Positive and negative  
hallucinations --Induction of dreams --Time and space distortion, and elicitation of  
mystical states --Relaxation techniques --Glove anesthesia and analgesia --Pain  
management through control of autonomic functions  
(from Barber & Adrian, Eds., *Psychological Approaches to the Management of  
Pain*, 1982)

The author describes cases treated by Erickson (one in which he used 12 hours of  
training, in one session, reported in Rossi's 1980 edited writings of Milton Erickson,  
Vol. IV) and by Sacerdote.

Author notes that the Hilgards, in *Hypnosis in the Relief of Pain* (1975), describe  
the use of hypnosis in treating patients with cancer pain. In all three--Butler (1954),  
Lea, Ware, and Monroe (1960), and a larger study by Cangello (1961), both success  
and failure are reported. As the Hilgards point out, about 50% of the patients  
studied were able to reduce their pain--a percentage the Hilgards remark is rather  
close to what successful clinicians tend to report.

Morrow, Gary R. (1984). Appropriateness of taped versus live relaxation in the  
systematic desensitization of anticipatory nausea and vomiting in cancer patients.  
*Journal of Consulting and Clinical Psychology*, 52 (6), 1098-1099.

Investigated the suggestion that the relaxation part of systematic desensitization--an  
effective treatment for the nausea and vomiting experienced by approximately 25%  
of cancer patients in anticipation of chemotherapeutic treatments-- could be learned  
from a prerecorded audiotape prior to meeting a psychologist for treatment. 10  
cancer patients who had developed anticipatory nausea or vomiting were assigned  
to either a live-relaxation or a tape-relaxation group. Results show that 4 of 5 Ss  
assigned to the tape-relaxation group experienced nausea while listening to the  
prerecorded audiotape, while none of the patients in the live-relaxation group  
reported nausea when subsequently listening to an audiotape made during the live  
presentation of relaxation.

Newton, Bernauer (1984, October). The use of imagery in the treatment of cancer  
patients. [Paper] Presented at the annual meeting of the Society for Clinical and  
Experimental Hypnosis, San Antonio, TX.

Several hundred cancer patients were treated with the Simonton visualization  
method, with the additional factor that they were hypnotized for the visualization.  
In a long term follow-up study, those patients who were treated for at least 6 months

and are still alive had imagery that was vivid, persistent, positive, and passive ("passive" here meaning an underlying sense of calm). Those who died had the opposite kind of images, and retrospective review of clinical notes indicates their aggressive images reflected desperation. Of the patients who were treated less than six months, a few lived. Their images also were vivid, persistent, and positive.

**Petrucci, Ralph J.; Harwick, Robert D. (1984). Role of the psychologist on a radical head and neck surgical service team. *Professional Psychology: Research and Practice*, 15, 538-543.**

Surgery for head and neck cancers often produces disfiguration and a sense of hopelessness in patients, and it may also results in a lack of self-acceptance, depression, and covert hostility. Psychologists are often called on to help such patients deal with drug abuse, suicidal behaviors, strong characterological disorders, noncompliance, and overall adjustment. Behavioral management and anxiety-reduction strategies, such as relaxation exercises and visual imagery, are often helpful. (17 ref).

**Gardner, G. Gail; Lubner, Alison (1982-83). Hypnotherapy for children with cancer: Some current issues. *American Journal of Clinical Hypnosis*, 25 (2-3), 135-142.**

The authors review some of the problems that now face clinicians and researchers working in the field of hypnotherapy for pediatric cancer patients. These include (1) understanding and dealing with resistance and refusal, (2) developing preventive hypnotherapeutic strategies for children who will survive cancer, and (3) carrying out research that clarifies the value of hypnotherapy with childhood cancer patients and elucidates when and how specific approaches can best be utilized.

**Hall, Marian D. (1982-83). Using relaxation imagery with children with malignancies: A developmental perspective. *American Journal of Clinical Hypnosis*, 25 (2-3), 143-149.**

Developmental theory has been the foundation for this program of relaxation-imagery therapy with its goal of increasing the efficacy of immune mechanisms, thus increasing the survival rate of children with malignancies and/or improving the comfort and quality of their lives. Three basis constructs--the impact of social stress, the positive development of attachment and the negative effects of separation and loss, and the stages of concept formation relating to the functioning of the human body, the processes of disease and death--are basic approaches to the use of imagery-relaxation as an integral part of a comprehensive care plan.

**Hilgard, Josephine R.; LeBaron, Samuel (1982). Relief of anxiety and pain in children and adolescents with cancer: Quantitative measures and clinical observations. *International Journal of Clinical and Experimental Hypnosis*, 30, 417-442.**

Children and adolescents with cancer, chiefly forms of leukemia, aged 6 to 19 years, underwent medical treatments which required repeated bone marrow aspirations, normally a painful and anxiety-provoking experience. Data were obtained in baseline bone marrow observations on 63 patients, who were then offered the opportunity to volunteer for hypnotic help in pain control. Of the 24 patients who accepted hypnosis, 9 were highly hypnotizable. 10 of the 19 reduced self-reported pain substantially by the first hypnotic treatment (the prompt pain reducers) and 5 more reduced self-reported pain by the second treatment (the delayed pain reducers) while none of the 5 less hypnotizable patients accomplished this. The latter benefitted by reducing anxiety. Short case reports illustrate the variety of experiences.

Analysis of baseline observations before any therapeutic intervention revealed age and sex differences. The difference between self-reported and observed pain was not statistically significant for patients under age 10 but was significant for the patients age 10 and older ( $p < .001$ ). There were minor but significant sex differences both in observed pain ( $p < .01$ ) and in self-reported pain ( $p < .05$ ), with the females reporting more pain.

Hoffman, Mark L. (1982/83). Hypnotic desensitization for the management of anticipatory emesis in chemotherapy. *American Journal of Clinical Hypnosis*, 25 (2-3), 173-176

A hypnotic treatment employing systematic desensitization was used to alleviate anticipatory nausea and vomiting in a middle-aged man undergoing chemotherapy for Hodgkin's Disease. After four treatment sessions, all nausea associated with chemotherapy was eliminated. Results of this treatment are compared with those of another hypnotic treatment recently reported by Redd et al (1982), and reasons for differences are discussed. [Redd, W. H., Andersen, G. V. & Minagawa, R. Y. (1982). Hypnotic control of anticipatory emesis in patients receiving cancer chemotherapy. *Journal of Consulting and Clinical Psychology*, 50, 14-19.]

