7-12 yr. olds received 2 role-playing tests in 1 session and London's Children's Hypnotic Susceptibility Scale (CHSS) 1 wk. later. Performances were compared to a previous sample of 42 children who had received the same tests in reverse order of administration. Means of the role test were essentially the same in both samples. 1 of the role tests, Dramatic Acting, was unrelated to hypnotic susceptibility in both samples; the other, Hypnotic Simulation, was uncorrelated with overall susceptibility in the present sample, unlike the previous one, but seemed to have inhibited 1 aspect (Subjective Involvement scores) of performance on the CHSS. Order of administration of the simulation test and CHSS also differentially affected some Overt Behavior item scores; CHSS functioned as a rehearsal for the subsequent simulation performance of low-susceptibles, and the simulation test had the same function for the CHSS performances of high-susceptibles. **Andreasen, A. G.; Singer G. (1966). Hypnosis and hypnotizability: Delusion or simulation?. International Journal of Clinical and Experimental Hypnosis, 14 (3), 257-267.**

**Because Sutcliffe (see 36:4) showed that hypnotic suggestions are not comparable in sensory content with real stimuli, the postulated difference between "pseudoperception" and "simulation" as indexed by reported subjective experiences of hypnotic Ss was tested. From 215 undergraduates, 30 high-susceptibility (HS) and 30 low-susceptibility (LS) Ss made kinesthetic and visual judgments of horizontality. A significant response, not attributable to simulation, was found only for the HS-hypnosis induction group; the effect was not attributable individually to susceptibility, hypnosis induction, or motivation. It is concluded that hypnosis, defined by this significant interaction effect between high susceptibility and hypnosis induction can be interpreted as a pseudoperceptual response to suggestion. Orne, Martin T.; Evans, Frederick J. (1966). Inadvertent termination of hypnosis with hypnotized and simulating subjects. International Journal of Clinical and Experimental Hypnosis, 14, 61-78.

6 highly hypnotizable Ss and 6 unhypnotizable Ss, instructed to simulate hypnosis, were given hypnotic instructions by means of a tape-recording. Continuous measures of subjective hypnotic depth and GSP were recorded to allow E to take the role of technician. After Ss had been hypnotized by the tape-recorder, a light went out, the tape-recorder stopped, and E rushed from the room--apparently in search of a fuse box. The Ss were observed for 30 min. through the 1-way screen. During this time the hypnotic suggestions appeared to lose their effectiveness and the hypnotized Ss gradually awoke. However, 5 of 6 simulating Ss behaved as though they were in hypnosis throughout. 5 of 6 deeply hypnotized Ss assumed that the fuse really had blown, whereas 5 of 6 simulating Ss perceived the "accident" to be part of the experiment. It was concluded that it is necessary to construct a situation in which both groups perceive the power failure to be genuine. (PsycINFO Database Record (c) 2002 APA, all rights reserved)

Brady, J. P.; Levitt, E. E. (1964). Nystagmus as a criterion of hypnotically induced visual hallucinations. Science, 146, 85-86.

Hypnotized Ss who report hallucinating a visual situation which would ordinarily elicit optokinetic nystagmus demonstrate nystagmus under these conditions. They and control Ss are unable to feign nystagmus in the waking state, either by imagining the situation or by direct efforts to simulate the eye movements. Thus an objective criterion is provided for the presence of visual hallucinations. (PsycINFO Database Record (c) 2002 APA, all rights reserved)

Shor, Ronald E. (1964). A note on shock tolerance of real and simulating hypnotic subjects. International Journal of Clinical and Experimental Hypnosis, 12 (4), 258-262.

Prior to the induction of hypnosis, Ss who later in an experiment were actually to be hypnotized selected lower criterion electric shock levels than did Ss who later were only to simulate hypnosis. This is the 1st quantified objective difference found to date between the behavior of Reals and Simulators. (PsycINFO Database Record (c) 2002 APA, all rights reserved)

1960

Sutcliffe, J. P. (1960). 'Credulous' and 'sceptical' view of hypnotic phenomena. International Journal of Clinical and Experimental Hypnosis, 8 (1), 73-102.

The author distinguishes between 2 interpretations of hypnotic phenomena: the credulous (S does or does not experience what the hypnotist suggests) and the skeptical (S reports what is suggested regardless of the "reality" of his experience). 2 groups of Ss (distinguished with respect to the presence or not of genuine hypnotic behavior and posthypnotic amnesia) were placed in a 3 [control (not under hypnotic trance), hypnotic trance, nontrance acting (S asked to act as if conditions were as suggested)] by 2 (stimulus present or not) design involving paraesthesias, hallucinations, and delusional thinking. Evidence (such as GSR, interference in thinking due to feedback, test measures of delusion) suggests that S does not misperceive the real situation, but misreports it. Yates, Aubrey J. (1960). Simulation and hypnotic age regression. International Journal of Clinical and Experimental Hypnosis, 8 (4), 243-250.

(Author's Discussion) "It is clear from the results reported above that Sutcliffe was correct in hypothesizing that Ss placed in the experimental situation described will attempt to make use of the counting method. It is equally clear that his suggestion that this artifact might account for True's (1949) results is not supported by the results of this experiment. Ss using the method in the waking state do better than chance expectations, but fall far short of the achievement of the Ss hypnotically regressed by True.

"There still remains the problem of explaining the results obtained by True (1949), and of accounting for the discrepancy between his results and those of Best and Michaels (1954). With regard to the former, the present author has suggested in a review of the literature on hypnotic age regression (Yates, in press), that the degree to which earlier habits (in this case "information") may be reactivated is a function of the degree to which those habits have been subsequently interfered with. It is arguable that simple pieces of information, although "forgotten", may lie dormant in the "memory system", but be capable of reactivation under appropriate circumstances, \_because the trace has not been interfered with by subsequent learning.\_ Complex structures, on the other hand, would be more difficult to re-evoked, because such factors as retroactive inhibition would interfere with the structure of the memory trace.

"The discrepancy between the results of True (1949) and Best and Michaels (1954) could be due to the small sample (n = 5) used by the latter compared with the former (n = 50). A more probable explanation lies, however, in differences in the hypnotic procedure used by the authors. Both Yates (in press), and Reiff and Scheerer (1959) have drawn attention to the importance of this variable. Although neither True, nor Best and Michaels, give sufficient details of their procedures, it seems possible at least that True regressed his Ss much more slowly than Best and Michaels. In other words, it may be important gradually to regress Ss back to the age level required under hypnosis, if that period is to be genuinely reinstated" (p. 249).

NOTES

The experimental task involved identifying the day of birthday at age 10, 7, and 4.

1953

Beigel, Hugo G. (1953). Prevarication under hypnosis. Journal of Clinical and Experimental Hypnosis, 1 (3), 32-40.

## NOTES

Author describes three cases in which hypnosis was used to confirm or disconfirm information provided in the waking state. All three cases involved marital relationships and mistrust. "It is interesting that, awakened from the hypnotic state, none of the subjects made the slightest attempt to deny any of the admissions made" (p. 39).

## SKIN/DERMATOLOGY

1993

Everett, John J.; Patterson, David R.; Burns, G. Leonard; Montgomery, Brenda; Heimbach, David (1993). Adjunctive interventions for burn pain control: Comparison of hypnosis and Ativan. Journal of Burn Care and Rehabilitation, 14, 676-683.

Thirty-two patients hospitalized for the care of major burns were randomly assigned to groups that received hypnosis, lorazepam, hypnosis with lorazepam, or placebo controls as adjuncts to opioids for the control of pain during dressing changes. Analysis of scores on the Visual Analogue Scale indicated that although pain during dressing changes decreased over consecutive days, assignment to the various treatment groups did not have a differential effect. This finding was in contrast to those of earlier studies and is likely attributable to the low baseline pain scores of subjects who participated. A larger number of subjects with low baseline pain ratings will likely be necessary to replicate earlier findings. The results are argued to support the analgesic advantages of early, aggressive opioid use via PCA or through careful staff monitoring and titration of pain drugs.

Forbes, E. J.; Pekala, R. J. (1993). Psychophysiological effects of several stress management techniques. Psychological Reports, 72, 19-27.

Progressive muscle relaxation and hypnosis both increased skin temperature and reduced pulse rate, and deep abdominal breathing reduced skin temperature. Hypnotic susceptibility had no effect on the psychophysiological measures.

Kraft, Tom (1993). Using hypnosis with cancer patients: Six case studies. Contemporary Hypnosis, 10, 43-48.

Hypnosis can be used in a number of different ways for helping patients suffering from cancer. As well as pain relief, hypnosis may be used to correct insomnia that does not respond to sleeping tablets; for the reduction in skin irritation and dyspnoea when these are due to organic causes, and for treatment-related over-eating. Some patients will use hypnosis in a symbolic way. When this occurs, just as in dream interpretation, it is important to ask the patient for associations, so that these symbols can be understood. Hypnosis can be an extremely useful addition to the medical armamentarium, and should be employed as an adjunct to standard forms of cancer treatment. This paper reports six case studies in which hypnosis was used to help cancer patients.

Pekala, Ronald J.; Ersek, Barrett (1993). Firewalking versus hypnosis: A preliminary study concerning consciousness, attention, and fire immunity. Imagination, Cognition and Personality, 12, 207-229.

This study assessed the subjective effects associated with firewalking, and compared them with the subjective effects associated with hypnosis and a baseline condition (eyes closed sitting quietly). Twenty-seven subjects, who walked over hot coals during a firewalk ceremony, completed

questionnaires about what they subjectively experienced during the firewalk. Their experiences were subsequently compared with those of subjects (n = 246) who experienced hypnosis and a baseline condition. The data suggested that firewalking, as assessed across all subjects, is characterized by high levels of volitional control and rationality, and a very absorbed attentional style wherein the mind is one-pointed, and consciousness is characterized by strong feelings of joy and high levels of internal dialogue. Firewalking was also found to be associated with significantly more joy, one-pointedness of thought, absorption, and internal dialogue than hypnosis or the baseline condition. In addition, a cluster analysis suggested two subgroups of firewalkers based on their subjective experiences of the firewalk. Interestingly, analyzing the attentional experiences among these firewalkers who got slightly burned, versus those who did not, revealed significant differences. A one-pointed and absorbed attentional focus may be the critical variable for the fire immunity observed in firewalking.

## NOTES

About 500 people walked across coals, in 3-4 steps. At end of weekend, 71 said they would complete a questionnaire and it was mailed to them. Of those, 27 responded (25 of 26 in an average of 23 days). Hence, 5% of the population who walked responded to the questionnaire, and it was some time later. Three of 24 reported minor blisters. Those who didn't get burned reported less detachment, less of a feeling of being out of their bodies, and more thoughts than the firewalkers who got slightly burned.

Pekala has defined an altered state of consciousness as associated with the perception of being in an altered state of awareness (the subjective sense of altered state --SSAS [30]), and a change in the patterning or configuration of the subsystems or dimensions of consciousness. A discrete state of consciousness, as defined by Pekala, is associated with a significant pattern change but no perceived alteration in state of consciousness (no SSAS). An identity state of consciousness, on the other hand, is defined as having neither a significantly perceived alteration in state of awareness nor a perceived pattern change among dimensions of consciousness in reference to another state of consciousness. Since the PCI can measure both intensity and pattern effects, it can be used to assess for altered, discrete, and identity states of consciousness.

Using a cluster analysis they found that one group of 16 subjects reported the firewalk experience to be characterized by a significant alteration in awareness and experience (body image, time sense, etc.), and significant intensities of internal dialogue, positive and negative affect, and arousal, while a second group of six subjects reported little alteration in consciousness or experience, little losses in rationality or control, and less internal dialogue, positive and negative affect or arousal than the larger group.

Whereas hypnosis is usually associated with a loss in control (the classic suggestion effect), firewalking was found to be associated with increased control, a more aroused state, and more fear! Firewalking appears to be a more absorbed and one-pointed state than even hypnosis.

The nature of attentional experience is similar across firewalkers (DAQ results).

Both firewalking and hypnosis meet the criteria for altered states of consciousness (different pattern and different subjective experience), but they are not altered states in reference to each other; they are discrete states of consciousness in reference to each other, because there is a significantly different patterning of PCI dimensions between the two conditions, but no significant SSAS. This suggests that the firewalk state is qualitatively different from the hypnotic state (as induced by the induction procedure to the Harvard Scale) and probably represents a different type of state of consciousness than hypnosis. Firewalkers obtained a lower mean hypnoidal state score than hypnosis subjects, so it does not appear that the fire immunity is due to being in a "hypnotized" state.

The fact that there appears to be two groups of successful firewalkers, one of which did not report much alteration in consciousness, calls into question the theorizing concerning the importance of alteration in state of consciousness as being etiologically related to successful firewalking. Since about 25 percent of the firewalkers clustered into what appears to be a nonaltered state of awareness, this

suggests a sizable percentage of subjects who did not report any significant alteration in consciousness and experience.

Hence, what may be important is not an alteration in consciousness, but rather an alteration in attention. The cluster analysis revealed a relatively unitary attentional state across all subjects suggesting that attention was deployed in a rather similar manner across all subjects, that is, with very high absorption and one-pointedness. It was also the DAQ dimensions, and not the PCI dimensions, that successfully discriminated a trend between the blistered and nonblistered firewalkers. Hence, high levels of one-pointedness and absorption, that is, how attention is deployed during firewalking may be more critical (than an alteration in consciousness in general) for the fire immunity observed during firewalking.

Zachariae, Robert; Bjerring, P. (1993). Increase and decrease of delayed cutaneous reactions obtained by hypnotic suggestions during sensitization. Studies on dinitrochlorobenzene and diphenylcyclopropenone. *Allergy*, 48, 6-11.

Cutaneous reactivity to challenge with dinitrochlorobenzene (DNCB) and diphenylcyclopropenone (DCP) was studied in 16 subjects following hypnotic suggestions to increase and to decrease response during sensitization. The immunoreactivity to DNCB and DCP was modulated by direct suggestions and guided imagery under hypnosis. Subjects were high in hypnotizability as measured by the Harvard Group Scale of Hypnotic Susceptibility. Measurement of skin reactions to the challenge one month after sensitization was performed double blindly. Results showed a significant (.01) difference in visually scored reactions to DCP and DNCB between the group instructed to increase reaction to DCP and decrease reaction to DNCB and the group given the opposite instructions. A nonsignificant difference (.055) in skin thickness measured by ultrasound was found between the two groups. The study supports previous reports of experimental modulation of immunoreactivity and indicates that the specific immunological processes involved in the development of all allergic reactions may be susceptible to psychological factors.

1992

Ewin, Dabney M. (1992). Hypnotherapy for warts (verruca vulgaris): 41 consecutive cases with 33 cures. *American Journal of Clinical Hypnosis*, 35, 1-10.

Published, controlled studies of the use of hypnosis to cure warts are confined to using direct suggestion in hypnosis (DSIH), with cure rates of 27% to 55%. Prepubertal children respond to DSIH almost without exception, but adults often do not. Clinically, many adults who fail to respond to DSIH will heal with individual hypnoanalytic techniques that cannot be tested against controls. By using hypnoanalysis on those who failed to respond to DSIH, 33 of 41 (80%) consecutive patients were cured, two were lost to follow-up, and six did not respond to treatment. Self-hypnosis was not used. Several illustrative cases are presented. NOTES 1:

NOTES

"I do not consider self-hypnosis necessary, and I believe it may be contraindicated. Once the change in sensation has been acknowledged by an ideomotor signal, I suggest that the subconscious will take care of healing the warts and that the patient should ignore them and get interested in other things. Self-hypnosis would require regularly giving attention to the warts, and a high rate of cure is obtained without it. In their controlled study using DSIH with adults, Johnson and Barber (1978) included daily self-hypnosis and got cures in only 3 of 11 (27%) of the hypnotic group. This is the poorest result in the published literature. Their control group of 11 patients was given waking suggestions to 'practice imagining that the specified wart(s) were tingling for a few minutes each day until they were gone' and got no change in 3 months. Hellier (1951) got remission in 27 of 74 (36%) patients just using sham x-ray, (waking suggestion without any self-hypnosis). Spanos et al. (1988) instructed their hypnotic

group to 'count their warts every day, and after each counting to close their eyes and spend 3 to 4 minutes imagining the warts on their target hand disappearing.' Only 2 of 8 patients (25%) with a single wart cleared, while 9 of 14 (69%) with multiple warts lost one or more warts at 6- weeks' follow-up. My impression is that conscious daily attention to the lesion is contrary to normal body healing of injuries such as cuts, burns, sprains, in which healing progresses best when ignored while undue attention increases suffering" (pp. 3-4).

All Ss were private patients referred for hypnotherapy; most were diagnosed clinically.

"...I found that there were sexual implications in 7 of the 16 miscellaneous warts in patients over 13, so I separated the cases into pre- and postpuberty to evaluate the results" (p. 4).

"An early success was with a medical student (Case 28) with whom I used suggestions of warmth, with the blood vessels dilating and bringing in antibodies, leukocytes, opsonins, etc. Changes were visible in 3 days. This biased me toward using 'warm,' but two of the children (Cases 6 and 9) got no result until I gave them a choice. Using ideomotor signals they chose cold. Only two healed with 'warm,' while five did with 'cold.' All of them had either had the warts cauterized or frozen previously and had a personal feeling about heat and cold. I've learned to give the patient a choice on the first visit" (p. 5).

"Three... were first treated using DSIH without result and later responded to hypnoanalysis. After obtaining an ideomotor signal that there was no more subconscious value to the warts, the suggestion was given that the body's healing processes would take over without any more conscious attention by the patient. No self-hypnosis was prescribed" (pp 7-8).

Gildston, Phyllis; Gildston, Harold (1992). Hypnotherapeutic intervention for voice disorders related to recurring juvenile laryngeal papillomatosis. International Journal of Clinical and Experimental Hypnosis, 40 (2), 74-87.

Recurring juvenile laryngeal papillomatosis is resistant to cure, and thus usually requires multiple operations which may lead to the extensive proliferation of vocal fold scar tissue. Severe hoarseness, sharply lower pitch, and weak loudness levels are common sequelae. Adjunctive hypnotherapy can increase motivation for change, speed up the acquisition of vocal skills, and possibly even facilitate or sustain remission of growths in selected patients. An 8-year-old girl with severe active eruptions went into remission after 16 sessions, and a 12-year-old boy, already in remission at the beginning of the intervention period, remained free of neoplasms throughout the regimen. Whether or not hypnosis contributed significantly to the sanguine results, it is probable that, at the least, the hypnotic intervention facilitated the achievement of certain technical objectives in voice therapy.

Hajek, P.; Jakoubek, B.; Kyhos, K.; Radio, T. (1992). Increase in cutaneous temperature induced by hypnotic suggestion of pain. Perceptual and Motor Skills, 74, 737-738.

Eight patients with atopic eczema and six healthy subjects were given hypnotic suggestion to feel pain in the upper part of the back and in one case on the palm. An average local increase in skin temperature of 0.6 degrees centigrade (detected by thermovision) occurred under this condition. For some patients cutaneous pain threshold was increased before the experiment by means of repetitive hypnotic suggestion of analgesia. These subjects reported feeling no pain subjectively, but the local change in skin temperature was equal in both cases. The results suggest a central mechanism induced by measuring changes in pain threshold in the skin, which changes are independent of local changes in blood flow. Local pain in the middle of the upper part of the back, and in one subject for comparative purposes in the region of the right palm, was induced during a single hypnotic session by specific suggestion which emphasized a subjective feeling of local pain lasting for 6 minutes. In four of the eczema patients long-lasting cutaneous analgesia was induced before this experiment by a different suggestion which stressed the impossibility of conducting pain from the skin to the brain and which

was repeated in ten consecutive hypnotic sessions. The spatial thermal reaction of the skin surface was monitored, with consecutive recordings taken at 20-sec. intervals before and after finishing the hypnotic suggestion of pain. There was a gradual increase in temperature (1.08 degrees Fahrenheit). In the four eczema patients with long-lasting cutaneous analgesia treated equally, the thermal reaction of the skin was similar to that described above although no subjective feeling of pain was reported. These subjects reported feeling only that their skin was getting warmer at the specified place.

**1991**

Hajek, P. R.; Radil, T.; Jakoubek, B. (1991). Hypnotic skin analgesia in healthy individuals and patients with atopic eczema. Homeostasis in Health and Disease, 33, 156-157.

**NOTES**

The cutaneous pain threshold was measured before, during, and after 10 sessions of hypnosis in 14 healthy and 13 atopic eczema patients. A control group of 10 healthy subjects who were not hypnotized was also evaluated. Cutaneous pain threshold increase was correlated with improvement of eczema and was correlated with hypnotizability.

**1990**

Gauld, Alan (1990). The early history of hypnotic skin marking and blistering. British Journal of Experimental and Clinical Hypnosis, 7, 139-152.

**NOTES**

Reviews the history of alleged hypnotic skin marking and blistering from 1785 to 1917. Various early studies are described and brought to bear upon certain long-standing and recurrent controversies. The conclusion is drawn that, even by the end of the period surveyed, the available evidence warranted the belief that such phenomena sometimes occur. However, there were also occasional examples of their occurrence through suggestion without hypnosis, and it remained unclear to what extent hypnosis had played a special role in their production.

Hajek, P.; Jakoubek, B.; Radil, T. (1990). Gradual increase in cutaneous threshold induced by repeated hypnosis of healthy individuals and patients with atopic eczema. Perceptual and Motor Skills, 70, 549-550.

Gradual increase in cutaneous pain threshold was found in healthy subjects and patients with atopic eczema during repeated hypnotic sessions with specific suggestions. This increase was less in the former than in the latter group. Repeated threshold measurements did not influence the threshold. The analgesic effect outlasted the hypnotic sessions by several months. It could be, however, suddenly reduced by appropriate hypnotic suggestion.

**NOTES**

Cutaneous pain threshold was measured in "time in seconds from onset of heat source of defined size, distance from skin, and temperature, to subjective threshold percept of pain" (p. 549). Used two symmetrical locations on both forearms, at healthy areas of the skin. Ten hypnotic sessions were induced in each S three times weekly, each lasting one hour.

Suggestions were the following type: "The "conduction of switch to the brain is interrupted." Your "immunologic system will digest the damaged skin cells like a shark."

Subjects were 14 healthy subjects and 13 patients with atopic eczema treated for years with the usual medications, unsuccessfully or with complications.

There was gradual increase in cutaneous pain threshold across the 10 sessions, especially for the patient group. Control experiments with repeated threshold measurements in repeated sessions without hypnosis showed no changes.

"Time of increases in cutaneous pain threshold was associated with improvement of atopic eczema. Both effects correlated significantly ( $r = 0.8$ ) with hypnotizability as measured by the Stanford scale" (pp. 549-550).

"In 9 patients without further hypnotic sessions a slow spontaneous decay of the cutaneous pain threshold was observed during a 17-mo. period. Special experiments performed with six repeatedly hypnotized healthy subjects showing increased thresholds did prove, however, that the cumulative analgesic effect could be reduced to control values immediately by using the hypnotic suggestion that the 'skin sensitivity returns to normal values.'

"These results suggest a close association between hypnosis and activation and/or deactivation of endogenous analgesic systems (irrespective of whether they are of opioid or nonopioid nature)" (p.550)

Mason, Albert A. (1990, January). A psychoanalyst looks at a hypnotist; or, where the elephant skinned boy took me. [Paper] Presented at the Psychoanalytic Center of California Scientific Meeting.

#### NOTES

"The results of working with hypnotism experimentally in the production of anaesthesia for surgery, dentistry and obstetrics; in controlled series of treatments of asthmatics, skin disorders, and allergic manifestations; as well as its clinical use, have convinced me that it is a delusional state akin to mania which depends on the omnipotent denial of mental pain. The mania is stimulated by the hypnotized subject having phantasies of an omnipotent object that it fuses with and shares in the omnipotence. The hypnotist has similar unconscious phantasies about himself. Both subject and hypnotist projectively identify with each others' phantasies, and together produce phenomena like anaesthesia which can be likened to delusional states. In fact, true hallucinations can also be deliberately produced. "I believe that similar psychotic mechanisms can also occur in life between parents and children and in other relationships, and produce delusional states. These form a continuum from intractable narcissism on the one side, through Christian Science and the denial of evolution in the center, to frank folie a deux and transexualism on the other side. The therapeutic course of these states seems quite dissimilar from that of psychosis arising without the encouragement of external objects."

Spanos, Nicholas P.; Williams, Victoria; Gwynn, Maxwell I. (1990). Effects of hypnotic, placebo, and salicylic acid treatments on wart regression. Psychosomatic Medicine, 52, 109-114.

Subjects with warts on their hands and/or feet were randomly assigned to a hypnotic suggestion, topical salicylic acid, placebo, or no treatment control condition. Subjects in the three treated groups developed equivalent expectations of treatment success. Nevertheless, at the six-week follow-up interval only the hypnotic subjects had lost significantly more warts than the no treatment controls.

Theoretical implications are discussed.

#### NOTES

Study involved 15 females, 25 males (18-35 yrs old) with warts on at least one hand or foot, recruited through posters and newspaper ads; N = 10 in each condition. Hypnotic treatment consisted of 10 minute induction (modified from T. X. Barber's 1969 book) and a suggestion for wart regression that was 2 minutes in duration (the skin around warts was 'beginning to tingle and grow warm'; 'vividly imagine the warts shrinking and dissolving away'; 30 second break; repeated the suggestions). For Ss with warts on more than one limb the complete suggestion procedure was repeated for each wart-infected limb.

Results indicate psychological factors can influence course of some virally produced disorders; that self-medicating with over-the-counter products doesn't explain suggestion-induced wart regression; that expectation of treatment success is the most important variable in psychologically induced wart regression. "Hypnotic subjects attained significantly higher CURSS:S scores than did control subjects. Nevertheless, it is unlikely that between group differences in hypnotizability accounted for the group differences in wart regression. Two previous experiments (3) that used the CURSS found that hypnotizability failed to predict wart loss in either hypnotic suggestion, nonhypnotic suggestion, or placebo treatments, and even in the present study the hypnotic treatment failed to differ from either the real or placebo treatment on CURSS:S scores, and none of the treatments differed significantly on the CURSS:O scores. Our finding and earlier findings that hypnotic subjects reported more intense suggested sensations than placebo subjects is consistent with the hypothesis that vivid suggested imagery facilitates wart loss (7, 8) .

"An alternative hypothesis emphasizes that only our hypnotic suggestion treatment encouraged subjects to see themselves as developing cognitive control over their own wart regression. This hypothesis suggests that subjects' subjective sense of cognitive involvement in and control over treatment outcome (as opposed to the vividness of their suggested imagery) may have been the important psychological factor in wart regression. It would be of interest in a future study to manipulate subjects' sense of cognitive involvement in their treatment independently of suggested imagery in order to assess the relative contributions of these variables to wart regression" (pp. 113-114).

1989

Reid, S. (1989). Recalcitrant warts: Case report. British Journal of Experimental and Clinical Hypnosis, 6, 187-189.

NOTES

Recalcitrant warts which persisted for 5 years despite treatment cleared in 51 days with hypnotherapy. A cause/effect relationship between hypnotherapy and resolution was shown by at first excluding and then including the left hand from the suggestions given.

1988

Noll, Robert B. (1988). Hypnotherapy of a child with warts. Journal of Developmental and Behavioral Pediatrics, 9 (2), 89-91.

NOTES

Child with 82 warts was treated using hypnosis; suggestions for removal from face only resulted in 8 of 16 facial warts disappearing after one treatment and two weeks. (Child had previous experience with hypnosis for pain and anxiety associated with lumbar punctures and bone marrow aspirates.)

Spanos, Nicholas P.; Stenstrom, Robert J.; Johnston, Joseph C. (1988). Hypnosis, placebo, and suggestion in the treatment of warts. Psychosomatic Medicine, 50, 245-260.

Two experiments assessed the effects of psychological variables on wart regression. In Experiment 1, subjects given hypnotic suggestion exhibited more wart regression than those given either a placebo treatment or no treatment. In Experiment 2, hypnotic and nonhypnotic subjects given the same suggestions were equally likely to exhibit wart regression and more likely to show this effect than no treatment controls. In both experiments, treated subjects who lost warts reported more vivid suggested imagery than treated subjects who did not lose warts. However, hypnotizability and attribute

measures of imagery propensity were unrelated to wart loss. Subjects given the suggestion that they would lose warts on only one side of the body did not show evidence of a side-specific treatment effect. Tsushima, W. T. (1988). Current psychological treatments for stress-related skin disorders. Cutis, **42**, 402-404.

Surveys current methods used by psychologists in the management of stress-related skin disorders, including hypnosis, relaxation training, biofeedback, operant conditioning, and cognitive behavioral therapy. These techniques offer promise in the treatment of certain dermatologic conditions, but the limited amount of well-controlled and replicated studies of their use suggests that caution be taken in their application.

**1987**

Dobkin de Rios, Marlene; Friedmann, Joyce K. (1987). Hypnotherapy with Hispanic burn patients. International Journal of Clinical and Experimental Hypnosis, **35** (2), 87-94.

This paper examines a culturally sensitive hypnotherapeutic intervention for Hispanic burn patients who suffer symptoms of the post-traumatic stress disorder and discusses the outcome of 27 patients seen by the authors (a medical anthropologist and a clinical psychologist), over a 3.5-year period. Given the difficulties of recent monolingual, Mexican migrants in responding to psychological interventions that are not culturally sensitive, the hypnotherapeutic interventions and procedures developed by the authors provide a plan for systematic desensitization and cultural concordance to make rehabilitation of Hispanic burn patients more effective.

Locke, Steven E.; Ransil, Bernard J.; Covino, Nicholas A.; Toczydlowski, Janice; Lohse, Christopher M.; Dvorak, Harold F.; Arndt, Kenneth A.; Frankel, Fred H. (1987). Failure of hypnotic suggestion to alter immune response to delayed-type hypersensitivity antigens. Annals of the New York Academy of Sciences, **496**, 745-749.

The ability to alter delayed-type hypersensitivity via hypnotic suggestion was tested in 12 highly hypnotizable, untrained subjects and 30 non-hypnotized controls. Subjects were skin tested bilaterally with a standardized panel of delayed hypersensitivity antigens and instructed either to enhance or suppress the skin test response (STR) unilaterally. Compared to controls, STR's showed no effect of hypnotic suggestion with regard to either the area of induration or the degree of inflammation assessed histologically.

Minichiello, William E. (1987). Treatment of hyperhidrosis of amputation site with hypnosis and suggestions involving classical conditioning. International Journal of Psychosomatics, **7-8**.

Hyperhidrosis of an amputation site utilizing hypnosis and/or behavioral strategies has not been reported in the literature. This case report is on the successful use of hypnosis utilizing principles of classical conditioning in the treatment of a patient with hyperhidrosis of an amputated limb with two previous unsuccessful sympathectomies. The patient possessing moderate hypnotic ability as measured by the Stanford Hypnotic Clinical Scale (SHCS), reported a pre-treatment score of 10 on a 0-10 severity and intensity of sweating scale, and a post-treatment score of 0. All gains were maintained at the two-year follow-up.

#### NOTES

The patient was hypnotized while an electric fan was blowing on his stump and prosthesis. Direct suggestions were given according to procedures of thermal biofeedback. The suggestions were: 1. You will notice in days ahead that your stump feels increasingly cooler and drier. 2. You will feel

throughout the day as if a cool breeze from a fan is blowing on your stump. 3. Whenever you pay attention to your leg during the day, particularly after the first few hours of the morning, you will associate that leg with a cool dry breeze from a fan blowing on it. 4. You will increasingly develop the power to cool and dry your stump.

The results were that 2 1/2 weeks later patient reported reduced frequency and intensity of sweating and significant healing of the stump ulcers; rating = 2. One month later, patient reported continued progress with almost normal skin color and stump condition; the patient discontinued disability, and returned to work. Patient returned one month later reporting, "It's cured and my physician can't believe it." Rating = 0.

Author concludes that hypnosis should be tried prior to more invasive traditional procedures. In this case two previous sympathectomies failed to correct the condition and a third sympathectomy was being contemplated.

Shertzer, C. L.; Lookingbill, D. P. (1987). Effects of relaxation therapy and hypnotizability in chronic urticaria. Archives of Dermatology, 123, 913-916.

15 patients with chronic urticaria of 7.8 years' average duration. Compared with baseline and control session values, the hypnosis session provided relief of pruritus as measured by 3 self-report parameters. There was no change in the number of hives. All Ss were given a standard test for hypnotizability. Assuming that the results were not biased by their preceding relaxation sessions, we determined that 6 Ss were hypnotizable and nine were non hypnotizable. Ss in both groups improved symptomatically, but hypnotizable Ss had fewer hives and became more symptomatic during the control (testing and history taking) session. Hypnotizable Ss also more frequently related stress as a causative factor. At a follow-up examination five to 14 months after the completion of the experimental sessions, six patients were free of hives and an additional seven reported improvement.

1984

Raynaud, Jeanne; Michaux, Didier; Bleirad, Guilhem; Capderou, Andre; Bordachar, Janine; Durand, Jacques (1984). Changes in rectal and mean skin temperature in response to suggested heat during hypnosis in man. Physiology and Behavior, 33, 221-226.

Rectal temperature, mean skin temperature and heart rate were recorded in 7 subjects during hypnosis, induced either alone or while sensations of heat were suggested. During hypnosis alone, a fall in the heart rate of about 10 beat-min<sup>-1</sup> was the only autonomic response observed; body temperatures were unaltered. In contrast, during hypnosis with suggestion of heat, the following changes occurred: (1) Mean rectal temperature decreased 0-.20 degrees C. (p<.05) within 50 min. Its mean time course differed significantly from that for hypnosis alone (p<0.001). (2) Comparison of individual rectal temperature time sequences showed that in fact this temperature only declined in 4 subjects out of 7, and tended to form a plateau located 0.35 degrees C below the value of the preceding waking state. Despite reinforcement of heat suggestion, the plateau continued until the end of the hypnotic trance. (3) Mean skin temperature tended to rise. (4) When hypnosis with suggestion ceased, both rectal and skin temperatures very slowly returned to their levels during the preceding waking state.

1983

Borgeat, Francois; Goulet, Jean (1983). Psychophysiological changes following auditory subliminal suggestions for activation and deactivation. Perceptual and Motor Skills, 56, 759-766.

This study was to measure eventual psychophysiological changes resulting from auditory subliminal activation or deactivation suggestions. 18 subjects were alternately exposed to a control situation and to 25-dB activating and deactivating suggestions masked by a 40-dB white noise. Physiological measures (EMG, heart rate, skin-conductance levels and responses, and skin temperature) were

recorded while subjects listened passively to the suggestions, during a stressing task that followed and after that task. Multi-variate analysis of variance showed a significant effect of the activation subliminal suggestions during and following the stressing task. This result is discussed as indicating effects of consciously unrecognized perceptions on psycho-physiological responses.

**Braun, Bennett G. (1983). Psychophysiological phenomena in multiple personalities and hypnosis. American Journal of Clinical Hypnosis, 26 (2), 124-137.**

#### NOTES

"Conclusion. As can be seen from the above example, the final common pathway, physiologic expression, which is seen in multiple personality is not bizarre when compared with physiologic changes achieved in non-multiples using hypnosis or, in certain cases, non-multiples without the use of hypnosis. A form of hypnosis/autohypnosis\* may be a common denominator. The neurophysiologic changes shown by Putnam et. al. (1982), but not observed by Coons (1982), may well have a similar explanation. The question of the neurophysiologic effect of hypnotic suggestion has not as yet been studied with appropriate controls or safeguards.

"That multiples do show significant changes in their psychophysiological response patterns cannot be denied. To consider that the psychophysiological changes of multiple personality are so rare or different as to make multiples 'freaks' is not only a disservice to them, but to medical science, since it blocks thinking. The study of multiple personality will further our understanding, theorizing, and treatment of mental and physical illness" (p. 134). "\*These terms are being used here in the generic sense" (p. 134).

**Spiegel, David (1983). Hypnosis with medical/surgical patients. General Hospital Psychiatry, 5, 265-277.**

The role of hypnosis as a tool in the treatment of problems commonly encountered among medical and surgical patients is examined. Hypnosis is defined as a change in state of mind far more akin to intense concentration than sleep. Diagnostic implications of differences in hypnotic responsivity are explored, and scales suitable for use in the clinic are examined. Uses of hypnosis in treating anxiety, pain, childbirth, psychosomatic symptoms, seizure disorders, neuromuscular dysfunction, and habits are described and evaluated. The phenomenon of hypnosis is presented as a means of exploring the mind-body relationship in a controlled fashion, providing information of diagnostic importance while at the same time allowing hypnotizable patients to intensify their concentration and interpersonal receptivity in the service of a therapeutic goal.

1982

**Credidio, Steven G. (1982). Comparative effectiveness of patterned biofeedback vs meditation training on EMG and skin temperature changes. Behaviour Research and Therapy, 20, 233-241.**

Examined whether a low arousal, relaxation pattern of frontalis EMG decreases and peripheral skin temperature increases could be attained more effectively through biofeedback or meditation training. 30 21-59 yr old females were randomly assigned to 1 of 3 groups: patterned biofeedback, clinically standardized meditation, or control. Prior to training, Ss were administered the Eysenck Personality Inventory. Each S was seen weekly for 7 sessions. Subjective experiences and time spent practicing at home were also recorded. Results indicate that the meditation group showed significantly lower EMG levels at the end of treatment than did the control group. The biofeedback group had difficulty in patterning the 2 feedback signals simultaneously. Extraverts in the control group had the highest EMG levels. The most positive subjective reports came from Ss in the meditation group. It is suggested

that meditation offers a viable alternative as a relaxation procedure, requiring little time to learn and devoid of any performance criteria levels.

Spanos, Nicholas P.; McNeil, Conrad; Stam, Henderikus J. (1982). Hypnotically 'reliving' a prior burn: Effects on blister formation and localized skin temperature. Journal of Abnormal Psychology, **91** (4), 303-305.

60 Ss who had previously been burned were "hypnotically age regressed" and given both suggestions to "relive" the burn experience and suggestions that a blister was forming. Although 17 Ss reported vividly imagining the burn events, none showed localized skin-coloration changes or evidence of blister formation. Moreover, skin temperature measured before, during, and after age regression indicated no overall suggestion effects. Nevertheless, 1 S did show differential skin-temperature response to the suggestion. This S had showed only moderate hypnotic susceptibility on the Harvard Group Scale of Hypnotic Susceptibility. (10 ref) NOTES 1:

#### NOTES

The male subject who appeared to show changes in response to the suggestion increased temperature differences between the burn site and the contralateral site from .3 degrees C before the imagining period to a maximum of 2.7 degrees C during the imagining period and decreased to 0 degrees C after the imagining period. However, temperature differences between the adjacent sites remained very small (never more than .1 degree C) throughout the session. This subject answered "no" to all seven items on the skin-sensitivity questionnaire. He testified postexperimentally to being only "slightly hypnotized" (score 1), "not at all age regressed" (score 0), and to have experienced imagery that was only 50% as vivid as the real experience. (His HGS:AS score was 8.)

#### 1980

Crosson, B. (1980). Control of skin temperature through biofeedback and suggestion with hypnotized college women. International Journal of Clinical and Experimental Hypnosis, **28** (1), 75-87.

4 groups of 9 college women attempted to raise finger temperature relative to forehead temperature during hypnosis. After a hypnotic induction, each group of Ss received 1 of the following treatments for temperature control: (a) biofeedback, (b) suggestion and imagery, (c) biofeedback plus suggestion and imagery, and (d) a relaxation, false-feedback control. Groups were initially balanced for hypnotic susceptibility. Between-subject differences in baseline temperatures were statistically controlled. After 4 training sessions, only Ss in the groups receiving biofeedback and biofeedback plus suggestion and imagery demonstrated evidence of learned temperature control, and only Ss in the biofeedback group demonstrated a significantly greater ability to control skin temperature than Ss in the control group. Changes in temperature during hypnotic induction did not appear to affect changes during the subsequent treatment. There was no significant correlation between hypnotic susceptibility and temperature control for Ss in any group, contrary to popular assumption. Future research should attempt to ascertain if combined use of biofeedback and hypnosis offers any advantages to the use of biofeedback alone.

#### 1979

Burrows, Graham D.; Collison, D. R.; Dennerstein, L. (Eds.) (1979). Hypnosis 1979. New York: Elsevier/North-Holland Biomedical Press.

Di Piano, Frank A.; Salzberg, H. C. (1979). Clinical applications of hypnosis to three psychosomatic disorders. Psychological Bulletin, **86**, 1223-1235.

Studies of hypnosis in the treatment of skin disorders, headaches, and asthma were reviewed in terms of outcomes and methodological soundness. Some studies focused on changing physiological functions, others on increasing insight in their patients, and still others on altering patients' perceptions of their symptoms. Methodological weaknesses included lack of control groups, nonrandom assignment of patients to treatment conditions, and confounding of treatment effects or lack of control for placebo effects. Additional weaknesses centered around the use of single outcome measures and the failure to assess the specific roles of mediating variables. Most of the studies reviewed showed positive treatment effects. However, there is equivocal evidence that hypnosis can directly influence autonomic functioning. Hypnosis may be valuable in facilitating one's capacity to gain insight into how one's symptoms developed and are maintained. In addition, hypnotic procedures have resulted in some success when used to indirectly alleviate symptoms by altering how individuals perceive their disorders and how these disorders affect their lives.

**1976**

Dugan, Michelle; Sheridan, Charles (1976). Effects of instructed imagery on temperature of hands. Perceptual and Motor Skills, 42, 14.

**NOTES**

Sixteen college student volunteers were involved in the research. Subjects were randomly assigned to two groups, either to warm or to cool their hands. All 10 subjects attempting to cool their hands were able to cool at least one hand, and six people cooled both hands. For those trying to warm their hands, five warmed at least one hand and one was able to warm both hands. Four people were able to cool their hands without hypnosis, conditioning, or feedback.

Clawson, T. A.; Swade, R. H. (1975). The hypnotic control of blood flow and pain: The cure of warts and the potential for the use of hypnosis in the treatment of cancer. American Journal of Clinical Hypnosis, 17 (3), 160-169.

Case histories show that hypnosis can control massive bleeding and pain, and it can remove warts, probably by stopping blood flow to them. We propose that blood flow to cancerous tumors can likewise be controlled, which could destroy them outright, or which control could be a useful adjunct to chemo- or radio-therapy.

**1974**

Hilgard, Ernest R. (1974, October). Visceral control through hypnosis. [Paper] Presented at the International Congress of Physiological Sciences, New Delhi.

NOTE The author reviews evidence of hypnosis and/or suggestion effects on skin: removal of warts, raising blisters, controlling chemically induced inflammation, modifying temperature. He concludes that although there may be dramatic results, the contributions of suggestion and hypnosis 'remain ambiguous.'

**1968**

Reid, Allen F.; Curtsinger, George (1968). Physiological changes associated with hypnosis: The effect of hypnosis on temperature. International Journal of Clinical and Experimental Hypnosis, 16, 111-119.

STUDIED THE PHYSIOLOGICAL EFFECT ON TEMPERATURE OF HYPNOSIS. UNDER NEUTRAL HYPNOSIS, 20 SS EXPERIENCED AN INCREASE OF ORAL TEMPERATURE

AVERAGING .6DEGREES F, WHICH SUBSIDED AFTER TERMINATION OF THE TRANCE. WHEN SKIN TEMPERATURE ON THE FOREHEAD, CHEST, AND HAND WERE MEASURED ON 4 SS, THERE WAS AN EVEN MORE PRONOUNCED INCREASE; MEASUREMENTS ON THE VOLAR SURFACE OF THE FOOT WERE EQUIVOCAL. CONTROL ORAL TEMPERATURE MEASUREMENTS USING RELAXATION WITHOUT HYPNOSIS SHOWED NO SIGNIFICANT INCREASE. IT IS CONCLUDED THAT NEUTRAL HYPNOSIS IS GENERALLY ACCOMPANIED BY AN INCREASE IN ORAL AND SKIN TEMPERATURE. (GERMAN + SPANISH SUMMARIES) (PsycINFO Database Record (c) 2002 APA, all rights reserved)

1965

Barber, Theodore Xenophon (1965). Physiological effects of 'hypnotic suggestions': A critical review of recent research (1960-64). Psychological Bulletin, 201-222.

Recent studies are reviewed which were concerned with the effectiveness of suggestions given under "hypnosis" and "waking" experimental treatments in alleviating allergies, ichthyosis, myopia, and other conditions and in eliciting deafness, blindness, hallucinations, analgesia, cardiac acceleration and deceleration, emotional responses, urine secretion to sham water ingestion, narcotic-like drug effects, and other phenomena. The review indicates that a wide variety of physiological functions can be influenced by suggestions administered under either hypnosis or waking experimental treatments, and direct and indirect suggestions to show the particular physiological manifestations are crucial variables in producing the effects.

Bernstein, Norman R. (1965). Observations on the use of hypnosis with burned children on a pediatric ward. International Journal of Clinical and Experimental Hypnosis, 13 (1), 1-10.

Several cases are described and observations made about the interplay of forces between staff, patient, and therapist, as well as the expectations of the patients to assess how these factors influenced the use of hypnosis. Hypnosis appears to be a particularly useful means for reaching isolated and depressed children with burns and for improving the morale of the staff team working with these children. The results may be along specific lines in terms of pain tolerance and improved eating, or in general improvement of cooperativeness and mood on the part of the child. 1964

Black, Stephen (1964). Mind and body. London: Kimber.

## NOTES

Defines psychosomatic disease as one that responds to psychotherapy. Believes only 5% are highly hypnotizable, that hypnosis is learnable in 1/2 hour, that hypnosis is not a useful treatment for psychosomatic disorders because you can't use interpretation [of unconscious]. The 'unconscious' is "... a complex of informational systems derived from such primaevial mechanisms" (p. 133). "Primaevial mind is involved in these mechanisms of genetics and immunology" (p. 133). "There is thus a 'somatic mind' which is unconscious and presumably without any means of verbalization of experience--and a 'cerebral mind' which is conscious" (p. 133). The dividing line is not clear.

Rapport is discussed on pp. 160, 169 as one of the spontaneous characteristics of hypnosis, in the absence of suggestion. The same for posthypnotic suggestion (rapport and amnesia). Spontaneous physiological changes in hypnosis relate to mind-body relationships (p. 169)

Conditioned reflex is discussed on p. 161

"...the subjective evidence indicates that a perceptual change involving any sensory modality can be produced by DSUH" [direct suggestion under hypnosis] p. 178. Suggestion can selectively affect different parts of the body p. 197.

Research: "Hypnosis is not only the most important and practical way of proving the existence of the unconscious--which is still in doubt in some circles--but is in fact the only way in which unconscious mechanisms can be manipulated under repeatable experimental conditions for purposes of investigation" (p. 152).

Mind-body is "amenability to control" Catatonia, which characterizes both animal and human hypnosis, seen in hypnosis, is induced by constriction (i.e. disorientation). The Cartesian concept of mind and body tends to confuse the issue p. 157.

Rapport is discussed (p. 157).

Suggestion (p. 159) "It was this concept of 'suggestion'--which so obviously parallels 'amenability to control' in animals--that eventually established hypnosis in the French schools of psychiatry as a state of increased suggestibility. ... still the standard definition of hypnosis in most medical psychiatric textbooks and in lay dictionaries" (p. 159).

Black (1969) did some biochemical sleuthing to learn how information transmitted by words becomes information encoded somatically, as when psychosomatic allergies flare and recede or disappear. What accounts for suggestion "curing" an allergic skin reaction in one part of the body while another part not included in the suggestion remains reactive? What accounts for the instantaneous skin allergy cure which sometimes occurs with suggestion (in 24 hours)?