LeBaron, Samuel; Zeltzer, Lonnie (1982, October). The effectiveness of behavioral intervention for reducing chemotherapy related nausea and vomiting in children with cancer. [Paper] Presented at the annual meeting of the Society for Clinical and Experimental Hypnosis, Indianapolis, IN.

Eight children (nine to seventeen years, Mean age 12.1) with cancer received behavioral intervention for chemotherapy related nausea and vomiting. Within three to five days after the administration of each course of chemotherapy, patients rated (1-10 scale; 1 = none, 10 = all the time or maximal amount) their nausea and vomiting and the extent to which chemotherapy bothered them and disrupted their daily routine. After a pre-intervention assessment of 2.5 courses of chemotherapy, patients received intervention (Mean = 2.6 courses). Significant reductions following intervention (Wilcoxon matched-pairs signed ranks test) were found in nausea ( $Z = 2.37$ ,  $p < .02$ ), vomiting ( $Z = 2.52$ ,  $p < .01$ ), bother ( $Z = 2.24$ ,  $p < .02$ ), and disruption of

activities ( $Z = 2.38, p < .02$ ). This preliminary study indicates that chemotherapy side effects can be reduced through behavioral intervention.

Lyles, Jeanne Naramore; Burish, Thomas G.; Krozely, Mary G.; Oldham, Robert K. (1982). Efficacy of relaxation training and guided imagery in reducing the aversiveness of cancer chemotherapy. *Journal of Consulting and Clinical Psychology, 50*, 509-524.

Fifty cancer patients receiving chemotherapy, 25 by push injection and 25 by drip infusion, were assigned to one of three conditions for their chemotherapy treatments: (a) progressive muscle-relaxation training plus guided-relaxation imagery; (b) therapist control, in which a therapist was present to provide support and encouragement but did not provide systematic relaxation training; and (c) no-treatment control. Patients participated in one pretraining, three training, and one follow-up session. Results indicated that during the training sessions, patients who received relaxation training, relative to patients in either of the other two conditions, (a) reported feeling significantly less anxious and nauseated during chemotherapy, (b) showed significantly less physiological arousal (as measured by pulse rate and systolic blood pressure) and reported less anxiety and depression immediately after chemotherapy, and (c) reported significantly less severe and less protracted nausea at home following chemotherapy. The attending nurses' observations during chemotherapy confirmed patient reports. In general, patients in the therapist control condition and the no-treatment control condition did not differ significantly from each other. The differences among conditions generally remained significant during the follow-up session. The data suggest that relaxation training may be an effective procedure for helping cancer patients cope with the adverse effects of their chemotherapy.

Margolis, Clorinda G. (1982-83). Hypnotic imagery with cancer patients. *American Journal of Clinical Hypnosis, 25* (2-3), 128-134.

This is a clinical report on the use of hypnotic imagery to reduce pain and discomfort in cancer patients. Deep relaxation, ego strengthening, imagery, and suggestions for changes in perception and awareness are the principal techniques used to reduce suffering and to produce a sense of well-being among cancer patients treated at different stages of disease. Hypnotic intervention involving six patients is described, with emphasis on the ease with which positive transference is established and the effectiveness with which it may be used to enhance therapeutic effects.

Meares, Ainslie (1982-83). A form of intensive meditation associated with the regression of cancer. *American Journal of Clinical Hypnosis, 25* (2-3), 114-121.

Elsewhere I have reported a number of cases of regression of cancer following intensive meditation. This type of meditation is characterized by extreme simplicity and stillness of the mind, and so differs from other forms using a mantra, awareness of breathing or visualization of the healing process. Any logical verbal

communication by the therapist stimulates intellectual activity in the patient. So communication is by un verbalized phonation, reassuring words and phrases, and most important, by touch. There follows a profound reduction in the patient's level of anxiety which flows on into his daily life. The non-verbal nature of the meditative experience initiates a non-verbal philosophical understanding of other areas of life.

Oliver, George W. (1982-83). A cancer patient and her family: A case study. *American Journal of Clinical Hypnosis*, 25 (2-3), 156-160.

In recent years, increasing numbers of mental health workers have been attempting to use techniques of psychotherapy to influence the course of malignant disease. This paper reviews in detail the course of treatment of one female patient with an inoperable malignancy and conveys a sense of the clinical experience of working intensively with a cancer patient and her family. It shows the complex levels of interaction within the patient herself, between the patient and her family, and between the therapist and her family and within the therapist himself during different phases of the therapeutic journey.

Redd, William H.; Andrykowski, Michael A. (1982). Behavioral intervention in cancer treatment: Controlling aversion reactions to chemotherapy. *Journal of Consulting and Clinical Psychology*, 50 (6), 1018-1029.

During the protracted course of cancer chemotherapy, approximately 25% of patients develop aversion reactions to treatment by becoming nauseated and/or vomiting before their chemotherapy treatments. This phenomenon has been conceptualized as a result of respondent conditioning. Since commonly used antiemetic drugs do not reliably control anticipatory nausea/emesis, behavioral techniques of control have been studied. They include hypnosis used in conjunction with guided-relaxation imagery, progressive muscle relaxation with guided imagery, and systematic desensitization. (67 ref)

Redd, William H.; Andresen, Graciela V.; Minagawa, Rahn Y. (1982). Hypnotic control of anticipatory emesis in patients receiving cancer chemotherapy. *Journal of Consulting and Clinical Psychology*, 50 (1), 14-19.

#### NOTES

Deep muscle relaxation hypnosis controlled nausea, gagging, retching in all cases. Anticipatory emesis recurred when hypnosis was not used. During subsequent sessions in which hypnosis was reinstated, anticipatory emesis was again controlled.

Redd, William H.; Rosenberger, Patricia H.; Hendler, Cobie S. (1982-83). Controlling chemotherapy side effects. *American Journal of Clinical Hypnosis*, 25 (2-3), 161-172.

Severe nausea and vomiting are commonly experienced by cancer patients after receiving chemotherapy treatments. Moreover, approximately 25% of these patients develop conditioned aversions to treatment and become nauseated before they receive their chemotherapy injections. The use of deep muscle relaxation hypnosis in conjunction with guided imagery to control pre- and post-chemotherapy nausea and emesis is discussed. Theoretical and clinical issues raised by this application of hypnosis in cancer treatment are also addressed.

Rosenberg, Simon W. (1982-83). Hypnosis in cancer care: Imagery to enhance the control of the physiological and psychological 'side-effects' of cancer therapy. *American Journal of Clinical Hypnosis*, 25 (2-3), 122-127.

The use of surgery, radiation, and chemotherapy has resulted in increased control of malignancy and prolonged survival for cancer patients. These modalities also carry significant morbidity. Normal physiological homeostasis is often altered by both the neoplasm and its treatment. The diagnosis, treatment, and social stigma of cancer exact profound psychological impact. Hypnosis effectively can control the range of both physiological and psychological 'side-effects' of cancer and its therapy. This paper will delineate those effects of hypnosis of proven value to the cancer patient. Incorporation of images into each phase of a hypnosis session will be demonstrated with an actual case history and annotated transcript. Imagery as a therapeutic modality will be discussed in general, and specific suggestions and images will be given.

Shapiro, Arnold (1982-83). Psychotherapy as adjunct treatment for cancer patients. *American Journal of Clinical Hypnosis*, 25 (2-3), 150-155

During the past ten years psychotherapy as adjunct treatment for cancer patients has become increasingly common. The use of hypnosis as an integral part of that treatment has also burgeoned. This report will follow the progress of two cancer patients in psychotherapy. While each is highly individual, the commonalities which allow treatment to be systematic will be quite apparent. The ability to minimize pain and discomfort, the ability to keep the white cell count high despite ongoing chemotherapy, and augmenting the ability of the body's immune system to fight the disease are utilized by both of the patients. All of the above are accomplished through the use of visual imagery in the trance state. Visual imagery is also used to reach feelings which patients are often unable to verbalize, and of which they often claim to be unaware. Other aspects of therapy such as the gradual shift from despair to hope and even confidence, and the development of more assertive behavior are discussed.

Reviews research on psychophysiology of cancer, effect of stress on host resistance, cancer prediction from personality traits, psychological theories of cancer aetiology, and psychological characteristics of patients with different types of neoplasms. The hypnotherapy of cancer patients is outlined in terms of its effect upon the

malignancy, relief of discomfort, and psyche of the cancer patient. Recommends direction of hypnotherapeutic treatment of cancer patients.

#### NOTES

"In summary, the radical treatment of malignancies presents a number of hypnotherapeutic opportunities. Not only can hypnotherapy help alleviate disease-related symptoms, but it can also limit some of the distressing side-effects of the treatments. The patient can gain needed hope by having the impact of his disease lessened. The hypnotherapeutic relationship also provides a useful base from which to deal with the issues of terminal illness, of death, and of dying.

"Implications for the future basically revolve around the issue of supportive hypnotherapy during radical treatment. As the use of chemotherapy of malignancies increases, there will be many opportunities for successful hypnotherapeutic interventions" (pp. 7-8).

Gardner, Gail G. (1976). Hypnosis and mastery: Clinical contributions and directions for research. *International Journal of Clinical and Experimental Hypnosis*, 24 (3), 202-214.

This paper explores the concept of mastery in relation to hypnotherapy by pulling together clinical observations and suggesting directions for research. It is suggested that a sense of mastery may enhance the effectiveness of hypnosis, either by facilitating induction, or by strengthening hypnotherapeutic suggestions, or by maintaining hypnotherapeutic gains. Moreover, the question is raised as to whether hypnotherapy, as compared with other psychotherapeutic approaches, better facilitates the development of a sense of mastery.

Clawson, T. A.; Swade, R. H. (1975). The hypnotic control of blood flow and pain: The cure of warts and the potential for the use of hypnosis in the treatment of cancer. *American Journal of Clinical Hypnosis*, 17 (3), 160-169.

Case histories show that hypnosis can control massive bleeding and pain, and it can remove warts, probably by stopping blood flow to them. We propose that blood flow to cancerous tumors can likewise be controlled, which could destroy them outright, or which control could be a useful adjunct to chemo- or radio-therapy

Sacerdote, Paul (1970). Theory and practice of pain control in malignancy and other protracted or recurring painful illnesses. *International Journal of Clinical and Experimental Hypnosis*, 18 (3), 160-180.

Recent neuroanatomical and neurophysiological experimental data suggest absence or presence of pain and changes in pain intensity as expressions of the balance between sensory (peripheral) and central (centrifugal) inputs at synaptic stations. Psychological activities by contributing to the centrifugal input influence

conduction, transduction, and perception of pain stimuli. Hypnotically induced analgesia and anesthesia are therefore acceptable as neurophysiological realities. Methods for hypnotic alterations of pain based upon these premises are described utilizing neurophysiological mechanisms, psychodynamic changes, establishment of new behavioral patterns, or changes in time-space concepts and percepts. Case presentations illustrate some of these multiple psychological and physiological approaches to pain control. (Spanish & German summaries) (28 ref.) Slater, Roger C.; Flores, Louis S. (1963). Hypnosis in organic symptom removal: A temporary removal of an organic paralysis by hypnosis. *American Journal of Clinical Hypnosis*, 5 (4), 248-255.

#### NOTES

"Summary and Conclusions. A detailed case study is reported on the use of hypnosis with beneficial results in an instance of eventually proved organic brain disease. Three other confirmatory case reports of organic disease definitely benefitted by the use of hypnosis are briefly cited.