Skin sensitivity tests in highly hypnotizable Ss who were also very allergic were inhibited by direct suggestion under hypnosis under highly controlled experimental conditions--and in one subject the effect (inhibition) was relatively permanent--ruling out (he suggests) a neurological mechanism. He did further experiments to examine whether the result was due to an instant neurological mechanism and a long-term endocrinal mechanism.

p. 212 He ruled out peripheral blood flow as the cause of diminished skin sensitivity (there was no change in blood flow with suggestions of heat or cold). Therefore decrease in blood flow couldn't explain in neurovascular terms the 'instant' inhibition of skin sensitivity (allergy) tests. Was it due to systemic--especially adrenal-- changes? He demonstrated increases in plasma cortisol under hypnosis with suggestions of fear. On p. 230 he summarizes the facts he established by skin sensitivity tests, plasma- cortisol studies, and histology - endocrinological.

Furieux, W. D. (1964). The heat-illusion test and the structure of suggestibility. International Journal of Clinical and Experimental Hypnosis, 12 (3), 169-180.

2 similar forms of the heat-illusion test are shown to correlate to a smaller degree than would be expected if they measure the same attribute. The 2 versions also differ in the way in which they correlate with other suggestibility tests. It is shown that linear regression techniques are not appropriate for analyzing the data concerned. The interaction of various nonlinear relationships with a difference in "difficulty," as between the 2 forms of the illusion, seems to provide an adequate explanation for the results. It is suggested that these nonlinear relationships may indicate the existence of an attribute which prevents some Ss from responding to any suggestibility test, irrespective of what the specific mechanisms of response may be. 1963

Black, Stephen; Edholm, O. G.; Fox, R. H.; Kidd, D. J. (1963). The effect of suggestion under hypnosis on the peripheral circulation in man. Clinical Science, 26, 223-230.

NOTES

"Summary. 1. The effects on the circulation in the forearm and hand of both direct and indirect suggestion under hypnosis of thermal stimuli have been studied. 2. The induction of hypnosis did not

significantly alter the forearm blood flow, but a small reduction in hand blood flow was usually observed. Pulse rate in general slowed slightly as did respiration rate. 3. The effect of body heating on forearm and hand blood flow was not modified by hypnosis. 4. Direct suggestion under hypnosis of body heating or body cooling, with and without body heating, produced only small changes. 5. The changes associated with suggestion were not related to the thermal suggestion. Whatever the suggestion, the usual response was a reduction in hand blood flow and an increase in forearm blood flow. 6. The rise of body temperature with heating was not modified by direct suggestion, under hypnosis, of body cooling. 7. No change in body temperature could be elicited by suggestion. 8. In a few experiments marked changes in forearm blood flow occurred. These appeared to resemble the changes in the circulation produced by emotional stimuli. 9. The smaller changes more frequently observed were also similar to those produced by mild emotional stimuli" (p. 229). [N.B. The Subjects were normal, healthy adults, N = 9, between 21-45 years old; highly hypnotizable, amnesic for trance.]

Paul, Gordon L. (1963). The production of blisters by hypnotic suggestion: Another look. Psychosomatic Medicine, 25 (3), 233-244.

NOTES: Presents a critical evaluation of reported attempts to produce nonherpetic skin blisters through hypnotic suggestion. Even though the majority of these reports are grossly lacking in controls, experimental design, etc., and are subject to alternative explanations, the author concludes that skin anomalies have been produced by suggestion in some instances. Additional studies of psychogenic vascular changes add credence to the possibility of central control of these phenomena. It is also concluded that these reactions do not appear to be limited only to hypnotized Ss.

## SLEEP

2002

Hammond, D. C. (2002). Treatment of chronic fatigue with neurofeedback and self-hypnosis.. NeuroRehabilitation, 16, 1-6..

A 21 year old patient reported a relatively rapid onset of serious chronic fatigue syndrome (CFS), with her worst symptoms being cognitive impairments. Congruent with research on rapid onset CFS, she had no psychiatric history and specialized testing did not suggest that somatization was likely. Neuroimaging and EEG research has documented brain dysfunction in cases of CFS. Therefore, a quantitative EEG was done, comparing her to a normative data base. This revealed excessive left frontal theta brainwave activity in an area previously implicated in SPECT research. Therefore, a novel treatment approach was utilized consisting of a combination of EEG neurofeedback and self-hypnosis training, both of which seemed very beneficial. She experienced considerable improvement in fatigue, vigor, and confusion as measured pre-post with the Profile of Mood States and through collaborative interviews with both parents. Most of the changes were maintained at 5, 7, and 9 month follow-up testing.

## NOTES

Includes hypnosis as one of the recommended interventions for pain.

1994

**Brown, Gail W.; Riddell, Rodney; Summers, David; Coffman, Brent (1994, August). Use of hypnosis by practitioners in the school setting. [Paper] Presented at the annual meeting of the American Psychological Association, Los Angeles.**

## **NOTES**

**Hypnosis is a therapeutic procedure that is appropriate for some school-age clients. Through the use of hypnosis that utilizes metaphors and imagery, children can be empowered to find unique solutions to their problems. Children enjoy the feeling of power and mastery that they have when able to perform hypnotic phenomena. They like to play magic and can be told that a finger or other body part will become numb. Because a major goal of hypnotherapy is to teach a child to be an active participant in his or her own behalf, the focus is on creating solutions and mastering the situation rather than enduring the problems. Four case studies demonstrate the utility of hypnosis in the treatment of phantom pain and nausea, sleep terror disorder, school phobia, and spider phobia. In each case, treatment goals were realized. Because the solutions were self-generated, the behavioral changes maintained over time and situation.**

**Case #1: Hypnosis was used to help alleviate phantom limb pain and nausea during chemotherapy following amputation of the right leg at the knee due to cancer in a thirteen-year-old male. The client had indicated that he loved nature and enjoyed the mountains. The metaphor described a young tree that has just begun to grow small silvery leaves. The spring floods tear the limbs and branches from the stump. The deep roots and stump of the tree are all that remain. The tree is not the same as before the flood. Its roots are stronger, its base more sturdy compared to the branches and limbs. The young tree has withstood the catastrophe of the torrent of waters and is even stronger than before. To counter the nausea and vomiting associated with chemotherapy a switch mechanism metaphor was used. The client was adroit with computers and had no difficulty picturing a switch located in his brain which could "turn off" the nausea from chemotherapy. A room contained all the unpleasant feelings that were being experienced. In this room is a light of a particular color that represents all the unpleasant sensations. Press the key on the computer that controls the switch to turn off the colored light in that room. Suggestions for healing were also given. Your body has known for years how to heal. Visualize the battle between good and bad cells and the victory of the good cells.**

**Case #2: Hypnosis was used to alleviate sleep terror disorder in a ten-year-old female. The onset of the subject's parasomnic symptomatology appeared to coincide with her starting kindergarten and her family's relocation shortly before. The initial treatment consisted of progressive relaxation, deep breathing, and the visual image of her "secret safe place." An induction utilizing a variety of images was presented. Hiking barefoot on a cool moss covered mountain trail, sitting in an alpine meadow on a warm summer afternoon, and flying proved most effective in facilitating trance. The participant was told to "Visualize all your anxiety and tension as hard grey rocks. Pick up these rocks and place them in your pockets. Go to the front porch of your "secret safe place and on the porch is a "magic hefty bag." Place your hard grey rocks that contain all your anxiety and tension in the magic bag. Once in the bag, the rocks will no longer weight you down, you will be free of any feelings of stress or tension. Your bed is magic; it is covered with a special glue which will keep you in a reclining position until you are fully rested and ready to awaken."**

**Case #3: Hypnosis was used in the treatment of school phobia in a nine-year-old male. The student experienced intense anxiety whenever separation from the primary caretaker occurred. The teacher stated that this boy experienced frequent absences and crying spells that were only relieved by phone calls to his mother or the presence of his mother next to him in class. In preparation for the intervention, the student was asked to draw a picture of how he felt inside during a panic attack. He drew a fire. He also said that only his mother could put that fire out. This information was utilized in creating a metaphor that described a house in a small town. "The mother had left, and a young boy was left alone. While at home, the boy looked out the window and saw several boys trying to burn a**

neighbor's yard! Acting quickly, he called the fire department, grabbed the fire extinguisher and unraveled the garden hose. He was able to extinguish the fire. The neighbors and friends were very happy and praised the boy's performance. When his mother heard the good news, she quickly returned home and held a celebration in his honor." Following the metaphor, hypnotherapy continued with suggestions about fire extinguishers that the subject could use to put out emotional fires.

**Case #4:** Hypnosis was used in the treatment of spider phobia. Diagnosis of phobia was made in this eleven-year-old female when the fear or avoidance behavior was distressing. The child's strained facial expressions occurred even at the thought of seeing what she described as "a creepy, crawly creature with 8 legs." Preparatory to her first induction the participant was read the story of *Charlotte's Web* (White, 1980) to facilitate the imagery for future hypnotic work. In the following session systematic desensitization was accomplished using characters from the story of *Charlotte's Web*. During the third session the subject was age regressed to the first time she remembered seeing a spider. She recalled playing in the woods outside her family home on an island and seeing a large web stretched between two trees with a very large spider in the center of its web. She was then asked to remain at that place to look closely at that spider as it was most likely Charlotte or one of Charlotte's family. Upon closer investigation she saw not only Charlotte but "teeny-tiny babies." The event was reconstructed as a happy experience. The imagery provided by *Charlotte's Web* permitted the subject to fantasize her previous frightful experience and reframe spiders as cute little "teeny-tiny" babies with admirable human qualities.

**1993**

**Becker, Philip M. (1993). Chronic insomnia: Outcome of hypnotherapeutic intervention in six cases. American Journal of Clinical Hypnosis, 36, 98-105.**

Chronic dyssomnia is highly prevalent and has multiple etiologies. Hypnotherapy has been reported as beneficial for insomnia, but the description of the subject populations has been limited. A group of patients was evaluated at a sleep disorders center for a dyssomnia that occurred on at least 3 nights per week for 6 months or more. Six patients accepted hypnotherapy for their persistent psychophysiological insomnia and other sleep disorder diagnoses. Three patients responded to two sessions of structured hypnotherapy. The three responders remained improved at 16-month follow-up. Factors that seemed to contribute to long-term response in this small group of patients included a report of sleeping at least half of the time while in bed, increased hypnotic susceptibility, no history of major depression, and a lack of secondary gain.

**1992**

**Kohen, Daniel P.; Mahowald, Mark W.; Rosen, Gerald M. (1992). Sleep terror disorder in children: The role of self hypnosis in management. American Journal of Clinical Hypnosis, 34, 233-244.**

This paper describes four children, ages 8 to 12 years, with frequent, prolonged, or dangerous disorders of arousal. None had any significant psychological or behavioral problems. Each had a polysomnogram that showed sudden arousals out of slow-wave sleep associated with complex behavior. All responded to a short course of imipramine, 20 to 60 mg at bedtime, followed by and in conjunction with training in relaxation and mental imagery (self-hypnosis). Once the correct diagnosis was made, the treatment strategy was to (1) demystify the symptom complex through education, (2) establish prompt control of the symptoms with the use of imipramine, (3) train the children in self-regulation with self-hypnosis, and (4) discontinue the medication while maintaining control of the arousals. Over a 2-3 year follow-up all children remain asymptomatic. This is the first report of successful use of self-hypnosis for the treatment of polysomnogram- proven disorders of arousal in the

pediatric population. Also reported are seven additional children who were treated equally successfully with hypnosis without the use of medication.

Lippincott, Brian (1992). Owls and larks in hypnosis: Individual differences in hypnotic susceptibility relating to biological rhythms. American Journal of Clinical Hypnosis, 34, 185-192.

In 1986 Coleman developed the Owl and Lark Questionnaire to differentiate morning people from evening people, with owl individuals being more alert during the evening phase and lark individuals being more alert during the morning phase. Rossi has hypothesized that the bimodal peaks of hypnotizability found by Aldrich and Bernstein in 1987 were caused by alterations in owl and lark circadian rhythms. In the current study I used the Harvard Group Scale of Hypnotic Susceptibility, Form A to test compliance with hypnotic suggestions among 42 graduate students at three times of the day: in the morning, in the evening, and, as a control, in the middle of the night. Owls were more hypnotizable than larks in the morning, and larks were also significantly more hypnotizable in the evening than owls. There was no difference between the two groups in the middle of the night. A possible implication of this study is that one fundamental mechanism of therapeutic hypnosis is the entrainment of psychobiological rhythms.

#### NOTES

The author tested Subjects at 8-10 a.m., 4-6 p.m., and midnight to 2 a.m. because they were the times when owls and larks could be most easily differentiated (morning and late afternoon) or were most equal (night). The goal was "to determine if individuals differentiated by the Owl and Lark Questionnaire have different peaks of hypnotizability associated with the rest phases of their biological rhythms." (P. 187).

"To control for practice effects (Cooper, Banford, Schubot, & Tart, 1967), one third of the subjects started rotating at each of the three test times and proceeded in clockwise order (morning-evening-night; evening-night-morning; night-morning-evening).

"There were at least 24 hours between tests to assure that boredom from the testing was not a factor" (p. 188).

DISCUSSION. "Rossi has extended Erickson's naturalistic approach and has hypothesized the entrainment of the ultradian biological rhythms as a possible factor in therapeutic hypnosis. ... Rossi states: 'The ultradian theory of hypnotherapeutic healing proposes that (1) the source of psychosomatic reactions is in stress-induced distortions of the normal periodicity of ultradian cycles and, (2) the naturalistic approach to hypnotherapy facilitates healing by permitting a normalization of these ultradian processes.' (Rossi, 1982, p. 23)" (pp. 189-190).

"If owls and larks were not separated, the results of this study would show no differences in hypnosis. Perhaps this is why Hollander et al. (1988) found no change in hypnotizability using a direct-suggestion measure after a 2-day training in Ericksonian techniques" (p. 190).

#### 1991

Brown, Peter (1991). Ultradian rhythms of cerebral function and hypnosis. Contemporary Hypnosis, 8, 17-24.

As a consequence of his observations of the clinical work of Milton Erickson, Ernest Rossi has proposed an 'ultradian rhythm theory of hypnosis'. Rossi demonstrated that the spontaneous changes in cognition, affect and behaviour which occur as part of the ultradian cycle (which Erickson referred to as 'the common everyday trance') are similar to the changes which occur during hypnosis. A review of studies of the phasic changes in hemispheric function suggests that ultradian changes do parallel the changes found in hypnosis.

## NOTES

Falling asleep and waking up are regulated by two separate mechanisms rather than being opposite poles of one mechanism (Winfree, 1980). Kleitman (1961) suggested a 90-min cycle, the basic rest-activity cycle (BRAC). In addition to physiological alterations, there are alterations in cognition, mood and behavior (Rossi & Cheek, 1988); vigilance (Okawa, Matousek & Petersen 1984); peripheral blood flow (Ramano & Gizdulich, 1980); respiratory amplitude (Horne & Whitehead, 1976); visual evoked potentials (Zimmerman, Gortelmeyer & Wiemann, 1983); pupillary diameter, stability and reactivity to light, and saccadic eye movements (Lavie & Kripke, 1981).

These diurnal variations may relate to hypnotic behavior. There is a recurring increase in daydream and fantasy, as well as visual imagery (Kripke & Sonnenschein, 1978). "There is evidence for a parallel recurring cognitive and emotional cycle with increased emotional responsiveness and a more subjective cognitive processing of information (Evans, 1972; Holloway, 1978; Overton, 1978; Thayer, 1987). Subjects appear to repeat the cycle approximately 16 times per day, with a range of 70-120 minutes. Kripke and Sonnenschein (1978) noted that the subjects were personally unaware of any repeating cycle in their mental lives" (p. 19).

The brainstem arousal mechanisms seem to be implicated in periodic changes in the EEG. Ultradian rhythms are "more easily detected under conditions of increased sleep need, reduced external performance demand and lowered motivation to focus externally (Broughton, 1985)" (p. 20). Sterman (1985) observed that the rhythm was most marked in resting state and disappears during complex visuomotor tasks. Relationship of EEG patterns to attentional patterns indicate there may be two different forms of attention, one for focused awareness (often thought to be associated with trance state) and the other a generalized vigilance (which would be reduced in hypnosis). Ultradian changes in consciousness reflected in the EEG may suggest increased internal absorption associated with visual imagery, a feature of the trance state.

"There has recently been a partial direct confirmation of Rossi's hypothesis. Aldrich and Bernstein (1987 [International Journal of Clinical and Experimental Hypnosis]) reported a bimodal distribution of Harvard Group Scale Hypnotic Susceptibility (HGSHS) scores when they are done at different times throughout the day. They note the parallel of the changes in HGSHS scores and the circadian variations in body temperature which suggest changes in hypnotic responsiveness coinciding with the fluctuations of physiological rhythms.

"Other support comes from some highly original work involving breathing rhythms. There are cyclic alterations in relative air flow between the left and right nostrils with an average period of 2-3 hours (Hasegawa & Kern, 1977). This nasal ultradian rhythm is correlated with an increase in contralateral cerebral hemispheric activity (Werntz, Bickford, Bloom & Shannahoff-Khalsa, 1981, 1983; Klein, Pilon, Prosser & Shannahoff-Khalsa, 1986). The alterations in hemispheric function do appear to be related to changes both in the style of cognition, particularly in an increase in vivid visual imagery, and in performance on specific tasks (Klein et al., 1986). Thus these studies support the notion of an ultradian rhythm of cerebral function which is associated with characteristic physical manifestations mediated by the autonomic nervous system. Whether or not these changes are directly related to the findings reported by Aldrich and Bernstein has yet to be established" (p. 21).

The authors conclude that "the most consistent evidence for ultradian rhythms is demonstrated by the mechanisms of the hypothalamic-limbic system and by brain-stem mechanisms that regulate arousal and attention processes (Parmeggiani, 1987); neuroendocrine regulatory mechanisms (Follenius, Simon, Brandenberger & Lenzi, 1987) and autonomic nervous system function (Bossom, Natelson, Levin & Stokes, 1983; Gordon & Lavie, 1986). These studies also suggest an ongoing dynamic interaction between cortical and subcortical structures throughout the ultradian cycle (Parmeggiani, 1987), and suggest that these interactions may be of great significance in hypnosis" (p. 21).

Clarke, J. H.; Reynolds, P. J. (1991). Suggestive hypnotherapy for nocturnal bruxism: A pilot study. American Journal of Clinical Hypnosis, 33, 248-253.

Although one can find many case reports of hypnotherapy for bruxism, there is a paucity of scientific research on the subject. This study describes the use of suggestive hypnotherapy and looks at its effectiveness in treating bruxism. Eight subjects who reported bruxism with symptoms such as muscle pain and complaints of bruxing noise from sleep partners were accepted into the study. An objective baseline of the bruxing was established using a portable electromyogram (EMG) detector attached over the masseter muscle during sleep. Hypnotherapy was then employed. Both self-reports and posttreatment EMG recordings were used to evaluate the hypnotherapy. Long-term effects were evaluated by self-reports only. The bruxers showed a significant decrease in EMG activity; they also experienced less facial pain and their partners reported less bruxing noise immediately following treatment and after 4 to 36 months.

DeKoninck, J.; Brunette, R. (1991). Presleep suggestion related to a phobic object: Successful manipulation of reported dream affect. Journal of General Psychology, 118, 185-200.

When compared with subjects who received presleep suggestions for negative affect, subjects who received positive affect suggestions had significantly higher levels of positive emotions in their dreams, rated their own dreams as more pleasant, and had significantly lower levels of anxiety, sadness, and aggression. This supports the hypothesis that presleep suggestion can be an effective technique in influencing the affective dimension of the dream.

## NOTES

"In summary, some of our recent data suggest that there are a number of interacting reliable correlates of hypnotizability ... . None relate to suggestibility in the traditional sense. ... Hypnotizability is related to the ability to process cognitive information during sleep, to the physiological ease of falling asleep, and to a dimension of subjective sleep characteristics we have labeled the 'control of sleep' (involving ... the ability to fall asleep easily and readily at will, and the tendency to take naps). Additional data have suggested that the concept of absorption can be meaningfully divided into subfactors that reflect the volitional control over the absorption process that correlates with hypnotizability in both normal and patient populations. ... (C)ontrolled absorption correlates significantly with hypnotizability in both normal and patient populations—a result that might be predicted from the concept of multiple pathways as correlates of hypnotizability (J. R. Hilgard, 1970). ... Finally, both the control-of-sleep dimension and hypnotizability relate to the reductions of symptoms and psychopathology even when psychiatric patients are not treated with hypnotic techniques" (pp. 164-165).

Somer, Eli (1991). Hypnotherapy in the treatment of the chronic nocturnal use of a dental splint prescribed for bruxism. International Journal of Clinical and Experimental Hypnosis, 39, 145-154.

A behavioral medicine case is described in which the patient was treated with a combined approach involving both hypnoanalytic and hypnobehavioral techniques. A 55-year-old man with bruxism was referred after 10 years of craniomandibular treatment because of his dependency on a dental splint prescribed for nocturnal use. A projective hypnoanalytic exploration helped to uncover and

consequently resolve an earlier conflict that had been reactivated in the patient's work situation and which had become a constant source of mental and muscular tension. The hypnoanalytic exploration was followed by a cognitive-behavioral hypnotic intervention that was tape-recorded and prescribed for bedtime practice. Pre- and posttherapy psychological, physiological, and self-report measurements corroborated the patient's sense of well being that came with his newly found ability to sleep without the dental splint. The importance of considering multiple etiological factors in the treatment of such psychosomatic disorders as bruxism is discussed.

Badia, Pietro (1990). Memories in sleep: Old and new. In Bootzin, Richard R.; Kihlstrom, John F.; Schacter, Daniel L. (Ed.), Sleep and cognition (pp. 67-76). Washington, DC: American Psychological Association.

#### NOTES

Reviews literature. Conclusion: First, with reinforcement for responding, control of learned behavior can be maintained reliably by stimuli presented during sleep. Second, when stimuli are presented 4 min or more apart, behavioral control results in little or no change in sleep structure, in daytime sleepiness, or in perceptions of sleep quality. Neither perceived wakefulness nor wakefulness as it is scored on the sleep record are necessary for responding, although stimulus/response events typically result in brief EEG or EMG change. Third, within-subject, within-night variance in responsiveness is complexly related to time of night, sleep stage, and REM/NREM cycle.

#### NOTES

Subjects were 19 male student nurses who met a criterion of having EEG alpha density of at least 40% during an eyes closed, waking condition. They slept in the laboratory for two nights in succession, while being monitored by an EEG, and were told only that sleep cycles were being studied. Suggestions were presented while they were sleeping, e.g. "Whenever I say the word itch, your nose will feel itchy until you scratch it" "Whenever I say the word pillow, your pillow will feel uncomfortable until you move it." Then they were tested by Experimenter saying the cue word ("itch" or "pillow") during subsequent REM periods later that night and again on the next night. (The suggestions were not repeated on the second night; but two new suggestions were given on the second night when possible.)

After the Subjects awakened in the morning, they were interviewed to test their memory for the events that had occurred, and also cue words were presented in the context of a word association test to assess memory indirectly by observing behavioral and physiological responses. A more detailed inquiry was made after the second night.

The results were as follows. Ss responded to a mean of 21% of cue words administered. Ss continued to demonstrate REM sleep for at least 30 seconds for 71% of all cues administered, indicating that they were not aroused by the cue. When a suggestion was successfully completed (i.e., without eliciting alpha activity) it was not repeated. However, the cue words were tested in several subsequent REM periods. Cue word testing occurred immediately (during the same REM period as the suggestion) on the same night, as well as in a later REM period, and during REM on Night 2 (after the suggestion had been given during Night 1).

Correct responses were given for 20% of immediate, 23% of delayed, and 23% of carry-over conditions. Ss did not remember the suggestion, verbal cues, or their responses when they awoke. Since Ss often responded to the cue the next night without repetition of the suggestion itself, the authors

inferred amnesia rather than forgetting had occurred. Responses were not elicited by repeating the cue word in the waking state, but appeared to be specific to the sleep condition.

Six Ss returned five months later for a third night of testing. Four had shown carryover response on Night 2 to a Night 1 suggestion. When verbal cues were presented (without re-administering the suggestion) those 4 Ss responded, even though there was no intervening waking memory about the procedure or the suggestions. Some Ss responded even more frequently than during the original two nights; hypnotic depth did not seem to account for the increased responsivity. Experimenters attempted to reverse the amnesia observed during the waking condition by using hypnosis, age regression, and other hypnotic techniques, with some positive effect. The author speculates that perhaps the techniques originally used to probe morning recall were not sufficiently sensitive. He also raises the question of whether this waking state amnesia is related to the amnesia for night dreams when people awaken in the morning.

The relationship between hypnotizability and sleep suggestibility was analyzed. Hypnotizability was measured with the Harvard Group Scale, several weeks later, by Experimenters who were blind to the Ss' rate of responding to suggestions given during sleep. More hypnotizable Ss slept through the verbal stimuli more than low hypnotizable Ss; so they slept longer and more cues could be tested. Ss who responded most frequently to sleep-induced suggestions were more responsive to hypnosis. Analysis of response rate percentage (which controls for higher number of cues administered when Ss slept longer) showed that correlations between sleep suggestibility and hypnotizability were higher for percentage of delayed responses than for percentage of immediate responses.

Analysis by type of item on the hypnotizability scales suggested that the correlation with sleep suggestibility was due to the hallucinatory-reverie and the posthypnotic- dissociative clusters of hypnotic behavior, which are more difficult kinds of items. Correlations were significant for carry-over responses but not for immediate responses. These items represent phenomena experienced by Subjects who can be deeply hypnotized. The author reports that this relationship observed between hypnotizability and response to sleep-induced suggestions was not significant in a later study by Perry et al. (1978).

This author raises a question about why high hypnotizable subjects sleep better than low hypnotizables. The 6 Ss who were least susceptible accounted for 48% of all awakenings that occurred during the 2 experimental nights; the 6 Ss who were most hypnotizable accounted for only 26% of the awakenings ( $p < .01$ ).

Because sleep learning ("hypnopedia") has been extensively practiced in Russia and Eastern Europe, especially for language learning, the author investigated language learning with nine subjects. (Hoskovec, 1966, and Rubin, 1968, have reviewed the hypnopedia literature, which suggests that only "suggestible" subjects respond; it is not clear whether "suggestible" refers to hypnotizable, or whether expectation of success is cultivated by information given in the waking state.) The nine Ss had responded to the suggestions at least twice while remaining asleep, had no waking recall of the suggestions, but were given pre-sleep instructions (increasing expectancy) that they would learn during sleep.

The verbal association material ("A is for apple; P is for palace;" etc.) was given during EEG sleep stages 2, 4, and REM. (Eight letter-word stimuli pairs were given, two per sleep stage whenever possible.) When they awakened, Ss were asked to check "any familiar word" on a list of 10 words beginning with the letter A, with the letter P, etc. So the probability was .10 for each of the eight lists that they might check one correct word by guessing. They also responded to two dummy lists containing letter-word pairs not used during sleep.

None of the dummy list words were checked, whereas 28% of the administered words were correctly checked; also, Ss selected the correct letter (without identifying the word and with instructions not to "guess") in an additional 17% of all lists. Words were rarely recalled from Stages 2 and 4, but Ss often recognized letters from those stages. False positives (incorrectly recalled words or letters) was almost

never observed. Furthermore, no control Subjects (people who had not received a presleep set that they would recall) recalled any words correctly.

It was observed that whenever words presented during REM were later recalled, a transient slower frequency alpha (10.25 Hz vs. 9.64 Hz,  $p < .01$ ) had been evoked within 30 sec after the presentation of the stimuli during sleep.

Total recall of words correlated with the Harvard Group Scale of Hypnotic Susceptibility .69 and the Stanford individually administered scale .42, for the 7 Ss administered hypnotizability tests.

The author concludes that under optimal conditions, sleep learning of relatively easy material can occur with subsequent waking recall.

## 1989

Kramer, Richard L. (1989). The treatment of childhood night terrors through the use of hypnosis - a case study: A brief communication. International Journal of Clinical and Experimental Hypnosis, 37 (4), 283-284.

Night terrors are nocturnal episodes of intense autonomic arousal which are manifested by loud shouting or screaming in terror. The sufferer is not awake and is generally completely amnesic for the episodes. Night terrors and other sleep disturbances, such as somnambulism, are disorders of arousal (Broughton, 1968; Fisher, Kahn, Edwards, & Davis, 1973; Guilleminault, 1987). A 10-year-old white male was treated for a 6-year-long bout of night terrors. The hypnotic induction consisted of the finger lowering technique where the middle 2 fingers were raised and the individual was asked to watch the fingers as they "go to sleep." He was given suggestions for dropping off to sleep gradually and for rotating cycles of sleep. The regularity and continual movement of the cycles of sleep were emphasized. He was also given direct suggestions for not dropping too quickly into an extremely deep stage of sleep. He has not had a recurrence of night terrors since that time (approximately 2 years). Psychodynamic issues are discussed as is the need for further research.

Stanton, Harry E. (1989). Hypnotic relaxation and the reduction of sleep onset insomnia. International Journal of Psychosomatics, 36, 64-68.

A hypnotic relaxation technique was compared to stimulus control and placebo conditions as a means of reducing sleep onset latency (SOL). Forty-five subjects were matched on their baseline SOL as measured through sleep diaries. They were randomly assigned to one of the three groups and experienced four weekly sessions of 30- minutes' duration, with demand effects being controlled through the use of counter- demand instructions. Data generated by the study suggested that the particular hypnotic relaxation treatment used was effective in helping Ss sleep more quickly. Neither stimulus control nor placebo groups recorded similar improvement.

## 1988

Gabel, Stewart (1988). The right hemisphere in imagery, hypnosis, rapid eye movement sleep, and dreaming: Empirical studies and tentative conclusions. Journal of Nervous and Mental Disease, 176, 323-331.

Reviews studies that have addressed the issue of whether there is an increased activation or efficiency of right-hemispheric processes during imagery, hypnosis, REM sleep, and dreaming. Evidence strongly supports the notion of increased right- hemispheric activation in simple imaginal or visual states during usual consciousness. There are also studies supporting this view of REM sleep, dreaming, and hypnotic phenomena. It is concluded, however, that the lack of adequate studies, contradictory or negative findings, and moderating variables (e.g., task difficulty, cognitive style) make it difficult to draw definitive conclusions concerning right-hemispheric processes.

1987

Nadon, Robert; Laurence, Jean-Roch; Perry, Campbell (1987). Multiple predictors of hypnotic susceptibility. Journal of Personality and Social Psychology, 53, 948-960.

Report two experiments in which various measures thought to be related to hypnotizability were analyzed by stepwise discriminant analysis.

Absorption and preference for an imagic style of thinking predicted hypnotizability. Addition of 2 other variables in Experiment 2--a Sleep-Dream score derived from Evans's Cognitive Control of Sleep Mentation subscale and Gibson's Dream Questionnaire, and the Belief in the Supernatural subscale of the Taft Experience Questionnaire--increased the correct classification of the medium-hypnotizable subjects from chance levels to 74%. Argue for a confirmatory and hierarchical approach in future studies to explore correlates of hypnotizability more fully. NOTES 1:

#### NOTES

The following notes were made at an SCEH presentation: [Robert Nadon, Hypnotizability: A Correlational Study Involving Experiential, Imagery, and Selective Attention Variables.]

Author used a number of variables that have related to hypnotizability in single measure studies to predict with a multiple  $r$ . 30 male and 30 female Ss, given Harvard (?) then screened on Form A, and finally on Form C. Classed as Low (0-2), Medium (5-10 without amnesia), and High (11-12 with amnesia).

Belicki, Kathryn; Belicki, Denis (1986). Predisposition for nightmares: A study of hypnotic ability, vividness of imagery, and absorption. Journal of Clinical Psychology, 42 (5), 714-718.

The relationships of nightmare frequency to hypnotic ability, vividness of visual imagery, and the tendency to become absorbed in fantasy-like experiences were examined. Subjects were 841 undergraduate university students who participated in group tests of hypnotic ability, after which they estimated the number of nightmares that they had experienced in the prior year. In addition, 406 of the subjects completed Marks' Vividness of Visual Imagery Questionnaire, and Rotenberg and Bowers' Absorption scale. Of the subjects, 76% reported experiencing at least one nightmare in the prior year; 8.3% indicated one or more per month. Individuals with frequent nightmares scored higher on hypnotizability, vividness of visual imagery, and absorption.

#### NOTES

620, Belicki & Bowers, 1982 ABSTRACT: Investigated the role of demand characteristics in dream change by comparing dream report change following pre- and postsleep administrations of instructions to pay attention to specific dream content. This design was based on the assumption that if presleep instructions merely distort dream reports rather than influence actual dreams, report change should be observable following a postsleep instruction. 42 undergraduates were prescreened with the Harvard Group Scale of Hypnotic Susceptibility (Form A), which allowed experimenters to examine the role of hypnotizability in dream change. Significant differences were observed only following the presleep instructions. It is concluded that report distortion as a result of paying attention to a dimension of dream content was insufficient to account for dream report change following presleep instructions. Hypnotic ability correlated significantly with the amount of dream change.

Kissin, Benjamin (1986). Conscious and unconscious programs in the brain. (1 ). New York: Plenum Press.

## NOTES

Hypnosis is discussed in terms of inhibition/excitation mechanisms in the central nervous system, with both feedback and feedforward controls and lateralizing controls. The author employs a concept of engrams (neural representations of an idea, represented throughout the neocortex) to discuss sensation and perception as well as conscious and unconscious processes. Sensory information is processed serially with encoding of information mostly on the conscious level (but sometimes, less efficiently, on the unconscious level); and it also is processed in parallel. Parallel processing operates almost entirely at the unconscious level and is basic to perception.

Associative phenomena are explained in terms of overlapping engrams, so that two 'related hypercomplex engrams' could be assumed to have at least one simple engram in common. With Premack, he describes three types of engrams: veridical (primary sensory data perceived), abstract (formalized representations of concepts like line drawings of dog or house; Premack's iconic representations), and symbolic (more complex entities that encompass an entire class of objects, actions, or ideas and may have artificial symbols such as words).

With Neiser he suggests that thinking (verbal and nonverbal) involves logical sequential processing of cognitive engrams of external (environmental), internal (visceral), and intracerebral (ideational) origin. Evoked response investigations shed light on the nature of such engrams, their distribution in brain tissue. John, Bartlett, Slumokochi, & Kleiman (1973) found that an error in choice discrimination learning (cats learning colors) is accompanied by the cortical evoked potential of the stimulus associated with that (erroneous) behavior, not the evoked potential of the true stimulus. In other words, ERPs represented the idea, not the actual visual stimulus provided to the cat.

Emotional/motivational influences are part of every cognition (R. S. Lazarus's position). Interaction of motivational-emotional and cognitive engrams seems to occur primarily in the inferior temporal lobe and the entorhinal cortex. The interaction involves the upper rhinencephalon, the amygdaloid-hippocampal complex, the septal region, the cingulate gyrus, and the inferior and medial aspects of temporal lobe of the cortex. He also explains classical and operant conditioning (on pp. 75-76) in terms of the association of engrams.

The author's position is that consciousness is the subjective equivalent of brain activity in the 'alerting' and 'awareness' systems. Awareness of the environment ('general, vague') appears to involve the limbic area (thalamus and basal ganglia), while more specific awareness of the self entails a system stretching from the basal ganglia through the parietal lobe (posterior aspect).

Normal alert consciousness involves the noradrenergic reticular activating system, as well as associated excitation of the general awareness system in the involved thalamic- basal gangliar nuclei and the self-awareness system in the posterior inferior parietal lobe system. Altered states of consciousness characterized by a relaxed hazy sense of the world involves thalamic activation of the self-awareness system. Dreaming involves activation from cholinergic cells in the pons. "Impaired general awareness occurs with lesions of the thalamic-basal gangliar centers while impaired self-awareness occurs with lesions in the posterior inferior parietal lobes. Finally, in certain physiological states such as sleep, hypnosis, and so on, the entire awareness system--the thalamic-basal gangliar and posterior inferior parietal nuclei--may be activated by different activation systems, such as the cholinergic in the pons or the dopaminergic in the thalamus, to produce different states of consciousness" (p. 82).

Consciousness is described as having seven dimensions: alertness, attention, arousal (heart rate, GSR), activation (EEG, evoked potential), affect, and the two awarenesses. The seven are related, so that changes in any one usually are correlated with changes in others (though dissociation among the seven

also can be demonstrated). Motivational-emotional arousal produces electrophysiological activation of the brain, which is translated epiphenomenally into alertness and awareness; awareness is focused through attention onto the cognitively and motivationally significant events in the internal and external environments to determine the final sequence of drive-oriented behavioral responses.

The EEG is useful for diagnosing different states of consciousness: beta and gamma waves alertness, stemming from locus coeruleus and

reticular activating system delta (2-4/sec) waves coma alpha synchronized relaxing influences stemming from

thalamus; low level of awareness as in twilight sleep or hypnagogic states theta, delta inactivity due to less stimulus from locus coeruleus

reticular activating system influences; associated with increased inhibitory thalamic and septal-hippocampal impulses radiating upward to the

cortex. In some altered states of consciousness there is theta-wave activity, indicating influences from the inhibitory septal-hippocampal circuit.

The reticular activating system (RAS) and thalamus interact in complex ways. The RAS is essential to maintain consciousness, but if destroyed stepwise (in animal research) a low-grade type of consciousness can be maintained by thalamus and basal ganglia. The thalamus has two kinds of influence: it inhibits the cortex, as in sleep; and stimulates the cortex in the form of activating alpha waves. "The median thalamus is also related in a feedforward-feedback circuit with the inhibitory septal-hippocampal complex which generates theta-wave activity, thus accounting for the close association between alpha and theta wave activity in sleep and in other altered states of consciousness" (p. 86).

Thus there are two different activating systems originating in the lower brain stem: the norepinephrine locus coeruleus system that is associated with normal behavior, and the cholinergic FTG neurone system of REM sleep. The relationship of the latter to consciousness, awareness, self awareness, etc. is unknown, since the only time that it is readily observed is during REM sleep. The author reports that altered states of consciousness (e.g. hypnosis, fugue, alpha state) resemble Stage 1 sleep, rather than REM sleep, physiologically, with the central locus of activation in the medial thalamus rather than the RAS and locus coeruleus.

"It appears then that consciousness may be driven by one or another of three different activation centers: the norepinephrine RAS (emanating from the locus coeruleus), the cholinergic FTG cell system in the pons, and the dopaminergic alpha rhythm system radiating upward from the thalamus (Fig. 6-2). Brain activation by each of these centers is associated with a different state of awareness" (p. 91). The relative contribution from each center determines qualitative aspects of awareness.

The author refers to Mesulam and Geschwind (1978) who traced the self-awareness system from amygdala/hippocampus/midbrain to the inferior parietal lobe where they converge with the body's proprioceptive neural tracts. What results is "a sense of self that was not necessarily present in the sense of general awareness stemming from the median thalamic-basal gangliar complex" (p. 97).

The thalamic-basal gangliar complex is both a center for emotional reception and a relay station for somatosensory events. Both somatic sensory reception and somatosensory elements of emotion are also represented in the parietal lobe. "Affective and somatosensory stimuli, which are constant and persistent even though we are unaware of them most of the time, produce the sense of one's body which is the most basic element in the 'sense of self.'... It is most probable that a major component of the sense of self is produced by the constant barrage of affective and somatosensory stimuli converging from all parts of the body; the majority of these stimuli may not reach consciousness most of the time but they must register a sense of feeling in the thalamus and parietal cortex even though the individual may be unconscious of it" (p. 100).

The author presumes that most of the incoming stimuli that define self are unconscious. "Whether sense-of-self stimuli are unconscious because of constant habituation ... or whether they are

unconscious because they are transmitted predominantly to the right hemisphere ..., it appears that the major components of the self- concept are unconscious rather than conscious" (p. 102).

"Even the acutely self-aware component of the self-concept, by definition conscious, varies markedly in different altered states of consciousness. The conscious awareness of oneself in the alert condition is different from (1) that in the twilight state, (2) that in dreams, (3) that in hypnosis, (4) that under the influence of alcohol, (5) that under the influence of other sedatives, (6) that under the influence of stimulants, and (7) that under the influence of hallucinogens. In that sense the acute sense of self is a function of the momentary chemical and physiological state of the brain" (p. 102).

" ... the decision-making apparatus of the brain is lodged largely in a consortium of neocortical centers including the prefrontal lobes (integration), the posterior inferior lobes (motivation and emotion), the anterior and posterior associational areas (cognition), the posterior inferior parietal lobes (self-awareness), the left-hemispheric language centers (language), and the precentral frontal lobe motor area (motor). Within the context of this integrated cortical complex, self-awareness functions are somewhat stronger on the right hemisphere while language and decisional activities are somewhat stronger on the left" (pp. 102-103).

The Chapter titled "Attention as directed consciousness" is relevant for investigations of hypnosis but is not included in these notes.

1984

Nugent, William R.; Carden, Nick A.; Montgomery, Daniel J. (1984). Utilizing the creative unconscious in the treatment of hypodermic phobias and sleep disturbance. American Journal of Clinical Hypnosis, 26 (3), 201-205.

An Ericksonian hypnotherapeutic procedure is designed to access and direct creative unconscious processes toward the creation and implementation of satisfactory solutions to recurrent problem behaviors. The use of the procedure is described in 3 cases. Two of the cases involve treatment of severe hypodermic needle phobias. The third case involves use of the procedure in treatment of a somnambulistic sleep disturbance. Possible curative forces tapped by the procedure, suggestions for its continued use, and suggestions for further investigation of the procedure are also discussed.

## NOTES

The procedure involved: 1. Pretrance discussion of unconscious mental processes 2. Hypnosis, followed by "Now your unconscious mind can do what is necessary, in a manner fully meeting all your needs as a person, to insure that [desired therapeutic outcome], and as soon as your unconscious knows that you will [desired therapeutic outcome] it can signal by [appropriate ideomotor signal]" 3. Post-ratification. Example: "'Now your unconscious mind can do what is necessary, in a manner fully meeting all your needs as a person, to insure that you remain comfortably awake and alert anytime you receive an injection in the future, and as soon as your unconscious knows you will remain comfortably awake and alert when receiving an injection it can signal by lifting your right hand into the air off the chair.' This suggestion was [their] communicative effort to access and direct unconscious processes to the creation and implementation of altered behavioral responses to injections. Three minutes after the suggestion, B's right hand lifted jerkily into the air. She was then awakened and experienced a complete amnesia for the trance period" (p. 203).

"[They] then carried out a procedure to ratify the therapeutic change. This process presumably further develops expectancy of change, confirms change at the unconscious level, and puts doubt into any conscious beliefs contrary to positive change. This step is standardly carried out as was done with B. [They] had B sit with her hands resting on the arms of the chair. [They] told her they would ask her unconscious mind a question that only it would know the answer to. It could answer 'yes' to the question by lifting her left hand, 'no' by lifting her right hand, and 'I don't know' or 'I don't want to

answer' by lifting both hands. Then the question was asked, 'In the future, will B remain comfortably awake and alert anytime she receives an injection or a blood test?' After a few minutes her left hand jerked momentarily into the air. After some discussion about the ideomotor response and her trance experience they dismissed her with the prescription to 'await the surprising results'" (p. 203).

The authors cite as a source for their work two books: Erickson, Rossi, and Rossi, *Hypnotic Realities*, 1976, pp. 226-230; also Erickson & Rossi, *Hypnotherapy*, 1979.

1983

Woolfolk, Robert L.; McNulty, Terrence F. (1983). Relaxation treatment for insomnia: A component analysis. *Journal of Consulting and Clinical Psychology*, 51 (4), 495-503.

Four relaxation treatments for sleep onset insomnia were compared with a waiting-list control. Treatments were varied in the presence or absence of muscular tension-release instructions and in the use of either images or somatic sensations as foci of attention. Analysis of data from 44 insomniacs recruited from the community showed all treatment conditions to be superior to no treatment in reducing latency of sleep onset and ratings of fatigue. The presence of muscle tension-release was unrelated to outcome. There was a nonsignificant trend for visual imagery treatments to be superior to somatic- focusing treatments in reducing sleep onset latencies. Treatments employing visual focusing were superior to somatic-focusing treatments in reducing the number of nocturnal awakenings. At 6 months follow-up only the imagery treatments showed significant improvement over pretreatment levels on latency of sleep onset. Visual- focusing treatments produced significantly greater reductions in sleep onset latency at follow-up than did the somatic-focusing treatments. Results are discussed in light of previous research addressing the mechanisms underlying the treatment of insomnia by relaxation methods.

1982

Belicki, Kathryn; Bowers, Patricia (1982, October). Dimensions of dissociative processing, absorption and dream change following a presleep instruction. [Paper] Presented at the annual meeting of the Society for Clinical and Experimental Hypnosis, Indianapolis, IN.

NOTES

Subjects' tendency to have things pop into their mind when asked to imagine, image them, or to do a divergent thinking task is correlated with behavior change out of awareness (dissociated), change in dream content in response to indirect suggestion - the request to pay attention to a certain element in their dreams. Effortless imagining (as opposed to working at it), a particular type of dissociative phenomenon, is associated with dream change.

Stam, Henderikus J.; Spanos, Nicholas P. (1982). The Asclepian dream healings and hypnosis: A critique. *International Journal of Clinical and Experimental Hypnosis*, 30 (1), 9-22.

The present paper critically evaluates the popular contention that the dream healings which occurred in antiquity at the Asclepian temples resulted from the unwitting use of hypnosis. This contention is found wanting and it is argued instead that these reported healings can be understood better by considering them in their cultural context.

1981

Nardi, T. J. (1981). Treating sleep paralysis with hypnosis. *International Journal of Clinical and Experimental Hypnosis*, 29 (4), 358-365.

The use of hypnosis in the management of sleep paralysis is described and discussed. 2 cases are presented in which autohypnosis was used to desensitize the patients to the anxiety that accompanied their sleep paralysis. The autohypnosis also provided a means of terminating the attacks. Follow-up data suggests that this approach may serve to decrease the frequency of sleep paralysis attacks.

1980

Bauer, K. E.; McCanne, T. R. (1980). An hypnotic technique for treating insomnia. International Journal of Clinical and Experimental Hypnosis, 28 (1), 1-5.

A technique for treating insomnia with short-term hypnotherapy is presented. 2 cases are presented to illustrate the clinical application of the technique. The treatment procedure, which incorporates the demand characteristics of the therapeutic setting, positive expectancies, a reduction in physiological arousal, and a reduction of excessive cognitive activity is discussed in terms of current theories of insomnia.

Schneck, Jerome M. (1980). Hypnotherapy for narcolepsy. International Journal of Clinical and Experimental Hypnosis, 28 (2), 95-100.

The effective use of hypnotherapy for control of narcoleptic sleep episodes experienced by a 40-year-old woman is described. Measures included posthypnotic suggestions for deliberate and automatic hand movements by the patient, serving as signals to ward off sleep attacks. Such signals within visual imagery were also incorporated into treatment. Narcolepsy and the narcoleptic tetrad are described in pertinent detail. The hypnotic measures presented here can serve as a guide for efforts by other therapists to deal with this problem. So far as the present author knows, hypnotherapy for narcolepsy has not been discussed previously in scientific literature.