" The first patient had been adequately studied repeatedly for organic brain disease. Because the studies led to an uncertain indefinite unconfirmed suspicion of psychogenic epilepsy, the patient was returned with a recommendation for continued treatment and observation by the author, a general practitioner. Hence, she was, after still further study for organic disease, treated symptomatically by hypnosis with beneficial results. This led to the erroneous conclusion that the patient's disability was probably functional. A sudden fatal outcome of the actual but unrecognized brain disease led to a correct but post- mortem diagnosis of astrocytoma of the brain, Grade IV.

"This report and those given to supplement it raise significant questions about the importance and value of hypnosis in organic disease. These include the challenging question of the extent to which the use of hypnosis can potentiate the natural corrective forces of the body; the need to recognize the value of hypnosis in effecting beneficial results in organic disease; the need to qualify the reliability of hypnosis as a differential diagnostic procedure in relation to psychogenic and organic disability; and the possibility and extent of the amelioration or actual correction of known organic illness" (p. 254).

Cangello, V. W. (1961). The use of hypnotic suggestion for pain relief in malignant disease. *International Journal of Clinical and Experimental Hypnosis*, 9, 17-22.

Using hypnotic suggestion, pain relief was attempted in 22 cases. 13 of these patients showed a decrease in narcotic requirements. Duration of effectiveness was from 1 week to 4 1/2 months. It is concluded that this method should be tried before resorting to either chemical or surgical procedures since it is relatively simple to perform, has no harmful complications, and is not unduly time consuming. From *Psyc Abstracts* 36:02:2II17C. (PsycINFO Database Record (c) 2002 APA, all rights reserved)

## NOTES

"At the present time it appears that there are several problems in which hypnosis is an acceptable and perhaps preferable method of anesthesia. Some of these problems include cases in which chemical analgesics and depressants are contraindicated or dangerous because of respiratory or cardiac disease. It may be indicated with patients who have demonstrated sensitivity to certain local anesthetics. Hypno-anesthesia may be used in cases in which repeated chemical anesthesia tends to have a debilitating effect on the patient with an already disturbed physiology, such as patients with thermal injuries who require multiple repeated debridements and dressings. Hypnosis may also obviate the debilitating effects of prolonged chemical anesthesia" (p. 156).

Stokvis, B. (1956). The application of hypnosis in organic diseases. *Journal of Clinical and Experimental Hypnosis*, 4 (2), 79-82.

## SUMMARY

Hypnotherapy, applied as a symptomatic treatment, is especially indicated in those cases of organic diseases in which the patient has neurotically elaborated his physical suffering. In cases presenting neither etiological nor secondary psychic factors one may try to improve the patient's condition by hypnotic treatment. Description of a case (hypnotherapy in a woman with carcinoma mammae)[sic]. The writer's lack of appreciation of hypnotherapy in organic diseases does not include the treatment of diseases which are definitely psychosomatically determined" (pp. 81-82).

## CANCER

Hendler CS, Redd WH Fear of hypnosis: The role of labeling in patients' acceptance of behavioral interventions *Behav Ther.* 1986;17(1):2-13 One hundred and five outpatient cancer chemotherapy patients were interviewed to assess their attitudes toward hypnosis and relaxation as well as to determine their beliefs in and willingness to try a behavioral procedure. Patients were randomly assigned to groups receiving identical descriptions labeled 'hypnosis', 'relaxation', or 'passive relaxation with guided imagery'. The description stressed the behavioral components of hypnosis and relaxation rather than the nonbehavioral techniques often associated with hypnosis such as age regression and posthypnotic suggestion. Patients believed hypnosis to be a powerful process that involved loss of control and altered states of consciousness. When compared with a group of college students, patients held significantly more fearful, conservative views about hypnosis. Patients who received a description of an intervention labeled 'hypnosis' were significantly less likely to believe the procedure would effectively control their nausea and vomiting and were significantly less likely to state they would try the procedure than patients in the other two label conditions. This reaction to the label occurred independently of patients' degree of nausea, vomiting, and pain due to their chemotherapy treatments.

Hockenberry-Eaton MJ. Cotanch PH. Evaluation of a child's perceived self-competence during treatment for cancer. *Journal of Pediatric Oncology Nursing* 1989;6(3):55-62 The purpose of this study was to evaluate the effect of self-hypnosis on the perceived self-competence of children undergoing treatment for cancer and to determine longitudinal differences in perception of self-competence over time. Twenty-two children were randomized into an experimental group (taught self-hypnosis) and a control group (given standard care). Data were collected using the Harter Perceived Self-Competence Profile (HPSCP) during four courses of chemotherapy. A decrease in mean scores for the control group was found compared with the hypnosis group, which showed an increase in mean scores in five of six domains. Both groups showed a statistically significant increase in the scholastic cognitive domain and social acceptance domain from the time of diagnosis compared with the second test period. Ten children had a visible physical disability. These children were found to have significant decreases in the domains of athletic competence, social acceptance, and global self-worth. Decreases remained significant throughout all test periods in the athletic competence domain for the children with a visible physical disability. This study is unique in that the researchers evaluated children's perception of self-competence over time. These findings support previous studies and identify the need for nurses to become actively involved in helping children develop effective coping skills during chemotherapy for cancer.

Jacknow DS. Tschann JM. Link MP. Boyce WT. Hypnosis in the prevention of chemotherapy-related nausea and vomiting in children: a prospective study. *Journal of Developmental & Behavioral Pediatrics* 1994;15(4):258-64 To study the effectiveness of hypnosis for decreasing antiemetic medication usage and treatment of chemotherapy-related nausea and vomiting in children with cancer, we conducted a prospective, randomized, and controlled single-blind trial in 20 patients receiving chemotherapy for treatment of cancer. Patients were randomized to either hypnosis or standard treatment. The hypnosis group used hypnosis as primary treatment for nausea and vomiting, using antiemetic medication on a supplemental (p.r.n.) basis only, whereas the control group received a standardized antiemetic medication regimen. Nausea, vomiting, and p.r.n. antiemetic medication usage were measured during the first two courses of chemotherapy. Anticipatory nausea and vomiting were assessed at 1 to 2 and 4 to 6 months postdiagnosis. Patients in the hypnosis group used less p.r.n antiemetic medication than control subjects during both the first ( $p < .04$ ) and second course of chemotherapy ( $p < .02$ ). The two groups did not differ in severity of nausea and vomiting. The hypnosis group experienced less anticipatory nausea than the control group at 1 to 2 months postdiagnosis ( $p < .02$ ). Results suggest self-hypnosis is effective for decreasing antiemetic medication usage and for reducing anticipatory nausea during chemotherapy.