1979

Crasilneck, Harold B. (1979). Hypnosis in the control of chronic low back pain. American Journal of Clinical Hypnosis, 22, 71-78.

Twenty-nine patients were referred because of low back pain. Five were excluded on psychological grounds because they were highly masochistic, extremely depressed, or manifested a low frustration tolerance. Of the 24 in the treatment group, 18 of the patients had surgery two or more times, and six one time. In each case low back pain returned within three to six months after surgery. Twenty of the patients were addicted to or excessively dependent on medications including acetaminophen, secobarbital, codeine phosphate, oxycodone hydrochloride, and morphine sulphate. Common factors among the patients included (1) consistent pain which was primarily organic in origin, (2) analgesic dependence, (3) insomnia, (4) reactive depression, (5) excessive interpersonal dependence, and (6) a fear of becoming a lifelong 'backache cripple.' Twenty patients responded positively; four patients failed to respond to the repeated hypnotic induction techniques and were considered failures. Sixteen reported an average of 80% relief during the first four sessions, and all 20 patients reported an average of 70% relief (based on verbal estimates by patients) by the sixth session. Fifteen voluntarily discontinued medication by the third week of therapy, and the rest were withdrawn by their physicians during the ensuing four weeks. Most patients were seen daily the first week, three times the second week, twice the third week, and thereafter as necessary. The mean number of out-patient sessions was 31 over an average of nine months. All patients were taught self-hypnosis. None of the individuals retained their addiction, and only occasionally did they require analgesics. Patients were seen by their referring physicians as needed during the course of hypnotherapy, and frequent consultations between the therapists created a combination of treatments best suited for each patient. It is concluded that

hypnosis may be utilized maximally as an important adjunct to other therapeutic methods in the treatment of low back pain.

Turner, Ralph M.; Ascher, L. Michael (1979). Controlled comparison of progressive relaxation, stimulus control, and paradoxical intention therapies for insomnia. Journal of Consulting and Clinical Psychology, 47 (3), 500-508.

Assessed the effectiveness of treatment programs based on progressive relaxation, stimulus control, and paradoxical intention in the context of sleep difficulties for 50 volunteer Ss. The results indicate that each of the therapeutic procedures significantly reduced sleep complaints in contrast to placebo and waiting list control groups. No differences were observed among the 3 active techniques. (1 1/2 p ref).

1977

Schneck, Jerome M. (1977). Sleep paralysis and microsomatognosia with special reference to hypnotherapy. International Journal of Clinical and Experimental Hypnosis, 25, 72-77.

Sleep paralysis is described in connection with a patient whose episodes incorporated the experience of her entire body feeling extremely small. The psychological implications of the paralysis and her microsomatognosia are discussed. Comparisons are made with other perceptual distortions involving the sense of change in body size. The characteristics of sleep paralysis and associated personality patterns are delineated. This material is discussed with special reference to experiences of patients in hypnosis, especially hypnotherapy and hypnoanalysis.

1972

Kratochvil, Stanislav; Macdonald, Hugh (1972). Sleep in hypnosis: A pilot EEG study. American Journal of Clinical Hypnosis, 15 (1), 29-37.

Six highly susceptible Ss were hypnotized and allowed to sleep in the laboratory during the night. Hypnotic rapport was tested after each of two awakenings, and simple suggestions were also administered in different stages of sleep. After awakening, hypnotic rapport was still present. In sleep, the Ss did not react to suggestions in stages 3 and 4. They sometimes reacted in stage 2, but usually woke up either during listening or during responding to the suggestion. In stage REM the Ss usually responded well to the suggestions; they sometimes woke up and sometimes not. The results are taken as a proof that hypnosis can continue after periods of sleep which occur during hypnosis. The question whether hypnosis and sleep can occur simultaneously or only alternately is discussed.

1970

Kratochvil, Stanislav (1970). Sleep hypnosis and waking hypnosis. International Journal of Clinical and Experimental Hypnosis, 18, 25-40.

Subjected 6 highly susceptible female students to a short-term training procedure to induce 2 different types of hypnosis: (a) a sleep hypnosis, and (b) an active waking hypnosis. Ss behavior in both types, during the carrying out of 11 standard suggestions, was rated by 2 independent Os. The behavior in both artificially induced types of hypnosis differed significantly at the 1% level in the expected direction. The failure to obtain more dramatic results is attributed to the shortness of training, to the implicit demands concerning activity, or to Ss' personality traits, which may lower the intrapersonal variability. The relevance of the results for the Pavlovian theory of hypnosis is discussed: They do not support the hypothesis that behavioral characteristics which resemble sleep are intrinsic phenomena of

the hypnotic state. (Spanish & German summaries) (34 ref.) (PsycINFO Database Record (c) 2003 APA, all rights reserved)

1967

Dittborn, J. M.; O'Connell, D. N. (1967). Behavioral sleep, physiological sleep and hypnotizability. International Journal of Clinical and Experimental Hypnosis, 15, 181-188.

A SLEEP-INDUCTION PROCEDURE REQUIRING MANUAL RESPONSE TO A REPETITIVE AUDITORY SIGNAL WAS ADMINISTERED TO 52 SS WHO HAD CLEAR ALPHA ACTIVITY IN THEIR WAKING EEG AND WHOSE HYPNOTIZABILITY WAS KNOWN. THE OCCURRENCE OF SLEEP WAS DEFINED BY PHYSIOLOGICAL, BEHAVIORAL, AND SUBJECTIVE CRITERIA. NEITHER THE TENDENCY TO DEVELOP EEG SLEEP NOR THE ABILITY OF SOME SS TO RESPOND WHILE IN EEG SLEEP WAS RELATED TO HYPNOTIZABILITY. HYPNOTIZABILITY WAS RELATED TO A TYPE OF DISSOCIATION BETWEEN EEG SLEEP AND BOTH BEHAVIORAL AND SUBJECTIVE SLEEP SHOWN BY 5 SS, ALL HIGHLY HYPNOTIZABLE. (SPANISH + GERMAN SUMMARIES) (PsycINFO Database Record (c) 2002 APA, all rights reserved)

1966

Hoskovec, J. (1966). Hypnopedia in the Soviet Union: A critical review of recent major experiments. International Journal of Clinical and Experimental Hypnosis, 14, 308-315. (Abstract in Psychological Abstracts 41: 149, and in American Journal of Clinical Hypnosis, 1967, 4, 295)

Major Soviet hypnopedia (sleep-learning) experiments were conducted by Balkhashov (1965); Khil'chenko, Moldavskaya, Kol'chenko, and Shevko (1965); Kulikov (1964); Svyadosch (1962); Zavalova, Zukhar', and Petrov (1964); Zukhar', Kaplan, Maksimov, and Puskna (1965). The results of these experiments show that learning during sleep is possible when a 'suggested set' to perceive and remember the learning material during sleep is involved. Selection of Ss according to hypnotizability or primary suggestibility seems to be an important prerequisite. The influence of hypnopedia on the mental health of Ss is evaluated. (Author's abstract, in AJCH.)

Tart, Charles T. (1966). Some effects of post-hypnotic suggestions on the process of dreaming. International Journal of Clinical and Experimental Hypnosis, 14, 30-46.

2 highly hypnotizable Ss were studied for 43 nights in order to assess the feasibility of controlling various aspects of their Stage 1 dreaming. Using posthypnotic suggestion they were caused to awaken at either the beginning or end of their Stage 1 dream periods, dream all night, and not dream at all. The experimental procedure was effective in producing awakenings at the beginnings and end of dream periods; its effect on Stage 1 dream time was unclear and, if present, was rather small. Earlier reports of the efficacy of posthypnotic suggestion in affecting Stage 1 dream content were confirmed. (PsycINFO Database Record (c) 2002 APA, all rights reserved)

1964

Domhoff, Bill (1964). Night dreams and hypnotic dreams: Is there evidence that they are different?. International Journal of Clinical and Experimental Hypnosis, 12, 3, 159-168.

The evidence against equating night dreams and hypnotic dreams is reviewed in the light of 2 developments in dream research--Dement and Kleitman's (1957a; 1957b) physiological and behavioral indicators of dreaming and Hall's (1951; 1963) quantitative studies of dream content. It is concluded that: the equivalence of the EEG patterns of the hypnotic trance and the "dream" stage of

sleep (Stage I) cannot be ruled out; the psychologically-important question of content differences between night and hypnotic dreams has never been examined in a controlled, quantitative manner. (48 ref.) (PsycINFO Database Record (c) 2002 APA, all rights reserved)

The sleep suggestibility test (SST) was individually administered to a group of young volunteer soldiers. There was increased susceptibility with each successive SST administration. It was possible to transform suggested sleep into somnambulistic hypnosis in a majority of Ss. (PsycINFO Database Record (c) 2002 APA, all rights reserved)

**King, C. D. (1963). The states of human consciousness. New York, NY: University Books. (Reviewed in American Journal of Clinical Hypnosis 7, 1964, 96.)**

#### NOTES

From the book review by Stanley Abrams, AJCH: [The book] "is more philosophical and mystical than scientific. ... [and describes] the four states of consciousness: sleep, waking, awakesness, and objective consciousness. ... For man to attain completeness and normalcy he must achieve the state of awakesness. According to the author, however, only a relatively few have approached this stage of consciousness and his description of it is quite vague. When one has reached awakesness he is able to understand and actually perceive the world in a novel and unique manner. ... The final stage of awareness, objective consciousness, is characterized as the experiencing of cosmic phenomena in the same fashion as external reality is understood in the awakened state. The author indicated that this stage has not as yet been attained by man, but it does lie within his potential. ... The only treatment of hypnosis is the author's statement that the waking state is the same as the hypnotic state because suggestibility exists in both" (p. 96).

**Mishchenko, M. (1961). The hypnotic condition as a process of nervous excitation. In Proc. Third World Congress of Psychiatry, Montreal, Canada, I. (pp. 704-708). (Abstract in American Journal of Clinical Hypnosis 1964, 7, 101.)**

Subjects were selected with certain predispositions for the hypnotic state and studied in the waking, hypnotic and experimental sleep states by motor conditioned reflexes modified to a specific function of the frontal system. Excitable, active students of music and literature were found most excitable as subjects, subjects tending to be passive showed no hypnotic responses. Experimental sleep abolished the motor-conditioned reflexes, quite contrary to hypnotic findings. (M.H.E. abstract in AJCH).

Andreev, B. V. (1960). Sleep therapy in the neuroses. New York: Consultants Bureau. (Reviewed by Milton H. Erickson in American Journal of Clinical Hypnosis, 1962, 4, p. 203)

#### NOTES

The book summarizes research on sleep therapy conducted at the Pavlov Clinic for Nervous Diseases, at the Pavlov Institute of the Academy of Sciences of the USSR. It provides a history of sleep therapy, which M. H. Erickson states "is as old as antiquity," and details about the Russian research. Hypnosis and suggestion were two of many different procedures used to prolong sleep. 200-item bibliography.

Barretto, Alberto L. (1960). Sugestiones nocturnas para corregir los malos habitos infantiles [Nocturnal suggestions used to correct bad habits in children]. Revista de la Latino-Americana Hipnologia Clinica, 1 (2), 29-32. (Abstracted in American Journal of Clinical Hypnosis, 1961, 4, 65)

The article discusses a method of nocturnal suggestions (during sleep) as a simple and effective method for the correction of bad habits in children (enuresis, nail biting, finger sucking, excessive use of candies, poor appetite, etc.).

Diamant, J.; Dufek, M.; Hoskovec, J.; Kristof, M.; Pekarek, V.; Roth, B.; Velek, M. (1960). An electroencephalographic study of the waking state and hypnosis with particular reference to subclinical manifestations of sleep activity. International Journal of Clinical and Experimental Hypnosis, 8, 199-212.

#### (Author's Conclusions)

EEG records have been investigated in 10 patients in a waking state and under hypnosis. It was shown that no differences existed between these two states in terms of EEG. EEG signs of decreased wakefulness can be demonstrated in some of the patients, but these were also present without hypnosis. This latter effect appears to be subclinical sleep activity (Roth), frequently seen particularly in neurosis. Reactibility to external stimuli under hypnosis was also, in most cases, equivalent to reactions in the waking state. The authors incline to the view that EEG data does not support the concept that the nature of hypnosis and sleep is qualitatively the same.

1959

Platonov, K. I. (1959). The word as a physiological and therapeutic factor: The theory and practice of psychotherapy according to I. P. Pavlov. ( 2nd). Moscow: Foreign Languages Publishing House.

#### NOTES

On pp. 75-76 the author discusses conditioning in hypnosis. Most of the theoretical material is in the first part of the book; the rest consists of case studies. He presents the position that the activity of the cortex and subcortex are different during states of waking and suggested sleep.

Note: Much of the Russian research done during "suggested sleep" involves subjects who are hypnotized for a long period of time--sometimes hours. Routinely, in treatment, they would give corrective suggestions and then tell the person to "sleep" and would leave them in the "sleep" for an hour or longer.

"Thus, it appears from the foregoing that the basic peculiarities of the activity of the cerebral cortex manifesting themselves in the state of suggested sleep are as follows: 1. In addition to the division of the cerebral hemispheres into sections of sleep and wakefulness typical of the hypnotic sleep of an animal,

there is also a functional dissociation of the two signal systems and within the second signal system. 2. The activity of the second signal system under these conditions is not only confined to the narrow framework of the rapport zone, but is also frequently of a passive nature being directly dependent on the verbal influences of the hypnotist. Outside these influences there is no (or hardly any) activity. 3. A considerable increase in the coupling function with respect to the stimuli of the second signal system is noted at the same time in the rapport zone. This especially favours the formation of new cortical dynamic structures under the verbal influences of the hypnotist, these structures representing the physiological basis for effectuating the suggested actions and states.

"The foregoing peculiarities manifest themselves in the fact that the entire external second signal activity of the subject is reduced only to direct answers to the questions of the hypnotist with no independent reactions to any influences, including verbal, coming from other people (so-called isolated rapport). This is understandable, since the activity of the second signal system lying outside the rapport zone is inhibited" (pp. 73-74).

"As to the problem of the peculiarities of the conditioned reflex activity during suggested sleep, it will be noted that this problem has not been very extensively studied as yet. Nevertheless, the data of various authors are of indubitable interest, since they have revealed a number of specific peculiarities in the state of the higher nervous activity under these conditions.

"According to these data the conditioned reflex activity in suggested sleep undergoes certain changes. Thus, S. Levin observed in his early studies (1931) that in children under conditions of suggested sleep the motor and secretory conditioned reflexes elaborated earlier in the waking state grew very much weaker and that there was a dissociation both between the motor and secretory conditioned reflexes and between the unconditioned reflexes of salivation and mastication; he also observed the transitional (phasic) states--paradoxical, ultraparadoxical and inhibitory phases, all the way to the onset of complete sleep" (pp. 74-75).

Platonov indicates that conditioned reflexes may disappear during suggested sleep (Povorinsky & Traugott, 1936). Arousal from suggested sleep results in gradual restoration of the reflexes, with speech reactions inhibited first and restored last. Pen & Jigarov (1936) also showed that there is a weakening of conditioned reflexes, with increased latency, in suggested sleep. These authors showed that it is impossible to form new conditioned reflexes in deep states of suggested sleep, and the conditioning is difficult in lighter states.

"Y. Povorinsky's data (1937) indicate that the conditioned reflexes elaborated in the waking state have a longer latent period during suggested sleep and in some subjects they are completely absent. Under these circumstances, the reactions to the verbal influences of the hypnotist are retained even during the deepest suggested sleep. The more complex and ontogenetically later conditioned bonds of the speech-motor analyzer are inhibited first as the subject lapses into a state of suggested sleep and are disinhibited the last as the subject awakens from this state" (p. 75).

"B. Pavlov and Y. Povorinsky observe (1953) that the conditioned bonds reinforced by the words of the hypnotist are formed during suggested sleep faster than in the waking state. In this case, during the somnambulistic phase of suggested sleep verbal reinforcements, as a rule, provoke a stronger and longer reaction with a shorter latent period than a direct first signal stimulus" (p. 76). The conditioning that occurs during suggested sleep does not manifest during waking periods unless suggestions are given during the sleep to react after wakening. The author takes this to be evidence that conditioned reflex activity can be modified by verbal suggestions.

During the somnambulistic stage of suggested sleep, subjects are less adept at performing addition. This indicates that inhibition has spread to the second signal system. However, inhibition of different sensory systems seems to vary from person to person. Krasnogorsky (1951) reported one subject did not react to light, but hearing seemed to be more sensitive than in the waking state.

"All of the above testifies to the considerable changes in the character of cortical activity regularly occurring during suggested sleep and determining, on the whole, the specific nature of higher nervous activity, the systematic study of which should be the object of further research" (p. 77).

1956

Barber, Theodore Xenophon (1956). 'Sleep' and 'hypnosis': A reappraisal. Journal of Clinical and Experimental Hypnosis, 4, 141-159.

#### NOTES

"Summary.

"Some recent experiments and a reevaluation of the electroencephalographic findings indicate that the term 'hypnosis' has subsumed at least two more or less distinct phenomena: (a) 'hypnosis' preceded by 'trance-inducing suggestions' which is closely related to 'light sleep' and (b) 'hypnosis' without 'trance-inducing suggestions' which is often a 'waking' state.

"From this viewpoint we can begin to reevaluate the contradictory physiological experiments comparing sleep and hypnosis, the most favorable conditions for producing hypnosis, amnesia and decreased suggestibility in very deep hypnosis, and the reports of waking and sleeping hypnosis. We can also reappraise such thorny problems in hypnotic theory as the production of hypnosis by artificial means, autohypnosis, and animal hypnosis.

"The argument presented calls for further research. We should investigate (a) suggestibility during extreme relaxation; (b) response on hypnotic tests when the subject is told, "Go to sleep and I'll be back later to give you some tests'; (c) deep trance phenomena during sleep; (d) hypnotizability of good sleepers and insomniacs; (e) beneficial suggestions during sleep; (f) physiological functions during 'light sleep' and hypnosis; (g) the response of 'sleep-walkers' to standard hypnotic tests; (h) the relationship of 'light sleep' dreams to hypnotically induced dreams; and (i) the relationship of sleep amnesia to hypnotic amnesia" (pp. 153-154).

1954

Koster, S. (1954). Experimental investigation of the character of hypnosis. Journal of Clinical and Experimental Hypnosis, 2, 42-54.

#### NOTES

In waking, hypnosis, and sleep states 6 subjects were tested for knee-jerk height, key pressing to metronome signal, doing sums, recalling a story, etc. The Summary states:

"1. The height of the knee-jerk of all 6 subjects both in T and in "S" was much lower than in (W), the average height of all knee-jerks computed of the 6 subjects was both in T and in "S" only 39% of the average height in (W).

2. The [arm] catalepsy in T and in "S" continually existed.

3. The subjects in T and in "S" could hear well and perform active movements, though they reacted somewhat more slowly, and less forcibly than in (W) and sometimes only after some provocations.

4. The subjects both in T and in "S" could not only hear well, but could also present more or less complicated psychic impressions, reproducing them later again in "S" and also after the end of the experiment" (p. 50).

The author concluded, "Hypnosis is a sleeping-condition, but a special one. The specific difference consists of the fact that the subject's many impressions, which he would observe in a waking-condition, he does not observe now, and does not react to, aside from impressions coming to him through the hypnotist. It can then be said that there is not an absence but a decrease of the active relation with the outer world. This is exactly the same state as the one during sleepwalking and the writer must repeat

after all his investigations, what has already been stated: Essentially there is no difference between the condition of a hypnotized person and that of a sleepwalker" (p. 51).

## NOTES

Describes use of hypnosis in treating "combat fatigue" in field conditions during the Pacific campaign of WWII. Hypnosis was utilized for sleep and rest in tent hospitals in or near combat to avoid chemical sedation as well as for reliving and mastering traumatic events. The milieu was one of expectant recovery with patients pitching tents, digging foxholes and serving as litter bearers. Psychiatric admissions were 12.8% of the total with return to duty rates varying with intensity of combat and duration of campaign with over half returned to combat duty. Four detailed cases are reported.

## SMOKING

2001

Barber, Joseph (2001). Freedom from smoking: Integrating hypnotic methods and rapid smoking to facilitate smoking cessation. International Journal of Clinical and Experimental Hypnosis, **49** (3), 257-266.

Hypnotic intervention can be integrated with a Rapid Smoking treatment protocol for smoking cessation. Reported here is a demonstration of such an integrated approach, including a detailed description of treatment rationale and procedures for such a short-term intervention. Of 43 consecutive patients undergoing this treatment protocol, 39 reported remaining abstinent at follow-up (6 months to 3 years post treatment).

Gibbons, Don E. (2001). Experience as an art form: Hypnosis, hyperempiria, and the Best Me technique. San Jose CA: Authors Choice Press. ([[available online:] <http://www.iuniverse.com/bookstore/marketplace>])

## NOTES

The Best Me Technique is a procedure for constructing suggestions which incorporates many different dimensions of experience -- beliefs, emotions, sensations, thoughts, motives, and expectations -- for maximum involvement and effectiveness. Best Me suggestions may be used with either hyperempiria, an alert induction based on suggestions of mind expansion and increased alertness and sensitivity, or with more traditional forms of hypnotic induction.

2000

Green, Joseph P.; Lynn, Steven Jay (2000, August). Hypnosis and suggestion-based approaches to smoking cessation: An examination of the evidence. [Paper] Presented at the annual meeting of the American Psychological Association, Washington, D. C..

This article reviews 59 studies of hypnosis and smoking cessation from the point of view of whether the research provides support for hypnosis as an empirically supported treatment (Chambless and Hollon, 1998). Whereas hypnotic procedures generally yield higher rates of abstinence relative to wait list and no treatment conditions, hypnotic interventions are generally comparable to a variety of nonhypnotic treatments. The evidence for whether hypnosis yields outcomes superior to placebos is mixed. In short, hypnosis can not be considered to be a specific and efficacious treatment for smoking cessation.

Furthermore, in many cases, it is impossible to rule out cognitive/behavioral and educational interventions as the source of positive treatment gains associated with hypnotic treatments. Hypnosis can not, as yet, be regarded as a well-established treatment for smoking cessation. Nevertheless, it seems justified to classify hypnosis as a "possibly efficacious" treatment for smoking cessation. - Abstract taken from *Psychological Hypnosis: A Bulletin of [Amer Psychol Assn] Division 30*. Fall, 2000.

Capafons, A. (1999). Applications of emotional self-regulation therapy. In Kirsch, I.; Capafons, A.; Cardega, E.; Amigs, S. (Ed.), Clinical hypnosis and self-regulation: Cognitive-behavioral perspectives (pp. 331-349). Washington, D.C.: American Psychological Association.

This chapter reviews the main applications of emotional self-regulation therapy, which have received empirical support: smoking reduction, obesity, fear of flying, drug addictions, and premenstrual distress and dysmenorrhea. The logic of each treatment and main empirical results are summarized.

**1997**

Bayot, A.; Capafons, A.; Cardega, E. (1997). Emotional self-regulation therapy: A new and efficacious treatment for smoking.. American Journal of Clinical Hypnosis, 40 (2), 146-156.

We described emotional self-regulation therapy, a recently-developed suggestion technique for the treatment of smoking, and present data attesting to its efficacy. Of the 38 individuals who completed treatment, 82% (47% of the initial sample) stopped smoking altogether and 13% (8% of the initial sample) reduced their smoking. A follow-up at 6 months showed that 66% (38% of the initial sample) of those who had completed the treatment remained abstinent and reported minimal withdrawal symptoms or weight gain. In a no-treatment comparison group, only 8% reduced their smoking or became abstinent.

Johnson, David L. (1997). Weight loss for women: Studies of smokers and nonsmokers using hypnosis and multicomponent treatments with and without overt aversion. Psychological Reports, 80 (3, Pt 1), 931-933.

Study 1 compared 50 overweight adult female smokers (mean age 37.7 yrs) and 50 nonsmokers (mean age 41.2 yrs) in an hypnosis-based, weight-loss program. Smokers and nonsmokers achieved significant weight losses and decreases in Body Mass Index. Study 2 treated 100 women either in an hypnosis only (n = 50) or an overt aversion and hypnosis (n = 50) program. This multicomponent follow-up study replicated significant weight losses and declines in Body Mass Index. The overt aversion and hypnosis program yielded significantly lower posttreatment weights and a greater average number of pounds lost. (PsycINFO Database Record (c) 2003 APA, all rights reserved)

**1995**

Capafons, A.; Amigs, S. (1995). Emotional self-regulation therapy for smoking reduction: Description and initial empirical data.. International Journal of Clinical and Experimental Hypnosis, 43 (1), 7-19.

Self-regulation therapy (Amigs, 1992) is a set of procedures derived from cognitive skill training programs for increasing hypnotizability. First, experiences are generated by actual stimuli. Clients are then asked to associate those experiences with various cues. They are then requested to generate the experiences in response to the cues, but without the actual stimuli. When they are able to do so quickly and easily, therapeutic suggestions are given. Studies of self-regulation therapy indicate that it can be used successfully to treat smoking.

Holroyd, Jean (1995). Handbook of clinical hypnosis, by Judith W. Rhue, Steven Jay Lynn, & Irving Kirsch (Eds.) [Review]. International Journal of Clinical and Experimental Hypnosis, 43 (4), 401-403.

#### NOTES

"This is a book for the thinking clinician" (p. 401). "The editors are to be congratulated for making this volume much more coherent than most edited books" (p. 402). "My impression is that the book is best suited for an intermediate or advanced course on hypnotherapy, or for people who are already using hypnosis in treatment. Although there is some material on the basics of hypnotic inductions and a few introductory sample scripts for inductions, a beginners' course should probably use a different book, or this book could be accompanied by an inductions manual. ... I recommend it very highly" (p. 403).

#### 1993

Page, Roger A.; Handley, George W. (1993). The use of hypnosis in cocaine addiction. American Journal of Clinical Hypnosis, 36, 120-123.

An unusual case is presented in which hypnosis was successfully used to overcome a \$50-0 (five grams) per day cocaine addiction. The subject was a female in her twenties. Six months into her addiction, she acquired a commercial weight-control tape that she used successfully to stop smoking cigarettes (mentally substituting the word "smoking"), as well as to bring her down from her cocaine high and allow her to fall asleep. After approximately 8 months of addiction, she decided to use the tape in an attempt to overcome the addiction itself. Over the next 4 months, she listened to the tape three times a day, mentally substituting the word "coke." At the end of this period, her addiction was broken, and she has been drug free for the past 9 years. Her withdrawal and recovery were extraordinary because hypnosis was the only intervention, and no support network of any kind was available.

Spiegel, David; Frischholz, Edward J.; Fleiss, Joseph L.; Spiegel, Herbert (1993). Predictors of smoking abstinence following a single-session restructuring intervention with self hypnosis. American Journal of Psychiatry, 150, 1090-1097.

Examined the relation of smoking and medical history, social support, and hypnotizability to outcome with Spiegel's smoking-cessation program. A consecutive series of 226 smokers were treated with the single-session approach and followed up for 2 years. With a total abstinence criterion, 52% success was found after 1 week, and 23% abstinence at 2 years. Hypnotizability and having been previously able to quit smoking for at least a month significantly predicted the initiation of abstinence. Hypnotizability and living with a significant other person predicted 2-year maintenance. The results are superior to those of spontaneous efforts to stop smoking and suggest it is possible to predict which patients are most likely to respond and which patients are least likely to respond to such a brief intervention.

#### 1992

Spanos, Nicholas P.; Simulates, Ann; de Faye, Barbara; Mondoux, Thomas J.; Gabora, Natalie J. (1992-93). A comparison of hypnotic and nonhypnotic treatments for smoking. Imagination, Cognition and Personality, 12, 23-43.

Three experiments administered variants of Spiegel's (1970) smoking cessation procedure to smokers in hypnotic and nonhypnotic treatments. Follow-up periods were from twelve to twenty-four weeks depending on the experiment. Complete abstinence was an infrequent outcome in all three

experiments. Greater-than-control reductions in smoking for treated subjects were obtained in two of the experiments but, in both cases treatment and control subjects failed to differ significantly before the end of the follow-up period. Hypnotic and nonhypnotic treatments produced equivalent smoking reductions in all studies, and neither hypnotizability nor questionnaire assessments of motivation to quit correlated significantly with treatment outcome. Implications are discussed. NOTES 1:

#### NOTES

When the experimenters compared number of treatments they simply compared two sessions of Spiegel's one-session treatment with four sessions of it. The authors make the point that perhaps they should vary the four sessions.

"In all three of the present experiments the abstinence rates associated with the Spiegel treatment were very low. Our abstinence rates were similar to those reported in one earlier study [4 - Perry et al.], but substantially lower than those reported in three other studies [2, 22, 25]. The reasons for these discrepancies between studies remains unclear, but experiment 3 suggests that these discrepancies cannot be accounted for simply in terms of whether the subjects were drawn from a university or nonuniversity population, and experiment 2 suggests that the discrepancies are unrelated to the number of treatment sessions administered to subjects.

"The finding that hypnotic and nonhypnotic subjects in all three experiments attained equivalent reductions in smoking is consistent with other comparison studies in this area which indicate that hypnotic treatments are no more effective than various nonhypnotic procedures at inducing reductions in smoking [22, 25, 30]. More generally, these findings are consistent with comparison studies on a wide variety of clinical disorders (headache pain, warts, phobias, obesity) which indicate that hypnotic treatments are no more effective than nonhypnotic ones at producing therapeutic change (see [3] for a review).

"The failure to find significant correlations between smoking reduction and hypnotizability among treated subjects is also consistent with the findings of most studies in this area [3], but the reasons why significant correlations between these variables are found in some studies and not others remains unclear. Spanos [3] suggested that significant correlations between these variables are particularly likely when hypnotizability testing is integrated into the treatment protocol. Under these circumstances subjects are likely to form strong expectations about treatment success on the basis of their self-observed responses to the hypnotizability scale. Such expectations may, in turn, influence subjects' motivations to comply with the treatment regimen, the self-statements they make concerning their likelihood of quitting, etc. In all of the present experiments hypnotizability was assessed at the end of the follow-up period and, therefore, could not influence subjects' expectations of treatment success" (pp. 40-41).

Spiegel, David (1992, October). Hypnotizability. [Paper] Presented at the annual meeting of the Society for Clinical and Experimental Hypnosis, Arlington, VA.

#### NOTES

Dr. Spiegel announced that this was a last minute substitution for Fred Frankel's presentation on Hypnotizability.

We have ongoing a major replication of the study that we published on group therapy with terminally ill breast cancer patients. The matched control patients get educational materials but not psychotherapy. We are looking at NKC cytotoxicity and delayed hypersensitivity.

Tasks: spend 15 minutes discussing list of problems; 15 minutes discussing things like, "What is your spouse doing that doesn't help; what can we do to help it?" We get drop in NKC cytotoxicity immediately afterward, returning after 24 hrs to usual levels. Controls don't drop in NKC cytotoxicity. This measure of stress may be a predictor of survival time.

In Fawzy's study of group therapy with melanoma patients, they noted a significant difference at 6 months in interferon augmented activity of NK, which didn't hold up at a year. But at 6 years there were 10 of 40 deaths in control group vs 3 of 40 deaths in treated group. This is a vigorous effect.

Cohen's study of colds in New England J. of Med is another good clinical study.

There are two broad areas of relevance of hypnotizability to healing: 1. Hypnotizability as a trait: do highs differ in way they regulate body or mind? 2. Is there something you do when in hypnotized state that is different? Studies of treatment of warts with hypnosis are important 3. Transition between states, e.g. circadian rhythms; is there a shift in wakefulness between trance and nontrance states that affects health?

Psychiatric Diagnosis and self regulation. High hypnotizability is associated with certain psychiatric disorders (dissociative reaction, PTSD, MPD, etc.). Schizophrenics score much lower than normals (av. = 4 vs 7; replicated with the Hypnotic Induction Profile (HIP). Stanford Hypnotizability Scales show no difference in means, but do show a difference in range). I don't know what this means. But schizophrenics can falsely pass some Stanford Scale items, e.g. amnesia which they don't however reverse; so schizophrenics' hypnotizability scores may be inflated on Stanford scales. We don't see extremely high scores in schizophrenics.

Psychoactive medication doesn't affect scores of schizophrenics, but improves scores of anxiety neurotics (by reducing anxiety). Frischholz has an article coming out in a psychiatry journal that confirms this.

There is a lot of evidence that patients with dissociative disorders are more hypnotizable than other groups. Frischholz et al couldn't replicate Frankel's finding of higher scores in phobics. Pettinati et al found higher scores in bulimia and I haven't seen anything to counter that. Another idea is that high hypnotizables are very good at internal regulation

Spiegel & Ken Kline selected Ss who could regulate gastric activity. They got an 80% increase in gastric acid output while imagining eating; got 40% decrease in output when imagining something pleasant that wasn't imagining eating. Injected with pentagastrin, which induces gastric output, they still got a decrease in gastric acid output in the relaxation condition.

This suggests that hypnotizability should be a selection criterion for some research. See also Katz et al. 1974 (?) with acupuncture; and McGlashan, Evans & Orne on the placebo response.

Herbert Spiegel found that 2/3 of highs but 1/3 of lows were cured of phobia. Eye roll sign on the HIP, living with spouse/lover, rating self as hypnotizable, and giving a postcard follow-up response at one week post treatment were associated with 89% rate abstinence at 2 years follow-up, when only 23% overall of 223 were abstinent. Absence of those positive predictors was associated with only a 4% rate of abstinence.

1991

Court, John (1991). Lord of the trance. Journal of Psychology and Christianity, 10 (3), 261-265.

A verbatim account of hypnotically-based therapy utilizing Christian imagery serves as the basis for illustrating some of the benefits of this approach where therapist and client share the same value system. The interactions challenge some of the familiar objections to Christian involvement with hypnosis.

Holroyd, Jean (1991). The uncertain relationship between hypnotizability and smoking treatment outcome. International Journal of Clinical and Experimental Hypnosis, 39, 93-102.

Literature on the relationship between hypnotizability and smoking treatment outcome was reviewed. 91 private patients treated for smoking with hypnotherapy participated in an investigation designed to correct problems in some of the earlier research. 43% quit smoking by the end of treatment but only

16% abstained at least 6 months. Neither immediate quitting nor continued abstinence correlated with hypnotizability. Other variables hypothesized to predict smoking cessation also were not correlated with outcome: number of treatment sessions, need to smoke, motivation to quit, and gender. The low abstention rate may have impeded verification of a relationship between hypnotizability and treatment outcome.

## NOTES

In the Discussion, the author notes that the low overall abstention rate works against finding the predicted relationships, as did restricted range on the hypnotizability measure. "Secondly, the present research design in effect tested the potency of hypnosis (hypnotizable patients) against nonhypnotic treatment (nonhypnotizable control patients) in a research design recommended by Orne (1977). Intensive nonhypnotic involvement with the nonhypnotizable individuals over several sessions may have worked against finding differences between low and high hypnotizables" (p. 99).

"Patients generally did not complete the recommended four sessions ... and they generally were non-adherent to recommended follow-up telephone contact. The observed relationship between initial quitting and number of treatment sessions may exist because people who are responding to treatment stay in treatment longer, or because more treatment sessions provide a more potent intervention, or both" (p. 99). "Treatment contracts between patients and therapist increased the number of sessions that patients completed but did not increase their abstinence rate" (p. 100).

## 1990

Suedfeld, Peter (1990). Restricted environmental stimulation and smoking cessation: A 15-year progress report. International Journal of the Addictions, 25, 861-888.

The first successful use of restricted environmental stimulation therapy (REST) as a method of smoking cessation was reported in this journal in 1972. Since then, close to 20 papers and articles have further investigated this application. The results have been consistently positive and have further shown that--unlike most techniques--REST combines synergistically with other effective treatment modalities. The effect of REST seems to target primarily the major problem with other known treatments in this area: It substantially reduces the relapse rate among clients who quit smoking at the end of treatment. Furthermore, REST is safe, has no known adverse side effects, and is easily tolerated by most participants. Nevertheless, the method has not found wide acceptance among practitioners. This paper explores and answers some of the concerns that may be involved in its relative lack of popularity.

## NOTES

1:

## NOTES

Provides a thorough review of REST (restricted environmental stimulation technique) and smoking cessation, with analysis of why the technique has not been widely adopted, how to set up a lab (including costs and equipment), and the political considerations surrounding REST research (many of which would apply to hypnosis). The author describes how sensory restriction got a bad reputation in Hebb's lab. But both "brainwashing" and intensive interrogation rely primarily on overstimulation and intense stimulus bombardment; these are occasionally interrupted for brief periods to arouse fear and uncertainty about their resumption.

The optimal approach in treatment of smokers seems to be to combine an approach that maximizes immediate cessation rates, with REST which maximizes continuing maintenance rates. Tikalsky (1984) reported that combining REST with self-management training and the establishment of a social support group, there was a 6-month abstinence rate of 88%. (This was a clinical treatment study rather than a controlled experiment.)

"The estimated maintenance rates after REST converge at about 50%, about twice as high as those commonly accepted as characterizing the literature (see, e.g., Hunt and Bessalec, 1974; Shumaker & Grunberg, 1986). The unusually high maintenance rates (percentage of subjects who were abstinent at every follow-up throughout 12 months, using as the baseline those who had quit at end of treatment) are in most--although not all--cases combined with only average quit rates (using total number of followed-up subjects as the baseline), indicating that the initial impact of REST is less impressive than its effect on long-term maintenance" (p. 872).

Why is REST underutilized? Some say it is a placebo. But there is evidence that "expectancy has but little effect on objectively quantifiable (as opposed to subjective) measures in REST (Barabasz & Barabasz, 1990; Suedfeld, 1969b; Suedfeld, Landon, Epstein, & Pargament, 1971)" (p. 873). See also Suedfeld & Baker-Brown (1986).

How does REST work? "In REST, the normal flow of exogenous stimuli is suddenly and very drastically reduced. As a result, attention can be (in fact, must be, if the processing of information is a basic human need) refocused to the ongoing internal generation of physiological, cognitive, affective, memorial, imaginal, and other stimulation. This enables REST participants to concentrate on working out personal problems, including (if so desired) those related to the continuation or termination of their smoking habit" (p. 874).

Second, the removal of specific smoking-related cues interrupts automatic, overlearned response sequences so most clients report that they no longer smoke mechanically, and conditioned cravings for a cigarette are extinguished in many Ss.

It appears from the literature that low-arousal treatments such as hypnosis and meditation are reinforced by REST. REST should improve conditioning or cognitive change therapies because it improves learning and memory, and research supports this assumption. REST also should facilitate the acceptance of information ('messages') because it decreases defenses against novel or dissonant information, but that has not proven true in research to date.

1988

Jeffrey, L. K.; Jeffrey, T. B. (1988). Exclusion therapy in smoking cessation: A brief communication. International Journal of Clinical and Experimental Hypnosis, 36 (2), 70-74.

This study investigated the effect of exclusion therapy on the outcome of a 5-session treatment protocol for smoking cessation. A total of 120 Ss were randomly assigned to a group hypnotic and behavioral program which required 48 hours of pretreatment abstinence from use of tobacco products, or to an identical treatment which encouraged, but did not include, this pretreatment stipulation. Results indicated there were no significant differences between groups in dropout rates or number of Ss abstinent from smoking. For all Ss, including dropouts, the abstinence rate was 59.2% upon completion of treatment. It was 45.5% and 36.7% at 1- and 3-month follow-up, respectively.

Neufeld, V.; Lynn, Steven Jay (1988). A single-session group self-hypnosis smoking cessation treatment: A brief communication. International Journal of Clinical and Experimental Hypnosis, 36 (2), 75-79.

This study was designed to assess the efficacy of a manual-based, single-session group of self-hypnosis intervention. At 3 months follow-up, 25.92% of the total number of participants (14 male, 13 females) reported continuous abstinence, and at 6 months, 18.52% of the participants reported continuous abstinence. Reported social support and motivation to quit were both associated with successful outcome. Comparison of the current data with other findings reported by the American Lung Association (Davis, Faust, & Ordentlich, 1984) suggests that treatment effects may not be solely attributable to the use of a maintenance manual, education, and attention. Limitations of the research

associated with issues of experimental control, generalizability of the findings, and outcome measures are discussed.

Williams, J. M.; Hall, D. W. (1988). Use of single session hypnosis for smoking cessation. Addictive Behaviors, 13, 205-208.

Twenty volunteers for smoking cessation were assigned to single-session hypnosis, 20 to a placebo control condition, and 20 to a no-treatment control condition. The single-session hypnosis group smoked significantly less cigarettes and were significantly more abstinent than a placebo control group and a no-treatment control group at posttest, and 4-week, 12-week, 24-week, and 48-week follow-ups.

1987

Gmur, M.; Tschopp, A. (1987). Factors determining the success of nicotine withdrawal: 12-year follow-up of 532 smokers after suggestion therapy (by a faith healer). International Journal of Addictions, 22, 1189-1200.

In 1973, 532 heavy smokers were questioned prior to treatment by the faith healer Hermano and requestioned 4 months, 1 year, 5 years, and 12 years after the therapeutic ritual. From the moment of treatment, 40% of the subjects remained nonsmokers (with no relapse) after 4 months, 32.5% after one year, 20% after 5 years, and 15.9% after 12 years. At the time of the follow-up, 37.5% of the Ss were nonsmokers, the majority of them having stopped smoking again after suffering a relapse. To investigate factors determining success, Ss who for 12 years had uninterrupted abstinence were compared with those who for 12 years had continued to smoke almost without interruption. Personality factors, sociodemographic features, and characteristics of smoking behavior showed no demonstrable connection with the tendency to relapse. On the other hand, it did prove possible to explain 16% of the variance in the responses to treatment: in particular, high alcohol consumption, markedly addictive smoking, rare attendance at church, and the attitude that 'you have to believe in the treatment' were found to be conducive to relapse and addiction.

1986

Barabasz, Arreed F.; Baer, Lee; Sheehan, David V.; Barabasz, Marianne (1986). A three-year follow-up of hypnosis and restricted environmental stimulation therapy for smoking. International Journal of Clinical and Experimental Hypnosis, 34, 169-181.

Clinical follow-up data were obtained from 307 clients. Clinicians' experience level, contact time, and procedural thoroughness varied in 6 interventions for smoking cessation. An additional intervention combined hypnosis with restricted environmental stimulation therapy (REST). The major results suggest positive treatment outcomes to be related to greater hypnotizability, absorption, hypnotist experience level, procedural thoroughness, and client-therapist contact time. The least effective intervention (4% abstinence at 4-month follow-up) involved intern trainees using a short, single-session approach. The most effective procedure (47% abstinence at 19-month follow-up) involved the combination of hypnosis and REST. Data interpretation limitations are discussed.

Lambe, R.; Osier, C.; Franks, P. (1986). A randomized controlled trial of hypnotherapy for smoking cessation. Journal of Family Practice, 22, 61-65.

NOTES

242 patients who were smokers (49% of all patients in this group family practice) were contacted, and 180 (74%) who were interested in hypnosis as a method of helping them quit were included in the study. These 180 were randomly assigned to control and hypnosis groups. Of the 90 assigned to hypnosis: 50% 45 had at least 1 hypnosis session

7% 6 quit smoking before hypnosis 20% 18 declined hypnosis 23% 21 were lost to follow-up [This gives some idea about volunteer participation in research.]

1985

Jeffrey, Timothy B.; Jeffrey, Louise K.; Greuling, Jacquelin W.; Gentry, William R. (1985). Evaluation of a brief group treatment package including hypnotic induction for maintenance of smoking cessation: A brief communication. International Journal of Clinical and Experimental Hypnosis, 33 (2), 95-98.

Hypnotic, cognitive, and behavioral interventions were used in a 5-session treatment program to assist 35 Ss with maintenance of smoking cessation. 63% of the treated Ss discontinued smoking, and 31% maintained abstinence for 3 months ( $p < .005$ ). These results include 13 dropouts, all of whom were smoking at 3 months follow-up. No S in the waiting-list-control group quit smoking. The results demonstrate that a brief, group treatment program, including hypnotic techniques, can be effective for smoking cessation.

1980

Holroyd, Jean (1980). Hypnosis treatment for smoking: An evaluative review. International Journal of Clinical and Experimental Hypnosis, 28 (4), 341-357.

17 studies of hypnosis for treatment of smoking published since 1970 were reviewed. Abstinence after 6 months posttreatment ranged from 4% to 88%. Effectiveness of treatment outcome was examined in terms of: S population, individual versus group treatment, standardized versus individualized suggestions, use of self-hypnosis, number of treatment sessions and time span covered by the treatment, and use of adjunctive treatment. At 6 months follow-up, more than 50% of smokers remained abstinent in programs in which there were several hours of treatment, intense interpersonal interaction (e.g., individual sessions, marathon hypnosis, mutual group hypnosis), suggestions capitalizing on specific motivations of individual patients, and adjunctive or follow-up contact. The 17 studies are presented in sufficient detail to permit clinicians to follow the published procedures, and recommendations are made for future research.

Powell, Douglas H. (1980). Helping habitual smokers using flooding and hypnotic desensitization techniques: A brief communication. International Journal of Clinical and Experimental Hypnosis, 28 (3), 192-196.

A subgroup of individuals who were helped to stop smoking by hypnosis or other means returned to consuming a few cigarettes a day. A flooding and hypnotic desensitization technique assisted 4 of 7 individuals who resumed smoking in becoming and remaining abstinent for a 6- to 9-month follow-up period.

1979

Pederson, Linda L.; Scrimgeour, William G.; Lefcoe, Neville M. (1979). Variables of hypnosis which are related to success in a smoking withdrawal program. International Journal of Clinical and Experimental Hypnosis, 27 (1), 14-20.

65 habitual smokers were randomly assigned to one of 4 groups: live-hypnosis plus counseling, videotape-hypnosis plus counseling, relaxation-hypnosis plus counseling, and counseling alone. The content and mode of presentation of the hypnosis session varied among the first 3 groups. At 6 months posttreatment, the live-hypnosis plus counseling group contained significantly more abstainers than the other 3 groups. The importance of the specific content of the hypnosis session and the presence of the hypnotherapist for the effectiveness of the procedure is discussed.

Perry, Campbell; Gelfand, Robert; Marcovitch, Phillip (1979). The relevance of hypnotic susceptibility in the clinical context. Journal of Abnormal Psychology, 88 (5), 592-603.

Despite experimental evidence that hypnotic susceptibility is a relatively stable characteristic of the individual, and one that is very difficult to modify, clinical investigators tend to see susceptibility as irrelevant to therapeutic outcome. Such investigators view motivational and interpersonal variables as more essential to the therapeutic change. The evidence for the clinical relevance of hypnotizability is sparse and contradictory. Most existing studies stem from medical hypnosis and indicate that susceptibility plays an important role in the successful treatment of such conditions as clinical pain, warts, and asthma. Two studies are reported that seek to pursue a contrary finding reported by Perry and Mullen, who found that susceptibility was unrelated to the successful treatment of a socially learned behavior (cigarette smoking). Both studies confirmed the earlier finding of a lack of relation. In Study 1, however, stepwise multiple regression analysis located three inventory items concerning the motivation of cigarette smokers. The combination of items was found to predict outcome for 67.39% of 46 clients treated either by hypnosis or by rapid smoking. The finding was replicated in Study 2, which utilized a combined hypnosis - rapid smoking technique and employed a different therapist. The outcome for 9 of the 13 quitters and 37 of the 62 nonquitters across the two studies could be predicted by the three motivational questionnaire variables.

1978

Stanton, Harry E. (1978). A one-session hypnotic approach to modifying smoking behavior. International Journal of Clinical and Experimental Hypnosis, 26, 22-29.