Kuttner L. Bowman M. Teasdale M. Psychological treatment of distress, pain, and anxiety for young children with cancer. *Journal of Developmental & Behavioral Pediatrics* 1988;9(6):374-81 The study compared the efficacy of hypnotic "imaginative involvement," behavioral distraction and standard medical practice

for the reduction of pain, distress and anxiety in children with leukemia, during bone marrow aspirations. Two age groups of children, 3 to 6, and 7 to 10 years, were randomized to the three treatment groups. Two intervention sessions were given. At first intervention, observational ratings of distress indicated significant reductions for the younger group in the hypnotic treatment, whereas the older group achieved significant reductions in both treatment conditions for observer-rated pain and anxiety. At second intervention, all groups showed reductions and the control group appeared to be contaminated. The hypnotic method with its internal focus had an all-or-none effect, whereas distraction appeared to require that coping skills be learned over one session or more.

Rapkin DA, Straubing M, Holroyd JC. Guided imagery, hypnosis and recovery from head and neck cancer surgery: an exploratory study. *International Journal of Clinical & Experimental Hypnosis* 1991;39(4):215-26 The value of a brief, preoperative hypnosis experience was explored with a sample of 36 head and neck cancer surgery patients. 15 patients volunteered for the experimental hypnosis intervention. 21 patients who received usual care (no hypnosis) were followed through their hospital charts and were used as a comparison group. Hypnotic intervention and usual care groups were comparable in terms of relevant demographic variables. Postoperative hospitalizations for the hypnotic intervention group were significantly shorter than for the usual care group. Within the hypnotic intervention group, hypnotizability was negatively correlated with surgical complications and there was a trend toward a negative correlation between hypnotizability and blood loss during surgery. Findings suggest that imagery-hypnosis may be prophylactic, benefitting patients by reducing the probability of postoperative complications and thereby keeping hospital stay within the expected range. Recommendations are presented for a controlled, randomized, clinical trial with a sufficiently large sample to provide the opportunity for statistical analysis with appropriate power.

Richardson MA, Post-White J, Grimm EA, Moye LA, Singletary SE, Justice B. Coping, life attitudes, and immune responses to imagery and group support after breast cancer treatment. *Alternative Therapies in Health and Medicine* 1997;3(5):62-70 **BACKGROUND:** The pilot study used clinical trial methodology to differentiate the effects of imagery and support on coping, life attitudes, immune function, quality of life, and emotional well-being after breast cancer. **METHODS:** Women (N = 47) who completed treatment for primary breast cancer, excluding stage IV, were randomly assigned to standard care (n = 15) or six weekly support (n = 16) or imagery (n = 16) sessions. Self-report measures included Ways of Coping-Cancer, Life Attitude Profile, Quality of Life (FACT-B), Profile of Mood States, and Functional Support. Immune measures included natural killer cell activity, plasma neopterin, interferon-gamma, interleukins 1 alpha, 1 beta, and 2, and beta-endorphin levels. Differences between groups over time were tested using general linear models, adjusted for pretest score and covariates (age, stage, and months posttreatment). **RESULTS:** For all women, interferon-gamma increased, neopterin decreased, quality of life improved, and natural killer activity remained unchanged.

Compared with standard care, both interventions improved coping skills (seeking support) and perceived social support, and tended to enhance meaning in life. Support boosted overall coping and death acceptance. When comparing imagery with support, imagery participants tended to have less stress, increased vigor, and improved functional and social quality of life. **CONCLUSION:** Although imagery reduced stress and improved quality of life, both imagery and support improved coping, attitudes, and perception of support. The clinical implications of these changes warrant further testing.

Sellick SM, Zaza C Critical review of 5 nonpharmacologic strategies for managing cancer pain *Cancer Prev Control* 1998 Feb;2(1):7-14 **Purpose:** Health care professionals at 2 Ontario cancer centres were surveyed to determine their familiarity with, perceptions of and interest in learning more about nonpharmacological strategies for the management of cancer pain. Evidence-based education sessions were subsequently developed for the 5 strategies in which participants were most interested. This article presents the results of critical literature reviews concerning the effectiveness of the 5 strategies: acupuncture, massage therapy, hypnosis, therapeutic touch and biofeedback. **Methods:** The databases MEDLINE (1966 to June 1997) CINAHL (1982 to June 1997) and PsychoINFO Lit (1980 to June 1979) were searched systematically for randomized controlled trials (RCTs) of the 5 nonpharmacologic strategies. The authors' personal files and reference lists of relevant papers and main texts were also searched. The quality of the trials was reviewed according to established criteria. **Results:** The search yielded 1 RCT of acupuncture, 1 of massage therapy and 6 of hypnosis. The studies of hypnosis suggested that there is much support for its use in the management of cancer pain. The evidence was either lacking or less clear for the other therapies examined. **Conclusion:** Because patients use a wide variety of nonpharmacologic strategies regardless of their effectiveness, clinicians need to be familiar with available research and able to discuss those strategies for which the evidence is strong, weak or nonexistent. More research on the effectiveness of nonpharmacologic strategies for pain management is needed.

Barinaga, Marcia (1992). Giving personal magnetism a whole new meaning. Science, 256, 967.

### **NOTES**

Cited in Noetic Sciences Review, Autumn, 1992. This geobiologist has discovered that the human brain contains billions of tiny magnets--some 7 billion of them, each so small that their total weight is only one/millionth of an ounce. In magnetite-containing bacteria, the crystals are used as a compass needle which orients the bacteria with respect to the Earth's magnetic field. In birds, bees, and fish, where concentration of the mineral is a few orders of magnitude higher than he found in the human brain, it is used as a navigational aid. He plays down the possible

connection to weak electromagnetic fields that supposedly cause cancer (unless fields could induce very weak electrical fields inside the cells, disrupting cellular function). Other possible interpretations: a means for cells to store excess iron, or part of a magnetic sensing system, or a vestigial system left over in evolution from when we were more directly connected with the earth's magnetic field and may have relied on it for navigation or migratory movement.

Bayot, A.; Capafons, A.; Cardega, E. (1997). Emotional self-regulation therapy: A new and efficacious treatment for smoking.. American Journal of Clinical Hypnosis, **40** (2), 146-156.

We described emotional self-regulation therapy, a recently-developed suggestion technique for the treatment of smoking, and present data attesting to its efficacy. Of the 38 individuals who completed treatment, 82% (47% of the initial sample) stopped smoking altogether and 13% (8% of the initial sample) reduced their smoking. A follow-up at 6 months showed that 66% (38% of the initial sample) of those who had completed the treatment remained abstinent and reported minimal withdrawal symptoms or weight gain. In a no-treatment comparison group, only 8% reduced their smoking or became abstinent.

Burish, Thomas G.; Snyder, Susan L.; Jenkins, Richard A. (1991). Preparing patients for cancer chemotherapy: Effect of coping preparation and relaxation interventions. Journal of Consulting and Clinical Psychology, **59** (4), 518-525.  
Burish, Thomas G.; Snyder, Susan L.; Jenkins, Richard A. (1991). Preparing patients for cancer chemotherapy: Effect of coping preparation and relaxation interventions. Journal of Consulting and Clinical Psychology, **59** (4), 518-525.

60 cancer chemotherapy patients were randomly assigned to 1 of 4 treatments: (a) relaxation training with guided relaxation imagery (RT), (b) general coping preparation package (PREP), (c) both RT and PREP, or (d) routine clinic treatment only. All patients were assessed on self-report, nurse observation, family observation, and physiological measures and were followed for 5 sequential chemotherapy treatments. Results indicate that the PREP intervention increased patients' knowledge of the disease and its treatment, reduced anticipatory side effects, reduced negative affect, and improved general coping. RT patients showed some decrease in negative affect and vomiting, but not as great as in past studies. The data suggest that relatively simple, 1-session coping preparation intervention can reduce many different types of distress associated with cancer chemotherapy and may be more effective than often-used behavioral relaxation procedures.

Cangello, V. W. (1961). The use of hypnotic suggestion for pain relief in malignant disease. International Journal of Clinical and Experimental Hypnosis, **9**, 17-22.

Using hypnotic suggestion, pain relief was attempted in 22 cases. 13 of these patients showed a decrease in narcotic requirements. Duration of effectiveness was from 1

week to 4 1/2 months. It is concluded that this method should be tried before resorting to either chemical or surgical procedures since it is relatively simple to perform, has no harmful complications, and is not unduly time consuming. Capafons, A. (1999). Applications of emotional self-regulation therapy. In Kirsch, I.; Capafons, A.; Cardega, E.; Amigs, S. (Ed.), Clinical hypnosis and self-regulation: Cognitive-behavioral perspectives (pp. 331-349). Washington, D.C.: American Psychological Association.

**ABSTRACT:** This chapter reviews the main applications of emotional self-regulation therapy, which have received empirical support: smoking reduction, obesity, fear of flying, drug addictions, and premenstrual distress and dysmenorrhea. The logic of each treatment and main empirical results are summarized.

Clawson, T. A.; Swade, R. H. (1975). The hypnotic control of blood flow and pain: The cure of warts and the potential for the use of hypnosis in the treatment of cancer. American Journal of Clinical Hypnosis, 17 (3), 160-169.

Case histories show that hypnosis can control massive bleeding and pain, and it can remove warts, probably by stopping blood flow to them. We propose that blood flow to cancerous tumors can likewise be controlled, which could destroy them outright, or which control could be a useful adjunct to chemo- or radio-therapy.

Crasilneck, Harold B.; Hall, James A. (1962). The use of hypnosis with unconscious patients. International Journal of Clinical and Experimental Hypnosis, 10 (3), 141-144.

8 of 10 patients dying of cancer were found to continue a simple motor response to a hypnotic command, even though they revealed no other evidence of interaction with the environment and were considered unconscious by their physicians. Certain theoretical considerations are mentioned. (PsycINFO Database Record (c) 2002 APA, all rights reserved)

Crasilneck, Harold B.; Jenkins, M. T. (1958). Further studies in the use of hypnosis as a method of anesthesia. Journal of Clinical and Experimental Hypnosis, 6 (3), 152-158.

#### NOTES

"At the present time it appears that there are several problems in which hypnosis is an acceptable and perhaps preferable method of anesthesia. Some of these problems include cases in which chemical analgesics and depressants are contraindicated or

dangerous because of respiratory or cardiac disease. It may be indicated with patients who have demonstrated sensitivity to certain local anesthetics. Hypno-anesthesia may be used in cases in which repeated chemical anesthesia tends to have a debilitating effect on the patient with an already disturbed physiology, such as patients with thermal injuries who require multiple repeated debridements and dressings. Hypnosis may also obviate the debilitating effects of prolonged chemical anesthesia" (p. 156).

Dempster, C. R.; Balson, P.; Whalen, B. T. (1976). Supportive hypnotherapy during the radical treatment of malignancies. International Journal of Clinical and Experimental Hypnosis, 24, 1-9.

#### NOTES

"In summary, the radical treatment of malignancies presents a number of hypnotherapeutic opportunities. Not only can hypnotherapy help alleviate disease-related symptoms, but it can also limit some of the distressing side-effects of the treatments. The patient can gain needed hope by having the impact of his disease lessened. The hypnotherapeutic relationship also provides a useful base from which to deal with the issues of terminal illness, of death, and of dying.

"Implications for the future basically revolve around the issue of supportive hypnotherapy during radical treatment. As the use of chemotherapy of malignancies increases, there will be many opportunities for successful hypnotherapeutic interventions" (pp. 7-8).

Eimer, Bruce; Freeman, Arthur (1998). Pain management psychotherapy: A practical guide. New York NY: John Wiley & Sons, Inc..