Recent literature reviewing attempts to modify smoking behavior through the use of hypnosis is outlined, and an approach utilizing only 1 treatment is described. This single session includes: (a) the establishment of a favorable "mental set" on the part of the patient, (b) a hypnotic induction, (c) ego-enhancing suggestions, (d) specific suggestions directed toward the cessation of smoking, (e) an adaption of the "red balloon" visualization, and (f) success visualization. Of 75 patients treated by this technique, 45 ceased smoking. 6 months after the treatment session, 34, or 45%, were still nonsmokers, attesting to the efficacy of the method.

1977

Barkley, R. A.; Hastings, J. E.; Jackson, T. L., Jr. (1977). The effects of rapid smoking and hypnosis in the treatment of smoking behavior. International Journal of Clinical and Experimental Hypnosis, 25 (1), 7-17.

29 Ss were assigned to one of 3 treatment conditions and treated for their cigarette smoking over a 2-week period. These conditions were: group rapid smoking, group hypnosis, and an attention-placebo control group. All treatments produced significant reductions in average daily smoking rates during the treatment phase but all Ss returned to near baseline levels of smoking by the 6-week follow-up. The rapid smoking and hypnosis groups did not differ from the control group in smoking rates at treatment termination or at the 6-week follow-up. They also did not differ from the control group in

the number of Ss abstaining from smoking by treatment termination but did differ at follow-up. Eventually, at the 9-month follow-up, only Ss from the group rapid smoking condition had significantly more abstainers than the control group. The results suggested that rapid smoking can work as effectively in group procedures as previous individualized approaches had demonstrated. Group hypnosis, while less effective than some previous individualized approaches had indicated, was nevertheless only marginally less effective than the group rapid smoking procedure. The use of abstinence rates as opposed to average rates of smoking was strongly recommended as the best measure of treatment effectiveness for future research in this area.

1976

Watkins, Helen H. (1976). Hypnosis and smoking: A five session approach. International Journal of Clinical and Experimental Hypnosis, 24, 381-390.

An individualized method of treatment aimed at the reduction of smoking is described which is based on a study of the motivations of each client. Specialized suggestions and specifically-tailored fantasies are then initiated to undermine rationalizations and reinforce the person's commitment to stop smoking. A number of different techniques are mobilized within a hypnotic, "concentration-relaxation" approach and are combined with behavior therapy procedures to achieve strong counter-motivations to smoking. 78% of those who finished the program stopped smoking, and 67% were still not smoking at the end of 6 months. The individuals who were most resistant to the treatment appeared to be those who were using smoking as a way of controlling anger.

1975

Mullen, G.; Perry, C. (1975). The effects of hypnotic susceptibility on reducing smoking behavior treated by a hypnotic technique. Journal of Clinical Psychology, 31, 498-505.

In order to examine the relationship between hypnotizability and treatment outcome in which hypnosis is used, 54 people ages 19-47 who undertook to stop smoking were studied. Although it is logical that there should be a relationship, clinical anecdotal material published by people who used hypnosis (Freud, Weitzenhoffer, Lazarus, Sheehan, Orne) suggests that may not be the case. Hypnotic susceptibility was evaluated with a clinical procedure developed by Orne and O'Connell (the DRP). Patients were taught self hypnosis using a brief procedure developed by Herbert Spiegel. Baseline smoking rate and three-month follow-up with postcards mailed every week were employed as measures. Success in the treatment program was defined as a 50% reduction in smoking behavior. After 3 months, 7 people were abstinent, 10 had reduced smoking to criterion level (50%), 16 people had discontinued the investigation, and 21 did not change. Considering only the 15 most and 15 least hypnotizable, 12 of the 15 high susceptibles had reduced smoking by at least 50%, as compared to 5 of the 15 of the low susceptibles. (chi square = 4.88, df = 1, p<.05).

1972

Suedfeld, Peter; Landon, P. Bruce; Pargament, Richard; Epstein, Yakov M. (1972). An experimental attack on smoking (attitude manipulation in restricted environments, III). International Journal of the Addictions, 7 (4), 721-733.

Forty male cigarette smokers were Ss in a study which involved 24 hr of sensory deprivation (SD) and a brief anti-smoking message. On a measure of belief instability (errors in scaling the extremeness of statements about smoking), SD Ss showed more instability than controls; but the scores of Ss who heard the message were about equal, regardless of SD. Agreement with antismoking statements was highest in the SD-no message and message-no SD groups. While the message induced belief instability

and attitude change under normal circumstances, it had the opposite effect in SD. This may have been due to the stimulus value of the message and/or to the overt nature of the manipulation attempt. In spite of this, three months later SD Ss (regardless of message) reported smoking significantly less than controls. The results relate the known cognitive effects of SD to its effects on persuasibility, further explore the cognitive uncertainty model of attitude change, and indicate the potential usefulness of SD as a technique for bringing about significant attitudinal and behavioral change.

1970

Dengrove, Edward; Nuland, William; Wright, M. Erik (1970). A single-treatment method to stop smoking using ancillary self-hypnosis: Discussion. [Comment/Discussion] .

#### NOTES

Discusses H. Spiegel's (see PA, Vol. 45:Issue 1) smoking treatment method comparing it to behavior therapy and suggesting modifications to treat smokers not responding to the method as described. It is suggested that certain psychological conditions must become active for nonsmoking status to be achieved or maintained including: (a) recognizing the consequences of smoking to be imminent, (b) identifying oneself as a nonsmoker, (c) expecting and wanting to participate in a satisfying future, and (d) adopting a way by which the individual can gain control over smoking. The technique outlined deals with these 4 dynamic aspects and makes a significant contribution to the treatment of the smoker's problem. (German & Spanish summaries) (PsycINFO Database Record (c) 2003 APA, all rights reserved)

Hall, J. A.; Crasilneck, H. B. (1970). Development of a hypnotic technique for treating chronic cigarette smoking. International Journal of Clinical and Experimental Hypnosis, 18, 283-289.

4 hypnotic sessions were found successful, in the majority of cases, in eliminating cigarette smoking without undersirable substitution symptoms. Patients were strongly motivated by the referring physicians and by various nonhypnotic techniques incorporated into the treatment program. Examples are given of the specific nature of both the hypnotic and the nonhypnotic suggestions employed. (German & Spanish summaries) (PsycINFO Database Record (c) 2002 APA, all rights reserved)

Kline, Milton V. (1970). The use of extended group hypno-therapy sessions in controlling cigarette habituation. International Journal of Clinical and Experimental Hypnosis, 18, 270-282.

Results of the present experimental approach to the treatment of smoking habituation tend to be consistent with the view of smoking habituation as a dependence reaction, parallel to drug addiction, and with the concept that habituation must be examined as a psychosomatic entity. Therapeutic approaches must take into account the psychophysiological characteristics of deprivation behavior. Hypnosis, and particularly extended periods of hypnotherapy involving the reduction and control of deprivation behavior, seems to offer a promising approach to the therapeutic treatment of smoking habituation. (German & Spanish summaries) (17 ref.) (PsycINFO Database Record (c) 2003 APA, all rights reserved)

Nuland, William; Field, Peter B. (1970). Smoking and hypnosis: A systematic approach. International Journal of Clinical and Experimental Hypnosis, 18, 290-306.

Compared 2 methods of helping cigarette smokers stop smoking using 181 patients. After 6 mo., 60% of those treated with an active, personalized approach were not smoking. This approach emphasized: (a) the feedback, under hypnosis, of the S's own reasons for quitting, (b) maintaining contact with

the S by telephone, (c) use of meditation during hypnosis to obtain individualized motives, and (d) self-hypnosis. Only 25% of Ss were successfully treated by an earlier hypnotic procedure that did not systematically employ these features. (German & Spanish summaries) (PsycINFO Database Record (c) 2003 APA, all rights reserved)

Spiegel, Herbert (1970). A single-treatment method to stop smoking using ancillary self-hypnosis. International Journal of Clinical and Experimental Hypnosis, 18 (4), 235-250.

Discusses the 1st 615 patient-smokers who were treated with a single 45-min session of psychotherapy reinforced by hypnosis. Technique of treatment, including rationale of approach, induction procedure, assessment of hypnotizability, and training instructions to stop smoking are presented in detail. 6-mo follow-up study results are discussed. Of 44% who returned a questionnaire, hard-core smokers stopped for at least 6 mo. Another 20% reduced their smoking to varying degrees. Results of a 1-session treatment compare favorably with, and often are significantly better than, other longer-term methods reported in the literature. It is suggested that every habitual smoker who is motivated to stop be exposed to the impact of this procedure, or its equivalent, so that at least 1 of 5 smokers can be salvaged. (French & Spanish summaries). (PsycINFO Database Record (c) 2003 APA, all rights reserved)

Spiegel, Herbert (1970). A single-treatment method to stop smoking using ancillary self-hypnosis: Final remarks in response to the discussants. International Journal of Clinical and Experimental Hypnosis, 18 (4), 268.

Reexamines the major points of the author's papers (see PA, Vol. 45:Issue 1) on smoking modification. Data inclusion, therapy length, Ss' ability to change, and use of multiple therapists and tape recordings as reinforcement are discussed. It is concluded that the method should be used to "sharpen our techniques that we can relatively quickly learn who has the capacity to change for given goals, and then to help evoke the desired change as efficiently as possible." (PsycINFO Database Record (c) 2003 APA, all rights reserved)

1964

Stein, C. (1964). A displacement and reconditioning technique for compulsive smokers. International Journal of Clinical and Experimental Hypnosis, 12 (4), 230-238.

A procedure for reducing total anxiety in chronic smokers while ostensibly directed toward permissive alteration of the smoking pattern is presented. In light trance the motivated patient is taught: (a) elementary respiratory relaxation (natural sigh), (b) displacement of emphasis from inhaling smoke to exhaling clean fresh air, (c) enhancement of satisfaction from other pleasurable factors -- touch, shape, color, aroma, flame, smoke clouds, and taste, (d) to puff, hold smoke in mouth, inhale fresh air through nose and exhale through mouth. In most cases practice in stressing positive qualitative smoking pleasure soon results in automatic quantitative reduction of cigarette consumption. 5 brief case reports are presented.

1956

Hershman, Seymour (1956). Hypnosis and excessive smoking. Keywords: addiction, medical, smoking

NOTES

"Conclusion: Several methods are described wherein psycho-biologic techniques can be used with hypnotic procedures to treat excessive cigarette smoking with relatively permanent results. These

techniques include symptom substitution, reeducation, reconditioning, reassurance and persuasion. The use of fantasy evocation, visual imagery, etc. by means of the hypnotic state produces an increase in the patient's responsiveness to therapy.

"Several case histories have been presented to illustrate some of the various techniques and their reactions. These procedures can readily be made available to a vast number of people with gratifying results. It is felt that all professional people in the therapeutic fields should be aware of the excellent use which can be made of hypnosis, and should acquaint themselves with hypnotic techniques in order to utilize them to the best interests of their patients. It is important to note that psychodynamic orientation is essential to the proper utilization of hypnosis and that the training received by the stage entertainer lacks this important element" (p. 29).

## **SOCIAL CONTROL**

**1991**

**Kinnunen, Taru; Zamansky, Harold S.; Block, Martin L. (1991, August). Is the hypnotized subject lying?. [Paper] Presented at the annual meeting of the American Psychological Association, San Francisco.**

To determine whether or not hypnotized subjects misrepresent or lie about their hypnotic experiences, electrodermal skin conductance responses were measured while groups of deeply hypnotized subjects and simulators responded to questions about their experiences to a series of suggestion. 89% of the responses of the hypnotic subjects met the criteria for truthfulness, while 65% of the responses of the simulators indicated deception. Differences between "reals" and simulators were highly significant. The relevance of the results for the nature and theory of hypnosis is discussed. (ABSTRACT from Bulletin of Division 30, Psychological Hypnosis, Provided by former Editor, James Council.)

**Wagstaff, Graham F. (1991). Hypnosis and harmful and antisocial acts: Some theoretical and empirical issues. Contemporary Hypnosis, 8, 141-146.**

## **NOTES**

The author analyses paper in same issue of this journal: Gibson, H. B. (1991). Can hypnosis compel people to commit harmful, immoral and criminal acts?: A review of the literature. He presents a critique from the point of view of "state" theorists, and concludes: "Where does this leave us? The area seems to be a potential minefield for any unsuspecting dissociationist. Personally, I think that both parsimony, and what empirical evidence there is, point to a non-state approach to this issue. However, despite the inevitable uncertainties and differences of opinion, there is perhaps a very obvious and important lesson to be gained by all from studies in this area. It has been fashionable to write off experimental studies on this topic on the grounds that subjects in these studies generally perceive the situation as 'safe'; this is not only the case in hypnosis research but also in general social-psychological work on obedience (see, for example, Orne & Holland, 1968; Mixon, 1974). Some have questioned this assumption that subjects only obey the experimenter when they perceive the situation to be safe (see Barber, 1969; Milgram, 1974), but what often goes unnoticed is the significance of this assumption in itself. If labeling a situation as 'hypnosis', or even just an 'experiment', can make subjects think that any apparently harmful act they are requested to perform is safe, think of the implications; here, in itself, is a potentially powerful, even lethal, mechanism by which people in hypnotic contexts may be induced to perform harmful and antisocial acts. They perform them because, given the context, they think it is safe to do so! In the study of Orne and Evans the venomous snake the subjects were instructed to grasp was placed behind an 'invisible' glass screen, and the acid they were instructed to throw at the experimenter had been, allegedly unknown to them, replaced by a harmless

liquid; one wonders, however, if writers would be so dismissive if the liquid that Orne and Evans' subjects threw at the experimenter had actually burned him, or the snake that they picked up had actually killed them" (pp. 144-45).

1990

Coe, William C. (1990). Are the Conclusions Valid? Invited discussion of Levitt, Baker, and Fish: Some conditions of compliance and resistance among hypnotic subjects. American Journal of Clinical Hypnosis, 32 (4), 237-239.

#### NOTES

The authors confounded variables, e.g. hypnotic susceptibility and monetary incentive (in Study IV), and Study IV was different from the other 3 studies, so that any differences/similarities between these studies can't be attributed to susceptibility level, degree of incentive, or interaction between them.

A simulator design would clarify why 50% of Ss in Study IV did not resist and lost \$100; also, postexperimental interviews focusing on Ss' reasons for resisting or not resisting would be helpful. Did nonresisters actually believe that they would receive \$100 for resisting?

The Subject population was not homogeneous in occupation, and students are financially poorer than others--which would affect incentive strength. Were those who resisted the ones who could use the money the most?

Small sample sizes obviating statistical tests is a problem. Coe nevertheless evaluates 4 variables in terms of the 'power' of their effects on hypnosis: 1. Susceptibility level. Studies I, II, and III all show correlations between hypnotizability and compliance with resistance, suggesting that high hypnotizables are not as susceptible to resistance manipulation; however across studies, highs in one study seem to comply at the same rate as lows in another study, and as many as 50% of high hypnotizables in the strong incentive (\$100) study were able to resist suggestions. 2. View of the Hypnotist. Coe states that one can't evaluate the question with the data given. One would need an experimental condition that would also create a negative view of the hypnotist, as all samples tended to view the hypnotist positively. 3. View of Resistance Instructor. Again, one would need a research design that separates the effects of hypnotic susceptibility from effects of Ss' views of the resistance instructor. "Nevertheless, Study IV suggests that for high susceptibles the view of the resistance instructor has little effect. Three resisters viewed him as positive, whereas the other three viewed him as negative; further, nearly all of the nonresisters viewed him as neutral" (p. 238). 4. Degree of Incentive. This too was confounded with susceptibility level, as "the higher value was only offered to the very high susceptibles in study IV. Half of them took it, half did not" (pp. 238-239).

Coe also remarks that "the expectational effects on subjects of being in an experiment have not been addressed adequately. It is possible that the experimental paradigm as currently presented is incapable of providing an unambiguous answer to the question of coercion. In naturalistic settings subjects may react quite differently than they do when they know they are participating in an experiment" (p. 239).

Spiegel, David (1990). Theoretical and empirical resistance to hypnotic compliance. Invited discussion of Levitt, Baker, and Fish: Some conditions of compliance and resistance among hypnotic subjects. American Journal of Clinical Hypnosis, 32 (4), 243-245.

#### NOTES

Does hypnosis bypass the will, facilitate coercion? The hardest thing for trauma victims to do is to admit helplessness. Furthermore, it is interesting that these same dissociative phenomena seem to be elicited by traumatic experience, the stark imposition of involuntariness (Stutman & Bliss, 1985; Spiegel, Hunt, & Dondershine, 1988). What, then, are we to make of experiments that purport to show that hypnotizable and hypnotized individuals comply with hypnotic instructions irrationally? At some

level this challenges our comfortable belief that we always act in our enlightened self-interest, unaffected by unwanted influence. If that can happen even once, our pride of self-ownership is reduced.

Taken as a whole, the studies show that high hypnotizables comply with hypnotic instructions, even in the face of resistance instructions, whereas low hypnotizables are less likely to, especially when conditions foster a relatively less negative view of the resistance instructor. As the authors note, subjects always viewed the hypnotist more positively than the resistance instructor, which in itself suggests the nonrational influence intrinsic to hypnosis. Free will is not abrogated, it is simply not exercised. The Ss are fundamentally choosing whether or not to comply. Half of the highs in Study IV resisted the hypnotic instruction. However, hypnotized individuals tend to narrow the focus of attention, thereby reducing their ability to consider alternatives such as the resistance instruction.

William James (1890) believed that all ideas were invitations to action. Why, then, do we not act on every idea we have, he pondered on a snowy morning while lying in bed. He observed that he would try to get himself to arise by picturing himself doing so. "Why, then, am I still in bed?" He realized that he was editing the primary idea, reflecting on how cold it was, how long it would take to light a fire, and how much time he had until his classes. In a state characterized by a narrowing of the focus of attention, we are less likely to edit the primary idea, and therefore more likely to act. In the experiments presented, the resistance instructor attempts to act as an external editor on the primary hypnotic instruction. Those capable of focusing attention sufficiently disattend to the editing and comply. These studies show that, thankfully, hypnosis is less than automatic submission to instruction but, interestingly, more than simple conscious response to new information.

Weitzenhoffer, Andre M. (1990). Are induced automatisms necessarily coercive? Invited discussion of Levitt, Baker, and Fish: Some conditions of compliance and resistance among hypnotic subjects. American Journal of Clinical Hypnosis, 32 (4), 245-246.

## NOTES

"For the sake of maintaining historical accuracy, I would like first to remark that the ability of hypnotized Ss to resist suggestions was probably never a central issue in the Nancy-Salpetriere controversy. The main quarrel was about other fundamental matters (Crocq, 1900; Barrucand, 1967). It also needs to be said that Pierre Janet should not be seen as representing the Salpetriere in the above controversy. Very little of his extensive writings reflect the ideas of Charcot with whom he was associated for only 4 years (1889- 1893) (Barrucand, 1967; Ellenberger, 1970). Lastly, let it be noted that the association of automatism with hypnotic behavior antedates Bernheim. Despine wrote about it at length as early as 1868, and Charcot (1882) clearly stated before Bernheim that automatic responses to suggestions were characteristic of induced somnambulism. This was at least one view they shared.

Referring to the material quoted from my 1978 paper, the authors assert Bernheim's definition of automatism implies a subject responding to a suggestion qua suggestion is "unable to resist" it. But all the definition says is that the will does not directly enter into the production of automatisms. It does not say the will cannot effectively intrude at some point or other. This definition, quoted out of context, was part of a more extensive discussion of what the nature of an automatism was for Bernheim. The discussion also went into details regarding the conditions under which Bernheim understood automatisms can occur and hold sway. In this greater context, Bernheim (1888a, 1888b) viewed the occurrence of automatisms as normally subject to control by the ego processes responsible for volitional activities. He saw the degree to which a person's behavior can be controlled by automatisms initiated by suggestions to be a function of the extent to which certain ego processes become inactive, ineffective, or cooperatively permit the automatisms to occur. Bernheim recognized that both cognitive and relational factors played an important part in the latter case. Bernheim (1888a, 1888b) also stated

that data he had collected showed subjects could resist suggestions to varying degrees, with only 17%, who made up the class of somnambules, being totally incapable of resisting" (pp. 245-246). "Stating the matter more concretely, I doubt many people would speak of an individual having been 'coerced' into producing a knee-jerk reflex under appropriate stimulation. Should the situation be any different in the case of other reflexes and, more particularly, the reflex ideodynamic action presumed to underlay suggested acts (Weitzenhoffer 1978, 1989)? I do not think so. It seems to me that what the authors have really and directly examined in their article is the extent to which the classical suggestion effect can be countered by conscious, voluntary control" (p. 246).

1988

Coons, P. M. (1988). Misuse of forensic hypnosis: A hypnotically elicited false confession with the apparent creation of a multiple personality. International Journal of Clinical and Experimental Hypnosis, 36 (1), 1-11.

A case is presented in which there was flagrant misuse of forensic hypnosis. The patient, a woman in her early 30s, was accused of shooting her 2 children. During a hypnotic interview, the police hypnotist used an extremely suggestive interrogative technique, and the suspect produced an apparent secondary personality who confessed to the shootings. Subsequently the prosecutor tried to enter the "hypnotic confession" as evidence against the defendant. The evidence was dis-allowed because of the manner in which it was obtained and because of the lack of verification from other sources. The literature regarding the use of forensic hypnosis is reviewed as is the literature regarding multiple personality and the experimental production of multiple personality-like phenomena.

1986

Sands, Steven (1986, August). The use of hypnosis in establishing a holding environment to facilitate affect tolerance and integration in impulsive patients. Psychiatry, 49.

This paper is concerned with the use of hypnosis in establishing a facilitating and holding environment in the treatment of impulsive behavior across a range of diagnoses. The reason for this cross-diagnostic viewpoint is to underscore the common sources of such action and the needs to be met in its treatment. Illustrations from work with two patients are presented: One was a hypomanic and bulimic woman who was successful in her profession; the other was an underemployed and sometimes unemployed schizophrenic man. Both were inclined to self-defeating impulsive action---bulimia in the woman, assault in the man.

1981

Conn, J. H. (1981). The myth of coercion through hypnosis: A brief communication. International Journal of Clinical and Experimental Hypnosis, 29 (2), 95-99.

A brief history of coercion through hypnosis is presented. Hypnosis is not an external "force," which can be used to overcome a subject's "will power." It can be used as an alibi, a folie a deux, a neurotic compromise, a legitimatization, or rationalization of behavior, as well as being genuine, involuntary, automatic hypnosis. Unwitting simulation occurs frequently. Laboratory crimes and stage hypnosis are "make believe" performances occurring in a completely protected situation. Neither a long-term relationship, nor an attempt to distort perception is a necessary or sufficient cause of coercion. The possibility of "motivated helplessness," a "self-fulfilling prophecy" or a "believed in efficacy" must be considered. Coercion through hypnosis is a myth which will not disappear so long as it is fostered by uninformed hypnotists, who believe that all initiative and self-determination is surrendered by the subject to an "all powerful" hypnotist.

1975

Spear, J. E. (1975). The utilization of non-drug induced altered states of consciousness in borderline recidivists. American Journal of Clinical Hypnosis, 18, 111-126.

Utilizing non-drug induced altered states of consciousness, various modes of interior reflection, behavior modification and reprogramming of conscious attitudes and values were utilized with 49 borderline recidivists. Such offenders were so determined by the Department of Corrections, Probation and Parole Office, District II. No coercion was used to induce such individuals to enter the program and there was no reprisal for stopping therapy at any time. Over a two and one-half year period the recidivist rate among this group was less than 5%. It is suggested that non-drug induced altered states of consciousness combined with indirect as well as symbolic techniques may prove to be the most effective means of criminal rehabilitation.

#### NOTES

Berderline recidivists were "individuals, who, in the opinion of the P.O. [probation officer] were, in all probability, to be returned to prison within a few months, or less, if there wasn't a major change in attitude and actions" (p. 111). Therapy employed closed circuit TV with bi-directional audio and induction of altered state of consciousness using an ophthalmology-type rotary prism. Therapy involved (s) recall of relaxed state when under stress, (2) exploration of early conditioning events, (3) self evaluation during the ASC, (4) use of symbolic mental exercises and mental practice for similar circumstances in normal waking state, (5) suggestions for setting goals and ideals, (7) a type of logotherapy, (7) 'nudging' the person to examine their relationship with their concept of God. The author noted in the parolees: (1) low levels of self esteem, (2) depression, (3) going into deep levels of altered states once trust was established with the therapist.

1954

Howarth, Edgar (1954). Postscript to a new theory of hypnosis. Journal of Clinical and Experimental Hypnosis, 2, 91-92.

#### NOTES

Referring to a theory of internal and external signalling systems, the author describes situations in which an individual's behavior comes under other than willed control by virtue of external circumstances. "In normal behavior the individual provides his own 'will' and may, to some extent, choose among a variety of alternative action sequences on the basis of guiding integrations between the second (externally directed) signalling system and the primary (internally directed) signalling system. ... it appears that a considerable degree of control may be obtained by the 'top' semantic command system over internal process, particularly those 'inhibited' by the cranial and sacral subdivisions of the 'autonomic' nervous system. .. [In anecdotal case reports] control was gained over breathing, heart rate and bladder and the person may feign death for several days. In such cases surface wounds do not exude other than lymph. The method for such control remains for experimental examination, but a necessary part of the procedure seems to be the use of mild occasional reward during a prolonged period of fasting. Solitary confinement is also necessary and both deserts and prison cells are reported ... to have been used" (pp. 91-92).

1953

Beigel, Hugo G. (1953). Prevarication under hypnosis. Journal of Clinical and Experimental Hypnosis, 1 (3), 32-40.

## NOTES

Author describes three cases in which hypnosis was used to confirm or disconfirm information provided in the waking state. All three cases involved marital relationships and mistrust. "It is interesting that, awakened from the hypnotic state, none of the subjects made the slightest attempt to deny any of the admissions made" (p. 39).

Guze, Henry (1953). The phylogeny of hypnosis. Journal of Clinical and Experimental Hypnosis, 1 (3), 41-46.

## NOTES

"The continuity of hypnotic phenomena from infrahuman through human organisms has created an array of problems in interpretation" (p. 41). "Unfortunately, most investigators in animal hypnosis have concerned themselves mainly with states of immobility. Because of this, they have neglected to recognize that hierarchical and group reactions of animals are just as fit in the category of hypnotic behavior" (pp. 41-42). "It is postulated in this paper that hypnosis or hypnotizability is a phylogenetically derived characteristic strongly akin to emotional readiness. It differs in expression from organism to organism within a species and from species to species" (p. 45).

Marcuse, F. L. (1953). Anti-social behavior and hypnosis. Journal of Clinical and Experimental Hypnosis, 1, 18-20.

## NOTES

"The problem of whether an individual under hypnosis can be caused to commit an act contrary to his or her moral code must be paraphrased to ask whether an individual under hypnosis can be caused to commit an act which is socially and objectively reprehensible. When the question is so phrased and suitable technique is used, it is the writer's opinion that the answer is yes" (p. 20).

## SOCIAL PRESSURE

1994

Spanos, Nicholas P.; Burgess, Cheryl A.; Burgess, Melissa Faith (1994). Past-life identities, UFO abductions, and satanic ritual abuse: The social construction of memories. International Journal of Clinical and Experimental Hypnosis, 42 (4), 433-446.

People sometimes fantasize entire complex scenarios and later define these experiences as memories of actual events rather than as imaginings. This article examines research associated with three such phenomena: past-life experiences, UFO alien contact and abduction, and memory reports of childhood ritual satanic abuse. In each case, elicitation of the fantasy events is frequently associated with hypnotic procedures and structured interviews which provide strong and repeated demands for the requisite experiences, and which then legitimate the experiences as "real memories." Research associated with these phenomena supports the hypothesis that recall is reconstructive and organized in terms of current expectations and beliefs.

## SOCIAL PSYCHOLOGY

1997

Kihlstrom, John F. (1997). Convergence in understanding hypnosis? Perhaps, but perhaps not quite so fast. International Journal of Clinical and Experimental Hypnosis, 45 (3), 324-332.

The study of hypnosis has been plagued by conflict. Although a more recent trend has been the search for convergence among disparate points of view, two highly salient issues remain contentious: the question of whether hypnosis involves alterations in consciousness, and the nature and correlates of individual differences in hypnotic response. Theoretical convergence is a laudable goal, but not at the expense of obscuring the complexity of hypnosis as a state of altered consciousness, a cognitive skill, and a social interaction. Perhaps the best prescription for convergence in hypnosis is the cautious conviction advocated by Kenneth S. Bowers and so clearly exemplified in his own research. - Journal Abstract

#### NOTES

"Modern cognitive psychology and cognitive science have come to a point where, at long last, they are prepared to take seriously the problem of consciousness, and of the relations between conscious and unconscious mental life (e.g., Kihlstrom, in press). Hypnosis has something unique to contribute to this discussion, but it will not do so if it achieves convergence by ignoring the alterations of consciousness that lie at the core of the experience of hypnosis" (p. 328). "Hypnosis is a complex phenomenon, simultaneously a social interaction, with hypnotist and subject interacting in a larger sociocultural context, and a state of altered consciousness, involving basic cognitive mechanisms underlying perception, memory, and thought. When we do eventually achieve consensus on a theoretical account of hypnosis, that account will have to invoke the constructs of both cognitive and social psychology" (p. 329).

Lynn, Steven Jay (1997). Automaticity and hypnosis: A sociocognitive account. International Journal of Clinical and Experimental Hypnosis, 45 (3), 239-250.

This article provides an overview of a new theory of suggested involuntariness in hypnosis, developed in conjunction with Irving Kirsch. The theory is based on the following ideas. First, high hypnotizable participants enter hypnosis with a conscious intention to feel and behave in line with suggested experiences and movements. Second, people who are easily hypnotized hold firm expectations that they will succeed in following the suggestions of the hypnotist. Third, the intention and expectation in turn function as response sets in the sense that they trigger the hypnotic response automatically. Fourth, given the intention to feel and behave in line with the hypnotist's suggestions, hypnotized individuals show no hesitation to experience the suggested movements as involuntary because (a) these movements are actually triggered automatically, and (b) the intention to cooperate with the hypnotist as well as the expectation to be able to do so create a heightened readiness to experience these actions as involuntary. - Journal Abstract

Nadon, Robert (1997). What this field needs is a good nomological network. International Journal of Clinical and Experimental Hypnosis, 45 (3), 314-323.

Research in the field of hypnosis lacks a coherent structure on which to build. This lack of a mature nomological network stems from fundamental disagreements concerning the construct validity of hypnotizability, which in turn stem in part from different research practices across laboratories. For these reasons, the field has had less impact on psychology and medicine than is warranted by the numerous sophisticated scientific studies that have been conducted during the past three decades. - Journal Abstract

#### NOTES

Author refers to Cronbach & Meehl, 1955, for these definitions. "Construct validity is ordinarily studied when the tester has no definite criterion measure of the quality with which he is concerned,

and must use indirect measures. Here the trait or quality underlying the test is of central importance, rather than either the test behavior or the scores on the criteria" (p. 282, C & M). "Scientifically speaking, to 'make clear what something is' means to set forth the laws in which it occurs. We shall refer to the interlocking system of laws which constitute a theory as a nomological network' (p. 290, C & M, emphasis omitted). Author suggests that progress in developing a nomological network is dependent upon standardization of research procedures, such as the hypnosis scales used, the inductions used, and the description of hypnosis given to research subjects. He recommends using the Harvard Group Scale of Hypnotic Susceptibility, Form A, the Stanford Hypnotic Susceptibility Scale, Form C, and the Waterloo-Stanford Group C Scale of Hypnotic Susceptibility "perhaps with agreed-on modifications to include subjective experience as is the case with the CURSS" (p. 321).

Nash, Michael R. (1997). Why scientific hypnosis needs psychoanalysis (or something like it). International Journal of Clinical and Experimental Hypnosis, 45 (3), 291-300.

The author contends that some contemporary hypnosis theories are restricted and narrow in scope, rendering them unnecessarily isolated from mainstream models of human development, psychopathology, and personality functioning. They seem to explain hypnosis and little else. The author contrasts this with psychoanalysis, which, although sometimes overly expansive, does nonetheless lend itself to the generation of specific hypothesis via careful deduction from a general theory of human behavior and experience. For illustrative purposes, the author criticizes the sociocognitive perspective of hypnosis contending that at present it is too narrowly inductive in focus, overvalues social influence, and has its own problems with reification. The author suggests remedies for these difficulties. - Journal Abstract

Ruehle, Beth L.; Zamansky, Harold S. (1997). The experience of effortlessness in hypnosis: Perceived or real. International Journal of Clinical and Experimental Hypnosis, 45 (2), 144-157.

Hypnotized individuals who successfully respond to a suggestion typically report that the response requires little or no cognitive effort. It is important, however, to distinguish between whether this effect occurs in actual effort or is only perceived. In addition, the authors distinguish between cognitive effort expended to initiate a response and that required to maintain it. The authors examine the different predictions of four theories-compliance theory, sociocognitive theory (Lynn & Rhue, 1991), Hilgard's (1986) neodissociation theory, and Bowers's (1992) theory of dissociated control-regarding both of these distinctions. Experimental evidence bearing on the various predictions is examined. Additionally, the authors propose a number of design modifications that may help sort out the variables contributing to the effortlessness of the hypnotic response. -- Journal Abstract

1995

Ganaway, George K. (1995). Hypnosis, childhood trauma, and dissociative identity disorder: Toward an integrative theory. International Journal of Clinical and Experimental Hypnosis, 43 (2), 127-144.

It is contended that prevailing exogenous trauma theory provides in most cases neither a sufficient nor a necessary explanation for the current large number of diagnosed cases of dissociative identity disorder (multiple personality disorder) and related dissociative syndromes purported to have arisen as a response to severe early childhood physical and sexual abuse. Relevant aspects of instinctual drive theory, ego psychology, object relations theory, self psychology, social psychological theory, sociocultural influences, and experimental hypnosis findings are drawn on to demonstrate the importance of adopting a more integrative theoretical perspective in the diagnosis and treatment of severe dissociative syndromes. Further cooperative experimental and clinical research on the etiology, prevalence, and clinical manifestations of the group of dissociative disorders is strongly encouraged.

Sarbin, Theodore R. (1995). On the belief that one body may be host to two or more personalities. International Journal of Clinical and Experimental Hypnosis, 43 (2), 163-183.

The belief in the validity of the multiple personality concept is discussed in this article. Two scaffolding constructions are analyzed: dissociation and repression. As generally employed, these constructions grant no agency to the multiple personality patient. The claim is made that the conduct of interest arises in discourse, usually with the therapist as the discourse partner. In reviewing the history of multiple personality and the writings of current advocates, it becomes clear that contemporary users of the multiple personality disorder diagnosis participate in a subculture with its own set of myths, one of which is the autonomous actions of mental faculties. Of special significance is the readiness to transfigure imaginings into remembering of child abuse, leading ultimately to the manufacture of persons. The implications for both therapy and theory of regarding the patient as agent in place of the belief that the contranormative conduct is under the control of mentalistic faculties are discussed.

1994

Epstein, Seymour (1994). Integration of the cognitive and the psychodynamic unconscious. American Psychologist, 49 (8), 709-724.

Cognitive-experiential self-theory integrates the cognitive and the psychodynamic unconscious by assuming the existence of two parallel, interacting modes of information processing: a rational system and an emotionally driven experiential system. Support for the theory is provided by the convergence of a wide variety of theoretical positions on two similar processing modes; by real-life phenomena--such as conflicts between the heart and the head; the appeal of concrete, imagistic, and narrative representations; superstitious thinking; and the ubiquity of religion throughout recorded history--and by laboratory research, including the prediction of new phenomena in heuristic reasoning.

Mulhern, Sherrill (1994). Satanism, ritual abuse, and multiple personality disorder: A sociohistorical perspective. International Journal of Clinical and Experimental Hypnosis, 42 (4), 265-288.

During the past decade in North America, a growing number of mental health professionals have reported that between 25% and 50% of their patients in treatment for multiple personality disorder (MPD) have recovered early childhood traumatic memories of ritual torture, incestuous rape, sexual debauchery, sacrificial murder, infanticide, and cannibalism perpetrated by members of clandestine satanic cults. Although hundreds of local and federal police investigations have failed to corroborate patients' therapeutically constructed accounts, because the satanic etiology of MPD is logically coherent with the neodissociative, traumatic theory of psychopathology, conspiracy theory has emerged as the nucleus of a consistent pattern of contemporary clinical interpretation. Resolutely logical and thoroughly operational, ultrascientific psychodemonology remains paradoxically oblivious to its own irrational premises. When the hermetic logic of conspiracy theory is stripped away by historical and socio/psychological analysis, however, the hypothetical perpetrators of satanic ritual abuse simply disappear, leaving in their wake the very real human suffering of all those who have been caught up in the social delusion.

Spanos, Nicholas P. (1994). Multiple identity enactments and multiple personality disorder: A sociocognitive perspective. Psychological Bulletin, 116, 143-165.

People who enact multiple identities behave as if they possess 2 or more selves, each with its own characteristic moods, memories, and behavioral repertoire. Under different names, this phenomenon occurs in many cultures; in North American culture, it is frequently labeled multiple personality

disorder (MPD). This article reviews experimental, cross-cultural, historical, and clinical findings concerning multiplicity and examines the implications of these findings for an understanding of MPD. Multiplicity is viewed from a sociocognitive perspective, and it is concluded that MPD, like other forms of multiplicity, is socially constructed. It is context bounded, goal-directed, social behavior geared to the expectations of significant others, and its characteristics have changed over time to meet changing expectations.

Spanos, Nicholas P.; Burgess, Cheryl A.; Burgess, Melissa Faith (1994). Past-life identities, UFO abductions, and satanic ritual abuse: The social construction of memories. International Journal of Clinical and Experimental Hypnosis, 42 (4), 433-446.

People sometimes fantasize entire complex scenarios and later define these experiences as memories of actual events rather than as imaginings. This article examines research associated with three such phenomena: past-life experiences, UFO alien contact and abduction, and memory reports of childhood ritual satanic abuse. In each case, elicitation of the fantasy events is frequently associated with hypnotic procedures and structured interviews which provide strong and repeated demands for the requisite experiences, and which then legitimate the experiences as "real memories." Research associated with these phenomena supports the hypothesis that recall is reconstructive and organized in terms of current expectations and beliefs.

1992

Bowers, Kenneth S. (1992). Imagination and dissociation in hypnotic responding. International Journal of Clinical and Experimental Hypnosis, 40 (4), 253-275.

A neodissociative model of mind is better equipped than a social-psychological model to deal with the complexities of hypnosis, and of human behavior generally. It recognizes, as Coe's (1992) model does not, that behavior can be more automatically activated than strategically enacted. In particular, Coe's emphasis on human behavior as purposeful and goal directed does not distinguish between goal-directed behavior that serves a purpose, and goal-directed behavior that is performed on purpose. It is this distinction that permits goal-directed behavior to be dissociated from a person's conscious plans and intentions. In addition to offering a critique of Coe's "limited process" view of hypnosis, 4 main points are made in the interest of developing a slightly modified, neodissociation view of hypnosis. First, it is argued that goal-directed fantasies are more limited in their ability to mediate hypnotic responding than is commonly appreciated; as well, they do not seem to account for the nonvolitional quality of hypnotic responding. Second, it is argued that hypnotic ability is not unidimensional, with compliance and social influence more apt to account for the low than for the high hypnotizable's responsiveness to suggestion. Third, compared to low hypnotizables, the hypnotic responsiveness of high hypnotizables seems more likely to result from dissociated control. In other words, for high hypnotizables, hypnotic suggestions may often directly activate subsystems of cognitive control. Consequently, the need for executive initiative and effort to produce hypnotically suggested behavior is minimized, and such responses are therefore experienced as nonvolitional. Fourth and finally, while goal-directed fantasies typically accompany hypnotically suggested responses, they are in many cases more a marker of dissociated control than a mediator of suggested effects.

Coe, William C. (1992). Hypnosis: Wherefore art thou?. International Journal of Clinical and Experimental Hypnosis, 40 (4), 219-237.

The present paper focuses on the influences of social-political needs of various groups with interests in hypnosis (i.e., stage hypnotists, lay hypnotists, licensed practitioners, and researchers). While hypnosis is a specific topic of interest to groups with varying needs, it also serves as an example for other topics in psychology that may overlap the needs of other groups -- especially practitioners and researchers. The identity given to hypnosis varies depending upon which particular group of persons is offering the identity, and the nature of the identity reflects each group's biases and needs. These various identities, however, are not always acceptable, in part or in whole, by the other groups, as the needs of one or more may be in conflict with those of others.

Kirmayer, Laurence J. (1992). Social constructions of hypnosis. International Journal of Clinical and Experimental Hypnosis, 40 (4), 276-300.

Both clinical and experimental views of hypnosis are social constructions that reflect the biases and interests of practitioners and scientists. Each perspective offers useful metaphors for hypnosis. Underlying clinical uses of the term hypnosis are states of mind associated with imaginative reverie and automatic behavior based on procedural knowledge. Social discourse and narratives shape hypnotic experience, but they are themselves influenced by mechanisms of attention and automaticity. Study of hypnosis must proceed on both social and psychological fronts to account for the experience and clinical efficacy of hypnosis.

#### NOTES

"In accord with Coe, Sarbin, and other social-psychological theorists, I will argue that hypnosis, like all higher mental phenomena, is fundamentally social in nature. To accept this, however, does not obviate the role of distinctive processes of attention, imagery, and imagination. Hypnosis is a socially constructed context and ritual for evoking imaginative enactment and involuntary of "automatic" modes of experience and behavior. Contemporary social-psychological theorists have failed to sufficiently explore the nature of enactment. A satisfactory account of hypnosis must go much deeper into the cognitive and social construction of experience; only then can involuntary behavior be properly distinguished from self-deception and self-authorship from cultural construction" (p. 277).

Nadon, Robert; Dywan, Jane; Adams, Barbara (1992, October). The social psychology of depth reports: Skirting the important data. [Paper] Presented at the annual meeting of the Society for Clinical and Experimental Hypnosis, Arlington, VA.

#### NOTES

Radke & Spanos used a new 7-point scale that permitted Ss to say they passed an item but were not hypnotized, and only 25% (instead of 88% on usual 4-point scale) said that they were hypnotized.

Do we delude ourselves in thinking reports of hypnotic depth just reflect scale wording, or is something genuine being measured? Radke & Spanos found that breaking down Ss into low, medium, and high hypnotizable groups, the mediums are the ones who are affected by scale manipulations.

Perry, Campbell (1992). Theorizing about hypnosis in either/or terms. International Journal of Clinical and Experimental Hypnosis, 40, 238-252.

The present paper addresses 3 issues raised by Coe (1992). First, it maintains that the "altered state" issue of the 1960s remains buried in current dichotomous classifications of hypnosis theories as involving either "special processes" or the social- psychological position. Given the current diversity of the field, it appears imprudent to classify theorizing in either/or terms; additionally, despite a history of using the term "altered state" in a circular way, it is not an inherently circular formulation. It can be used descriptively simply to point to the observation that some individuals in hypnosis report subjective alterations. A second issue broached concerns the metaphorical status of the term "hypnosis"; it is accepted as a misleading metaphor inherited from 19th century investigators such as Braid, Faria, Puysegur, and Liebeault. Provided that it is recognized that this metaphor refers to a "domain" (E. G. Hilgard, 1973) of characteristically elicited behaviors, no problem ensues in retaining this metaphor derived from nocturnal sleep. A subsequent discussion of current conceptualizations of hypnosis indicates considerable agreement among investigators; there is much consensus that hypnosis is an individual differences phenomenon, in which imagination may, in some individuals, become so intense and so vivid, as to take on "reality value," to the extent that a hypnotized person may have difficulty in distinguishing fantasy from reality. The S abilities of imagery/imagination, absorption, dissociation, and automaticity (which may be proved to be an index of dissociation) are proposed as being the main ingredients of the hypnotic experience. Finally, a synergistic approach is proposed as a means of progressing beyond the current impasse of either/or theorizing.

#### NOTES

Frequency of reports of multiple personality disorder has varied over the centuries. The diagnosis is limited now to North America; and some therapists see more than others. Contemporary cases report severe child abuse, but this was much less so at the turn of the century.

There is an older syndrome, called demonic possession, which shares all of these characteristics. Demonic possession was diagnosed for almost 2000 years and the disorder included: secondary (demonic) selves, and the patient being amnesic during the personality take-over by a demon. The diagnosis was more prevalent during some periods (when Christianity was proselytizing but not when it was a state religion; then again in the 16th Century when Christianity was breaking up and both Catholics and Protestants had interest in it--each inspired by the other group). Demonic possession was more often found by some experts than others; and often was diagnosed as something else initially- - e.g. psychosomatic problems. Symptoms that were ambiguous were more definitive when patients were then seen by expert.

Some symptoms--convulsions, increased strength, and insensitivity to pain--were common across Europe. But in Catholic countries the possessed manifested a secondary personality: the demon, with a different voice, spoke through the person. This rarely happened in Protestant countries, where there were convulsions, amnesias, extra strength, etc. but no alter personality.

Why were there such different symptoms in Catholic and Protestant countries? The main difference was that Catholic countries used exorcism--getting information from the demon (name, when the demon entered the body, why, how long demon planned to stay). The exorcist didn't address the possessed person directly; he would say "I'm not talking to Mary; I'm talking to the demon." If the demon didn't reply, they would use brimstone, etc. to elicit a reply.

In Protestant countries it was believed that exorcism was inappropriate, because that would mean going to the Devil for help. They used prayer and fasting, but no attempt to communicate with the Demon. Hence, in France 20 nuns had secondary personalities, whereas in Protestant Salem, none of them had secondary personalities.

Often demon possession would occur to several people, with one person saying an image is attacking someone else, and then that second person would be possessed--so people would respond to social context, experience being possessed in terms of what that meant to them. Demonic possession was maintained by the community, so it was a social phenomenon.

Reports of ritual abuse then occurred, with witches talking about mockery of the Catholic mass, etc. Modern historians say these were fantasies, and that there were no witches' Sabbaths or ritual abuse of children.

One could infer that a therapist may be carrying out a secularized exorcism when he diagnoses multiple personality disorder.

To examine the contribution of social context to the reports of alternate personalities, we conducted a series of experiments.

We experimentally studied people instructed to simulate "an accused murderer remanded for psychiatric evaluation," and to behave as a criminal would. [They were hypnotized?] We used the interview employed with hypnotized Ss calling for a different part of themselves to speak. Of these simulators, 80% reported a secondary personality, and almost 100% claimed amnesia.

We took the people who displayed a secondary personality and amnesia and gave them psychological tests. They gave different pictures on the semantic differential [for the different personalities?].

A second experiment looked at how students would develop an alter personality. They were hypnotized and age regressed "to a past life," and were told about reincarnation. We then studied those who reported a past life. For half we told them people with a past life were likely to be born of a different race, etc. (because that is rarely reported spontaneously). Those who were told this were more likely to incorporate that information in their report of a past life experience.

In a third study, we told them that people in past eras, being less enlightened, tended to punish their children more. Those given this information were more likely to report abuse than those who were uninstructed.

A fourth study looked at how a hypnotist could influence the belief that it is a real past life rather than fantasy. They varied what Ss were told: Group 1 was told reincarnation is real. Group 2 was told reincarnation is fantasy. Group 3 was not told anything.

The first group reported a stronger belief that it was real than fantasy. (Oddly, the neutral group was nearly as high.) The Fantasy group had lower mean rating for credibility.

Woody, Erik Z.; Oakman, Jonathan; Drugovic, Mira (1992, October). Fleshing out a two-component view of individual differences underlying hypnotic responsiveness. [Paper] Presented at the annual meeting of the Society for Clinical and Experimental Hypnosis, Arlington, VA.

NOTES

Balthazar and I pointed out that different psychological processes are implicated in hypnotizability scale items, depending on the difficulty of the item. One process is more important on easy items, the other on difficult items.

We correlated an external variable as a function of difficulty of the items. Used the Absorption scale as the non-hypnotic measure for the latent correlation (biserial correlations). As item difficulty increases, the correlation with Absorption increases (from .2 to .5).

This suggests a high level of Absorption is needed to pass difficult items on the hypnotizability scale. We argued that Absorption is connected to true hypnotic responsiveness.

Now we are looking for indicators of easy item responsiveness. Last year I tried to explain anomalies in the data, anomalies that disappeared with a full complement of Ss.

Another possible external variable to correlate with item difficulty is a social compliance type of attribute, but in the history of hypnosis those variables are not found. Therefore we used a model from alcohol research that investigates an expectancy type of suggestion.

In that model, Ss drank two drinks that were alcohol free, but one drink purportedly had alcohol. Ss were told that large amounts of alcohol affect changes in perception, and that we were testing whether small amounts did. They were tested for "feeling of sluggishness in limbs," etc. They rated a list of experiences they might be having. The 109 Ss had been tested on Harvard A scale in separate research. Ratings in the alcohol model had high internal consistency; this suggestion score correlated with hypnotizability in .2-.3 range.

The pattern of latent correlations would be predicted to be a graph with a negative slope, which the researchers obtained.  $R = -.77$

The easier the hypnosis item, the stronger the correlation with the expectancy measure. The easiest Harvard A scale items tap little more than those expectancy effects, and the hardest items have almost nothing to do with the expectancy effect.

What does this mean? We thought it was evidence of a social influence factor. Further work suggests we need to be more specific.

We measured the other putative variables: 1. Compliance Questionnaire (Gudjonsson, 1989); it evaluates the tendency to comply with requests, and to obey instructions; e.g., "I tend to go along even when someone is wrong." It has correlated with a measure of social conformity. 2. Suggestibility Questionnaire (which we developed). Items were based on interviews in which Ss told about everyday suggestible things--e.g. "When I hear about an illness I tend to get it. When someone tells me they smell something, I tend to also."

These Compliance and General Suggestibility tests correlated .12 and .07 respectively with the alcohol expectancy measure; nor did they correlate with each other. They do not measure the same trait. Also, though they correlated .18 and .26 with hypnotizability, neither variable showed the spectral pattern on latent correlation analysis.

Thus, we need to be more specific in linking the alcohol expectancy measure to hypnosis.

Most items on Harvard A scale are motor items of either direct suggestion or inhibition (challenge) type. The relationship of alcohol expectancy to direct motor items is strong; the relationship is weaker with motor challenge items (for which another process must be important).

We can think of will vs automatic control of behavior, as in the theory presented by Normal and Shallice. For well-learned behavior there are two levels of control: 1. low level - doesn't require conscious attention and control 2. higher level - relevant to initiation of action, planning

Direct motor suggestion response requires little attentional effort and the role of will is not important. There exists ambiguity for indeterminacy of the role of will and attention. Ambiguity offers an opportunity to attribute one's action to hypnosis. What happens in alcohol expectancy is different, but an ambiguous experience is happening due to "alcohol" in the drink--ambiguous experience is interpreted according to the context.

This differs from the neodissociation theory explanation, according to which the suggested behavior is enacted voluntarily but the voluntary aspect is separated from consciousness. To me, for simple motor acts the causality is inferred rather than perceived. For simple motor acts, no such higher level control is needed.

Motor challenge items have instructions to "try" to overcome; S must exert will. "Try to raise your arm" is different from "Raise your arm." The S could remain role consistent and not try; ambiguity is maintained and the S could look to the context for an explanation.

In the Normal and Shallice model, hypnosis weakens the higher system relative to the lower system. The S might be trying to exert will but experience it as less [influential] than in the normal state. Such capacity would not be tapped by an alcohol expectancy measure.

We think of individual differences in hypnotizability as multiple processes, like a tree that consists of more than one healthy branch but has plenty of dead wood to be pruned out.

## NOTES

"There are several different ways to classify the model that is expounded in this chapter. One may view it ... as an individual-differences model of hypnosis, because it emphasizes the significance of intragroup differences in the pattern of hypnotic performance. Alternatively, one may view it as a phenomenologically based model.... Invariably, however, single categories fail to do justice to the nature of theories, and hence it is perhaps wisest to view this theory as a means of exploring particular hypotheses about hypnotic phenomena that focus primarily on the meaning of suggestion as perceived by susceptible subjects. This model focuses, in a way that most other theories do not, on the motivational implications of the cognitive involvement of the susceptible subject in the events of the hypnotic setting. It offers a variant of contextual theories of psychological functioning, but is experiential in its emphasis rather than simply behavioral" (p. 537).

Van Dyck, Richard; Zitman, Frans G.; Linssen, A. Corry G.; Spinhoven, Philip (1991). Autogenic training and future oriented hypnotic imagery in the treatment of tension headache: Outcome and process. International Journal of Clinical and Experimental Hypnosis, 39, 6-23.

The aim of the present study was (a) to investigate the relative efficacy of autogenic training and future oriented hypnotic imagery in the treatment of tension headache and (b) to explore the extent to which therapy factors such as relaxation, imagery skills, and hypnotizability mediate therapy outcome. Patients were randomly assigned to the 2 therapy conditions and therapists. 55 patients (28 in autogenic therapy and 27 in future oriented hypnotic imagery condition) completed the 4 therapy sessions and 2 assessment sessions. Patients were to practice at home. No significant main effect or interaction effects for treatment condition or therapist was revealed. A significant effect for time in analyzing scores for headache pain, pain medication usage, depression, and state anxiety was found. In the self-hypnosis condition, pain reduction proved to be associated with depth of relaxation during home practice (as assessed with diaries) and capacity to involve in imagery (as assessed with the Dutch version of the Creative Imagination Scale). After statistically controlling for relaxation and imagery, hypnotizability scores (assessed by Stanford Hypnotic Clinical Scale) were significantly correlated with ratings of pain reduction. Results are discussed in the context of the neo- dissociation and social-cognitive models of hypnoanalgesia. The clinical relevance and the methodological shortcomings of the present study are also critically assessed. NOTES 1:

## NOTES

"Unexpectedly, pain reduction occurring in AT [autogenic training] appears to be brought about by different means than in hypnotic treatment. Not only imagery skills and hypnotizability, but also level of relaxation were unrelated to pain reduction achieved during AT. Since the first two therapy sessions of AT and hypnosis were identical and in both treatment conditions patients are explicitly instructed to relax, the absence of a relationship between depth of relaxation and pain reduction in AT cannot be easily explained" (p. 19).

1990

Fellows, Brian J. (1990). Current theories of hypnosis: A critical overview. British Journal of Experimental and Clinical Hypnosis, 7, 81-92.

The present state of theory in hypnosis is reviewed and observations are made concerning future prospects. The state- non-state issue continues to dominate theoretical debate, although no satisfactory reply has yet been made to T. X. Barber's criticisms of the 'hypnotic trance' concept. The impact of social-psychological theory has been considerable and the results of Spanos's hypnotic training programme could have significant implications for our understanding of hypnosis. Future theorizing should see a move towards a more integrated sociocognitive approach. Neodissociation theory has generally not fulfilled its early promise and is encumbered with the 'hidden observer' concept. The role of imaginative processes continues to be a dominant theme in hypnosis theory, although the relatively small correlation between imaginative and hypnotic abilities remains a problem. The links between hypnosis, sleep and relaxation deserve further research, although, as theories of hypnosis, their scope seems limited. Suggestibility and role enactment theories have shown few signs of development in recent years. Theoretical problems over the interpretation of hypnosis need to be more widely recognized and the use of question-begging terminology curtailed. One advantage of the imagination hypothesis is that it provides a bridge, or a point of convergence, between state and non-state approaches (Spanos & Barber, 1974). It also handles certain hypnotic phenomena very well. For example, the known facts of age regression can be readily interpreted, together with the oddities of age progression and past life regression, as imaginative reconstructions (Barber, 1979). However, other phenomena, such as amnesia and analgesia, are less easily explained.

Kihlstrom, John F.; McConkey, K. M. (1990). William James and hypnosis: A centennial reflection. Psychological Science, 1, 174-178.

For William James, hypnosis was both an experimental technique for creating divisions of consciousness, and a laboratory model of naturally occurring disorders of awareness. James' treatment of consciousness in hypnosis presages contemporary interests in dissociation and implicit cognition, and underscores the role of the self in conscious mental life. At the same time, James recognized the complexity of hypnosis as an interpersonal process. In the end, James' views suggest how a rapprochement between the cognitive and social approaches to hypnosis might be achieved.

Sherman, S. J.; Lynn, S. J. (1990). Social-psychological principles in Milton Erickson's psychotherapy. British Journal of Experimental and Clinical Hypnosis, 7, 37-46.

In this article we will suggest that social-psychological principles may be used to understand M. H. Erickson's psychotherapeutic approach. In addition to using an array of indirect suggestive approaches, Erickson exploited clients' reactance, increased their perceptions of control and mastery, altered the accessibility of thoughts and memories, and modified thoughts and behaviours. To

accomplish these therapeutic goals, Erickson used the following techniques: seeding, priming, confusion, script enactment, framing, explanation, and perspective modification.

#### NOTES

The authors present a model to account for the subjective experience of nonvolition. The model rests on four observations: (1) nonvoluntary responses "have all of the properties of behavior that is typically defined as voluntary" (p. 108); (2) "hypnotizable subjects can resist suggestions when resistance is defined as consistent with the role of a 'good' hypnotized subject" (p. 108); (3) "Hypnotic behaviors are neither reflexive/automatic ... nor manifestations of innate stimulus-response connections" (p. 108); (4) "Hypnotic performances consume attentional resources ... in a manner comparable to nonhypnotic performances" (p. 108). They continue, "At the same time, many of the cognitive operations and affective reactions that accompany hypnotic responding are not readily accessible to consciousness" (pp. 108-109).

Zane, Nolan W. S. (1989). Change mechanisms in placebo procedures: Effects of suggestion, social demand, and contingent success on improvement in treatment. Journal of Counseling Psychology, 36, 234-243.

Investigated the treatment effects of three social influence variables frequently implicated in psychotherapy placebos. Socially anxious male Subjects participated in an experimental treatment for reducing dating anxiety. Subjects were either given or not given specific suggestions for decreasing social anxiety, placed in conditions of high or low social demand, and received feedback indicating either high or moderate success on the therapy task. Results support the importance of social influence variables in therapeutic change. Contingent success had its greatest impact on personal attributes; suggestion affected skill behaviors; and social demand effects were found in the self- evaluation of heterosocial performance. Various social influences appear to mediate change differently and do not exert the generic effects commonly assumed to be characteristic of therapy placebos. Implications for outcome research are discussed.

Fowler, Keith (1988). Hypnotic transformation---three studies of theatrical role-playing: A brief communication. International Journal of Clinical and Experimental Hypnosis, 36, 249-255.

In order to provide student actors with an effective technique for dramatic characterization, a transformation procedure was devised, which incorporated hypnosis with Chekhov's (1953) technique of centering. 3 studies involving the procedure are described. Results suggest that in 25 of 26 Ss, hypnosis may have facilitated actors' apparent adoption of new personae.

Gorassini, Donald R.; Hooper, Cynthia L.; Kitching, Kathleen J. (1988). The active participation of highly susceptible hypnotic subjects in generating their hypnotic experiences. Imagination, Cognition and Personality, 7 (3), 215-226.

Hypnotized individuals have traditionally been considered to be detached from the control of their own suggested behavior. We tested this and the alternative notion that hypnotized subjects attempt to

self-generate the experiences (i.e., mainly of involuntariness) as well as produce the behaviors thought to be prototypical of high hypnotic ability. In an experimental investigation, highly susceptible hypnotic subjects were found to engage in the kind of imaginative activity that would be expected of individuals who were attempting deliberately to generate their experiences of involuntariness; they engaged as actively in imagery-generation as did subjects who were specifically instructed to imagine during suggested responding, and they experienced as much involuntariness as subjects in whom suggested movements were produced by an external physical force. The implications of these findings for the neodissociation and social psychological theories of hypnotic responding are discussed.

Hilgard, Ernest R. (1988). Response to contextual demands an insufficient account of hypnotic phenomena. [Comment/Discussion] .

#### NOTES

The author refers to one of his papers for a critique of the Spanos position that demand characteristics of the hypnotic situation account for hypnotic phenomena such as amnesia, analgesia, and "trance logic." The paper is Hilgard, E. R. (1987). Research advances in hypnosis: Issues and methods. *International Journal of Clinical and Experimental Hypnosis*, 35, 248-264.

Spanos, Nicholas P.; Gwynn, Maxwell I.; Della Malva, C. Lori; Bertrand Lorne D. (1988). Social psychological factors in the genesis of posthypnotic source amnesia. *Journal of Abnormal Psychology*, 97 (3), 322-329.

Three experiments assessed the role of social psychological variables in source amnesia. Experiment 1 found that low-hypnotizable subjects instructed to simulate partial amnesia were more likely to exhibit source amnesia than high-hypnotizable hypnotic or task-motivated subjects. Experiment 2 found equivalent rates of source amnesia in low-hypnotizable simulators and high-hypnotizable hypnotic subjects. In addition, the findings of Experiment 2 failed to support the idea that the instructions for partial amnesia given to simulators cued for the occurrence of source of amnesia as well as for the occurrence of partial amnesia. In Experiment 3, preliminary instructions that legitimated source amnesia as a role-appropriate response produced significantly more posthypnotic source amnesia than did neutral or no instructions. Together, the findings of the 3 experiments support the relation of source amnesia to experimental demands and subjects' expectations.

#### 1987

Gfeller, Jeffrey D.; Lynn, Steven Jay; Pribble, W. Eric (1987). Enhancing hypnotic susceptibility: Interpersonal and rapport factors. *Journal of Personality and Social Psychology*, 52 (3), 586-595.

This research supported the hypothesis that hypnosis can be thought of as a set of potentially modifiable social-cognitive skills and attitudes. A low-interpersonal- training treatment devised by Gorassini and Spanos (1986) was compared with a treatment designed to modify not only cognitive factors but also to augment rapport with the trainer and diminish resistance to responding (high-interpersonal training). Fifty percent of the initially un hypnotizable subjects in the high-interpersonal condition tested as being highly susceptible to hypnosis (high susceptibles) at posttest on the Harvard Group Scale of Hypnotic Susceptibility (Shor & Orne, 1962); 25% of the un hypnotizable subjects in the low-interpersonal condition responded comparably. Eighty-three percent of the medium-susceptibility (medium susceptibles) subjects tested as being highly susceptible at posttest in both conditions. Practice-alone control subjects' performance was stable across testings. The study was the first to demonstrate that treatment gains generalize to a battery of novel, demanding, suggestions (generalization index) that have been found to differentiate highly susceptible subjects from

unhypnotizable simulating subjects. The importance of rapport was evidenced by the finding that rapport ratings paralleled group differences in hypnotic responding and that rapport correlated substantially with susceptibility scores at posttest and with the generalization index. Whereas initial hypnotizability scores correlated significantly with retest susceptibility scores, initial hypnotizability failed to correlate significantly with the generalization index.

Hilgard, Ernest R. (1987). Research advances in hypnosis: Issues and methods. International Journal of Clinical and Experimental Hypnosis, 35, 248-264.

There are substantial areas of agreement upon the classical phenomena of hypnosis, illustrated by what we now have learned about hypnotic talent, amnesia, hallucinations, analgesia, and dissociative processes. While genuine advances in knowledge about hypnosis have been made in recent decades, differing orienting attitudes have kept some controversy alive, particularly in the interpretation of empirical findings. Differences of interpretation of the phenomenal and behavioral facts are to be expected in the present stage of developmental, cognitive, and social psychology.

NOTEThe author writes of the "domain of hypnosis" as within the larger domain of social psychology (because it is usually interpersonal); cognitive psychology (because of alterations in perception, imagination, memory, and thought); developmental and personality psychology (because of individual differences); and physiological psychology (because of neurophysiological aspects).

In terms of what we know about hypnotic talent, he notes that high hypnotizability is not generally associated with psychopathology; that it may however be associated with a personality measure called absorption; and that there may be some inherited ability (Morgan, 1973). In the author's view, hypnosis is no longer considered simply a response to suggestion, since imagination and/or fantasy are very important.

In reviewing evidence of posthypnotic amnesia the author writes, "Subtleties in language require making careful distinctions among concepts such as compliance, suggestion, compulsivity, belief, self-deception, automaticity, the voluntary, the involuntary, and a happening. If these distinctions are glossed over, the choice of words (e.g., substituting compliance for response to suggestion) may give the impression that a finding departs more widely from conventional views than it does. We, too, have found that Ss used varied strategies or skills during amnesia, but this need not deny augmentation by suggestion.

"It takes genuinely high Ss to illustrate truly high posthypnotic amnesia... Many of the truly high hypnotizable individuals cannot break amnesia, no matter how hard they try" (p. 253).

Regarding the evidence for hypnotic hallucinations and trance logic, the author suggests that trance logic is not a clear concept because the Subject is capable of good logic while tolerating some inconsistencies. "It is ordinary logic to assume that if your hallucination is your own construction, it is you who can influence it by your own wishes. In the rare cases of transparent or diaphanous hallucinations there is still an 'out there' quality. People who report that they see wispy ghosts also see them as 'out there,' so that they qualify as hallucinations. The distinction appears to be one of perception and perception-like experiences within hypnosis rather than of logic" (p. 256).

In reviewing the evidence for hypnotic analgesia, the author acknowledges that pain relief is available with other kinds of interventions, or by using other kinds of psychological processes, but that does not diminish the contribution of hypnosis (which has a long and impressive clinical history). Following laboratory studies, it is noted that "the amount of alleviation of pain through hypnosis is positively correlated with the hypnotizability of the candidate for pain reduction. This result is not universally accepted, because some clinicians are convinced that those unsuccessful in hypnotic pain reduction are resisting hypnosis" (p. 256-257). In the present paper he acknowledges but does not review physiological literature on hypnoanalgesia.

Regarding the concept of dissociation, the author indicates that he considers it a more useful concept than the concept of trance or hypnotic state "when a person is only slightly or moderately involved in hypnosis ... . The advantage is that dissociations, as compared with altered states, can be described according to limited or more pervasive changes in the cognitive or motor systems that are being activated or distorted through suggestion in the context of hypnosis. Perhaps when all-inclusive enough, such changes can justify the use of the term trance or altered state, but I believe that these terms should be used, if at all, only for those for whom the immersion in the hypnotic experience is demonstrably pervasive" (pp. 258-259).

The author goes on to describe his initial discovery of the 'hidden observer' in an experimental context, and to relate the 'hidden observer' to others' earlier observations of a secondary report of an experience previously concealed from S's consciousness (Binet, 1889-1890/1896; Estabrooks, 1957; James, 1899; Kaplan, 1960). "The issues are still being worked on, but as in the case of trance logic the heart of the problem is not whether to speak of a hidden observer, but to recognize that there may be cognitive distortions in hypnosis even while some more realistic information is being processed in parallel, so that everything is not reportable by S" (p. 260).

Monteiro, Kenneth P.; Zimbardo, Philip G. (1987). The path from classroom seating to hypnotizability--a dead end: A brief communication. International Journal of Clinical and Experimental Hypnosis, 35, 83-86.

It has been proposed that classroom seating behavior predicts brain functioning involved in hypnotizability and in other cognitive processes. The present authors attempted to test this hypothesis and to replicate some earlier findings. The relationships between classroom seating preference, actual seating location, and hypnotizability in male and female students were investigated. No relationship was found between any of the seating measures and hypnotizability. These findings lend no support for the hypothesis that classroom seating predicts hypnotizability. This failure to replicate is discussed in relationship to the lack of theoretical grounding for the seating-hypnosis connection. NOTES 1:

#### NOTES

The authors review the literature, then present and test specific hypotheses that right-side seating preferences would be correlated with hypnotizability for males, while actual seating on the right side of the class would be associated with higher hypnotizability scores for females. This pattern should be more robust for right-handed than for left-handed students. They found no support for these hypotheses. They suggest that other measures of cognitive processing may correlate with a social behavior such as classroom seating. Monteiro & Zimbardo (unpublished ms.) found that the variables of field independence and field sensitivity predicted actual seating behavior in males and seating preference in females.

#### 1986

Spanos, Nicholas P.; Cross, Wendi P.; Lepage, Mark; Coristine, Marjorie (1986). Glossolalia as learned behavior: An experimental demonstration. Journal of Abnormal Psychology, 95, 21-23.

60 Ss listened to a 60-s sample of glossolalia (defined to them as pseudolanguage) and then attempted to produce glossolalia on a 30-s baseline trial. Afterward, half of the Ss received two training sessions that included audio- and videotaped samples of glossolalia interspersed with opportunities to practice glossolalia. Also, live modeling of glossolalia, direct instruction, and encouragement were provided by an experimenter. Both the trained subjects and untreated controls attempted to produce glossolalia on a 30-s posttest trial. About 20% of subjects exhibited fluent glossolalia on the baseline trial, and training significantly enhanced fluency. Seventy percent of trained subjects spoke fluent glossolalia on

the posttest. Our findings are more consistent with social learning than with altered state conceptions of glossolalia.

Spanos, Nicholas P.; Robertson, Lynda A.; Menary, Evelyn P.; Brett, Pamela J. (1986). Component analysis of cognitive skill training for the enhancement of hypnotic susceptibility. Journal of Abnormal Psychology, 95, 350-357.

Four treatments to enhance the hypnotic responsiveness of subjects who pretested as low in hypnotic susceptibility were compared. Complete skill training included information aimed at encouraging (a) positive attitudes, (b) the use of imagery strategies, and (c) an interpretation of hypnotic behavior as active responding. Partial training included only components (a) and (b). Both training packages enhanced attitudes toward hypnosis to an equivalent degree. However, complete training was much more effective than either partial training or no treatment at enhancing behavioral and subjective responding on two different posttest scales of hypnotic susceptibility. More than half of the subjects who received complete training, but none of the partial training or control subjects, scored in the high-susceptibility range on both posttests. Subjects explicitly instructed to fake hypnosis and those in the complete skill-training treatment exhibited significantly different patterns of posttest responding. Findings support social psychological perspectives that emphasize the importance of contextual factors in hypnotic responding.

Sweeney, Carol A.; Lynn, Steven Jay; Bellezza, Francis S. (1986). Hypnosis, hypnotizability, and imagery-mediated learning. International Journal of Clinical and Experimental Hypnosis, 34, 29-40.

The relationship between hypnotizability, imagery utilization ability, and hypnosis was examined in a study described to Ss (N = 157) as an 'imagery experiment.' In Session 1, the Tellegen Absorption Scale (Tellegen, 1976) was completed and the imagery-mediated paired-associate learning task was administered as a baseline measure. In Session 2, either hypnosis, task motivation, or no treatment instructions were administered and the learning task was repeated with a different word list (each 15 high, 15 low imagery pairs). In Session 3, the Harvard Group Scale of Hypnotic Susceptibility, Form A (Shor & E. C. Orne, 1962) was administered. Overall, recall was superior for high imagery words. Hypnotizability was not associated with imagery-mediated recall. Recall performance, however, was correlated with Tellegen Absorption Scale scores. Interestingly, learning and recall performance decreased between Sessions 1 and 2 for hypnotized Ss but remained the same for task motivated and control Ss. The decrease in performance was mediated by less concern for performance and diminished anxiety. Self-reports of imagery utilization did not differ among groups of Ss.

## NOTES

The authors review literature on the relationship between hypnotizability, hypnosis, and imagery abilities, noting that results are conflicting. One reason for differing results may be that imagery scales are self-report measures, subject to reporting bias of varying types. The imagery-mediated paired-associate learning paradigm, using high and low imagery paired associates, may address that reporting bias issue.

This investigation used 157 Ss grouped into high (9-12), medium (5-8), and low (0-4) hypnotizability levels on the basis of the Harvard Scale. Given the fact that high imagery words are usually recalled more easily than low imagery words (Paivio, 1971), a relationship observed between hypnotizability and imagery-mediated recall would elucidate the role of imagery utilization for memory functions.

The experimental conditions included hypnosis, task motivation, and a no treatment control condition, in order to evaluate the possible enhancement effects of hypnosis on imagery utilization for memory

functions. The task motivation group was included to control for motivational factors, and the no treatment control condition to control for the practice effects of repeated testing.

The word pair stimuli were from Paivio et al (1968): 30 pairs consisting of 15 high and 15 low imagery noun pairs. Each Subject participated in three experimental sessions.

Session 1. Ss were told that they were in an experiment on imagery to remember pairs of words. They completed the Tellegen Absorption Scale, then were given instructions for using imagery for recalling words, and for rating vividness and clarity of each image immediately after it was formed. Finally they performed the learning task.

Session 2. Ss received either hypnosis, task motivation instructions ("try to form good interacting images of the word pairs" with exhortation to score as high as possible), or control (Like Session 1). No one in hypnosis group refused the induction (despite the fact that they were not forewarned in Session 1 that the experiment might involve hypnosis). Ss completed a questionnaire on the percentage of word pairs they used images to remember, how easy it was to block out or ignore distractions, how vivid and clear were images of words during recall, how concerned they were about their performance, and how much anxiety, if any, they experienced during the experiment.

Session 3. The Harvard Scale was administered. Three Ss declined to participate in the Harvard Scale administration.

The results were analyzed with a 3 x 2 x 2 x 2 repeated-measures ANOVA: hypnotizability, instruction (hypnotic induction, task motivation, no treatment), session (1 and 2), and pair imagery (high and low). The expected enhanced memory performance of high hypnotizables with high imagery words in the hypnosis condition did not emerge in the results. However, the expected stimulus-imagery effect was observed (a higher proportion of high imagery words than low imagery words recalled). The expected higher imagery ratings for hypnotized high hypnotizable Ss also was not found. Furthermore, there was a significant interaction effect for recall session by hypnotizability: low hypnotizable Ss rated imagery less vivid in Session 2 than in Session 1, while highs rated it more vivid in Session 2 than in Session 1. Thus, low hypnotizable Ss' imagery ratings actually decreased between Recall Session 1 and 2, while high hypnotizable Ss' imagery ratings increased between Recall Session 1 and 2.

While the Absorption Scale correlated with the Harvard (.28,  $p < .001$ ) and with various measures of recall, hypnotizability did not correlate with any of the recall measures. The questionnaires administered during Session 2 suggested that hypnotized Ss were less concerned and anxious than the no treatment control Ss, and less concerned than the Ss receiving task motivation instructions.

In their Discussion, the authors speculate that the strong stimulus-imagery effects might have made it unlikely for them to find differences between high, medium, and low hypnotizable Ss in imagery-based paired associate learning. They suggest including word pairs that range across the continuum of imagery ratings in future research. They also speculate that differences between hypnotizability levels might be found (as 'T Hoen reported in 1978 publication) if Ss were required to respond in a shorter time interval, or if hypnotizability were measured by a scale with more cognitive items than the Harvard Scale--both conditions in 'T Hoen's research protocol.

"The most striking finding of the present research is that instead of facilitating performance in an imagery-mediated recall task, hypnosis resulted in a decrement in recall relative to control conditions. In the hypnotic condition, the amount of learning actually decreased from one session to the next (waking-hypnosis) but remained equivalent in the task motivation (waking-task motivation) and no treatment groups (waking-waking)" (p. 37). The authors note that it is not possible to determine from their research design whether hypnosis interfered with the learning task, the retrieval task, or both.

"The findings suggest that hypnotizability may be related to reported vividness and clarity of imagery but unrelated to the actual ability to utilize imagery in an imagery-mediated paired-associate learning task. ... Although high hypnotizables' self-report ratings of imagery and vividness increased, their recall performance was not accordingly enhanced. The disparity between subjective and objective

measures underscores the importance of including both types of measures in studies of imagery abilities" (pp. 37- 38).

To a considerable degree, this study controlled for Ss' expectancies regarding hypnosis better than some earlier studies. This study differs from earlier research in that (1) Experimenters didn't test hypnotizability prior to the imagery-mediation task; and (2) the study was defined as an experiment on imagery, and hypnosis was not mentioned until just before the induction in Session 2.

"In conclusion, the present results indicate that, under certain conditions, hypnosis may decrease Ss' motivation and performance. No support was provided for the ability of hypnosis to facilitate imagery utilization and performance on an imagery-mediated task. The results are compatible with the views proffered [sic] by theoreticians who have emphasized the importance of expectancies and the experimental context (e.g., Barber, 1979; Coe & Sarbin, 1977; M. T. Orne, 1951, 1959; Spanos, 1982)" (p. 38).

Zamansky, Harold S.; Clark, Lorene E. (1986). Cognitive competition and hypnotic behavior: Whither absorption?. International Journal of Clinical and Experimental Hypnosis, 34, 205-214.

According to the widely held absorption notion, the successful response to hypnotic suggestions requires S to focus attention on the content of these suggestions and to avoid incompatible and contradictory cognitive activities. This assumption was tested by exposing high, middle, and low hypnotizability Ss continuously to incompatible suggestions and images as they attempted to respond to the direct suggestions of the hypnotist. Performance under these circumstances was substantially as effective as in baseline sessions (without incompatible suggestions) for the high and medium hypnotizable Ss. On the other hand, fewer than half of the low hypnotizability Ss responded successfully. The results are viewed as compatible with both a social enactment and a neodissociation interpretation of hypnosis.

#### NOTES

Subjects were 58 volunteer students divided into 12 high (8-12), 26 medium (5- 7) and 20 low (<5) hypnotizables on the basis of the Stanford Hypnotic Susceptibility Scale, Form A (SHSS:A). Depending on the number of suggestions passed during the SHSS:A, 2-4 'target suggestions' were selected from among those each S passed. All Ss had passed at least one of the target suggestions.

The target suggestions that had been successfully passed were readministered with incompatible suggestions and imagery being given to the S. For example, the S might be asked to practice the opposite response, to note and remember the movements and muscles used to produce the response, to think that they should be able to resist the suggestion, to picture themselves performing the opposite response by recalling the earlier practice experience. For example, while giving a suggestion for arm rigidity, the Experimenter might say "Picture yourself bending your arm" or "Imagine what it would be like to bend your arm." The S was even encouraged to perform another competing response , e.g. to bend the other arm, and to try to use that experience in resisting the target suggestion. The S was requested to verbalize the incompatible thoughts out loud while performing the target suggestion. Nevertheless, the direct suggestion also was interspersed, as, "You will find, nevertheless, that your right arm won't bend."

**RESULTS.** All 12 highs passed at least one target item and 10 passed all of the target items. 23 of 26 medium suggestible Ss passed at least one item and 17 passed all of them. Only 8 of 20 low hypnotizable Ss passed at least one target suggestion; 7 passed all of them however. Usually the low hypnotizables had only one or two target items, since they passed few items on the original SHSS:A test.

In their Discussion, the authors state, "Despite popular opinion, therefore, it appears that it is not necessary for the good hypnotic S to be fully 'absorbed' or to be 'imaginatively involved' (J. R.

Hilgard, 1979) in the direct suggestions of the hypnotist to perform these suggestions successfully. ... It is the responses of the lows that were quite clearly degraded by the presence of conflicting thoughts and images" (p. 209).

As a control study, the authors tested 11 other Ss who had low hypnotic susceptibility, to determine whether the effect found with lows (that they could resist) was actually a function of test-retest unreliability. They administered 1-2 target suggestions without contradictory suggestions two or more times. The results were that, once a S had passed a suggestion once, they continued to pass it (even when it was administered 3-4 times). "If anything, the suggestions sometimes appeared to gain in effectiveness with repetition" (p. 210).

The authors did another control study with 17 highs, 9 medium Ss, and 8 lows, in which the conflicting suggestion was given by a hypnotist who did not know the hypnotizability of the S: after S was hypnotized, hypnotist A wrote the "target" on a slip of paper, left the room, and hypnotist B entered and gave the conflicting suggestions for that target. All 17 highs and 7 of the 9 medium hypnotizable Ss passed, but only 2 of 8 lows were able to do so.

The authors conclude, "It may well be that processes such as absorption and imaginative involvement may facilitate the successful response to hypnotic suggestions, but, clearly, the utilization of such processes is not essential for the successful hypnotic performance of high and medium hypnotizability Ss" (p. 212).

1985

Banyai, Eva I.; Meszaros, Istvan; Csokay, Laszlo (1985). Interaction between hypnotist and subject: A social psychophysiological approach (preliminary report). In Waxman, David; Misra, Prem C.; Gibson, Michael; Basker, M. Anthony (Ed.), Modern trends in hypnosis (pp. 97-108). New York: Plenum Press.

There is a vast amount of literature demonstrating that hypnotic susceptibility is a stable personality trait. In the course of our practice of teaching beginners to hypnotize, however, it occurred to us that hypnotists without sufficient previous training frequently measured a lower level of hypnotic susceptibility than the true score. It has to be emphasized that hypnosis is a special altered state of consciousness which develops as a result of an interaction between a hypnotist and a subject. The failure of beginners to induce hypnosis could be explained by considering an insufficient participation of the hypnotist in this interaction. The purpose of the present study was to analyze the necessary and sufficient subjective, behavioral and physiological alterations in both participants of the hypnotic interaction. During successful and unsuccessful hypnotic inductions the subjective experiences, behavioral manifestations and physiological indicators including respiration, ECG, EMG, EOG, GSR and bilateral fronto- occipital EEG leads, were recorded simultaneously in the hypnotists and the hypnotized subjects. The results indicate that hypnotic induction is successful if a mutual "tuning" of the other person occurs not only on the subjective and behavioral levels, but first of all on the psychophysiological level.

Spanos, Nicholas P.; Weekes, John R.; Bertrand, Lorne D. (1985). Multiple personality: A social psychological perspective. Journal of Abnormal Psychology, 94, 362-376.

The part of an accused murderer remanded for pretrial psychiatric evaluation was role played by 48 college students. Role players were assigned to interview treatments that varied in how extensively they cued for symptoms of multiple personality. The most explicit treatment (i.e., Bianchi treatment, n = 16) included a hypnotic interview that was used in diagnosing a suspect in the "Hillside strangler" rape- murder cases as suffering from multiple personality. A less explicit hypnotic treatment (n = 16) and a nonhypnotic treatment (n = 16) were administered to the remaining role players. Most subjects

in the Bianchi treatment displayed the major signs of multiple personality (e.g., adoption of a different name, spontaneous posthypnotic amnesia). In a later session subjects who role played as multiple personalities performed very differently on psychological tests administered separately to each role-played identity. Those who failed to enact the multiple personality role performed similarly when tested twice. Findings are discussed in terms of a social psychological formulation that emphasizes the roles of active cognizing, contextual cueing, and social legitimization in the genesis of multiple personality.

Spanos, Nicholas P.; de Groot, Hans P.; Tiller, Dale K.; Weekes, John R.; Bertrand, Lorne D. (1985). 'Trance logic,' duality, and hidden observer responding in hypnotic, imagination control, and simulating subjects: A social psychological analysis. Journal of Abnormal Psychology, 94 (4), 611-623.

Tested the hypothesis that a tolerance for logical incongruity characterizes hypnotic responding and is related to reports of duality experiences during age regression and hidden-observer responding during suggested analgesia. 30 undergraduates (the "reals") with high scores on a responsiveness-to-suggestion scale were randomly assigned to hypnotic or imagination control treatments, while 15 undergraduates with low scores were assigned to a simulation treatment in which they were instructed to fake hypnosis. Ss were assessed on 6 indicators of logical incongruity, given age-regression suggestions and perception tasks, administered a suggestion for analgesia and hidden observer instructions, and interviewed. Results do not support the hypothesis. The differences in responding that did emerge between reals and simulators were accounted for by the different task demands to which Ss were exposed. These behavioral differences, which have been previously interpreted in terms of intrinsic characteristics of hypnosis, may instead reflect a combination of between-treatments differences in demands and between- Ss differences in the interpretation of those demands and in the ability to fulfill them.

1984

Spanos, Nicholas P.; McNeil, Conrad; Gwynn, Maxwell I.; Stam, Henderikus J. (1984). Effects of suggestion and distraction on reported pain in subjects high and low on hypnotic susceptibility. Journal of Abnormal Psychology, 93 (3), 277-284.

84 18-30 year old undergraduates high or low in hypnotic susceptibility (the Carleton University Responsiveness to Suggestion Scale) immersed an arm in ice water on 2 separate trials. Within susceptibility levels, Ss were randomly assigned to 3 groups, with an equal number in each group. Between trials, Ss in 1 group were administered a suggestion to imagine their hand as numb and insensitive, those in a 2nd group practiced a distraction task to be used during the 2nd trial (shadowing words), and those in a 3rd group (controls) received no special instructions. The suggestion significantly lowered rated pain in high but not in low susceptibles. Contrary to dissociation accounts of hypnotic susceptibility and suggested analgesia, low susceptible shadowers showed as much reduction in rated pain as high susceptibles given suggestion. The social psychology of the experimental pain assessment situation is discussed.

Spanos, Nicholas P.; Tkachyk, M.; Bertrand, L. D.; Weekes, J. R. (1984). The dissipation hypothesis of amnesia: More disconfirming evidence. Psychological Reports, 55, 191-196.

Hypnotic subjects were administered a suggestion to forget a previously overlearned word list. Before cancellation of the suggestion they were challenged twice to try and recall the words. Subjects in one group received a second challenge immediately after response to the first. Those in the second group were given a 15-min. delay before their second challenge. Subjects in both groups showed less amnesia

after the second challenge than after the first, but the length of delay between challenges had no effect on amnesia scores. These findings are inconsistent with the hypothesis that hypnotic amnesia involves an involuntary blockage of memory that decays spontaneously with time.

1983

Council, James R.; Kirsch, Irving; Vickery, Anne R.; Carlson, Dawn (1983). 'Trance' versus 'skill' hypnotic inductions: The effects of credibility, expectancy, and experimenter modeling. Journal of Consulting and Clinical Psychology, 31 (3), 432-440.

A hypnotic induction procedure based on social learning principles (skill induction) was compared with a traditional eye-fixation/relaxation trance induction, a highly credible placebo induction, and a no-induction base-rate control. The trance induction surpassed the skill induction only on the Field Inventory, a measure of hypnotic depth that contains items corresponding to suggestions contained in the trance induction. Experimenter modeling was not found to enhance the effectiveness of the skill induction. Skill and trance inductions elicited slightly higher behavioral scores on the Stanford Hypnotic Susceptibility Scale: Form C than did the placebo induction. However, this difference was not obtained on other measures of hypnotic responsibility and depth. Significant correlations were found between expectancy, absorption, and responsiveness on all dependent measures. Multiple regression analyses indicated that the relationship between absorption and responsivity was mediated by expectancy. The results are interpreted as supporting the hypotheses that hypnotic responses are elicited by the expectancy for their occurrence and that induction procedures are a means of increasing subjects' expectancies for hypnotic responses.

#### NOTES

Trance induction resulted in a higher score on subjective experiences (cognitive & perceptual distortions) but not higher suggestibility scores than cognitive- behavioral skill induction. 2) Trance and cognitive-behavioral inductions got slightly higher scores in suggestibility than placebo biofeedback induction. 3) All inductions did better than a "no induction" control group on subjective and behavioral indices of hypnosis.

One of the goals of this research was to examine the contribution of experimenter modeling to the behavioral skill induction that "trains the subject in hypnosis skills and requires the subject's conscious cooperation in learning cognitive strategies that will enhance hypnotic responsivity" (p. 432). Another goal was to assess the contribution of "a subject's expectancies for the occurrence of behaviors perceived as being involuntary" (p. 433). A third goal was to determine whether congruence between a subject's beliefs about hypnosis and the rationale for a particular induction would increase expectancy. Two different skill inductions were employed (one with, one without a model). Subjects were asked to predict their performance, based on a description of the induction that they would receive. The contributions of credibility and expectancy were assessed using a highly credible placebo (pseudo biofeedback of EEG theta rhythm).

The investigation used only subjects who had never experienced hypnosis.

Independent variables included Rotter's (1966) Internal-External Locus of Control Scale, Rotter's (1967) Interpersonal Trust Scale, and Tellegen's Absorption Scale (Tellegen & Atkinson, 1974). Mediating variables included a measure of induction credibility based on Borkovec and Nau (1972), and a 20-item inventory measuring expectancies for hypnotic performance. Dependent variables included 20 standard hypnotic suggestions taken from the Stanford Hypnotic Susceptibility Scale, Form C; the Creative Imagination Scale; ratings of the 'realness' or experienced intensity of each suggestion; and the Field Inventory of Hypnotic Depth (Field, 1965).

The authors conclusion reads as follows: "The results of this study may be summarized as follows: (a) Traditional trance hypnotic inductions and cognitive- behavioral skill inductions were shown to be

equally effective in eliciting experiential and behavioral responses to hypnotic suggestions, although trance subjects reported a somewhat greater alteration in conscious experience. (b) Experimenter modeling was not found to be an effective component of the skill induction package. (c) Subjects' expectancies for hypnotic responses, reported prior to hypnotic induction, bore a very strong relationship to hypnotic responsiveness. (d) A highly credible placebo induction resulted in levels of expectancy and hypnotic responsiveness generally comparable to those produced by trance and skill hypnotic inductions. (e) Absorption was significantly correlated with expectancy, but was not found to be significantly related to responsiveness once variance due to expectancy was taken into account. Thus the relationship between absorption and hypnotic responsiveness appears to be mediated by expectancies.

"In sum, these results suggest that various hypnotic inductions elicit expectancies for responding to hypnotic suggestions and that these expectancies are sufficient to elicit hypnotic responses. Further studies are needed to determine the nature of the relationship between absorption and hypnotic response expectancies" (p. 439).

Spanos, Nicholas P.; Gwynn, Maxwell I.; Stam, Henderikus J. (1983). Instructional demands and ratings of overt and hidden pain during hypnotic analgesia. Journal of Abnormal Psychology, 92 (4), 479-488.

Sixteen highly hypnotizable subjects rated the intensity of cold pressor pain during a baseline trial and again during three hypnotic analgesia trials. During each analgesia trial, subjects were instructed to give overt reports that reflected consciously experienced pain and covert reports that reflected the intensity of "hidden" pain. Treatment instructions administered before the first analgesia trial did not specify the relationship between overt pain and covert pain. Instructions given before the remaining two analgesia trials indicated that hidden pain would be either more intense or less intense than overt pain. Until they were given explicit information about the relative intensities of the pain, subjects reported no differences in the magnitude of overt and covert pain, contrary to the dissociation hypothesis of hypnotic analgesia. Consistent with social psychological formulations of the hidden observer phenomenon, subjects reported both higher covert than overt pain and lower covert than overt pain depending on the instructions they were administered.

Wagstaff, Graham F. (1983). Comment on McConkey's "Challenging hypnotic effects: The impact of conflicting influences on response to hypnotic suggestion". [Comment/Discussion].

## NOTES

"Probably the most consistent finding to emerge from McConkey's review is that hypnotic subjects tend to respond in accordance with what they feel the hypnotist really wants, regardless of conflicting experimental demands" (p. 13).

1982

Spanos, Nicholas P.; Bridgeman, M.; Stam, H. J.; Gwynn, M. I.; Saad, C. I. (1982-83). When seeing is not believing: The effects of contextual variables on the reports of hypnotic hallucinations. Imagination, Cognition and Personality, 2, 195-209.

When administered a hallucination suggestion most high susceptible hypnotic and task-motivated subjects reported that they "saw" the suggested object. When asked what they meant by "saw," however, almost all indicated that they had imagined the object but did not believe that it had actually been present. On the other hand, simulating subjects maintained that the suggested object had been "really there." Simulators were also more likely than non-simulators to provide "life-like"

descriptions of the suggested object (e.g., solid rather than transparent, colored, highly vivid). These findings are consistent with the view that hypnotic hallucinations are context-generated imaginings. They also indicate that unique or unusual psychological processes like "trance logic" need not be posited to account for the descriptions of "hallucinatory" experiences proffered by hypnotic subjects.

## NOTES

It was observed that hypnotized Ss reported more vivid (and longer sustained) imagery than task motivated Subjects. Hypnotized Ss did not differ from high susceptible simulators on vividness of imagery or how long they experienced the imagery, but did report shorter and less vivid imagery than simulators who were low hypnotizables.

### 1981

An attempt was made to relate hypnotic susceptibility to an objective measure of compliance in a real-life setting. Hypnotic susceptibility scores for 235 college graduates, who graduated between the years 1971-1979, were compared to their records for alumni annual giving. Those who had made at least 1 contribution to the college since graduation were significantly higher in hypnotic susceptibility than those who had made no contribution. The results suggest that willingness to respond to a persuasive appeal may be related to a person's susceptibility to hypnosis.

### 1979

Provides a social psychological interpretation of the interrelations among demonic possession, mesmerism, and hysteria. It is argued that the reciprocal role relationship of mesmerist and magnetized S in the 18th and 19th centuries involved the secularization of the role relation that had existed between exorcist and demonically possessed. The commonalities between these 2 sets of social roles are delineated, some of the variables leading an individual to learn and enact the possessed role are outlined, and several lines of historical evidence pertaining to the influence of the exorcist-demonic relationship on the mesmeric relationship are outlined. The influence of the possessed role in shaping the role of the hysterical patient is also discussed. The use of hysteria as a modern explanatory concept in histories of possession and mesmerism, however, is criticized. (198 ref).

### 1978

Coe, William C. (1978). The credibility of posthypnotic amnesia: A contextualist's view. International Journal of Clinical and Experimental Hypnosis, 26 (4), 218-245.

This paper attempts to demonstrate how the contextual view rather than the formist-mechanistic view may be more helpful in understanding posthypnotic amnesia. As a point of departure, the criterion for credible posthypnotic amnesia is defined as Ss' phenomenal experiences which are observed indirectly through their counterfactual statements expressed with a high degree of conviction. To make sense of such self-reports, concepts flowing from contextualism, the view of man as an active person in an everchanging series of contexts, are employed. Concepts such as plots, reinforcement contingencies, trust, belief systems, involvement, ambiguousness, and self-observation may be postulated in understanding how people come to believe in their own counterfactual reports and to convince others of their credibility. Recent research on source amnesia, disrupted retrieval, and breaching posthypnotic amnesia is also critically evaluated. The conclusion is reached that the data are not compelling and their interpretations have been overstated.

Hearn, Greg (1978, November). Susceptibility and the process of social interaction in the hypnotic context. [Unpublished manuscript] (Submitted as a partial requirement for the B. S. degree with honours in psychology at the Univ of Queensland)

The hypothesis was tested that the process of social interaction between hypnotist and subject is dependent upon the susceptibility level of subjects. Using Interaction Process Analysis (Bales, 1950), the interaction patterns of 16 high susceptibles and 16 low susceptibles were analyzed. Susceptibility level had been pretested with the HGSHS:A. The hypnotist was then instructed on how to control for differences in the process of interaction which were isolated and the initial hypnotic session was repeated on a new sample. This time the performance and interaction patterns of six high susceptibles and six low susceptibles were compared. Results suggested that trait differences give rise spontaneously to differences in the process of interaction and some combination of these effect the subjects final hypnotic performance. Hence it is argued that an interactionist framework would aid the understanding hypnotic responsivity.