#### NOTES

"Pain Management Psychotherapy" (PMP) provides a clear and methodical look at pain management psychotherapy beginning with the initial consultation and work-up of the patient and continuing through termination of treatment. It is a thoughtful and thorough presentation that covers methods for psychologically assessing the chronic pain patient (structured interviews, pain assessment tests and rating scales, instruments for evaluating beliefs, attitudes, pain behavior, disability, depression, anxiety, anger and alienation), treatment planning, cognitive-behavioral therapy techniques, and a range of hypnotic approaches to pain management. The book covers both traditional (cognitive and behavior therapy, biofeedback, assessing hypnotizability, choice of inductions, designing an individualized self-hypnosis exercise) as well as newer innovative techniques (e.g., EMDR, pain-relief imagery, hypno-projective methods, hypno-analytic reprocessing of pain-related negative experiences). An extensive appendix reproduces in their entirety numerous forms, rating scale, inventories, assessment instruments, and scripts.

The senior author, Bruce Eimer, states in his online comments on Amazon.com that "most therapists hold the belief that 'real' chronic pain patients are quite impossible

to help. This book attempts to dispel these misguided beliefs by providing a body of knowledge, theory, and techniques that have proven value in understanding and relieving chronic physical pain." He also states that "the challenge for the therapist is to persuade the would-ne patient/client that he or she has something to offer that can help take way pain and bring back more pleasure. This challenge is negotiated through the therapeutic relationship. However, the therapist just can't be 'warm, accepting, non-judgmental and empathic'. The therapist must also have knowledge and skills relevant to relieving pain. Only then can the therapist impart such knowledge, and in teaching these skills to the pain patient, help the patient become something of a 'self-therapist'. . . I dedicate this book to everyone who wants to find ways to make living with pain more comfortable, and to the ongoing search for better ways to relieve pain."

Gardner, G. Gail; Lubner, Alison (1982-83). Hypnotherapy for children with cancer: Some current issues. American Journal of Clinical Hypnosis, 25 (2-3), 135-142.

The authors review some of the problems that now face clinicians and researchers working in the field of hypnotherapy for pediatric cancer patients. These include (1) understanding and dealing with resistance and refusal, (2) developing preventive hypnotherapeutic strategies for children who will survive cancer, and (3) carrying out research that clarifies the value of hypnotherapy with childhood cancer patients and elucidates when and how specific approaches can best be utilized.

Gardner, Gail G. (1976). Hypnosis and mastery: Clinical contributions and directions for research. International Journal of Clinical and Experimental Hypnosis, 24 (3), 202-214.

This paper explores the concept of mastery in relation to hypnotherapy by pulling together clinical observations and suggesting directions for research. It is suggested that a sense of mastery may enhance the effectiveness of hypnosis, either by facilitating induction, or by strengthening hypnotherapeutic suggestions, or by maintaining hypnotherapeutic gains. Moreover, the question is raised as to whether hypnotherapy, as compared with other psychotherapeutic approaches, better facilitates the development of a sense of mastery.

Grant, Guy (1977). The psychophysiology and hypnotherapeutic management of cancer. Australian Journal of Clinical Hypnosis, 5, 35-49.

Reviews research on psychophysiology of cancer, effect of stress on host resistance, cancer prediction from personality traits, psychological theories of cancer aetiology, and psychological characteristics of patients with different types of neoplasms. The hypnotherapy of cancer patients is outlined in terms of its effect upon the malignancy, relief of discomfort, and psyche of the cancer patient. Recommends direction of hypnotherapeutic treatment of cancer patients.

Grossarth-Maticek, R.; Eysenck, H. J. (1991). Creative novation behaviour therapy as a prophylactic treatment for cancer and coronary heart disease: Part II - Effects of treatment. Behaviour Research and Therapy, 29, 17-31.

#### NOTES

Reports on what they call creative novation behavior therapy or "autonomy training" to prevent cancer and coronary heart disease in prone individuals. This individually tailored cognitive-behavioral program includes the use of hypnosis and of imagery. When administered individually (20-30 hours) in a group (6-15 sessions of up to several hours) or via bibliotherapy with 4-6 hours of individual therapy, the outcome was better than that of control subjects. After 13 years, 45 of 50 cancer-prone subjects in individual treatment were still alive (and none of the 5 deaths were from cancer), while among 50 control subjects, 31 died, 16 from cancer. This study along with Spiegel et al. (1989) article in Lancet have important implications for health care.

Hall, Howard R. (1982-83). Hypnosis and the immune system: A review with implications for cancer and the psychology of healing. American Journal of Clinical Hypnosis, 25 (2-3), 92-103.

This paper presents a review of the body's immune system as an introduction to a discussion of the implications of those processes for cancer and the healing mechanisms.

#### NOTES

Presents a review of the body's immune system as an introduction to a discussion of the implications of those processes for cancer and the healing mechanisms.

Hall, Marian D. (1982-83). Using relaxation imagery with children with malignancies: A developmental perspective. American Journal of Clinical Hypnosis, 25 (2-3), 143-149.

Developmental theory has been the foundation for this program of relaxation-imagery therapy with its goal of increasing the efficacy of immune mechanisms, thus increasing the survival rate of children with malignancies and/or improving the comfort and quality of their lives. Three basis constructs--the impact of social stress, the positive development of attachment and the negative effects of separation and loss, and the stages of concept formation relating to the functioning of the human body, the processes of disease and death--are basic approaches to the use of imagery-relaxation as an integral part of a comprehensive care plan.

Hallaji, J, Ja'far (1962). Hypnotherapeutic techniques in a central Asian community. International Journal of Clinical and Experimental Hypnosis, 10, 271-274. (Abstracted in Index Medicus, 63, Mar. S-543)

The semimonastic Sufi practitioners of Afganistan treat physical as well as psychosomatic disorders by a method which is reminiscent of Mesmerism, and they claim cures even for illnesses such as tuberculosis and cancer. A treatment session for 18 patients is described. (PsycINFO Database Record (c) 2002 APA, all rights reserved)

Harper, Gary W. (1999). A developmentally sensitive approach to clinical hypnosis for chronically and terminally ill adolescents. American Journal of Clinical Hypnosis, 42 (1), 50-60.