1974

Spanos, Nicholas P.; Barber, Theodore Xenophon (1974). Toward a convergence in hypnosis research. American Psychologist, 29 (7), 500-511.

#### NOTES

The authors believe that there is general agreement that "responding to suggestions involves at least two interrelated factors. The first can be conceptualized as a willingness on the part of the subject to cooperate with the experimenter in fulfilling the aims of the suggestions. The second can be described as a shift in cognitive orientation from an objective or pragmatic perspective to one of involvement in suggestion-related imaginings" (p. 500).

They suggest that the two major theoretical positions lead to different approaches to research. "The construct trance or hypnotic state, despite its inherent vagueness and lack of amenability to operational definition, continues to dominate state conceptualizations of hypnosis. This construct seems to refer to a state that differs, not simply quantitatively, but in some basic, qualitative way, from waking states and from states of sleep. As Bowers (1966) noted, 'Most [present-day] investigators interested in hypnosis believe that there is an hypnotic state which fundamentally differs from the waking state [p. 42].' This belief makes it much more likely that it will be state theorists who will conduct studies aimed at establishing a physiological basis for the hypothesized fundamental alteration. The state theorists are also more likely than the nonstate theorists to pursue research that might indicate that hypnotic performance involves unique or highly unusual changes in perceptual functioning or in cognitive functioning, such as trance logic (Orne, 1959). Although studies of this type have generally produced negative or inconclusive findings (Barber, 1979, 1970a, 1973; Barber & Ham, 1974; Hilgard, 1972; Johnson, 1972; Johnson, Maher, & Barber, 1972; Sarbin & Slagle, 1972), they have on occasion yielded some provocative results (Graham, 1979).

"On the other hand, the guiding assumption of the nonstate theorists -- that the good hypnotic subject is not fundamentally different from the normal individual who is cooperating in a social situation in which he is asked to experience suggested effects -- will lead these investigators to continue their studies of situational and social-psychological antecedents of hypnotic performance. The nonstate investigators may be expected to probe further into the effects of such variabls as how the situation is defined to the subject, what attempts are made to remove fears and misconception, and how the suggestions are worded (Barber & DeMoor, 1972; Spanos, 1973). The basic assumption of the nonstate theorists will also continue to influence their conceptualization of hypnotic performance as a set of socially influenced cognitive skills or abilities. However, despite these differences in the research proclivities of state and nonstate investigators, theoretical convergences of the type outlined in this article indicate that a good deal of the future research carried out by proponents of both paradigms will dovetail in focusing on the role of imaginative processes in hypnotic performance" (pp. 508-509).

1967

Barber, Theodore Xenophon (1967). Reply to Conn and Conn's 'Discussion of Barber's 'Hypnosis as a causal variable...'. International Journal of Clinical and Experimental Hypnosis, 3, 111-117.

A REPLY TO J. H. CONN AND R. N. CONN (SEE 42:1). IT IS MAINTAINED THAT (1) INVESTIGATORS HAVE NOT AS YET SUCCEEDED EITHER IN DENOTING THE HYPNOTIC STATE WITHOUT CIRCULARITY OR IN DEMONSTRATING THAT IT PLAYS A ROLE IN ELICITING THE PHENOMENA THAT ARE TO BE EXPLAINED; AND (2) RECENT EXPERIMENTS HAVE SHOWN THAT S'S TESTIMONY THAT HE IS "IN" OR "OUT" OF HYPNOSIS IS DEPENDENT UPON MANY DENOTABLE ANTECEDENT VARIABLES INCLUDING WHAT S BELIEVES HYPNOSIS IS SUPPOSED TO INVOLVE AND WHETHER E IMPLIES TO S THAT HE JUDGES HIM TO BE "IN" OR "OUT." IT REMAINS TO BE DEMONSTRATED THAT S'S TESTIMONY IS ALSO FUNCTIONALLY RELATED TO THE PRESENCE OR ABSENCE OF THE HYPNOTIC STATE. (SPANISH + GERMAN SUMMARIES) (16 REF.) Conn, J.H.; Conn, R.N. (1967). Discussion of T. X. Barber's 'Hypnosis' as a causal variable in present day psychology: A critical analysis. International Journal of Clinical and Experimental Hypnosis, 15 (3), 106-110.

T. X. BARBER'S (SEE 39:2) STATEMENT THAT THE TERM HYPNOSIS BE ABANDONED PRESUPPOSES THAT IT MUST BE RIGIDLY DEFINED AND THAT A PROPER DEFINITION MUST DENOTE "NECESSARY AND SUFFICIENT" CONDITIONS. NEITHER PROPOSITION IS VALID SINCE HYPNOSIS IS ESSENTIALLY A HUMAN RESPONSE. BARBER'S VARIABLES ARE ENDOWED WITH A FLEXIBILITY DENIED TO HYPNOSIS. THE SCIENCE OF VARIABLES IS OPPOSED TO THE AMBIGUOUS TERM HYPNOSIS BECAUSE IT DENOTES TOO MANY VARIATIONS IN TECHNIQUE AND RESPONSE. NEVERTHELESS, THE OBJECTIVE SCIENCE OF VARIABLES MAY ONLY APPEAR OBJECTIVE BECAUSE IT OMITTS AREAS OF LIFE TO WHICH ITS METHODS DO NOT APPLY. (SPANISH + GERMAN SUMMARIES) (PsycINFO Database Record (c) 2002 APA, all rights reserved)

Van der Walde, P. H. (1967). Trance states and ego psychology. International Journal of Clinical and Experimental Hypnosis, 15 (3), 95-105.

ANALYZES THE BASIC CHARACTERISTICS OF HYPNOSIS, WHICH COMPRISE INDIVIDUAL, INTERPERSONAL, AND CULTURAL VARIABLES. THESE ELEMENTS ARE UTILIZED IN A TRANSCULTURAL COMPARISON TO DEMONSTRATE THAT TRANCE PHENOMENA ARE GOAL-ORIENTED BEHAVIORS WHICH ARE EXPRESSED BY INDIVIDUALS WITHIN A GIVEN CULTURE BY METHODS WHICH ARE CULTURALLY SANCTIONED FOR ACHIEVING THOSE ENDS. THE DIFFERENCES BETWEEN TRANCE STATES CAN BE UNDERSTOOD TO REPRESENT CULTURAL VARIANTS OF SIMILAR PSYCHOLOGICAL MECHANISMS. (SPANISH + GERMAN SUMMARIES) (PsycINFO Database Record (c) 2002 APA, all rights reserved)

1963

Sarbin, Theodore R.; Lim, Donald T. (1963). Some evidence in support of the role-taking hypothesis in hypnosis. International Journal of Clinical and Experimental Hypnosis, 11, 98-103.

A study was conducted to test the hypothesis that hypnosis is a form of role-taking behavior. Independent measures of hypnotizability as measured on the Freidlander-Sarbin Scale and role-taking ability (improvisations) as judged by the Dramatics Department faculty were found to be significantly

related. Those rated high in role-taking were above the mean in hypnotizability, but some high on hypnotizability were low in dramatics ability. (PsycINFO Database Record (c) 2002 APA, all rights reserved)

1962

Orne, Martin T. (1962). On the social psychology of the psychological experiment, with particular reference to demand characteristics and their implications. American Psychologist, 17 (11), 776-783.

#### NOTES

"In summary, we have suggested that the subject must be recognized as an active participant in any experiment, and that it may be fruitful to view the psychological experiment as a very special form of social interaction. We have proposed that the subject's behavior in an experiment is a function of the totality of the situation, which includes the experimental variables being investigated and at least one other set of variables which we have subsumed under the heading, demand characteristics of the experimental situation. The study and control of demand characteristics are not simply matters of good experimental technique; rather, it is an empirical issue to determine under what circumstances demand characteristics significantly affect subjects' experimental behavior. Several empirical techniques have been proposed for this purpose. It has been suggested that control of these variables in particular may lead to greater reproducibility and ecological validity of psychological experiments. With an increasing understanding of these factors intrinsic to the experimental context, the experimental method in psychology may become a more effective tool in predicting behavior in nonexperimental contexts" (p. 783).

Glass, Louis B.; Barber, Theodore X. (1961). A note on hypnotic behavior, the definition of the situation and the placebo effect. Journal of Nervous and Mental Disease, 132, 539-541.

Subjects were tested for responses to hypnotizability tests under three conditions: after 20 minute induction, after being told they would not be hypnotized but would take tests of imagination (with motivating instructions to do well), after taking a placebo pill that "would make them deeply hypnotized." Of 12 Ss who dropped in score between Session 1 and Session 2, 11 attained higher scores following placebo than during the control session; mean scores under placebo and control (5.8 and 3.7) differed significantly,  $p < .01$ . Scores were as high in the third as the first session (5.8 and 6.3 respectively).

1959

Rosenberg, Milton J. (1959). A disconfirmation of the descriptions of hypnosis as a dissociated state. International Journal of Clinical and Experimental Hypnosis, 7 (4), 187-204.

#### NOTES

"SUMMARY. An experiment is described in which each of a group of hypnotic subjects received a posthypnotic suggestion reversing his affective response on an attitude issue of high interest. The consequent changes in the subjects' affect-related beliefs are compared to 'belief-changes' achieved by members of a group of subjects who were required to role-play the occurrence of 'affect reversal'.

"The data are interpreted as disconfirming the description of hypnosis as a dissociated state. Some reasons for the persistence of the dissociation description of hypnosis and some theoretical implications of the demonstration of non-dissociation are briefly discussed" (pp. 202-203).

The 11 hypnotic subjects were capable of achieving posthypnotic amnesia. Direct suggestions were given, in the opposite direction from attitudes detected with a 'cognitive structure test'. "For example one of the subjects, having expressed strong negative affect toward Negroes moving into white

neighborhoods, was given exactly the following hypnotic instructions: 'When you awake you will be very much in favor of Negroes moving into white neighborhoods. The mere idea of negroes moving into white neighborhoods will give you a happy, exhilarated feeling. You will have no memory for this suggestion having been made until the signal to remember is given'" (p. 193).

Wilcox, Warren; Faw, Volney (1959). Social and environmental perceptions of susceptible and unsusceptible hypnotic subjects. International Journal of Clinical and Experimental Hypnosis, 7 (3), 151-160.

## NOTES

### "Summary

1. The purpose of this study was to test the hypothesis that hypnotic susceptibility was positively related to the perception of fundamental aspects of the social and environmental milieu and, further, to consider the nature of hypnosis itself.
2. Ss for this study, 44 women and 36 men, were employed from a previous study (Faw and Wilcox, 1958). A mass hypnotic technique was used and susceptibility was operationally defined by the use of rating scales. The susceptible were found to have better personality adjustment than the unsusceptible.
3. New for this study were self-rating scales of the Ss' perception of parents, personal worries and problems, social activities as group or individually oriented, social activities in school, and physical care. The rating scales were administered several months prior to and independently of the hypnotic induction.
4. Interpretation of results support the hypothesis that the susceptible perceived their social and environmental milieu in more positive terms than did the unsusceptible. The susceptible perceived their parents in significantly stronger affectional and supportive relationships than did the unsusceptible. The susceptible were less concerned about adjustment to the opposite sex, not as worried about personal appearance, were more group oriented and more likely to engage in social activities than were the unsusceptible. Susceptible males were less frequently hospitalized than were unsusceptible males while susceptible females were more frequently hospitalized than were unsusceptible females.
5. Hypnosis was defined as a tendency to accept suggestions and to actualize, maintain and affirm them in the form of perceptual experiences activated by the stimulus situation as interpreted by the S and formulated by the hypnotist. The suggestions arouse expectancies or personal hypotheses which become a gauge to test the efficacy of the suggestions. Perceptualization is shaped by motives and past stimulation of the social and environmental milieu" (p. 158).

## 1958

Barber, Theodore Xenophon (1958). Hypnosis as perceptual-cognitive restructuring: II. "Post"-hypnotic behavior. Journal of Clinical and Experimental Hypnosis, 6 (1), 10-20.

## NOTES

The author presents "experimental evidence indicating that there is no essential difference between 'hypnotic' behavior and 'post-hypnotic' behavior" (p. 11).

### "Summary and Conclusions

"When 'somnambulistic' subjects were told to 'wake up' after they were given a 'post-hypnotic suggestion' and 'amnesia for the suggestion' they behaved as follows:

1. They opened their eyes and became relatively more aware of their surroundings.
2. They were aware that the signal for the 'post-hypnotic- behavior had special significance for them.

3. They were 'set' to 'obey the hypnotist's suggestions' from the moment they were told to 'wake up,' until they were convinced that their interpersonal relationship with the operator was no longer that of subject and hypnotist.

4. When the 'post-hypnotic suggestion' was uncomplicated and fitted into the normal pattern of behavior, the subjects carried it out without 'going deeper into trance,' i.e., without becoming relatively more 'detached' from their surroundings. However, when the 'post-hypnotic suggestion' was of such a nature that it was necessary for the subjects to 'go deeper into trance' to properly carry it out, the subjects did 'go deeper into trance.'

"Whether the subjects did or did not have amnesia for the 'post-hypnotic suggestion' was not important. 'Amnesic' and 'non-amnesic' subjects carried out the 'post-hypnotic' behavior in essentially the same way.

"These experiments indicate that:

1. If the operator properly manipulates the situation, the 'good' hypnotic subject is 'set' to carry out the operator's commands in the 'post-hypnotic' period in the same way as during 'hypnosis.'

2. If, in order to properly carry out the 'post-hypnotic suggestions,' it is necessary for the subject to 'go deeper into trance' -- i.e., to become relatively inattentive to stimuli not emanating from the operator -- the good subject will do so.

3. There is no essential- difference between the subject's behavior in the 'hypnotic' period and in the 'post-hypnotic' period.

4. If we are to continue speaking of 'suggestions' to be carried out in the post-hypnotic period we should term them 'post'-hypnotic 'suggestions'" (pp. 19-20).

Schneck, Jerome M. (1958). Relationships between hypnotist-audience and hypnotist-subject interaction. Journal of Clinical and Experimental Hypnosis, 6 (4), 171-181.

## NOTES

### "Summary

"Patients discussing or entering hypnotherapy are frequently influenced in their attitudes by some measure of direct or indirect contact with popular exhibitions of hypnosis. Expectations, interpretations, general behavior, and transference relationships are affected as a result. Previous papers by others have discussed and described popular exhibitions from the view of dangers and deception based on undeclared use of trained hypnotic subjects. The present paper is a study of a popular exhibition of hypnosis by a well known entertainer. Admixtures of good and rewarding entertainment method and poorly managed hypnotic technique are described. Stress is placed on the major approach involving impression by implication rather than elicitation of phenomena and clarification of claims with demonstration by challenge. The result is one of impressing the audience in regard to possible behavior under hypnosis without the actual proof of such claims. This is accomplished through reliance on the suggestibility and gullibility of the audience owing to its lack of experience and information. In most instances then, hypnotist-subject interaction is reduced to the most simple essentials. Stress is placed on the hypnotist-audience relationship. In some of the demonstrations there were varying degrees of subtle interplay between hypnotist-subject and hypnotist-audience relationships with the fostering of audience-subject identification and subject-hypnotist identification via coentertainer status. The hypnotist was capable at times of capitalizing on what he apparently sensed were the needs and likely reactions of certain subjects in connection with some forms of post-hypnotic behavior. The quality of the performance was mixed from an amusement point of view. Errors in technique occurred to a surprising degree in view of the hypnotist's extensive experience. Some entertaining highlights supported the performance. The relationship between hypnotist-audience and hypnotist-subject interaction are of interest within the larger context of interpersonal relations involving small and large groups.

1953

Glasner, Samuel (1953). Research problems in the educational and social psychological applications of hypnosis. Journal of Clinical and Experimental Hypnosis, 1 (2), 42-48.

#### NOTES

The author reviews literature in which hypnosis is used as an experimental research method in two general areas: hypnosis in learning and recall, and hypnosis in social psychology. "In summary, the application of hypnosis to research in the fields of educational and social psychology is practically virgin territory. Imaginative investigators should be able to develop numerous interesting experiments in these two great areas" (p. 47).

Glasner, Samuel (1953). Two experiments in the modification of attitude by the use of hypnotic and waking suggestion. Journal of Clinical and Experimental Hypnosis, 1, 71-75.

#### NOTES

Author's Conclusions: "In the light of the results, the following conclusions would appear to be justified:

1. Prestige suggestion can effect changes in an individual's response to an attitudes test.
2. Repeated prestige suggestion produces no more marked effect than does a single suggestion in changing social attitudes. However, the results seem to be more lasting with repeated suggestion.
3. Repeated hypnotic suggestion is considerably more effective than repeated waking suggestion in modifying social attitudes. But waking suggestion also seems to have some effect.
4. The effects of both hypnotic and waking suggestion vary greatly with different individuals.
5. The effect of repeated prestige suggestion in changing social attitudes apparently does not follow the pattern of the usual learning curve.
6. The changes noted seem to represent changes in basic attitude, and not merely changes in the response to a particular test" (P. 74).

The attitudes involved nationality preferences ("Negro, Turk, Hindu, or Chinamen" p. 71). The prestige suggestion, given in light hypnosis, was "The results on the test I gave you were rather disappointing. Most people think that we in the South are deeply prejudiced against the colored races. But that is a mis-understanding of our position. Certainly we University people have no actual dislike of Negroes, Chinamen, or Hindus. And it is our hope, in giving this test, to demonstrate our true attitude, which is far more tolerant than most people give us credit for. I am therefore going to give you the test again. I want you, of course, to give your honest preferences. But where you find a choice difficult, give the 'underdog' the benefit of the doubt. Do you understand? Give the 'underdog' the benefit of the doubt!" (p. 72).

#### SOCIAL SUPPORT

1993

Spiegel, David; Frischholz, Edward J.; Fleiss, Joseph L.; Spiegel, Herbert (1993). Predictors of smoking abstinence following a single-session restructuring intervention with self hypnosis. American Journal of Psychiatry, 150, 1090-1097.

Examined the relation of smoking and medical history, social support, and hypnotizability to outcome with Spiegel's smoking-cessation program. A consecutive series of 226 smokers were treated with the single-session approach and followed up for 2 years. With a total abstinence criterion, 52% success was found after 1 week, and 23% abstinence at 2 years. Hypnotizability and having been previously able to quit smoking for at least a month significantly predicted the initiation of abstinence.

Hypnotizability and living with a significant other person predicted 2-year maintenance. The results are superior to those of spontaneous efforts to stop smoking and suggest it is possible to predict which patients are most likely to respond and which patients are least likely to respond to such a brief intervention.

1992

Wickramasekera, Ian (1992, August). Hypnotic ability as a risk factor for psychopathology and pathophysiology. [Paper] Presented at the annual meeting of the American Psychological Association, Washington, DC.

Eighty-three patients with psychophysiological disorders seen prior to therapy were tested on the seven risk factors of the High Risk Model. Thirty-two percent of these patients were high on hypnotic ability, and hypnotic ability was unrelated to all of the other six risk factors. Mean social support and coping skills were significantly below the norm. Mean catastrophizing, negative affect (neuroticism), major life change and minor hassles were significantly above the norm. There are positive and significant correlations between hassles, negative affect and catastrophizing. There are also positive and significant correlations between coping skills and number and level of satisfaction with social support. There are negative and significant correlations between coping skills, catastrophizing, negative affect and hassles. There are also negative and significant correlations between satisfaction with social support, catastrophizing, and hassles. (ABSTRACT from the Bulletin of Division 30, Psychological Hypnosis, Fall, 1992, Vol. 1, No. 3.)

Matheson, G.; Drever, J. M. (1990). Psychological preparation of the patient for breast reconstruction. Annals of Plastic Surgery, 24, 238-247.

#### NOTES

Reviews over 100 women who had undergone rectus abdominis musculocutaneous flap reconstruction, the psychological issues motivating the patient for surgery, and psychological problems to be considered by the surgeon. A method of psychological preparation that was used and a report on the evaluative study of the program is included, and a protocol and verbalization for hypnotic relaxation is included.

Somer, E. (1990). Brief simultaneous couple hypnotherapy with a rape victim and her spouse: A brief communication. International Journal of Clinical and Experimental Hypnosis, 38 (1), 1-5.

This paper presents a case involving a rape victim and her emotionally affected spouse. Although the assault occurred before the couple met, the husband was too upset to concentrate when the victim wanted to share her rape-related feelings, nor could he provide the much needed empathy and support. This, apparently, was due to his difficulties in handling his own rage. Simultaneous couple hypnotherapy was used to allow the victim to share her experience under conditions safe for both her and her spouse. As he imagined in trance the rape account described by his age-regressed wife, he learned to identify his emotions and experience them in a controlled manner. During subsequent sessions, the husband was encouraged to include himself in his wife's abreaction and reshape the traumatic scene for both of them. The husband's rescuing behavior and the expressions of violent anger towards the perpetrator had several positive consequences. Not only did they change the abandonment component of the victim's traumatic memory, but they also helped the husband deal in better ways with his own feelings of anger. It also provided the couple with a helpful coping mechanism they later effectively applied under different circumstances.

1989

Spiegel, David; Bloom, J. R.; Kraemer, H. C.; Gottheil, E. (1989, October 14). The beneficial effect of psychosocial treatment on survival of metastatic breast cancer patients: A randomized prospective outcome study. Lancet, 888-891.

The effect of psychosocial intervention on time of survival of 86 metastatic breast cancer patients was studied using randomized prospective design. The one-year treatment consisted of weekly supportive group therapy with training in self-hypnosis for pain management, and resulted in significant reductions in mood disturbance and pain. Both the treatment and control groups had routine oncologic care. At ten-year follow-up, only three of the original 86 patients were still alive, and death records were obtained for the other 83. Survival from the time of randomization and onset of intervention was 36.6 (sd = 37.6) months for the treatment group, compared with 18.9 (sd = 10.8) months for the control group, and this difference was highly significant ( $Z = 3.94$ ,  $p < .0001$ ) using the Cox life table regression model. Kaplan-Meier survival analysis indicated that the divergence in survival began at 20 months after entry into the study, or 8 months after the treatment intervention ended. These unexpected findings suggest that intensive psychosocial support affects the course of the illness, although the mechanism by which it does so is not clear.

1986

Wickramasakera, Ian (1986). A model of people at high risk to develop chronic stress-related somatic symptoms: Some predictions. Professional Psychology: Research and Practice, 17, 437-447.

Certain measurable high-risk factors that predispose people to develop functionally based somatic disorders are identified. These risk factors compose a multidimensional model that encompasses variables involved in the predisposition, the precipitation, and the buffering of stress-related symptoms. These high-risk factors are (a) high or low hypnotic ability, (b) habitual catastrophizing cognitions and pessimistic belief systems, (c) autonomic lability or neuroticism, (d) multiple major life changes or multiple minor hassles over a short period of time, and (e) a deficit in support systems or coping skills or both.

1984

Wideman, Margaret V.; Singer, Jerome E. (1984). The role of psychological mechanisms in preparation for childbirth. American Psychologist, 39, 1357-1371.

Psychoprophylactic (Lamaze) preparation for childbirth consists of six to eight classes held during the last trimester of pregnancy. These classes include instruction in the anatomy and physiology of gestation and parturition, respiration techniques, controlled neuromuscular relaxation, visual focusing, and the training of a labor coach. Although the techniques are based upon psychological principles, they have remained largely unstudied by either psychologists or physicians. This article presents a brief history of the development of the training regimen and critically examines the few empirical studies that have been conducted. Because explanations for the efficacy of the preparation, if it exists, are equivocal, literature on the explicit components of the training--that is, information, respiration techniques, conditioned relaxation, cognitive restructuring, and social support--in situations other than child delivery are reviewed and their implications for the Lamaze method discussed. However, because there exist several, more implicit factors that may affect the type of child delivery a prepared woman experiences, the literature concerning social comparison, the effects of commitment and conformity, perceived control, and endorphin secretion are also discussed as they

may apply to psychoprophylactic preparation. Problems associated with the study of childbirth preparation are presented, and suggestions for the direction of future research are made.

1976

Dempster, C. R.; Balson, P.; Whalen, B. T. (1976). Supportive hypnotherapy during the radical treatment of malignancies. International Journal of Clinical and Experimental Hypnosis, 24, 1-9.

#### NOTES

"In summary, the radical treatment of malignancies presents a number of hypnotherapeutic opportunities. Not only can hypnotherapy help alleviate disease-related symptoms, but it can also limit some of the distressing side-effects of the treatments. The patient can gain needed hope by having the impact of his disease lessened. The hypnotherapeutic relationship also provides a useful base from which to deal with the issues of terminal illness, of death, and of dying.

"Implications for the future basically revolve around the issue of supportive hypnotherapy during radical treatment. As the use of chemotherapy of malignancies increases, there will be many opportunities for successful hypnotherapeutic interventions" (pp. 7-8).

**Bryant, Richard A.; Somerville, Ernest (1995). Hypnotic induction of an epileptic seizure: A brief communication. International Journal of Clinical and Experimental Hypnosis, 43 (3), 274-283.**

**This case study investigated the utility of hypnosis to precipitate a seizure in a patient with refractory epilepsy. The patient was twice administered a hypnotic induction and a suggestion to age regress to a day when he was distressed and suffered repeated seizures. The patient did not respond to the first hypnotic suggestion; however, an epileptic seizure was observed in the second hypnotic session. Videorecording and subdural electroencephalograph recording confirmed that he suffered an epileptic seizure. Postexperimental inquiry revealed that the patient used deliberate cognitive strategies to avoid**

seizure onset in the first session but adopted a more constructive cognitive style in the second session. Findings are discussed in terms of emotions, hypnosis, and cognitive style as mediating factors in the experimental precipitation of epileptic seizures.

1993

Litwin, R. G.; Cardena, E. (1993, August). Dissociation and reported trauma in organic and psychogenic seizure patients. [Paper] Presented at the annual meeting of the American Psychological Association, Toronto, Canada.

Early detection and differential diagnosis of non-epileptic seizures (NES) versus epileptic seizures (ES) is a major clinical issue in comprehensive epilepsy centers. Recent research suggests that differences in dissociative experiences between NES and ES patients may prove useful for diagnostic purposes. Non-epileptic seizures are frequently conceptualized as a dissociative response to past emotional trauma or abuse; dissociation in ES occurs as a result of electrophysiological abnormalities, most often associated with the temporal lobes. The purpose of this study was to evaluate the effectiveness for the differential diagnosis of NES from ES of several measures of dissociation and of a self-report measure for physical and sexual abuse. Four quantitative measures of dissociation were utilized in this study: the dissociative disorders interview schedule (DDIS), dissociative experience scale (DES), Tellegen absorption scale (TAS) and the Stanford Hypnotic Clinical Scale (SHCS). The incidence of sexual and physical abuse was obtained from structured questions in the DDIS. Forty-one patients being evaluated for intractable seizures participated in this study; 13 ES patients with non-temporal lobe involvement (ES/NTL), 18 ES patients with temporal lobe focus (ES/TLE) and 10 patients with NES spells of psychiatric origin. The main researcher was blind to these diagnoses until the study was completed. Results show a trend toward greater incidence of dissociative experiences in the NES versus ES group on the DDIS, TAS and DES, although these differences tended to be modest and not statistically significant, perhaps given the small N of the study. There were no significant trends or differences in dissociative experiences reported by ES/NTL patients versus ES/TLE patients. Contrary to the study's hypothesis, ES patients were slightly more susceptible to being hypnotized than NES patients. As hypothesized, a significant difference was that NES patients reported physical and sexual abuse of higher incidence and longer duration than did ES patients. Logistic regression analysis for prediction of NES using the DES, TAS and SHCS instruments correctly predicted only 10% of NES patients. However, exploratory logistic regression analysis using the demographic variables of gender, months of sexual abuse and years of recurrent seizures suggest that these characteristics may be specific and sensitive in the prediction of NES. Being a female, having a higher incidence and longer duration of abuse and fewer years of recurrent seizures all predicted significantly the existence of non-epileptic seizure events, allowing for a 95% accuracy in diagnostic prediction. Our findings reinforce prior research indicating that dissociation is an important symptom component of both ES and NES events. The trend toward more prevalent dissociative experiences in the NES group suggests that in depth examination of these differences and of key demographic variables may help differentiate between these two groups. (ABSTRACT from Bulletin of Division 30, Psychological Hypnosis, Fall 1993, Vol. 2, No. 3.)

1991

Persinger, M. A.; Makarec, Katherine (1991-92). Interactions between temporal lobe signs, imaginings, beliefs and gender: Their effect upon logical inference. Imagination, Cognition and Personality, 11, 149-166.

**Rotton's Paralogic Test, Wilson-Barber's Inventory of Childhood memories and Imaginings (ICMI) and the PPI (Personal Philosophy Inventory) were administered to 100 male and 100 female university students. Both sexes displayed moderately strong (0.50) correlations between content-selected and factor analyzed clusters of possible temporal lobe signs, exotic beliefs and the numbers of childhood imaginings. Although there were no sex differences between the accuracy of logical statements that contained paranormal or neutral content, males who displayed more temporal lobe signs were more accurate for logical items that contained paranormal content. Females who displayed more imaginings were more accurate for valid than for invalid items. Accuracy for items with paranormal content increased with exotic beliefs but not with conservative religious beliefs for both sexes. The relationship between exotic beliefs and accuracy for items with paranormal content was especially strong for females. These results suggest: 1) gender differences in the neurocognitive processes that contribute to logical problem solving and 2) accuracy may depend upon the degree to which the subject matter is commensurate with the person's history of enhanced temporal lobe signs, capacity for fantasy and imaginings and beliefs in exotic concepts.**

## **NOTES**

**Review of related literature indicates that Personal Philosophy Inventory (PPI) temporal lobe signs are correlated with temporal lobe EEG alpha but not occipital lobe alpha (Makarec & Persinger, 1990), with increased suggestibility (Persinger & DeSano, 1986; Ross & Persinger, 1987), with creativity and proneness towards fantasy (Persinger & DeSano, 1986; Ross & Persinger, 1987; Makarec & Persinger, 1987), and with reports of psi experiences and beliefs in such things as reincarnation and aliens in UFOs ('exotic themes') (Persinger & Makarec, 1987; Persinger & Makarec, 1990).**

**This experiment was designed to answer four questions: " 1) Do imagery and temporal lobe signs emerge from the same source of variance?; 2) Do males and females differ significantly in their incidence of imaginings and temporal lobe signs?; 3) Do males and females differ in their ability to solve logical problems?; and 4) Is the accuracy of problem solving affected by the subject matter of the problem and the problem solver's temporal lobe signs and capacity for imagery?" (p. 151).**

**The PPI consists of 140 true-false items that were selected with a goal of discerning temporal lobe signs within a normal population. One 30-item subscale has items that are similar to experiences reported by patients with verified electrical foci in the temporal lobes, albeit milder (the TLS or temporal lobe sign scale). Of these 30 items, 16 refer to ictal-like experiences (the CPES, or complex partial epileptic signs), and 14 refer to interictal-like behaviors (ILB). CPES items are items like "Sometimes an event will occur that has special significance for me only," and "While sitting quietly, I have had uplifting sensations as if I were driving over a rolling road." ILB items are items like "People tell me I blank out sometimes when people are talking," and "When I lose an argument I spend a lot of time thinking about what I should have said."**

**Wilson and Barber's Inventory of Childhood Memories and Imaginings (ICMI) has 52 true-false items that include reports of paranormal experiences (5 items), moderate imaginings (18 items) such as 'When I was a child I enjoyed fairytales,' and extreme imaginings (15 items) such as 'When I was a child or teenager, at times I was afraid my imagining would become so real to me that I would be unable to stop it.'**

**Rotton's Paralogic Test [unpublished, at Florida International University, Miami] has 16 syllogisms, each with major premise, minor premise, and conclusion. "The person must decide if the argument is valid (n = 8) or invalid (n = 8). Half of each of the valid and invalid arguments refer to mundane material while the other half of the arguments refer to paranormal-related material. An example of the former is 'If a president is a crook, he would be impeached; Congress did not impeach Nixon. Therefore Nixon is not a crook' and 'If flying saucers really existed, somebody would have photographed one. Nobody has ever photographed a flying saucer. Therefore, flying saucers do not exist'" (p. 153).**

Correlations were computed separately for males and females. Both groups increased in accuracy for paranormal items as their belief in things like reincarnation and UFOs ('exotic concepts') increased. Males with a higher number of temporal lobe signs demonstrated more accuracy for logic test items with paranormal (psi) content than logic test items with mundane content.

"The single most important correlation was between exotic beliefs and the interaction term for the Rotton scale; the coefficient was unusually strong (0.54) and highly statistically significant ( $p < 0.001$ ) for females only. Because of the manner in which the interaction term was calculated, this correlation meant that females who reported more exotic beliefs were also more accurate for valid items that contained paranormal content only" (p. 159).

In their Discussion, the authors write, "The significant positive correlations between exotic beliefs and the clusters of CPES items and extreme Wilson-Barber imagining items are expected associations according to Bear's concept of sensory-limbic hyperconnectionism [Temporal Lobe Epilepsy: A Syndrome of Sensory-Limbic Hyperconnectionism, *Cortex*, 15, pp. 357-384. It would predict that concepts (or word trains) that are unusual, strange or infrequent would be charged with emotional significance and personal value. Ideas that generate substantial imagery, such as time- travel, reincarnation and alien intelligence, would be particularly prone to this affective infusion from limbic sources.

Induction of such unique or intensified affective states, especially during childhood, would facilitate the development of more frequent or more extreme periods of dissociation in the adult. We have collected (unpublished) clinical evidence to suggest that the emergence of this pattern is found in the propensity for creative thinkers, including writers, poets, musicians, artists and scientists, to have had developmental histories that could have promoted temporal lobe lability without overt seizure activity; clusters of such "promoters" include mild physical abuse, febrile episodes, minor head injuries and likely hypoxic periods during extreme physical exertion (competitive athletics)" (pp. 161-162).

Another conclusion of the study is that males and females do not differ in their accuracy in solving syllogisms, but "the neurocognitive processes, as inferred from inventories of temporal lobe signs or childhood imaginings, by which the two sexes arrive at solutions may be quite different" (p. 162).

1988

DeBenedittis, Giuseppe; Sironi, Vittorio A. (1988). Arousal effects of electrical deep brain stimulation in hypnosis. *International Journal of Clinical and Experimental Hypnosis*, 36, 96-106.

In an earlier study, DeBenedittis and Sironi (1986) demonstrated that during depth EEG studies, electrophysiological correlates of hypnotic behavior emphasize the role of the limbic system in mediating the trance experience. In the case of a young man who was affected by medically resistant temporal lobe epilepsy and who was a potential candidate for surgical treatment, diagnostic depth EEG in hypnotic and non- hypnotic conditions offered a unique opportunity to stimulate limbic structures. This permitted an evaluation of the subjective and behavioral responses, as well as of the electrophysiological correlates. During hypnosis, repeated stimulations of the left and the right amygdala produced arousal from the hypnotic state each time, whereas the stimulation of other cerebral structures (e.g., temporal neocortex, Ammon's horn) or pseudostimulations were ineffective on the hypnotic state. These data represent the first experimental, controlled evidence of the amygdala's effects on the arousal from the hypnotic state in man, thus suggesting that hypnotic behavior is mediated, at least in part, by a dynamic balance of antagonizing effects of discrete limbic structures--the amygdala and the hippocampus.

NOTES

The patient was a 30-year-old man who had suffered from medically resistant psychomotor temporal lobe epilepsy since age 7; a diagnostic EEG showed right temporal seizure focus, concomitant with

independent, contralateral, temporal spiking abnormalities. Hypnotizability was measured at 6 on the SHSS:C; the patient was given two training sessions in hypnosis, with suggestions for "dissociation, rehearsal and reframing of spontaneous seizure events, desensitization of their negative emotional impact, and amnesia" (p. 99).

Electrodes were implanted in deep cerebral structures (amygdala, Ammon's horn) and corresponding superficial areas of temporal cortex, with confirmation of placement by X-ray. Two weeks later the patient's brain was stimulated on two consecutive days, first in the waking state (Session 1) and then in hypnosis (Session 2). (Antiepileptic medication was discontinued three days before the stimulation sessions.) False (placebo) stimulations were randomly provided along with the true stimulations.

The false (placebo) stimulations did not result in subjective or behavioral changes in either the waking or the hypnosis condition.

In the waking condition, a psychomotor seizure was produced by stimulation of Right amygdala and Left Ammon's horn; stimulation of Left amygdala evoked only the aura patient usually had before a seizure, or a brief lapse of consciousness. Stimulating the temporal neocortex did not evoke seizure activity.

In the hypnosis condition, arousal from hypnosis into the waking condition occurred with stimulation of amygdala (either Right or Left). Stimulation of the temporal neocortex or of the Right Ammon's horn did not arouse the patient. Stimulation of Left Ammon's horn led to abortive seizures, such that it could not be determined whether the hypnotic state had been interrupted. Stimulating the Right amygdala "triggered a psychomotor attack similar to that recorded during the waking stimulation, but with reduced emotional involvement" (p. 100). For the Left Ammon's horn, "waking stimulation always induced clinical seizures with prolonged after-discharge, whereas hypnotic stimulation evoked only abortive seizures, without after-discharge" (p. 100).

In their Discussion, the authors note that animal experimental literature suggests that stimulation of the cortico-medial amygdala facilitates arousal functions, of the baso-lateral amygdala diminishes arousal and produces sleep, and lesions of the amygdala lead to 'amygdala hangover' (Weiskrantz, 1956). "The animal with amygdala destruction appears tame and placid, with reduced social reactivity, insensitive to environmental changes and reluctant to initiate new behavior, unless highly motivated (Isaacson, 1976)" (p. 101-102).

In contrast, the animal research on hippocampus suggests it is involved in inhibitory functions (Isaacson, 1976), and may be the 'internal inhibitor' theorized by Pavlov (1955) to be responsible for animal hypnosis. With lesions, animals are more willing to undertake new behaviors, less inactive, less distractible during goal-oriented behavior (Isaacson, 1976). "Moreover, normal hippocampograms show typical, slow (theta) synchronous activity opposed to the arousal desynchronized activity of the electroencephalogram. During hypnosis, desynchronization of the normal, slow activity of the hippocampal Ammon's horn has been registered as compared with the waking hippocampogram, opposite to the slow synchronous activity of the amygdala" (p. 102).

The authors note that their results are at variance with the finding by Crasilneck et al. (1956) that their patient, during brain surgery for an epileptogenic focus, aroused from hypnosis each time they stimulated the hippocampus. They explain the discrepancy as due to the fact that the hippocampus was not simply stimulated, but in fact there was 'coagulation' of a hippocampal vessel each time. Quoting from Crasilneck et al. "'The patient did not complain of pain during this [brain] excision [in hypnosis] except on one noteworthy occasion, when a blood vessel of the hippocampal region was being coagulated. The patient suddenly awoke from the hypnotic trance ... She was immediately rehypnotized. ... The surgeon then purposefully 'restimulated' the same region of the hippocampus. Once again, the patient abruptly awakened from trance... [p. 1607].'"To the present authors, the description appears misleading and responsible for subsequent misinterpretation of the observation. Because on the first occasion the hypnotic arousal effect followed 'coagulation' of the hippocampal region, it may be assumed that 'restimulation' is a misnomer for repeated coagulation. From this it

may be inferred that the arousal effect observed by Crasilneck et al. (1956) could probably be ascribed to a hippocampal microlesion rather than to hippocampal stimulation. This could explain the apparent discrepancy" (p. 104).

Loewenstein, R. J.; Putnam, F. W. (1988). A comparison study of dissociative symptoms in patients with complex partial seizures, MPD, and posttraumatic stress disorder. Dissociation, **1**, 17-23.

Depersonalization and dissociative symptoms have been widely reported in chronic seizure disorder patients, especially those with temporal lobe involvement and complex partial seizures (CPS). It has been theorized that development of multiple personality disorder may be related to temporal lobe pathology. We administered the Dissociative Experiences Scale (DES) to 12 male patients with severe chronic epilepsy, primarily of the complex partial type. Patients had epilepsy from 1 to 30 years. Most were being evaluated for intractable seizures occurring several times per week. DES data on the epileptic patients were compared with DES data on 9 male MPD patients and 39 PTSD patients. MPD and PTSD patients were significantly different from CPS patients in median DES scores and all DES subscale scores. MPD and PTSD patients were far more similar on the DES, although MPD patients had a significantly higher score on the dissociation/psychogenic amnesia subscale of the DES. The authors conclude that there is little data to support a relationship between MPD, dissociation, and epilepsy.

1987

Makarec, K.; Persinger, M. A. (1987). Electroencephalographic correlates of temporal lobe signs and imaginings. Perceptual and Motor Skills, **64**, 1124-1126.

Significant correlations (0.50) were observed between scores for the Wilson-Barber Inventory of Childhood Memories and Imaginings and the experiences that are indicative of temporal lobe lability. In addition, positive correlations (0.42) occurred between temporal lobe EEG measures (scalp electrodes) and numbers of temporal lobe signs. The numbers of alpha seconds per minute from the occipital lobes were correlated (0.57) with the Wilson-Barber cluster that indicated interests in 'altered states'. Scores on the childhood imaginings section of the Wilson-Barber Inventory were correlated (0.44) with the numbers of spikes per minute over the temporal lobes when the eyes were closed.

## NOTES

"Persinger and DeSano (1986) found that people who display temporal lobe signs were also more likely to have more imaginings (as defined by Wilson and Barber's (1983) Inventory of Childhood Memories and Imaginings) and to be more suggestible as indicated by Spiegel's Hypnosis Induction Profile" (p. 1124).

Subjects in this investigation were 12 male and 18 female students, ages 18-39 (M = 25 years) Bipolar measures were taken from just above the ears (approximately T3-T4) and the occipital lobe (01-02). Number of alpha seconds per minute and number of spikes per minute from each lobe was taken for 10 minutes (5 successive pairs of 1 minute eyes- open, 1 minute eyes-closed).

"The total Wilson-Barber score was significantly ( $p < .01$ ) correlated ... with the major (0.46) and minor (0.50) temporal lobe clusters but not with two clusters of control items: normal psychological experiences (0.21) and mundane proprioceptive experiences (0.29). These correlations are similar to those in the Persinger and DeSano study (0.60, 0.50, 0.13, and 0.14, respectively). Like the first study (0.53), the items that were most associated with dissociation (depersonalization) were best correlated with the Wilson- Barber scores (0.60). The Wilson-Barber subcluster: adults' extreme experiences (Items 44 through 52, that indicate physiological changes associated with thinking) was again most

strongly correlated with the major (0.55) and minor (0.65) temporal lobe clusters; these values were 0.42 and 0.52 in the first study" (p. 1125).

"The only statistically significant ( $p < .01$ ) correlations between the Wilson-Barber scales and the EEG measures were between the number of alpha seconds from the occipital lobe (with the eyes closed) and the [Wilson-Barber] 'altered state' cluster ( $r = 0.57$ ; Items 33, 41, 42, 43). A weaker correlation (0.36) occurred between the number of alpha seconds per min. (eyes closed condition) and childhood vestibular experiences (items 1, 2, 3, 10, 24)" (p. 1126).

1986

DeBenedittis, Giuseppe; Sironi, Vittorio A. (1986). Depth cerebral electrical activity in man during hypnosis: A brief communication. International Journal of Clinical and Experimental Hypnosis, 34, 63-70.

To the authors' knowledge, hypnosis has never been induced in epileptic patients during a depth EEG study. This neurosurgical diagnostic procedure has been routinely used in medically resistant epileptic patients for the preoperative exact delimitation of the epileptogenic lesion. It offers a unique opportunity to obtain fundamental information on the possible neurophysiological mechanisms implicated in hypnosis. Observations were carried out on 1 patient affected by medically resistant partial seizures with complex symptomatology. A chronic deep electrode study explored rhinencephalic structures as well as specific target areas of the cerebral cortex. Background electrical activity during hypnosis showed a significant decrease of slow waves and an increase of alpha and beta rhythms, with constant increase of amplitude, when compared to activity in the pre- and posthypnosis states. Focal interictal abnormalities were dramatically reduced during hypnosis.

#### NOTES

Hypnotizability was assessed with the Barber Suggestibility Scale in order to test for suggestibility without a prior induction of hypnosis. The patient's score was 7 out of 8 possible. Patient was hypnotized with a standard induction procedure (Barber & Calverley, 1963).

Experimental Protocol: 15 minutes resting baseline; 15 minute test of mental imagery (waking suggestions with imagination instructions); hypnosis with progressive relaxation; suggestions for dissociation; suggestions for amnesia; arousal from hypnosis (the patient was successful with positive hallucinations, catalepsy, total amnesia, and spontaneous analgesia); and posthypnosis awake and alert (5 minutes eyes open, 5 minutes eyes closed, then 15-minute recording of post-treatment waking baseline).

EEG background activity was scored for the number of sec/minute of delta (0-4), theta (4-7), alpha (8-12), and beta (13-30) rhythms, for each 5-min period. Score = percent as related to the 1-minute epoch. Number, amplitude, and diffusion of interictal spikes also were measured but ictal activity was not recorded during the periods considered. Experimenters also measured heart rate, respiratory rate, and mean blood pressure.

ANOVA for 4 conditions (resting, waking suggestion, hypnosis, and posthypnosis) was computed for background and for focal interictal activities, and the t-test used to evaluate significant differences. ANOVA indicated a significant effect across the four experimental conditions for theta and alpha in the temporal anterior cortex, temporal posterior cortex, and frontal convexity cortex. The effect was attributable only to changes in theta and alpha between baseline and hypnosis (theta decreasing, alpha increasing as the patient went into hypnosis). No other significant difference was found. Following arousal from hypnosis, EEG activity was similar to the EEG activity before the induction.

Interictal focal abnormalities were reduced during hypnosis, compared with before hypnosis. The effect was due to changes in the area of Ammon's horn, the amygdala, the posterior temporal cortex, the mesial temporal cortex, and the inferior temporal cortex.

In their Discussion, the authors note that their data supports earlier work indicating that the limbic system is implicated in hypnosis. They cite the publications of Arnold (1959, *International Journal of Clinical and Experimental Hypnosis*) and Crasilneck, McCranie, and Jenkins (1956). The latter authors observed EEG records taken during brain surgery on one patient. Hypnosis terminated every time the hippocampus was stimulated, leading them to suggest that the hippocampus is part of the neural circuit involved in hypnosis.

"If it is assumed that a convulsion can be considered a result of both pathophysiological and emotional events operating in the individual, emotions being the most common precipitating factor in epilepsy, then any amelioration of one will raise the convulsive threshold or lower the seizure level (Goldie, 1979; MacCabe & Habovick, 1963). Although 'voluntary control of the alpha rhythm' was achieved over 40 years ago (Jasper & Shagass, 1941), only since 1969 has such control been used for clinical purposes (Kamiya, 1969). One striking characteristic of the EEG pattern of many epileptics is the absence of a 12 to 14 c/s rhythm normally recorded from the anterior portions of the brain (sensorimotor rhythm) and the presence of a 4 to 7 c/s rhythm at the same location (Olton & Noonberg, 1980). Biofeedback may enable the individual to increase the amount of sensorimotor rhythm and to decrease the amount of 4 to 7 c/s activity. As a consequence, clinically significant decreases in seizure activity have been found after biofeedback training (Serman, 1973, 1977).

"The present data demonstrate that in this female patient hypnosis induced a highly significant reduction of the interictal activity, concomitant with an increase of alpha and sensorimotor rhythm and a decrease of slow activity, similar to biofeedback but without prior training.

"In conclusion, a depth EEG study in one epileptic patient comparing EEG activity during hypnosis and pre- and posthypnosis suggests the following conclusions: (a) hypnosis may be associated with significant decrease of slow activity and an increase of alpha and relatively high frequency, beta activity; (b) electrophysiological correlates of hypnotic behavior support the possible role of the limbic system in mediating the trance experience; and (c) hypnosis is effective in reducing focal interictal abnormalities in this patient and so it can be considered a promising technique to prevent and/or reduce emotional precipitating factors and the tendency to develop seizure activity" (p. 69).

The article referenced regarding biofeedback training to reduce ictal activity is: Serman, M. B. (1973). Neurophysiologic and clinical studies of sensorimotor EEG biofeedback training: some effects on epilepsy. In L. Birk (Ed.), *Biofeedback: Behavioral medicine*. New York: Grune & Stratton, Pp. 147-165.

1984

Cocores, James A.; Bender, Andrew L.; McBride, Eugene (1984). Multiple personality, seizure disorder, and the electroencephalogram. *Journal of Nervous and Mental Disease*, 172, 436-438.

Used the EEG to study multiple personality in a 48-yr-old ambidextrous male admitted for alcohol detoxification and individual psychotherapy. Despite conflicting reports in the literature, no changes in the EEG were found that could not be ascribed to the normal changes seen in transitions from various states of alertness. The problems of differentiating multiple personality as a psychiatric entity in itself from those cases arising as a result of chronic partial or partial-complex epilepsy are discussed.

Gravitz, Melvin A. (1981). Non-verbal hypnotic techniques in a centrally deaf brain-damaged patient. *International Journal of Clinical and Experimental Hypnosis*, 29, 110-116.

Non-verbal techniques across several sensory dimensions were utilized with a brain-damaged centrally deaf 36-year-old female patient who had been referred for hypnotherapeutic relaxation. These included optical fixation on the therapist's hand with gradual thumb and fore-finger closure, vibratory stimuli, light shoulder pressures, arm stroking, manually facilitated air currents, and reinforcing homework assignments. With hypnotherapy, the patient's physical and emotional behavior was reported by her to have improved to a significant degree.

Gross, Meir, M. D. (1981). Hypnosis for dissociation -- diagnostic and therapeutic. Journal of the American Society of Psychosomatic Dentistry and Medicine, 28 (2), 49-56.

#### NOTES

Dissociative disorders might be at times very difficult to diagnose and treat, especially since they are very similar to epilepsy in general and to temporal lobe epilepsy in particular. Amnesia, fugue, changing personality and depersonalization are part of both disorders. Patients who suffer from dissociative disorders might be diagnosed and treated for epilepsy with anticonvulsive medications without any beneficial results. These patients are labeled as epileptics and have to face the social stigmata associated with being epileptic. The wrong label could even reinforce the sick role and make it become fixed and chronic.

Hypnosis was used to diagnose the dissociative disorder by using the hand levitation technique for the differential diagnosis. It was found by the author that patients who suffer from dissociative disorders would get into spontaneous hypnotic trance during the hand levitation. Hypnosis was used also for successful therapy of these patients.

Seven cases are presented in which the hand levitation technique was used to diagnose the dissociative disorder. They were also treated by hypnotherapy. Their treatment by hypnosis is discussed. The purpose of this paper is to introduce the hand levitation technique for the differential diagnosis of dissociative disorder and to emphasize the effectiveness of hypnotherapy in the treatment of this disorder. Sorting out the cases of dissociative disorders from the epileptics is very important clinically, since it can save many patients from the anguish of having to take anti-convulsants unnecessarily and having to face the social stigmata of being labeled as epileptic.

Slater, Roger C.; Flores, Louis S. (1963). Hypnosis in organic symptom removal: A temporary removal of an organic paralysis by hypnosis. American Journal of Clinical Hypnosis, 5 (4), 248-255.

#### NOTES

"Summary and Conclusions. A detailed case study is reported on the use of hypnosis with beneficial results in an instance of eventually proved organic brain disease. Three other confirmatory case reports of organic disease definitely benefitted by the use of hypnosis are briefly cited.

" The first patient had been adequately studied repeatedly for organic brain disease. Because the studies led to an uncertain indefinite unconfirmed suspicion of psychogenic epilepsy, the patient was returned with a recommendation for continued treatment and observation by the author, a general practitioner. Hence, she was, after still further study for organic disease, treated symptomatically by hypnosis with beneficial results. This led to the erroneous conclusion that the patient's disability was

probably functional. A sudden fatal outcome of the actual but unrecognized brain disease led to a correct but post- mortem diagnosis of astrocytoma of the brain, Grade IV.

"This report and those given to supplement it raise significant questions about the importance and value of hypnosis in organic disease. These include the challenging question of the extent to which the use of hypnosis can potentiate the natural corrective forces of the body; the need to recognize the value of hypnosis in effecting beneficial results in organic disease; the need to qualify the reliability of hypnosis as a differential diagnostic procedure in relation to psychogenic and organic disability; and the possibility and extent of the amelioration or actual correction of known organic illness" (p. 254).

## NOTES

A dream that occurred in natural sleep was used as the starting point for exploration in hypnosis, e.g. suggesting that the patient was seated in a movie theater and would see an element that had been in the dream, projected on the movie screen; then would see substitute pictures which had for him the same meaning as that element. "... as in the dream, commitments to reality [in hypnosis] are minimized and there are evidences of the archaic drive-oriented primary process and a loss of distance form the fantasy so that it becomes a transitory hallucinatory experience. In addition, the censorship function is reduced but not eliminated so that this case study is highlighted by the defensive symbolic substitutions provoked by the persistent demands of the therapist" (pp. 64-65).

## STATISTICS

**1997**

Green, Joseph P. (1997). Hypnotizability, the dissociative experiences scale, HGSHS: A amnesia, and automatic writing: Is there an association?. International Journal of Clinical and Experimental Hypnosis, 45 (1), 69-80.

The present study examined whether participants (N = 112) selected on the basis of high and low dissociative ability (Dissociative Experiences Scale [DES]; Bernstein & Putnam, 1986), high and low/simulating hypnotizability (Harvard Group Scale of Hypnotic Susceptibility, Form A [HGSHS:A]; Shor & Orne, 1962), and past performance on the HGSHS:A amnesia item differentially passed an automatic writing suggestion administered during a follow-up experiment. Results from a loglinear analysis supported a single main effect for hypnotizability. Low hypnotizable, simulating participants were more than six times as likely to pass the automatic writing suggestion than high hypnotizable participants. Results found dissociation status and past performance on an ostensibly dissociative suggestion (i.e., amnesia) to be independent of passing the automatic writing suggestion. Findings are discussed in light of other research regarding the relation between the DES and hypnotizability.

1996

Allen, John J. B.; Law, Heather; Laravuso, John J. (1996). Items for assessing posthypnotic recognition amnesia with the HGSHS:A and the SHSS:C. International Journal of Clinical and Experimental Hypnosis, 44 (1), 52-65.

A procedure for assessing posthypnotic recognition amnesia is described. A set of items for the Harvard Group Scale of Hypnotic Susceptibility, Form A and for the Stanford Hypnotic Susceptibility Scale, Form C were developed and analyzed for reliability and their ability to discriminate individuals who demonstrate posthypnotic amnesia. Recognition amnesia could be assessed as reliably as recall amnesia, and posthypnotic recognition amnesia identified a select subgroup of high hypnotizable individuals who had higher scores on the screening scales. These items may prove useful for assessing posthypnotic recognition amnesia in conjunction with widely used scales of hypnotic susceptibility.

Dixon, Mike; Labelle, Louise; Laurence, Jean-Roch (1996). A multivariate approach to the prediction of hypnotic susceptibility. International Journal of Clinical and Experimental Hypnosis, 44 (3), 250-264.

The present study examined the relation between various self-report measures and two measures of hypnotizability within a multivariate framework. A group of 748 participants was tested on the Harvard Group Scale of Hypnotic Susceptibility, Form A (HGSHS:A), the Tellegen Absorption Scale (TAS), as well as the Preference for an Imagic Cognitive Style (PICS) questionnaire. One hundred ninety of these participants also completed the Paranormal Experiences Questionnaire (PEQ). Data were analyzed using hierarchical multiple regression equations, and the results of the analyses indicated that both the TAS and PICS accounted for significant amounts of unique variance in each of two 373-member samples of HGSHS:A scores. A further sub-sample of participants (n = 161) was tested on the Stanford Hypnotic Susceptibility Scale, Form C (SHSS:C) to see if these results would generalize to another measure of hypnotizability. Hierarchical multiple regression analyses revealed that although the PEQ predicted significant amounts of unique SHSS:C variance over and above that predicted by the TAS, the PICS failed to do so. This inconsistency in results may be due in part to the generally low intercorrelation between the different hypnotizability scales and points to the need to develop new predictor variables that are orthogonal to each other. - Journal Abstract

Weitzenhoffer, Andre M. (1996). Catalepsy tests: What do they tell us?. International Journal of Clinical and Experimental Hypnosis, 44 (4), 307-323.

In a survey of 200 clinicians regarding their use of catalepsy tests, three fourths of the respondents indicated that they used these tests. In light of this response, and considering both the scientific importance of being able to identify the presence of hypnosis and the fact that catalepsy may account for up to eight of the other indications of hypnosis in use, it is relevant to inquire into the reliability and validity of catalepsy tests. It was found that of the three tests of catalepsy currently in use, only one has the potential for being a test of hypnosis proper and can also justifiably be said to be "of catalepsy." This one test, however, has many serious weaknesses that need to be eliminated if it is to be truly useful. - Journal Abstract

1995

Jacobs, Andrea L.; Kurtz, Richard M.; Strube, Michael J. (1995). Hypnotic analgesia, expectancy effects, and choice of design: A reexamination. International Journal of Clinical and Experimental Hypnosis, 43 (1), 55-69.

Previous research by Stam and Spanos suggests that if waking analgesia is followed by hypnotic analgesia, subjects refrain from maximally responding during the waking trial so they report less pain under hypnosis (i.e., a "holdback effect"). This hypothesis was re-examined using more stringent controls. Thirty-six highly susceptible subjects chosen by a combination of the Harvard Group Scale of Hypnotic Susceptibility, Form A and the Stanford Hypnotic Susceptibility Scale, Form C were randomly assigned to one of three treatment groups (waking analgesia followed by hypnotic analgesia, waking analgesia followed by waking analgesia, or hypnotic analgesia followed by waking analgesia). Each group received three 60-second immersions of cold pressor pain stimulation (baseline, Immersion 1, Immersion 2) and rated pain using a magnitude estimation and a category rating scale. The obtained results failed to support the hypotheses of a holdback effect or a "reverse-order holdback effect." Properties of within-subjects and between-subjects designs were considered in explaining the superiority of hypnotic analgesia over waking analgesia typically found in within-subjects models.

1994

Levitt, Eugene E. (1994). The one-tailed test: A statistical editorial. International Journal of Clinical and Experimental Hypnosis, 42 (1), 4-6.

#### NOTES

The writer concludes, "The point of these illustrations is that a one-tailed test is rarely appropriate in a pure science experiment. The researcher must present justification for the use of a one-tailed test beyond merely a directional hypothesis. This becomes an urgent requisite when the experimental finding is significant only when tested with a single tail, which is ordinarily true when one-tailed tests are used" (p. 6).

Nash, Michael R. (1994). Memory distortion and sexual trauma: The problem of false negatives and false positives. International Journal of Clinical and Experimental Hypnosis, 42 (4), 346-362.

Logically, two broad types of mnemonic errors are possible when adult psychotherapy or hypnosis patients reflect on whether they were sexually abused or not as a child. They may believe that they were not abused when in fact they were (false negative error), or they may believe they were abused when in fact they were not (false positive error). The author briefly reviews the empirical evidence for the occurrence of each of these types of errors, and illustrates each with a clinical case. Further, in considering the incidence, importance, and clinical implications of these errors, the author contends that clinical efficacy in no way assures that a false negative or a false positive has been avoided. A plea

is made for theorists and researchers to acknowledge that both categories of errors can occur and to conduct future clinical and laboratory research accordingly.

Oakman, J.; Woody, E. Z. (1994, October). Theoretical implications of a typological conception of hypnotic ability. [Paper] Presented at the annual meeting of the Society for Clinical and Experimental Hypnosis, San Francisco.

## NOTES

Analyses suggest a typology rather than continuous dimensions of hypnotic ability. One implication is that hypnotic ability is due to a developmental influence dividing people into two types, like forks in the road. For example consider the link between trauma, dissociation, and hypnotizability. Trauma may be one of the developmental paths toward hypnotic ability. Another pathway into hypnotic ability is early childhood imaginal involvements.

A problem of the developmental models is that there are low correlations between fantasy proneness and hypnotizability. The models make no assertions about covariation of these traits in a normal population, so the correlations are irrelevant in this example. Only when there is a high base rate [of high hypnotizable type?] would the correlation of hypnotizability be high.

Other implications of the typology view: 1. It would challenge existing measures of hypnotizability, which assume a sum of small influences. New measures of hypnotic ability may need to be created. Existing items are poor. We need to delete easy items and add more challenging items to the scales. Also we could add items from Openness to Experience scales, etc. Item content need not be homogenous; internal consistency is not necessary, and should be low. Ratings of a flat nose, short limbs and epicanthal fold have a zero correlation in the general population, but go together in Downs' syndrome. 2. It would require a revision in our thinking. We may need to drive a wedge between theories of hypnotizability and theories of hypnosis. Whether current theories are more applicable to the high type or the low type hypnotizability is not yet known. 3. Or we can explore how type members differ from non-type members. Meehl argues that types discovered by his methods are "causal promissory notes."

## 1993

Baker, Sharon L.; Kirsch, Irving (1993). Hypnotic and placebo analgesia: Order effects and the placebo label. Contemporary Hypnosis, 10 (3), 117-126.

Hypnotic and placebo pain reduction were compared in a sample of subjects whose hypnotic susceptibility was broadly representative of the general population. Replicating the order effect reported by Stam and Spanos in 1987 for highly hypnotizable subjects, hypnosis produced more pain relief than a 'pain-reducing analgesic' placebo only when the hypnosis trial followed the placebo trial. When the placebo was described to subjects as a 'hypnotic drug' that 'increases suggestibility', no differences were found regardless of order of presentation. Both hypnotizability and pain reduction were correlated with subjects' expectancies, and the partial correlation between hypnotizability and pain reduction, with expectancy controlled, was non-significant. These data suggest that, for most subjects, hypnotic analgesia is analogous to a placebo effect, although it may be more useful than a placebo because its administration does not require deception.

## 1992

Balthazard, Claude G.; Woody, Erik Z. (1992). The spectral analysis of hypnotic performance with respect to 'Absorption'. International Journal of Clinical and Experimental Hypnosis, 40, 21-43.

In factor analyses of the hypnosis scales, the essential result is that the items form a continuous, 2-dimensional fan-shaped pattern. This continuum is referred to as the "spectrum of hypnotic performance." "Spectral analysis" is introduced as an exploratory procedure which makes use of this notion of continuum or spectrum. Spectral analysis consists of a graphical display of the level of latent correlation between a variable and individual hypnotic performances when the latter are arranged according to their position in the spectrum. The spectral analysis of hypnotic performance with respect to absorption is illustrated using data from a sample of 160 Ss. The results indicate that absorption is more strongly related to difficult hypnotic performances than to easy ones. In particular, illustrative item characteristic curves are presented to show that although easy hypnotic performances do not require the processes tapped by individual differences in absorption, a certain level of absorption is necessary to pass difficult hypnotic items. In addition, a high level of absorption may be sufficient in and of itself for difficult hypnotic performances. These results are discussed in light of some speculations by Shor, M. T. Orne, and O'Connell (1962) and Tellegen (1978/1979) concerning the differential contribution of ability components to performance on difficult hypnotic suggestions. The results are also related to a variety of work in social psychological models of hypnotic performance.

## NOTES

Spectral analysis "consists of a graphical display of the level of latent correlation between a variable and individual hypnotic performances when these hypnotic performances are arranged according to their position in the spectrum---which is indexed by item difficulty" (p. 25). Difficulty (the proportion of Ss that pass a given item) is on the X-axis; the degree of latent correlation is on the Y-axis. "It is necessary to differentiate between the manifest and the latent relationship of a variable to a dichotomously scored hypnotic performance. The manifest relationship is given by the point biserial correlation and the latent relationship is given by the biserial correlation. ... By inspecting the overall pattern of these biserial correlations as a function of item difficulty, it is possible to overcome the difficulty-content confound, because the biserial correlations are not affected by item difficulty" (p. 25).

"Throughout the easy and middle ranges [of item difficulty], the biserial correlation of hypnotic performance with absorption remains slightly above .2, then it rises sharply in the difficult range--beginning roughly where only one in four Ss can pass the item--to a value slightly above .5 " (p. 27).

"In essence, the proportion of Ss that pass a particular hypnosis suggestion given a particular score on the absorption scale is being plotted" (p. 30).

In their discussion, the authors relate their position to that of other theorists. Shor, Orne, & O'Connell (1962) proposed that both ability and nonability components contributed to hypnosis, with ability being the primary determinant of hypnotic performance at deeper levels. Shor et al. found a correlation between depth ratings and a questionnaire that tapped 'hypnotic-like experiences' to be .45; the correlation was .84 when computed for only the Ss who became deeply hypnotized, but only .17 for Ss who were only lightly or medium-level hypnotized. They concluded that their questionnaire predicted hypnotizability only for the "deeper region" of hypnosis.

Tellegen (1978/1979) proposed a two-factor model, one factor being genuine responsiveness and the other being compliance . He suggested that various hypnosis test items draw on the two factors in differing degrees. Tellegen's genuine responsiveness factor would be similar to Shor et al.'s ability components, and Tellegen's compliance factor would be similar to Shor et al.'s non-ability components. (The Shor model goes farther than Tellegen in positing a gradual shift in the relative contributions of the two components as one moves from easy to difficult items, and this gradualness is part of the authors' spectrum model.)

The two-factor model is different from the general factor (plus special factors) model suggested by E. R. Hilgard (1965); Hilgard's general factor would probably correspond better to the Tellegen genuine

responsiveness factor and the Shor et al. ability component than to the compliance factor or nonability component, which probably would correspond more to the easier items on hypnotizability scales. Spanos et al. (1980) suggested that cooperativeness and expectation might be more important with ideomotor and challenge suggestions, and ability to treat imaginings as real (i.e. absorption) more important for more difficult cognitive items. Sarbin (1984) developed a typology with two types of individuals--those who respond to the hypnosis context by "joining the game" and knowingly create an illusion that their response is involuntary (the compliance kind of response), and those who convince themselves and others that their response is involuntary (the genuine responsiveness factor kind of response).

[Speaking of the context effects observed but not replicated 100% of the time, on the correlation between absorption and hypnotizability.] "It is possible that context effects may depend on the difficulty of the hypnotic suggestions and the latent abilities of the sample used. For relatively good hypnotic Ss performing relatively difficult suggestions, the correlation of absorption with hypnotizability may be stable across different contexts; however, for less able Ss performing relatively easy suggestions, the correlation, depending more on the 'non-ability' component, may be quite responsive to context manipulations. It might also be mentioned parenthetically that details of the instructions used to introduce the particular hypnosis scale employed may differentially pull for one kind of component or the other" (p. 39).

Green, Joseph P.; Lynn, Steven Jay; Carlson, Bruce W. (1992). Finding the hypnotic virtuoso -- another look: A brief communication. International Journal of Clinical and Experimental Hypnosis, 40 (2), 68-73.

Student volunteers who scored 9 (N = 20), 10 (N = 19), 11 (N = 26), and 12 (N = 15) on a live-administered Harvard Group Scale of Hypnotic Susceptibility (HGSHS:A) of Shor and E. Orne (1962) were retested with the individually administered Stanford Hypnotic Susceptibility Scale (SHSS:C) of Weitzenhoffer and Hilgard (1962). There appeared to be a break in HGSHS:A's predictive ability at 11 suggestions passed. Whereas a majority of Ss who passed at least 11 HGSHS:A suggestions retested in SHSS:C "virtuoso" range (i.e., passed at least 11 suggestions), a relatively small percentage of Ss who passed fewer than 11 HGSHS:A suggestions retested as SHSS:C virtuosos. These results are generally consistent with previous research (Register & Kihlstrom, 1986) using a standard taped-recorded (sic) HGSHS:A induction.

Stone, Mark H. (1992, October). Rasch scaling of hypnotizability. [Paper] Presented at the annual meeting of the Society for Clinical and Experimental Hypnosis, Arlington, VA.

NOTES: The author calibrated responses to the Stanford Scales of hypnotizability, which have not been used much by clinicians. Much of the data collected by Hilgard and Weitzenhoffer on the development of those scales was not published.

Rasch measurement techniques analyzed item data taken from the individual Form A and B manuals. The Rasch measurement involves natural Log odds, adjusted by variance of the respective persons. Thorndike's text explains this procedure taken from Wright & Stone, 1979, Best Test Design.

The calibration of items on Forms A and B of the Stanford scales indicates they differ greatly on difficulty and order of items. Items 1, 2, 3 are among the most difficult. Yet, items should follow item difficulty order.

For practicing clinicians, the mean and SD are inadequate to guide treatment. The practitioner wants to know how the patient responds to each item, compared with what would be expected (Like a Chi square). When data from misfit analysis is combined with clinical observation, we would get more understanding [of the patient's capabilities].

Not only are the 12 items not in order of difficulty, but there is redundancy. We could shorten the scale by selecting only items that span the same range of item difficulty: 4, 8, 10, 11, 2, 1 or 7, and 3. This

would give a screening scale with wider range measured, more finely graduated, better suited to diagnosing misfit. We could connect seemingly disparate scale items.

Form C has a perfect correlation between order of difficulty and order of administration, except for 12 which must be administered earlier.

Forms I and II [the Profile scales] deviate from the administration order and the difficulty order.

Only Form C seems to be located in the way the author would want, a Guttman type scale (which is Like Rasch's analysis).

1990

Edmonston, William E., Jr.; Moscovitz, Harry C. (1990). Hypnosis and lateralized brain functions. International Journal of Clinical and Experimental Hypnosis, 38, 70-84.

Bilateral EEG measures were obtained on 16 high hypnotizable Ss (scores of >8 on the Harvard Group Scale of Hypnotic Susceptibility, Form A, Shor & E. Orne, 1962), while performing hemisphere-specific tasks during hypnosis and a no-hypnosis control condition. Conditions and tasks were presented in counterbalanced order, and Ss served as their own controls. The data call into question the right hemisphere activation interpretation of lateralized brain function during hypnosis; rather, the data suggest a lack of task appropriate activity during hypnosis. The failure to attend to baseline activity measurements and the use of ratios to evaluate interhemispheric lateralization may contribute to potential misinterpretations of data. It is critical that activity changes of the separate hemispheres be taken into account in the interpretative process.

Tenenbaum, Steven J.; Kurtz, Richard M.; Bienias, Julia L. (1990). Hypnotic susceptibility and experimental pain reduction. American Journal of Clinical Hypnosis, 33 (1), 40-49.

We exposed 24 subjects high in hypnotic susceptibility and 24 subjects low in hypnotic susceptibility to a cold-pressor pain stimulus under either hypnotic or waking conditions, using each of two pain-reduction strategies (analgesia and distraction) separately. Trance depth level was held constant for hypnotized subjects. We used pain-tolerance levels as measures of pain, and we analyzed them by survival analysis. High susceptibles reported significantly lower pain ratings and kept their hands immersed longer in the cold water than low-susceptible subjects. There were no significant differences between hypnotic and waking condition subjects or between the different strategies. We have discussed the results in terms of a relationship in the literature between choice of experimental design (between-subjects or within-subjects) and the effectiveness of a hypnotic induction for suggested pain reduction.

#### NOTES

High hypnotizable Subjects scored 25 or above on the Wilson & Barber (1977) Creative Imagination Scale--the CIS (out of 40) and 4 or above on the Morgan & Hilgard (1979) Stanford Hypnotic Clinical Scale--SHCS (out of 5); Lows scored 15 or lower on the CIS and 2 or lower on the SHCS. Depth ratings during hypnosis were 7.4 for Highs, 2.3 for Lows; Tellegen Absorption scores were 25 and 18, respectively.

Subjects were assigned to either waking suggestion group or hypnosis group to avoid carryover effects across sessions, hence there were four groups: highs/waking procedure, highs/hypnotic procedure, lows/waking procedure, lows/hypnotic procedure. Each group was taught two strategies--analgesia or distraction--in a counterbalanced order, with administration of the Absorption Scale during a 15 minute rest in between the two procedures.

For hypnotic inductions, Experimenters provided an audiotape of an induction based on the SHCS, and had Ss report trance depth. When self-reported depth became less than baseline, following either

strategy training period, deepening procedures were used to re-establish the earlier depth level. Analgesia testing was not done blind as to subgroup membership and/or susceptibility.

The analgesia condition involved a suggestion of numbness in the hand and arm exposed to the cold pressor (Bassman & Wester, 1983). The distraction condition involved a suggestion to imagine a pleasant beach scene (Turk, Meichenbaum, and Gnest, 1984).

The number of individuals dropping out (removing their hands from the bath) at any one time period was measured, providing 'survival curves.' Pain tolerance was the same for Highs and Lows during baseline; also pain tolerance was the same for the hypnotic group as for the waking group. However, Low hypnotizable Ss removed their hands from the cold water faster than High hypnotizables: after 90 seconds only 60% of Lows, compared with 85% of Highs, remained. The same results occurred for distraction.

"In summary, both treatments allowed subjects to tolerate the cold pressor longer. There were no significant differences between subjects receiving or not receiving a hypnotic induction, and high-susceptibility subjects appeared to derive significantly greater benefit from treatment than did low-susceptibility subjects, as reflected by their tendency to tolerate exposure to the cold bath for greater lengths of time" (p. 46).

"High-susceptible subjects appeared to derive significantly greater benefit from treatment than did low-susceptible subjects, as reflected by their tendency both to tolerate exposure to the cold bath for greater lengths of time and to produce lower pain ratings" (p. 46).

"One issue that remains unresolved concerning the relationship between susceptibility and pain reduction is whether susceptibility is a transsituational capacity that is accessed by suggestion, or as Spanos, Hodgins, Stam, and Gwynn (1984) have asserted, simply an expectancy effect created by the susceptibility screening process, in which susceptibility screening appeared to act as a 'primary effect,' generating a successful experience related to hypnosis. The hypothesis that susceptibility is a capacity that can be accessed by suggestion is supported by the bulk of the literature on susceptibility and pain reduction, including research generated by both social-cognitive and neo-dissociation theorists (e.g., Hilgard, 1975; Spanos & Hewitt, 1980). In addition, susceptibility has proved to be a relatively stable trait, resistant to clinically significant modification (Crouse & Kurtz, 1984; Hilgard, 1975).

"Empirical resolution of this question would seem to require extension and replication of the Spanos, Hodgins, Stam, and Gwynn (1984) study, including exploration of whether screening at the end of the treatment phase of a suggestion experiment wipes out the relationship between susceptibility and successful suggestion for other hypnotic phenomena, such as amnesia, hallucination, time distortion, and so forth" (pp. 47-48).

Weekes, John R.; Lynn, Steven Jay (1990). Hypnotic suggestion type, and subjective experience - the order-effects hypothesis revisited: A brief communication. International Journal of Clinical and Experimental Hypnosis, 38, 95-100.

In a replication and extension of Field, Evans, and Orne's (1965) research, no support was found for the hypothesis that suggestion order is related to hypnotic responding. Confirming earlier findings, subjects were no more responsive to suggestions ordered from easy-to-difficult than they were to suggestions ordered from difficult-to-easy. Measures of subjective involvement in suggestions, involuntariness, and archaic involvement with the hypnotist were no more sensitive to order effects, nor were order effects more apparent with subjects who received direct versus indirect suggestions. Confirming earlier research, direct suggestions did facilitate suggestion-related involuntariness and response to the hypnotic amnesia item after cancellation, whereas indirect suggestions enhanced fears of negative appraisal by the hypnotist. Thus, authoritative suggestions enhance responding to a cognitive-delusional item relative to more permissive suggestions. Finally, female subjects were more involved in suggestions than were males, particularly in response to more difficult tests items.

1989

Balthazard, Claude G.; Woody, Erik Z. (1989). Bimodality, dimensionality and the notion of hypnotic types. International Journal of Clinical and Experimental Hypnosis, 37 (1), 70-89.

The notion of hypnotic types -- of qualitative differences in the mechanisms by which people respond to hypnotic suggestions -- is examined with respect to the kind of evidence that has traditionally been seen to support it. Bimodality in the distribution of hypnosis scores has been taken as evidence for two "types" of hypnotizability. It is argued that little can be said about the nature of underlying processes from the distribution of raw scores. The relationship of factor analytic results to possible underlying typologies is examined. It is concluded that the present evidence simply does not allow an evaluation of the merits of current typological formulations.

Spiegel, David; Bloom, J. R.; Kraemer, H. C.; Gottheil, E. (1989, October 14). The beneficial effect of psychosocial treatment on survival of metastatic breast cancer patients: A randomized prospective outcome study. Lancet, 888-891.

The effect of psychosocial intervention on time of survival of 86 metastatic breast cancer patients was studied using randomized prospective design. The one-year treatment consisted of weekly supportive group therapy with training in self-hypnosis for pain management, and resulted in significant reductions in mood disturbance and pain. Both the treatment and control groups had routine oncologic care. At ten-year follow-up, only three of the original 86 patients were still alive, and death records were obtained for the other 83. Survival from the time of randomization and onset of intervention was 36.6 (sd = 37.6) months for the treatment group, compared with 18.9 (sd = 10.8) months for the control group, and this difference was highly significant ( $Z = 3.94$ ,  $p < .0001$ ) using the Cox life table regression model. Kaplan-Meier survival analysis indicated that the divergence in survival began at 20 months after entry into the study, or 8 months after the treatment intervention ended. These unexpected findings suggest that intensive psychosocial support affects the course of the illness, although the mechanism by which it does so is not clear.

1985

Balthazard, Claude G.; Woody, Erik Z. (1985). The 'stuff' of hypnotic performance: A review of psychometric approaches. Psychological Bulletin, 98, 283-296.

Reviews psychometric investigations into the nature of the processes that underlie hypnotic performance and examines issues that underlie psychometric investigations of hypnosis scales, such as the Stanford Hypnotic Susceptibility Scale. The issues addressed are dimensionality and the problem of difficulty factors, the interpretation of factorial dimensions, and componential alternatives to the factor analytic approach. It is argued that hypnotic performances are most likely overdetermined in that they reflect the combined influence of a plurality of processes. The relevance of various componential models, each reflecting a different contemporary theoretical perspective toward hypnosis, and some of the implications of such models for future research are discussed. (77 ref).

Silverman, Lloyd H. (1985). 'Comments on three recent subliminal psychodynamic activation investigations': Rejoinder to Oliver and Burkham and to Porterfield. Journal of Abnormal Psychology, 94 (4), 647-8.

Considers the replies of A. L. Porterfield (see PA, vol 73:11991) and J. M. Oliver and R. Burkham (see PA, vol 73:11985) to the critique of the present author (see PA, vol 73:12007). The original criticisms are seen as valid. A critical deficiency in the design of Porterfield and S. L. Golding's (see PA, vol 73:11992) study is viewed as disqualifying it as a fair attempt at replication. It is suggested that

although Oliver and Burkham's (see PA, vol 69:1571) study was well-designed, statements made in their write-up are unwarranted. (12 ref)

1983

Myers, S. A. (1983). The Creative Imagination Scale: Group norms for children and adolescents. International Journal of Clinical and Experimental Hypnosis, 31 (1), 28-36.

This study presented the responsiveness of 1302 children and adolescents (ages 8-17) to the Creative Imagination Scale (CIS) of Wilson and Barber (1978) and Barber and Wilson (1978/79). The normative features of CIS were highlighted in the data analysis. Since items on CIS have been found to be related, a MANOVA was used for the analysis. There were significant differences in both sex and age. Females at each age level, 8 through 17, scored higher on CIS than males of the same age. Ss of ages 9, 10, and 11 obtained the highest scores, but only differed significantly from the scores for 15-year-old Ss. The other age groups did not differ significantly from each other. In addition, the stability of CIS was confirmed. The author would recommend CIS for Ss 9 years old through adult years, however, CIS should be administered individually to Ss 12 and 15 years old, due to peer pressure.

NOTES

This is a reply to Wagstaff, G.F. suggested improvement of visual acuity: A statistical reevaluation. IJCEH, 1983, 31, 239-240. Here, the authors suggest yet a third way of analysing the data initially presented by Sheehan, Smith, & Forrest in 1982 (A signal detection study of the effects of suggested improvement on the monocular visual acuity of myopes, IJCEH, 30, 138-146).

Wagstaff, Graham F. (1983). Suggested improvement of visual acuity: A statistical reevaluation. International Journal of Clinical and Experimental Hypnosis, 31 (4), 239-240.

NOTES

This is a re-analysis of data presented by Sheehan, E.P., Smith, H.V., & Forrest, D.W. (1982), A signal detection study of the effects of suggested improvement on the monocular visual acuity of myopes. International Journal of Clinical and Experimental Hypnosis, 40, 138-146. "In sum, a more appropriate conclusion to be drawn from Sheehan et al.'s (1982) results is that suggestions for improving visual acuity have little effect, but listening to music actually appears to reduce sensitivity. This reinterpretation of Sheehan et al.'s (1982) result is purely a comment on their conclusions, not their methodology.

Tellegen, Auke (1981). Practicing the two disciplines for relaxation and enlightenment: Comment on 'Role of the feedback signal in electromyograph biofeedback: the relevance of attention' by Qualls and Sheehan. Journal of Experimental Psychology: General, 110, 217-226.

High and Low Absorption Ss differ in set rather than in capability for attending to external or internal stimuli, as Qualls and Sheehan suggest. Trait x Treatment interaction for Absorption illustrates concept of personality dispositions being inherently interactive functional units. Provides a content analysis of Absorption scale (subscales) and relates absorption to other constructs in psychology. "It is not the internal versus external focus per se that play a decisive role but the subject's experiential versus instrumental set. For example, with two treatment levels, one would expect to obtain an

Absorption x Treatment interaction even if both treatment conditions required an external attentional focus, as long as they contrasted an experiential and an instrumental set" (pp 223-224).

Yanchar, R. J.; Johnson, H. J. (1981). Absorption and attitude toward hypnosis: A moderator analysis. International Journal of Clinical and Experimental Hypnosis, 29 (4), 375-382.

2 factors which have been found to correlate to a small degree with susceptibility are (a) an individual's attitude toward being hypnotized and (b) an individual's capacity for subjective involvement in an experience (absorption). The present study was an attempt to replicate previous findings by Spanos and McPeake (1975) and to extend these findings to determine if there was a significant interaction between these 2 factors in their relationship to susceptibility. 99 Ss (65 females and 34 males) completed the absorption questionnaire of Tellegen (1979) and the attitude questionnaire of Barber and Calverley (1966). Their hypnotic susceptibility was assessed with the Harvard Group Scale of Hypnotic Susceptibility, Form A (Shor & E. Orne, 1962). Attitude and absorption were found to have small positive correlations with susceptibility, results which corroborate previous research. The multiple regression analyses indicated that there were no significant interactions between the factors of attitude, absorption, and sex.

1980

Bornstein, P. H.; Rychtarik, R. G.; McFall, M. E.; Winegardner, J.; Winnett, R. L.; Paris, D. A. (1980). Hypnobeavioral treatment of chronic nailbiting: A multiple baseline analysis. International Journal of Clinical and Experimental Hypnosis, 28 (3), 208-217.

3 highly hypnotizable Ss were administered a hypnobeavioral treatment package in an attempt to alleviate chronic nailbiting behavior. The combined hypnotic and behavioral procedures included standard induction and deepening techniques, motivation enhancement, time-projection, self-reinforcement, aversion-relief, coping self-instructions, and posthypnotic suggestion. A multiple baseline design across Ss was employed as a means of evaluating the treatment intervention. Results for all Ss indicated immediate and dramatic increase in fingernail lengths concomitant with the introduction of treatment. At 3-month follow-up, 1 S demonstrated a moderate reversal effect while the remaining 2 Ss continued to indicate substantial progress. These findings were discussed with regard to the efficacy of hypnobeavioral treatment strategies and utilization of single-case experimental designs in future hypnotherapy research.

O'Grady, K. E. (1980). The Absorption Scale: A factor-analytic assessment. International Journal of Clinical and Experimental Hypnosis, 28 (3), 281-288.

95 female and 53 male introductory psychology students were administered the Tellegen Absorption Scale (Tellegen & Atkinson, 1974); the Repression-Sensitization Scale (Byrne, Barry, & Nelson, 1963); the F Scale (Adorno, Frenkel-Brunswick, Levison, & Sanford, 1950); the State-Trait Anxiety Inventory (Spielberger, Gorsuch, & Lushene, 1970); the Nowicki-Strickland Locus of Control Scale (Nowicki & Duke, 1974); and the Marlowe-Crowne Social Desirability Scale (Crowne & marlowe, 1964). A principal axis analysis of the inter-correlations indicated that 3 major factors could account for the bulk of variance among the 6 inventories. Inspection of the correlation matrix and the factor loadings showed that the Absorption Scale shared a quite modest amount of variance with the remaining scales, and that it appeared to represent a dimension entirely different than those found in the other measures. These results offer strong support to the notion that the Absorption Scale is tapping a relatively new personality dimension.

Connors, J. R.; Sheehan, P. W. (1978). The influence of control comparison tasks and between-versus within-subjects effects in hypnotic responsivity. International Journal of Clinical and Experimental Hypnosis, 26, 104-122.

Type of experimental design (between- versus within-subjects) and type of control task were examined for their differential effects on the magnitude of objective and state report test scores associated with response to items on the Stanford Hypnotic Scale of Susceptibility, Form C (Weitzenhoffer & Hilgard, 1962). In an integrated program of work exploring design effects in hypnotic research, Ss in each of 7 comparison conditions that involved hypnosis and 4 separate comparison conditions that did not involve hypnosis were tested twice on successive occasions. Three of the control tasks used (waking, imagination, and imagination [alert] instruction) were counterbalanced with hypnosis to analyze possible order effects associated with hypnotic test conditions. Data indexed the patterns of between-versus within-subjects effects associated with standard control tasks and also highlighted the order effects that accompanied them. Imagination instructions, in particular, pose specific difficulties that require attention when Ss are tested as their own controls.

Barber, Theodore Xenophon (1976). Pitfalls in human research: Ten pivotal points. Overview and recommendations. In Pitfalls in human research: Ten pivotal points.

#### NOTES

Be aware of underlying paradigm and how it influences every aspect of the research. Make assumptions more explicit. 2. Person who plans the study should be different from person who is responsible for data analysis. 3. Person who plans the study should not be person who serves as experimenter and collects the data. 4. Investigator should serve as "pilot" subject to gain insight into how the Ss view the experimental design, to tighten the design, and to change experimental instructions that are not clear to the Ss. 5. Use a tight experimental script or protocol that clearly specifies how the experimenter is to carry out each phase of the study, and that considers the various contingencies that may arise. 6. Give the experimenters sufficient supervised practice in implementing the protocol and in correctly and honestly recording the data. The experimenters should carry out pilot studies under supervision. 7. Understand the many kinds of data analyses that lead to misleading conclusions and the kinds of analyses that can be used appropriately with specified sets of data. 8. Judge the research on the validity of the design and procedures that are used to answer the questions that are posed rather than on the outcome or the results that are obtained. 9. Teachers should place much more emphasis on the value of carefully following the prescribed procedures and carefully and honestly recording the data. 10. Check often to see if the experimenters are faithfully implementing the experimental protocol and are carefully and honestly recording the data--e.g. by making tape recordings or video tapes, using one-way mirrors to observe, or by sending stooges, who give predetermined responses.

1971

Starr, Fay H. (1971). The remarriage of multiple regression and statistical inference: A promising approach for hypnosis researchers. American Journal of Clinical Hypnosis, 13, 175-179.

A multiple linear regression computer program is described as a general purpose procedure for the testing of hypotheses in hypnosis research. The claim is made, with supporting evidence, that virtually any hypothesis can be tested with the procedure, if the researcher's theory can be placed in the form of a predictive equation where one or more sources of information are used to predict some measure of

hypnosis. The hypothesis, stated in the null form, is applied algebraically as a restriction upon the predictive equation, thus yielding a second restricted, predictive equation. The squared multiple correlation coefficients of the two equations are compared in testing the hypothesis. Certain advantages, pedagogical and logical, are claimed, among which is the thought that if science is genuinely concerned with the description, modification, and prediction of behavior, here is a technique which keeps these goals in sight as hypotheses are used to test theories.

1964

Furneau, W. D. (1964). The heat-illusion test and the structure of suggestibility. International Journal of Clinical and Experimental Hypnosis, 12 (3), 169-180.

2 similar forms of the heat-illusion test are shown to correlate to a smaller degree than would be expected if they measure the same attribute. The 2 versions also differ in the way in which they correlate with other suggestibility tests. It is shown that linear regression techniques are not appropriate for analyzing the data concerned. The interaction of various nonlinear relationships with a difference in "difficulty," as between the 2 forms of the illusion, seems to provide an adequate explanation for the results. It is suggested that these nonlinear relationships may indicate the existence of an attribute which prevents some Ss from responding to any suggestibility test, irrespective of what the specific mechanisms of response may be. ## STRESS

Wood, Gary J.; Bughi, Stefan; Morrison, John; Tanavoli, Sara; Tanavoli, Sohrab; Zadeh, Homayoun H. (2003). Hypnosis, differential expression of cytokines by T-cell subsets, and the hypothalamo-pituitary-adrenal axis. American Journal of Clinical Hypnosis, 45 (3), 179-196.

Tested the hypothesis that hypnosis can differentially modulate T-cell subsets, and that this effect is mediated by changes in hypothalamo-pituitary-adrenal (HPA) mediators. Seven healthy, highly hypnotizable volunteers (aged 24-42 yrs) participated in 3 1-day sessions, a baseline and 2 intervention sessions. Hypnosis intervention entailed a standardized induction, suggestions for ego strengthening and optimally balanced functioning of the immune and neuroendocrine systems, and post-hypnotic suggestions for stress management and continued optimal balance of bodily systems. Blood samples were analyzed for T-cell activation and intracellular cytokine expression (Interferon [IFN]-gamma, Interleukin-2 [IL-2], Interleukin-4,) and HPA axis mediators (ACTH, cortisol, and beta-endorphin). The proportion of T-cells expressing IFN-gamma and IL-2 were lower after hypnosis. T-cell activation response to polyclonal stimulation was positively correlated with ACTH and beta-endorphin, while IFN-gamma expression was correlated with levels of cortisol. Further controlled studies utilizing hypnosis with patients in treatment are warranted in order to examine whether an altered T-cell response can be replicated in the presence of disease. 2002

Cardena, Etzel; Maldonado, Jose; Van der Hart, Onno; Spiegel, David (2002). Hypnosis (for posttraumatic conditions). [Paper] Presented at the annual meeting of the American Psychological Association, Chicago.

## NOTES

Authors discuss how hypnosis can be used "to stabilize the patient by providing techniques to enhance

relaxation and establish cues to induce a calm state outside of the therapeutic context. Specific suggestions may also be used to enhance ego strength and a sense of safety, to contain traumatic memories, and to reduce or at least control better such symptoms as anxiety or nightmares. ... [and] to intensify the therapeutic relationship, which can then be used for therapeutic purposes. 2) In the second stage of working-through and resolving traumatic memories, various hypnotic techniques can be used to help pace and control the investigation, integration and resolution of traumatic memories. ... 3) Finally, the goals of the third stage include achieving a more adaptive integration of the traumatic experience into the patient's life, maintaining more adaptive coping responses, and furthering personal development. Hypnotic techniques can be helpful in providing strategies to intentionally focus and shift attention as necessary; they can also be helpful in self integration through, for instance, rehearsals in fantasy of a more adaptive self-image, of new activities, and so on" (Bulletin of Division 30, Psychological Hypnosis, Fall, 2002, Vol. 11, No. 3, P. 15).

Kiecolt-Glaser, Janice K.; Marucha, Phillip T.; Atkinson, Cathie; Glaser, Ronald (2001). Hypnosis as a modulator of cellular immune dysregulation during acute stress. Journal of Consulting and Clinical Psychology, 69 (4), 674-682.

To assess the influence of a hypnotic intervention on cellular immune function during a commonplace stressful event, the authors selected 33 medical and dental students on the basis of hypnotic susceptibility. Initial blood samples were obtained during a lower stress period, and a second sample was drawn 3 days before the first major exam of the term. Half of the participants were randomly assigned to hypnotic-relaxation training in the interval between samples. Participants in the hypnotic group were, on average, protected from the stress-related decrements that were observed in control participants' proliferative responses to 2 mitogens, percentages of CD3-super(+) and CD4-super(+) T-lymphocytes, and interleukin 1 production by peripheral blood leukocytes. More frequent hypnotic-relaxation practice was associated with higher percentages of CD3-super(+) and CD4-super(+) T-lymphocytes. These data provide encouraging evidence that interventions may reduce the immunological dysregulation associated with acute stressors. 1998

Easterlin, Barbara L.; Cardena, Etzel (1998-99). Cognitive and emotional differences between short- and long-term Vipassana meditators. Imagination, Cognition and Personality, 18 (1), 69-81.

This study compared perceived stress and cognitive and emotional differences between two groups of Buddhist mindfulness [Vipassana] meditators. Nineteen beginning and twenty-four advanced meditators carried electronic pagers for five days and responded to daily random signals by completing an Experience Sampling form (ESF) containing items related to the dependent variables. As compared with beginners, advanced practitioners reported greater self-awareness, positive mood, and acceptance. Greater stress lowered mood and self-acceptance in both groups, but the deleterious effect of stress on acceptance was more marked for the beginners. These findings validate in a naturalistic setting some of the effects described in traditional Buddhist texts on mindfulness.

NOTES

"Meditation can be defined as the deliberate deployment of mental attention to obtain a particular patterning of consciousness. The aim of such control may be the stabilization of the stream of thought, greater relaxation, the attainment of an altered state, or the development of insights into the nature of mind [12]. Mindfulness meditation has sometimes been contrasted with concentration meditation as one of two main forms of meditation practice [13, 14]. The usual distinction is that mindfulness

involves opening awareness to all contents and processes of mind, whereas concentrative forms of meditation involve shutting out all stimuli extraneous to a single object of attention" (p. 70). Long-term meditators averaged 103 months and 85 days of retreat training. They did not differ from short-term meditators on measures of absorption, neuroticism, trait anxiety, or cognitive style; however they evidenced greater self-awareness and acceptance. The short-term meditators actually had more than a year of meditation experience so that differences between groups are not likely to be due to self-selection. The authors conclude that "meditation brings about sustainable changes in people's lives, above and beyond relaxation. ... [and] that greater conscious awareness through mindfulness techniques such as Vipassana meditation, increases acceptance, positive mood, and the ability to dispassionately observe one's mental states. These results have implications for clinical issues such as pain management and psychotherapy, in which acceptance and awareness are necessary ingredients for therapeutic change" (p. 78). JH

Wickramasekera, Ian E.; Kolm, Paul; Pope, Alan; Turner, Marsha (1998). Observation of a paradoxical temperature increase during cognitive stress in some chronic pain patients. Applied Psychophysiology and Biofeedback, 23 (4), 233-241.