Adolescents who suffer from terminal and/or chronic medical illnesses must face difficult developmental issues coupled with increased burdens of physical discomfort and uncertainty about survival. Clinical hypnosis is one technique that can be used to help these individuals gain a sense of comfort and control over their lives. I describe the use of a developmentally sensitive hypnotherapeutic intervention for chronically and terminally ill adolescents. I have used the technique for the reduction of various types of physical and psychological discomfort secondary to a range of medical problems such as cancer, end-stage renal disease, organ transplant, and HIV disease. The treatment focuses on the use of personalized procedures that attempt to increase perceptions of control through interactive formats. Movement through a personally intriguing journey is used as a metaphor for controlling and moving away from discomfort. I also present three case examples as well as general treatment recommendations for clinical use.

Hendler, Cobie S.; Redd, William H. (1986). Fear of hypnosis: The role of labeling in patients' acceptance of behavioral interventions. Behavior Therapy, 17, 2-13.

One hundred and five outpatient cancer chemotherapy patients were interviewed to assess their attitudes toward hypnosis and relaxation as well as to determine their beliefs in and willingness to try a behavioral procedure. Patients were randomly assigned to groups receiving identical descriptions labeled "hypnosis," "relaxation," or "passive relaxation with guided imagery." The description stressed the behavioral components of hypnosis and relaxation rather than the nonbehavioral techniques often associated with hypnosis such as age regression and posthypnotic suggestion. Patients believed hypnosis to be a powerful process that involved loss of control and altered states of consciousness. When compared with a group of college students, patients held significantly more fearful, conservative views about hypnosis. Patients who received a description of an intervention labeled "hypnosis" were significantly less likely to believe the procedure would effectively control their nausea and vomiting and were significantly less likely to state they would try the procedure than patients in the other two label conditions. This reaction to the label occurred independently of patients' degree of nausea, vomiting, and pain due to their chemotherapy treatments.

Hilgard, Josephine R.; LeBaron, Samuel (1982). Relief of anxiety and pain in children and adolescents with cancer: Quantitative measures and clinical observations. International Journal of Clinical and Experimental Hypnosis, 30, 417-442.

Children and adolescents with cancer, chiefly forms of leukemia, aged 6 to 19 years, underwent medical treatments which required repeated bone marrow aspirations, normally a painful and anxiety-provoking experience. Data were obtained in baseline bone marrow observations on 63 patients, who were then offered the opportunity to volunteer for hypnotic help in pain control. Of the 24 patients who accepted hypnosis, 9 were highly hypnotizable. 10 of the 19 reduced self-reported pain substantially by the first hypnotic treatment (the prompt pain reducers) and 5 more reduced self-reported pain by the second treatment (the delayed pain reducers) while none of the 5 less hypnotizable patients accomplished this. The latter benefitted by reducing anxiety. Short case reports illustrate the variety of experiences.

Analysis of baseline observations before any therapeutic intervention revealed age and sex differences. The difference between self-reported and observed pain was not statistically significant for patients under age 10 but was significant for the patients age 10 and older ( $p < .001$ ). There were minor but significant sex differences both in observed pain ( $p < .01$ ) and in self-reported pain ( $p < .05$ ), with the females reporting more pain.

Hoffman, Mark L. (1982/83). Hypnotic desensitization for the management of anticipatory emesis in chemotherapy. American Journal of Clinical Hypnosis, 25 (2-3), 173-176.

A hypnotic treatment employing systematic desensitization was used to alleviate anticipatory nausea and vomiting in a middle-aged man undergoing chemotherapy for Hodgkin's Disease. After four treatment sessions, all nausea associated with chemotherapy was eliminated. Results of this treatment are compared with those of another hypnotic treatment recently reported by Redd et al (1982), and reasons for differences are discussed. [Redd, W. H., Andersen, G. V. & Minagawa, R. Y. (1982). Hypnotic control of anticipatory emesis in patients receiving cancer chemotherapy. Journal of Consulting and Clinical Psychology, 50, 14-19.]

Holroyd, Jean (1996). Hypnosis treatment of clinical pain: Understanding why hypnosis is useful. International Journal of Clinical and Experimental Hypnosis, 44 (1), 33-51.

Clinical and experimental research literature indicates hypnosis is very useful for severe and persistent pain, yet reviews suggest hypnosis is not widely used. To encourage more widespread clinical application, the author reviews recent controlled clinical studies in which hypnosis compares favorably with other interventions; links advances in understanding endogenous pain modulation to a neurophysiologic view of hypnosis and hypnoanalgesia; relates the neurophysiology

of hypnoanalgesia to management of chronic pain; challenges the view that hypnotic pain control is only for the highly hypnotizable patient; and raises issues about how people learn to control pain with hypnosis. Training in hypnotic analgesia may usefully enhance nervous system inhibitory processes that attenuate pain.

#### NOTES

Hypnosis has been more effective for pain management than other cognitive behavioral interventions in studies of fibromyalgia (Haanen, Hoenderdos, Van Romunde, Hop, Malle, Terwiel, & Hekster, 1991); burn treatment (Patterson, Everett, Burns, & Marvin, 1992); and cancer bone marrow transplant procedures (Syrjala, Cummings, & Donaldson, 1992). Central nervous system gating or downward modulation of pain impulses may account for hypnotic pain control. "Hypnosis enables both amplification and attenuation of cortical response subsequent to sensory registration and prior to consciousness, depending on whether suggestions are for increasing or decreasing awareness (Blum & Barbour, 1979)" (p. 36). This type of inhibition may even be observed in the peripheral nervous system (see Hernandez-Peon, Dittborn, Borlone, & Davidovich, 1959/1960; Sharev & Tal, 1989; Kiernan, Dane, Phillips, & Price, 1995). Work by Helen Crawford (1994) suggests that frontal and limbic areas of the brain are involved in inhibitory patterns of brain activity, and that generation of theta EEG rhythms by lower centers is associated with the suppression of awareness of pain.