A total of 224 chronic pain somatoform disorder patients without obvious pathophysiology or psychopathology were found to have colder hands than nonpatients. A paradoxical temperature increase (PTI) in response to a cognitive stressor (mental arithmetic) was noted in a subset of these chronic pain patients. Patients were defined as "PTI" responders if, during cognitive stress, an increase in digital temperature occurred over a prior eyes closed resting condition. It was found that 49.4% of males and 42.6% of females in a total sample of 224 patients demonstrated PTI. The PTI patients had significantly colder hands than non-PTI patients prior to stress. A concurrent SCL measure of sympathetic activation found no difference between the PTI and non-PTI groups either at baseline or during cognitive stress. It appears from this data that PTI is specific to the peripheral vascular system of these patients and may be a marker of psychophysiological dissociation or trauma blocked from consciousness.

Enqvist, Bjorn; Fischer, Kerstin (1997). Preoperative hypnotic techniques reduce consumption of analgesics after surgical removal of third mandibular molars: A brief communication. International Journal of Clinical and Experimental Hypnosis, 45 (2), 102-108.

The effects of hypnosis in connection with surgery have been described in many clinical publications, but few controlled studies have been published. The aim of the present study was to evaluate the effects of preoperative hypnotic techniques used by patients planned for surgical removal of third mandibular molars. The patients were randomly assigned to an experimental (hypnotic techniques) or a control (no hypnotic techniques) group. During the week before the surgery, the experimental group listened to an audiotape containing a hypnotic relaxation induction. Posthypnotic suggestions of healing and recovery were given on the tape together with advice regarding ways to achieve control over stress and pain. The control group received no hypnotic intervention. Only one surgeon who was not aware of patient group assignments performed all the operations. Thirty-six patients in the control group were compared to 33 patients in the experimental group. Anxiety before the operation increased significantly in the control group but remained at baseline level in the experimental group. Postoperative consumption of analgesics was significantly reduced in the experimental group compared to the control group. Journal Abstract.

Faymonville, M. E.; Mambourg, P. H.; Joris, J.; Vrijens, B.; Fissette, J.; Albert, A.; Lamy, M. (1997). Psychological approaches during conscious sedation. Hypnosis versus stress reducing strategies: A prospective randomized study. Pain, 73 (3), 361-367.

Stress reducing strategies are useful in patients undergoing surgery. Hypnosis is also known to alleviate acute and chronic pain. We therefore compared the effectiveness of these two psychological approaches for reducing perioperative discomfort during conscious sedation for plastic surgery. Sixty patients scheduled for elective plastic surgery under local anesthesia and intravenous sedation (midazolam and alfentanil upon request) were included in the study after providing informed consent. They were randomly allocated to either stress reducing strategies (control: CONT) or hypnosis (HYP) during the entire surgical procedure. Both techniques were performed by the same anesthesiologist (MEF). Patient behavior was noted during surgery by a psychologist, the patient noted anxiety, pain, perceived control before, during and after surgery, and postoperative nausea and vomiting (PONV). Patient satisfaction and surgical conditions were also recorded. Peri- and postoperative anxiety and pain were significantly lower in the HYP group. This reduction in anxiety and pain were achieved despite a significant reduction in intraoperative requirements for midazolam and alfentanil in the HYP group (alfentanil: 8.7 +/- 0.9 microg kg(-1)/h(-1) vs. 19.4 +/- 2 microg kg(-1)/h(-1), P < 0.001; midazolam: 0.04 +/- 0.003 mg kg(-1)/h(-1) vs. 0.09 +/- 0.01 mg kg(-1)/h(-1), P < 0.001). Patients in the HYP group reported an impression of more intraoperative control than those in the CONT group (P < 0.01). PONV were significantly reduced in the HYP group (6.5% vs. 30.8%, P < 0.001). Surgical conditions were better in the HYP group. Less signs of patient discomfort and pain were observed by the psychologist in the HYP group (P < 0.001). Vital signs were significantly more stable in the HYP group. Patient satisfaction score was significantly higher in the HYP group (P < 0.004). This study suggests that hypnosis provides better perioperative pain and anxiety relief, allows for significant reductions in alfentanil and midazolam requirements, and improves patient satisfaction and surgical conditions as compared with conventional stress reducing strategies support in patients receiving conscious sedation for plastic surgery.

The effects of hypnosis, context reinstatement, and motivational instructions on accuracy of recall for factual information and facial recognition accuracy following a stressful event were assessed. None of the three techniques had a significant effect on factual memory or susceptibility to suggestion as assessed by true-false and multiple-choice tests. However, participants high in hypnotic susceptibility showed somewhat better memory on the true-false test, and hypnosis affected performance on the two photograph line-ups. In addition, hypnosis appeared to enhance facial recognition accuracy for participants who were low in anxiety, but not for those high in anxiety. Finally, there was evidence of a curvilinear relationship between self-reported anxiety at time of retrieval and facial recognition accuracy. -- Journal Abstract

Sapp, Marty; Farrell, Walter C. Jr.; Johnson, James Jr.; Kirby, Renee Sartin; Pumphrey, Khyana K. (1997). Hypnosis: Applications for rehabilitation counselors. Journal of Applied Rehabilitation Counseling, 28 (2), 43-49.

This article describes how the rehabilitation counselor can employ hypnosis. Hypnosis can be employed as a useful tool in working with individuals who have experienced a disability. It can be used to reduce anxiety and stress related to returning to work; it can help clients learn to reduce stress and to modify themselves, even if their environments cannot change; and it can be used to increase the self-esteem of clients with disabilities.

Wickramasekera, Ian; Pope, Alan T.; Kolm, Paul (1996). On the interaction of hypnotizability and negative affect in chronic pain: Implications for the somatization of trauma. Journal of Nervous and Mental Disease, 184 (10), 628-635.

The high risk model of threat perception predicts that high hypnotizability is a risk factor for trauma-related somatization. It is hypothesized that high hypnotizability can increase experimentally induced threat or negative affect, as measured by skin conductance level, in a linear or dose-response manner. This hypothesized interaction of hypnotic ability and negative affect was found in a consecutive series of 118 adult patients with chronic pain symptoms. Larger increases in skin conductance levels during cognitive threat were significantly related to higher levels of hypnotizability. In addition, individuals with high hypnotizability retained higher skin conductance levels than individuals with low hypnotizability after stress. The clinical implications of the interaction of hypnotizability and negative affect during threat perception and delayed recovery from threat perception are discussed in terms of cognitive mechanisms in the etiology and therapy of trauma-related dissociative disorders.

Holroyd, Jean (1995). Handbook of clinical hypnosis, by Judith W. Rhue, Steven Jay Lynn, & Irving Kirsch (Eds.) [Review]. International Journal of Clinical and Experimental Hypnosis, 43 (4), 401-403.

#### NOTES

"This is a book for the thinking clinician" (p. 401). "The editors are to be congratulated for making this volume much more coherent than most edited books" (p. 402). "My impression is that the book is best suited for an intermediate or advanced course on hypnotherapy, or for people who are already using hypnosis in treatment. Although there is some material on the basics of hypnotic inductions and a few introductory sample scripts for inductions, a beginners" course should probably use a different book, or this book could be accompanied by an inductions manual. ... I recommend it very highly" (p. 403).

Wickramasekera, Ian (1995). Somatization: Concepts, data and predictions from the high risk model of threat perception. Journal of Nervous and Mental Disease, 183, 15-23.

83 consecutive patients with chronic somatic complaints seen prior to therapy were tested on the 8 risk factors of the High Risk Model of Threat Perception. The model identifies 3 predisposing factors (hypnotic ability, catastrophizing, and negative affectivity) that amplify the probability that 2 triggering variables (major life change and minor hassles) will generate psychological or somatic symptoms unless the impact of the triggers and predisposers are buffered. 32% were high and 28% were low on hypnotic ability, which is more highs and lows than would be expected in a normal population. In the high and low hypnotic ability somatizers, the distribution of somatic and psychological symptoms is significantly different from the moderate group. Counterintuitively, hypnotic ability and major life change were orthogonal to all of the other risk factors.

1994

Marmar, Charles (1994, October). Peritraumatic dissociation and PTSD. [Paper] Presented at the annual meeting of the Society for Clinical and Experimental Hypnosis, San Francisco.

#### NOTES

Following trauma there is a tendency to more dissociation and vulnerability. We completed 3 recent studies. In 1991 Spiegel and Cardena presented review that found: 1. Early childhood abuse is associated with profound dissociation. 2. Repeated abuse is more important and profound than single

abuse for producing dissociation. 3. Dissociation in childhood and perhaps in adulthood has been viewed as an adaptive attempt to cope, to take distance in time, place, and person; does that confirm long term adaptation, or is it a risk factor? 4. Dissociation is not limited to childhood trauma; it occurs in adults exposed to overwhelming trauma. 5. In adults with PTSD, there is an increase in hypnotizability, which is interesting because most Axis I disorders are associated with reduced hypnotizability.

Peritraumatic dissociation is defined as an immediate dissociative response to trauma. We developed a scale that robustly captures the phenomena. The scale has both self report and rater versions.

Authors used this measure in many studies: combat trauma, accident trauma, victims of terrorism. The scale predicts who will be a PTSD patient 5 months later, even after controlling for initial response in first week (how many symptoms they had) and for the degree of trauma.

**Study 1 (Am. J. Psychiatry, June 1994)**

Studied 251 male Vietnam Theater Veterans, mean age 41 at time of study. Had high combat exposure and high risk for PTSD. Rater version of Peritraumatic Dissociative Experiences Questionnaire was used. There was a lot of variability in response, but one underlying dimension resulted from the factor analysis (and this factor accounts for 40- 50% of the variance).

Author hypothesized that those who have a greater response to trauma will have more problems later, and would predict stress symptoms but not necessarily psychopathology. The score correlates highly with: Mississippi Scale for PTSD .51; Horowitz's scales; Impact of Events Scale (Intrusion .53, Avoidance .60); MMPI derived PTSD .42; Dissociative Experiences Scale (recall of time of event) .41; and War Zone Stress Exposure .48.

MMPI-2 clinical scales had almost no correlation with this scale (using partial r's, and controlling for MMPI-2 PTSD scores).

Prediction of PTSD case classification from this scale, after taking into consideration other predictors: War Zone Stress War Zone Stress, DES War Zone Stress, DES, PDEQ-RV Kappa is .63

You know much more about who will be a case taking into consideration the DES and DEQ than just knowing the amount of stress. Peritraumatic stress is strongly associated with PTSD but not with psychopathology.

**Study 2**

Replicated Study 1 using 77 female veterans. Females Ss were more highly educated, older, more likely to be in a health profession role (trauma was working with death and dying, exposure to sex abuse and harassment, given even less support than the males). Yet women have had a better course of recovery, though rates were the same (30% developed PTSD after return from war).

Correlation with Impact of Event Scale (Intrusion .41 and Avoidance .40), but correlations with MMPI-2 are low (and with other PTSD scales are lower than with the males). Hierarchical multiple regression models show R squared doesn't increase with DES but does with PDEQ to Intrusion (less so to Avoidance).

This study replicates the same pattern, with peritraumatic dissociation strongly related to PTSD symptoms years later, and not to general psychopathology, even after accounting for the nature of the stress and for the degree of dissociation.

**Study 3**

After the 1989 Loma Prieta earthquake in Northern California we studied emergency services personnel involved in the collapse of a freeway in Oakland. 1000 rescue workers were involved. The workers (police, fire personnel, paramedics, CALTRANS road workers) involved one I-880 cohort and a replication cohort, with two control groups (smaller scale incidents like attending a child drowned in swimming pool, removing someone from a wrecked auto). In all 3 samples, 90% were male.

What characteristics of the person or their exposure account for which workers go on to cope and which will later have PTSD symptoms? Predictors: IES-I IES-A IES-H M-PTSD SCL-GSI.

Variables most associated with problems 1.5 to 3 years afterward were years of experience, exposure, adjustment (measured by the Hogan Personality Inventory measure of adjustment), social support, DES, and PDEQ. Regression analyses used the best predictors first: forced exposure, adjustment, years experience, locus of control, social support. For Intrusion scores there were modest but significant increments by the DES and PDEQ; for avoidance scores, there were very significant contributions (.072 and .078).

There is a robust relationship between the DES and PDEQ and how much hyperarousal there is afterward (.104 and .110 %). DES measures a trait, PDEQ measures a state; yet the latter continues to contribute even after accounting for variance by the DES.

The PDEQ also has been found to predict among rape victims who will have PTSD. This was replicated in different cultures and different language groups.

**FUTURE DIRECTIONS.** Authors plan to examine people with moderate to high exposure after the L.A. earthquake. They gathered personality and coping style data on the rescue workers to answer the question: what characterizes those who are more vulnerable to dissociative tendencies during trauma? There are treatment implications: given that those who develop the most profound response are the ones who will have more PTSD later, what are the implications?

Uncovering the trauma that caused the PTSD is often associated with re-dissociation. There is a question of how this should be managed.

The authors will attempt to see if they can predict in advance if a person would dissociate if exposed. Do those who dissociate have more childhood abusive environments? Hypothesis: there may be an interaction of childhood trauma and combat trauma that produces PTSD.

Spiegel, David (1994, October). Acute stress disorder and dissociation in DSM-IV. [Paper] Presented at the annual meeting of the Society for Clinical and Experimental Hypnosis, San Francisco.

#### NOTES

Starting with the theme on hysteria introduced by Frankel (1994), and Cardena (1994) on trance disorder [Spiegel notes that] in the West our problem is of individuality, so fragmentation of personality is our disorder. There is cultural content in the delusions of schizophrenia, and cultural content in dissociative disorders. We have further evidence of trauma being involved in dissociation. Trauma is the experience of being made into an object, and the core problem is helplessness (not anxiety or fear), and discontinuity in experience. Dissociation permits people to retain control of their minds when they have lost control of their bodies. The discontinuity of dissociation reflects the discontinuity of experience.

[This presentation included the material presented at an earlier meeting and is not reported in full here.]

The difficulty is the problem of lack of identity rather than too many identities.

Wickramasekera, Ian (1994). Psychophysiological and clinical implications of the coincidence of high hypnotic ability and high neuroticism during threat perception in somatization disorders. American Journal of Clinical Hypnosis, 37, 22-33.

The electrodermal response to cognitive threat of un hypnotized female patients with somatic symptoms and high on both hypnotic ability and neuroticism (H-H) was found to be significantly higher ( $p < .01$ ) than that of a matched group of female patients moderate on hypnotic ability and low on neuroticism (M-L). On verbal report the H-H and the M-L groups did not differ, but they were significantly different on a measure of self-deception (L scale) or repression. The above findings are consistent with predictions from the High Risk Model of Threat Perception (HRMTP), which states that people in the H-H group are both chronically and acutely more reactive to threat than the people

in the M-L group. This finding may have important theoretical, clinical, and financial implications for the diagnosis, therapy, and prevention of somatization disorders seen in primary medical care.

Wickramasekera, Ian; Pope, Alan T.; Kolm, Paul (1994, August). Chronic pain, hypnotic ability and skin conductance level. [Paper] Presented at the annual meeting of the American Psychological Association, Los Angeles.

The High Risk Model predicts that high hypnotic ability is a risk factor for the development of stress related psychophysiological disorders. It was hypothesized that greater threat perception as measured by skin conductance level (SCL) would be associated with higher levels of hypnotic ability. In a consecutive series of 118 adult patients with chronic pain symptoms, larger increases in SCL during cognitive stress were significantly related to higher levels of hypnotic ability. In addition, high hypnotic ability individuals retained higher SCL than low hypnotic ability individuals after stress. The clinical implications of high hypnotic ability for threat perception and recovery from thereat perception are discussed in terms of cognitive mechanisms in the etiology and therapy of chronic stress related disorders. (ABSTRACT from Bulletin of Division 30, Psychological Hypnosis, Fall 1994, Vol. 3, No. 3.)

1993

Spiegel, David; Koopman, Cheryl; Classen, Catherine; Freinkel, Andrew (1993, October). Dissociation, trauma, and DSM-IV Acute Stress Disorder. [Paper] Presented at the annual meeting of the Society for Clinical and Experimental Hypnosis, Arlington Heights, IL.

## NOTES

This represents a progress report on the research in our laboratory, which is different from traditional approaches that link childhood trauma to current problems. We say if there is a link between dissociation and trauma, one should find the symptoms in people who have trauma.

### Earthquake Research:

They examined data from Loma Prieta earthquake; Stanford had \$164 million damage. Oct 1989. [Presents data that he has presented before.] There was a drop in dissociative symptoms over 4 months. McFarlane found that numbing was the best predictor of later PTSD symptoms, and we find that too.

Most trauma researchers have focused on anxiety because that is what they are interested in; they have ignored dissociative experiences, because such symptoms are designed not to be noticed.

Andrew Frankel and Cheryl Koopman studied 15 journalists who saw Robert Alton Harris' execution-volunteers who reported on the execution, to whom the event did not personally threaten. 40% reported depersonalization experiences, 2/3 felt detached or estranged from others, 27% had problems remembering everyday activities, etc. Dissociative symptoms were especially high in TV journalists, lowest in radio journalists, and in the middle range in newspaper reporters.

### Oakland Fire Research:

Koopman & Classen looked at immediate psychopathology and later problems. They studied people of low, medium, and high exposure as defined by distance from the fire, which related strongly to both dissociative and anxiety symptoms.

There were strong relationships between the Mississippi PTSD scale scores and anxiety and dissociative symptoms (.50 and .59 respectively). People who reported recent life stress in the intervening period had higher PTSD and dissociative symptoms. The combination of initial dissociation and subsequent stress was additive in their relationships to PTSD.

People who had higher dissociation scores tended to do higher risk things (e.g., cross police barriers). This may explain how clinicians see patients who appear to get themselves re-victimized.

### Law Office Shooting Research:

We followed up on the 1993 shooting of 14 people (8 fatally) in a law office in San Francisco. Survivors filled out dissociation questionnaires in the office (N = 36). They had high scores on the Impact of Event Intrusion Scale. The more they thought they or colleagues were in danger, the higher their scores on anxiety and dissociation measures and on Impact of Event scale.

**Dissociation Definition:**

These studies led to a project, with Etzel Cardena, in trying to revise DSM-III-R, which doesn't capture the symptoms [of post traumatic dissociation]. In DSM-IV there will be the diagnosis of 308.3 Acute Stress Disorder, characterized as: A. Same as DSM-III-R, except it doesn't require that the trauma be "unusual" B. Requires 3 of 5 dissociative symptoms. C, D, and E are classic dissociative symptoms F, G, and H are delimiting factors (e.g., causes significant impairment, length of time, not due to other factor).

Also, the multiple personality disorder (MPD) diagnosis has been changed to Dissociative Identity Disorder. The problem for these patients is not in having more than one personality, but not having one functioning personality.

Walker, Leslie G.; Johnson, Vanessa C.; Eremin, Oleg (1993). Modulation of the immune response to stress by hypnosis and relaxation training in healthy volunteers: A critical review. Contemporary Hypnosis, 10, 19-27.

**NOTES**

They review literature on modulation of the immune response to stress with relaxation and/or hypnosis, and raise the following questions and conclusions: 1. It is not clear which dependent variables should be studied. 2. There is a need to clarify which independent variables are responsible for particular effects. 3. There is the question of moderator variables. 4. There is room for many more case studies, including single case research (given the uncertainties discussed and the costs of controlled studies). 5. There is evidence that pathways exist whereby the brain could alter or modulate aspects of immune reactivity. [They describe assigning 20 healthy volunteers randomly to experimental or control group. The experimental group received 3 weeks progressive relaxation and cue-controlled relaxation training, with hypnosis before exposure to an experimental stressor--video recording and playback of a doctor-patient role play. They evaluated not only the biochemical and immunological effects of relaxation training but also the effect in modulating the biological responses to stress.] 6. They concentrated on studies with healthy volunteers because there are already known immunological changes in patients who have tumors. However people with a healthy immune system may have a natural limit in how much they can improve their immune response with interventions like hypnosis.

Wickramasekera, Ian (1993, August). Some psychophysiological and clinical implications of the coincidence of hypnotic ability and neuroticism during threat perception. [Paper] Presented at the annual meeting of the American Psychological Association, Toronto, Canada.

**NOTES**

Although not addressing hypnosis specifically, this is a comprehensive review of literature on memory for negative emotional events relevant to issues of hypnosis and memory. The final conclusion is that emotional events are indeed remembered differently than neutral or ordinary events and are well retained with respect to the event itself and concerning central, critical detail (not peripheral detail). Such memories seem less susceptible to forgetting. There is evidence for dissociation between memory for emotional information and memory for specific event information. There is also evidence of amnesia or memory impairment effects after high-arousal events, with memory increasing as more time passes after the event. The functional amnesia effects are probably due to an interaction between

altered encoding operations and the specific retrieval circumstances aiding consciously and unconsciously controlled reconstructive processes. There is little evidence to support Loftus' contentions that emotional stress is bad for memory.

Claridge, Karen (1992). Reconstructing memories of abuse: A theory-based approach. Psychotherapy, 29, 243-252.

The recovery of traumatic memories is an important part of therapy with survivors of abuse. This article describes a conceptual framework for memory reconstruction based on Horowitz' (1986) theory of stress response syndromes. The client's history of intrusive symptoms provides a way to anticipate the nature of the trauma, even when no memory of it exists. Ongoing intrusive symptoms are used to retrieve memory fragments, and their emotional impact is used to build the client's emotional tolerance. Emphasis is placed on preparing for memories by identifying what the client will need when the memories return, building coping skills, and beginning to restructure cognitions at the "what if" stage of remembering. Case material is used to illustrate.

Isenberg, S. A.; Lehrer, P. M.; Hochran, S. (1992). The effects of suggestions and emotional arousal on pulmonary functions in asthma: A review and a hypothesis regarding verbal mediation. Psychosomatic Medicine, 54, 192-216.

This paper reviews the empirical literature on the relation between asthma, suggestion, and emotion, and proposes the hypothesis that these effects are mediated parasympathetically. The literature indicates that, among asthmatics, suggestion can produce both bronchoconstriction and bronchodilation, and that stress can produce bronchoconstriction. The proportion of asthmatic subjects showing bronchoconstriction to both suggestion and stress averages 35%-40% across studies, but, because of methodological considerations, might be conservatively estimated as closer to 20%. The effect is smaller for suggestion of bronchodilation, and is very short-lived among nonasthmatics. No clear connection has been found between these responses and such subject variables as age, gender, asthma severity, atopy, or method of pulmonary assessment, although some nonsignificant tendencies appear. Most studies in this literature used small n's and did not systematically examine various somatic, environmental, and demographic factors that could influence results. A hypothesis is presented regarding vagal mediation of psychological effects on the airways, as well as possible alternative mechanisms, and recommendations for future research to evaluate these hypotheses.

Mittleman, K. D.; Doubt, T. J.; Gravitz, Melvin A. (1992). Influence of self-induced hypnosis on thermal responses during immersion in 25 degrees C water. Aviation, Space & Environmental Medicine, 63, 689-695.

The efficacy of self-induced posthypnotic suggestion to improve thermogenic responses to head-out immersion in 25 degrees C water was evaluated in 12 males. An online computerized system permitted the change in body heat storage to be used as the independent variable and immersion time as the dependent variable. Two one- hour hypnotic training sessions were used. There were no differences in rates of heat production, heat loss, mean skin temperature, or rectal temperature between control and hypnotic immersions. Individual hypnotic susceptibility scores did not correlation with changes in thermal status. Ratings of perceived exertion during exercise were similar for both immersions, but perceived sensation of cold was lower during the second rest period of the hypnotic immersion. Three subjects used images of warm environments during their hypnotic immersion and lost heat at a faster rate than during control immersions. These results indicate that brief hypnotic training did not enhance the thermogenic response to cool water immersion.

Morse, Donald R.; Martin, John; Moshonov, Joshua (1992). Stress induced sudden cardiac death: Can it be prevented?. Stress Medicine, 8, 35-46.

Previously, psychosomatically induced death relative to stress, hypnosis, mind control, and voodoo was discussed. In this article, emphasis is on one aspect of that - stress induced sudden cardiac death (SCD). A brief review is presented of the sympathetic aspects of the acute stress response and stress induced SCD. Findings from previous studies are presented to highlight sympathetic aspects of the acute stress response. This is followed by a presentation of various strategies to prevent or decrease the possibilities for stress induced SCD. These include long-term measures (e.g. diet control, smoking control, hypertension control, stress management strategies) and immediate measures (e.g. calm, controlled approach, elicitation of the relaxation response, selected use of drugs, and heart rate variability monitoring). Relative to prevention strategies, findings are presented both from previous studies and new investigations.

Perry, Nancy W. (1992, Summer). How children remember and why they forget. The Advisor (Published by American Professional Society on the Abuse of Children), 5 (3), 1-2; 13-16.

## NOTES

'My memory is the thing I forget with.' (a child's definition, cited in Grossberg, 1985, p. 60)" (p. 1).

"Unlike the simpler forms of memory retrieval, free recall is strongly age-related... the recall skills of preschool children develop gradually" (p. 2). "...in some cases, younger children can provide more accurate information than adults (Lindberg, 1991). For example, if an event is particularly salient (as sometimes happens in cases of trauma), recall may be exceptionally good (Brainerd & Ornstein, 1991; Lindberg, 1991)" (p. 13).

"Children have limited ability to use memory strategies. For this reason, children often know more than they can freely recall" (p. 13).

"The use of rehearsal as a memory strategy is almost automatic for adults. ... Ten-year-olds also commonly use rehearsal to aid memory. Young children, however, have not mastered rehearsal (Harris & Liebert, 1991).

"Another memory strategy is imagery, which involves (1) mentally picturing a person, place, or object, or (2) visually associating two or more things that are to be remembered. Children develop imagery much later than other memory strategies. Indeed, some people never learn this memory strategy (Flavell, 1977)" (p. 13).

"... stress alone may not impair memory processes. Indeed, stress can lead to arousal, heightened attention, and improved encoding (Deffenbacher, 1983). However, stress that results from intimidation may lead to either impairment in encoding or problems in recalling or reporting memories" (p. 14).

"Because the effect of suggestion on material that has been well encoded tends not to be significantly different across age groups (Cohen & Harnick, 1980), it may be that younger children's inferior performance on suggestive tasks results from inferior encoding" (p. 15).

Spira, James L.; Spiegel, David (1992). Hypnosis and related techniques in pain management. Hospice Journal, 8, 89-119.

Hypnosis has been used successfully in treating cancer patients at all stages of disease and for degrees of pain. The experience of pain is influenced not only by physiological factors stemming from disease progression and oncological treatment, but also from psychosocial factors including social support and mood. Each of these influences must be considered in the successful treatment of pain. The successful use of hypnosis also depends upon the hypnotizability of patients, their particular cognitive style, their specific motivation, and level of cognitive functioning. While most patients can benefit from the use of hypnosis, less hypnotizable patients or patients with low cognitive functioning need to receive special

consideration. The exercises described in this chapter can be successfully used in groups, individual sessions, and for hospice patients confined to bed. Both self-hypnosis and therapist guided hypnosis exercises are offered.

Wickramasekera, Ian (1992, August). Hypnotic ability as a risk factor for psychopathology and pathophysiology. [Paper] Presented at the annual meeting of the American Psychological Association, Washington, DC.

Eighty-three patients with psychophysiological disorders seen prior to therapy were tested on the seven risk factors of the High Risk Model. Thirty-two percent of these patients were high on hypnotic ability, and hypnotic ability was unrelated to all of the other six risk factors. Mean social support and coping skills were significantly below the norm. Mean catastrophizing, negative affect (neuroticism), major life change and minor hassles were significantly above the norm. There are positive and significant correlations between hassles, negative affect and catastrophizing. There are also positive and significant correlations between coping skills and number and level of satisfaction with social support. There are negative and significant correlations between coping skills, catastrophizing, negative affect and hassles. There are also negative and significant correlations between satisfaction with social support, catastrophizing, and hassles. (ABSTRACT from the Bulletin of Division 30, Psychological Hypnosis, Fall, 1992, Vol. 1, No. 3.)

#### 1991

Morse, Donald R.; Martin, John; Moshonov, Joshua (1991). Psychosomatically induced death: Relative to stress, hypnosis, mind control, and voodoo: Review and possible mechanisms. Stress Medicine, 7, 213-232.

A common denominator in psychosomatically induced death is stress. Death can occur slowly, as from the preponderance of chronic stressor, or it can come on suddenly, as from an acute stressor. Sudden death is more likely in an individual with preexistent serious medical conditions, which were outlined. Seven types of individuals more prone to sudden death were outlined. Most cases of sudden death are related to the presence of a severely stressful situation in which there appears to be no means of control or escape. With mind control, hypnosis, and voodoo curses, circumstances can be manipulated to achieve severe stress and uncontrollability.

Palan, Bhupendra M.; Lakhani, Jitendra D. (1991). Converting a 'threat' into a 'challenge': A case of stress-related hemoptysis managed with hypnosis. American Journal of Clinical Hypnosis, 33 (4), 241-247.

A 24-year-old patient was treated using hypnosis for chronic repeated episodes of hemoptysis. The symptom episodes were related to academic examinations (perceived as a threat by the patient). Clinical examinations and laboratory investigations failed to indicate an organic cause for hemoptysis. He did not respond to empirical treatment trials. These negative findings suggested the psychosomatic nature of the illness. We used hypnotherapeutic ego-strengthening and guided-imagery approaches. This reduced his acute anxiety but failed to check hemoptysis. Use of explorative hypnotic dreaming revealed an emotional trauma as the possible cause of origin of the symptoms. We restructured the trauma experience during hypnotic regression. We advised him to skip the upcoming examination and conducted a total of six therapeutic sessions. The patient continued using self-hypnosis throughout the follow-up period of 3 years during which he remained symptom free and achieved remarkable academic progress. He now perceives an examination as a challenge.

Sapp, Marty (1991, August). The effects of hypnosis in reducing anxiety and stress in adults with neurogenic impairment. [Paper] Presented at the annual meeting of the American Psychological Association, San Francisco.

A repeated measures design was utilized to investigate the effects of hypnosis in reducing anxiety and stress in 16 adults with neurogenic impairment. Seven sessions were used to measure the efficacy of hypnosis. Session one was used to obtain a baseline level of anxiety and stress and to initiate hypnosis. Sessions three and six were used to obtain repeated measures of these emotions. Sessions two, four, and five were the treatment sessions. Session seven was used to conduct a four week follow-up on the effects of hypnosis. Levels of anxiety were measured by the State-Trait Anxiety Inventory, while stress was measured by the State-Trait Anger Expression Inventory. The results indicated a statistically significant decrease in anxiety and stress. Hypnosis also significantly increased levels of self-esteem. Finally, follow-up data demonstrated that the treatment gains were maintained. NOTES 1: NOTES

Hypnotizability was not related to treatment outcome. The average Barber Susceptibility Scale score was 3, which indicates that the subjects were fairly low in hypnotizability level.

Spiegel, David (1991, August). New directions in traumatic stress research. [Paper] Presented at the annual meeting of the American Psychological Association, San Francisco.

#### NOTES

Trauma is the experience of being made into an object of someone else's rage. It is a sudden discontinuity in experience: our physical and mental state can be changed radically. The experience of loss of control is what is most horrifying, more than fear of death. Guilt, (blaming oneself) helps deny the loss of control. People who experience trauma distance from the information but the cortex maintains the traumatic memories.

Author reviewed literature on effective interventions with trauma victims. 1. Harbor & Pennebaker: Contrast how earthquake victims can talk about it but rape victims often are isolated. The importance of having someone listen raises the question of usefulness of only writing about the trauma. 2. Greenberg: Studied 103 trauma cases; employed a clever methodology, using 2 control groups (but it is difficult for the imaginary control group to be free of associating to their own traumas). I believe the health findings, but it troubles me that there were intrusions (thoughts); the control group utilization [of health services?] went up. 3. Kilpatrick: It is important not to blame the victim for being traumatized. But there may be some people who for sociological or other reasons do not get out of dangerous situations. 4. Terri Orbach: There is a process of "going public" about the trauma, like in Alcoholics Anonymous disclosures. Trauma victims create an account and they go to someone else to tell about it.

Summary of what seems important about treatment: There are three means of working with trauma, with thinking, writing, and talking. If you just think but don't talk, assault rate goes up (Pennebaker); and if you don't talk with someone else you feel worse physically. In simply writing about the trauma, there may be an increase of mental intrusions, or avoidance. What seems to be beneficial is not just making sense to oneself about the experience cognitively, but the traumatized person must get feedback from another individual that they are not transformed as a person.

Stanton, Harry E. (1991). The reduction in secretarial stress. Contemporary Hypnosis, 8, 45-50.

30 secretaries from a large business firm were matched on their stress thermometer scores and one member of each pair was allocated at random to either an experimental group or a control group which discussed stress management procedures. The experimental group had two treatment sessions in

which they learnt a technique of induction, deepening and ego-enhancement which included (1) physical relaxation; (2) mental calmness; (3) disposal of unwanted mental and physical 'rubbish'; (4) removal of a negative barrier; and (5) enjoyment of a special place. The stress thermometer was administered on two further occasions, one immediately after completion of the second training session and one as a follow-up 2 months later. In addition, on these two occasions, subjects completed anecdotal reports, recording their impressions of the experiment. After completion of this first stage of the study, control group secretaries experienced the same two treatment sessions as had the experimental group. Results indicated that stress level was significantly lower both immediately after treatment and at the two-month follow-up.

Witz, Marylou; Kahn, Stephen (1991). Hypnosis and the treatment of Huntington's Disease. American Journal of Clinical Hypnosis, 34, 79-90

Describes two cases treated with a wide variety of hypnotic interventions. One was treated for 9 years and the other for 10 sessions. Hypnotic techniques and daily self-hypnosis appeared to ameliorate both physical and psychological difficulties, thereby enhancing the quality of life that remained for the patients. They noted that the increased sense of control that both patients experienced seemed to undercut the cycle of physical symptoms exacerbating psychological symptoms and these in turn increasing physical symptoms. The sense of control over physical symptoms clearly reduced anxiety and depression over the inevitable course of the disease, thereby facilitating tension reduction and overall adjustment to the disease. This reduced stress level may have in turn affected the disease itself. What is unmistakable is that the quality of life was greatly enhanced.

Ader, Robert; Felton, David; Cohen, Nicholas (1990). Interactions between the brain and the immune system. In Cho, Arthur K.; George, Robert; Blaschke, Terrence (Ed.), null (30, pp. 561-602). Palo Alto, CA: Annual Reviews Inc..

## NOTES

(From the SUMMARY) "Without attempting to cover all the literature, we have used stress effects and conditioning phenomena as illustrations to point out that behavior can influence immune function. We have also described data indicating that the immune system can receive and respond to neural and endocrine signals. Conversely, behavioral, neural, and endocrine responses seem to be influenced by an activated immune system. Thus, a traditional view of immune function that is confined to cellular interactions occurring within lymphoid tissues is insufficient to account for changes in immunity observed in subhuman animals and man under real world conditions.

"These data question seriously the notion of an autonomous immune system. ... The immune system is, indeed, capable of considerable self-regulation, and immune responses can be made to take place in vitro. The functions of that component of adaptive processes known as the immune system that are of ultimate concern, however, are those that take place in vivo. There are now compelling reasons to believe that in vivo immunoregulatory processes influence and are influenced by the neuroendocrine environment in which such processes actually take place ... . The immune system appears to be modulated, not only by feedback mechanisms mediated through neural and endocrine processes, but by feedforward mechanisms as well. The immunologic effects of learning, an essential feedforward mechanism, suggest that, like direct neural and endocrine processes, behavior can, under appropriate circumstances, serve an immunoregulatory function in vivo. Conceptually, the capacity to suppress or enhance immune responses by conditioning has raised innumerable questions about the normal operation and modifiability of the immune system via neural and endocrine processes.

"We do not yet know the nature of all the channels of communication between the brain and the immune system or the functional significance of the neural and endocrine interrelationships that have been established....

"This integrated circuitry has extensive ascending and descending connections among the regions cited. These regions also share many similarities. They are sites intimately involved in visceral, autonomic, and neuroendocrine regulation. The cortical and limbic forebrain regions mediate both affective and cognitive processes and may be involved in the response to stressors, in affective states and disorders such as depression, in aversive conditioning, and in the emotional context of sensory inputs from the outside as well as the inside world. From an immunologic perspective, these regions are the sites in which lesions result in altered responses of cells of the immune system; they are the regions that respond to immunization or cytokines by altered neuronal activity or altered monoamine metabolism; and they are the regions that possess the highest concentration of glucocorticoid receptors and link some endocrine systems with neuronal outflow to the autonomic and neuroendocrine systems. Thus, this circuitry is the major system of the CNS suspected to play a key role in responding to immune signals and regulating CNS outflow to the immune system" (pp. 587-589).

Andrews, Vivian H.; Hall, Howard R. (1990). The effects of relaxation/imagery training on recurrent aphthous stomatitis: A preliminary study. Psychosomatic Medicine, 52, 526-535.

Recurrent aphthous stomatitis (RAS) is one of the most common diseases of the oral mucosa. Although etiology remains unknown, immunological and emotional disturbances have been implicated in the pathogenesis of RAS. No consistently effective therapeutic regimen has been found. The present study investigates the voluntary modulation of RAS employing hypnosis-like relaxation/imagery training procedures. A multiple baseline design was used to evaluate change in frequency of ulcer recurrence. The role of psychological distress, ratings of perceived pain, and hypnotizability in the treatment of RAS were also examined. Results suggest that the relaxation/imagery treatment program was associated with a significant decrease in the frequency of ulcer recurrence for all subjects. Psychological distress was examined for relationship to ulcer recurrence and symptomatic changes with treatment, but no pattern was found. Finally, little support was found for the role of high hypnotic ability in the treatment of RAS.

Avants, S. Kelly; Margolin, Arthur; Salovey, Peter (1990-91). Stress management techniques: Anxiety reduction, appeal, and individual differences. Imagination, Cognition and Personality, 10, 3-23.

## NOTES

Four stress management techniques were evaluated for their general appeal, their immediate benefits, and the subjective experiences they evoke. One hundred undergraduates were randomly assigned to one of five treatment groups: (1) progressive muscle relaxation (PMR); (2) distraction imagery; (3) focused imagery; (4) listening to music; (5) sitting quietly (control). Distraction imagery and listening to music were the only techniques found to reduce anxiety to a greater extent than simply sitting quietly. The techniques differed in the way they made subjects feel, but not in their general appeal. Individuals with a 'blunting' coping style were more likely to find all five techniques appealing.

Tests used included the Miller Behavioral Style Scale, Cognitive-Somatic Anxiety Questionnaire of Schwartz, Davidson & Golman, Life Orientation Test of Scheier & Carver, Somatic Perception Questionnaire of Landy and Stern, Body Consciousness Questionnaire of L. C. Miller, Murphy, & Buss, Betts' Questionnaire Upon Mental Imagery, Shortened Form, State-Trait Anxiety Inventory, and Technique Evaluation Questionnaire of the authors.

Progressive muscle relaxation was according to Bernstein & Borkovec. Distraction imagery involved successively imagining a walk along a beach, a stroll across a flower filled meadow, sitting by a stream,

a walk into the woods, sitting in a cabin in the woods listening to the rain against the windowpane, all including images in a variety of sense modalities. Focused imagery involved creating an image of a stressor, then through symbolic imagery experiences Ss were guided through a typical day's events that might lead up to the stressor, reinterpreting cues associated with the stressor as signals that they are in control, visualizing encountering the stressor feeling strong and determined, and any physical sensations reinterpreted as 'energy' that would help them to cope, visualizing enjoying their success (from Crits-Cristoph & Singer. Music was a 20-min tape (10 min of music used in the distraction imagery tape--Natural Light by Steve Halpern & David Smith) and 10 min of music used in background of the focused imagery tape (Structures of Silence by Michael Lanz). A 5th group, Control, was instructed to sit quietly with eyes closed.

This data can be used in support of imagery-suggestion types of hypnosis (as in surgery study) reducing anxiety. It shows particularly strong effects for people high in cognitive anxiety or low in optimism, pre-treatment.

Discussion: "... we feel confident that our distraction techniques were more effective for the immediate relief of anxiety than was PMR. This conclusion is consistent with the Suls and Fletcher meta-analysis (29) that suggested that 'avoidance' is an effective short-term coping strategy. That distraction (positive) imagery may be a more useful clinical technique than focused (active involvement) imagery was concluded in a study comparing these two techniques in the treatment of phobias (24)" (p. 19. [Ref #24 is Crits-Cristoph & Singer (1983) in *Imagination, Cognition, and Personality*.]

"Pessimism and cognitive anxiety emerged as the only individual difference variables to influence anxiety reduction. Pessimism as measured by the LOT is cognitive in nature, with most of the items relating to expectations of negative outcomes; similarly, cognitive anxiety is characterized by worry and an inability to control negative thoughts and images. That individuals who perceive their world somewhat negatively should have entered the study more anxious than individuals who do not is hardly surprising. What is surprising is that despite an inverse relation between cognitive anxiety and the ability to relax, these individuals were able to benefit from whatever technique they performed to a greater extent than were individuals with a more positive outlook. In fact, after performing the technique, pessimists had reduced their anxiety to the level of optimists" (p. 19).

"The stress management techniques used in the current study did not differ in their appeal" (p. 20). "Our finding that PMR produced more somatic effects than did focused imagery and less cognitive effects than did distraction imagery, listening to music, or sitting quietly is consistent with the model of anxiety proposed by Davidson and Schwartz (17). Our findings are also generally consistent with a conclusion reached by Woolfolk and Lehrer (4): that although various techniques are generally stress reducing, they seem to have highly specific effects. However, we found no support for the hypothesis that individuals who express anxiety cognitively (or somatically) prefer and benefit most from techniques that produce cognitive (or somatic) effects. In fact, the extremely high correlation found between the cognitive and somatic anxiety subscales of the Schwartz et al. measure (5) casts some doubt on the usefulness of a cognitive-somatic distinction, as does the corr between the experience of physical symptoms under stress (the Somatic Perception Questionnaire) with the cognitive, as well as the somatic, anxiety subscale.

"The finding that blunterners experiences more 'somatic effects' regardless of the technique they were assigned may have been the result of a single response--'how much did mind-wandering interfere with performing the technique'--which was the only Factor 2 item that was highly inversely related to blunting. Since blunterners are more likely to perceive mind wandering as the essence of stress management rather than as 'interference,' we do not view this main effect as particularly illuminating" (p. 20). "However, our finding that blunterners experienced all techniques as appealing is consistent with the results of Martelli et al. (1) who found that individuals with low information-preference benefitted from what the authors labeled an 'emotion-focused' intervention, but which, in fact, included many of the quite diverse stress management techniques that we compared in the

current study. That 'avoiders' failed to benefit from any intervention in the Scott and Clum study (11) may be due to the nature of the stressor [postsurgical pain]. Our undergraduates may have been more like the Martelli dental patients in terms of their level of distress than were the Scott and Clum subjects who were patients undergoing major surgery (hysterectomy or cholecystectomy). Future research needs to examine possible three-way, technique by patient by stressor-type, interactions (cf. 19)" pp 20-21.

Evans, Frederick J.; Stanley, R. O. (1990). Psychological interventions for coping with surgery: A review of hypnotic techniques. Australian Journal of Clinical and Experimental Hypnosis, 18, 97-105.

Illness, hospitalization, and surgery pose many severe stresses for many patients, to the extent that their ability to understand and cope with what is happening may be significantly reduced. Many of these stresses result from the nature and significance of patients' surgical procedures and post-operative treatment. This paper reviews the range of psychological interventions aimed at helping patients cope with pre- and post-operative treatment regimens. The range and content of hypnotic interventions are examined in detail. It is concluded that more rigorous research studies are required to determine the relative effectiveness of different types of interventions and to evaluate the effects of patients' psychological characteristics on the effectiveness of these interventions.

Pekala, Ronald J.; Forbes, Elizabeth J. (1990, Spring). Subjective effects of several stress management strategies: With reference to attention. Behavioural Medicine, 39-43.

This study assessed variations in reported attentional experience associated with several stress management techniques (hypnosis, progressive relaxation, deep abdominal breathing) and baseline (eyes closed) as a function of hypnotic susceptibility. Three hundred nursing students experienced the stress management conditions and afterward completed a self-report inventory, the Dimensions of Attention Questionnaire (DAQ), in reference to each condition. The DAQ quantifies 12 aspects of attentional experience in a reliable and valid manner. The results demonstrated that progressive relaxation, hypnosis, and deep abdominal breathing are characterized by differences in reported attentional experience that are further moderated by an individual's hypnotic susceptibility. The clinical implications of these results are discussed.

#### NOTES

"Significant main effects were found for conditions for perspicacity, absorption, and control, with progressive relaxation associated with increased perspicacity and absorption, but with decreased control vis-a-vis hypnosis.

"Significant main effects for groups were found for perspicacity, locus, direction of attention, absorption, control, and vigilance. ... [Post-hoc comparisons] revealed that high susceptibles (vis-a-vis low susceptibles) reported increased perspicacity, absorption, a more inward-focused attention, more feelings of being out of their bodies, and decreased control and vigilance. High-mediums were also different from lows (in the same direction) for all of the above comparisons except for direction of attention. Low-mediums, along with lows, were different from highs for absorption and control.

"Significant interactions between conditions and groups were found for absorption, control, and vigilance. Whereas low susceptibles reported significantly increased absorption but significantly decreased control and vigilance during progressive relaxation than during hypnosis, high susceptibles reported no significant differences between relaxation and hypnosis for absorption, control, or vigilance" (p. 41).

The authors describe the differences found for deep abdominal breathing on p. 41.

"The interaction effects suggest that the experience of hypnosis and progressive relaxation are moderated by a person's hypnotic susceptibility--low susceptibles experience significantly greater absorption, but decreased control and vigilance during progressive relaxation than during hypnosis, although there are no such differences for high susceptibles. This suggests that progressive relaxation may be a 'better' procedure than hypnosis to use with low susceptibles, at least if one wants to increase absorption and decrease vigilance and control" (p. 42).

The authors also note that "deep abdominal breathing is associated with increased 'calmness of mind,' in reference to a baseline condition, as demonstrated by increased attentional detachment and equanimity, and decreased vigilance and density (the 'amount' of thoughts going through one's mind)" (p. 42).

Somer, E. (1990). Brief simultaneous couple hypnotherapy with a rape victim and her spouse: A brief communication. International Journal of Clinical and Experimental Hypnosis, 38 (1), 1-5.

This paper presents a case involving a rape victim and her emotionally affected spouse. Although the assault occurred before the couple met, the husband was too upset to concentrate when the victim wanted to share her rape-related feelings, nor could he provide the much needed empathy and support. This, apparently, was due to his difficulties in handling his own rage. Simultaneous couple hypnotherapy was used to allow the victim to share her experience under conditions safe for both her and her spouse. As he imagined in trance the rape account described by his age-regressed wife, he learned to identify his emotions and experience them in a controlled manner. During subsequent sessions, the husband was encouraged to include himself in his wife's abreaction and reshape the traumatic scene for both of them. The husband's rescuing behavior and the expressions of violent anger towards the perpetrator had several positive consequences. Not only did they change the abandonment component of the victim's traumatic memory, but they also helped the husband deal in better ways with his own feelings of anger. It also provided the couple with a helpful coping mechanism they later effectively applied under different circumstances.

1989

Palan, B.M.; Chandwani, S. (1989). Coping with examination stress through hypnosis: An experimental study. American Journal of Clinical Hypnosis, 31, 173-180.

Fifty-six volunteer medical students participated in three groups balanced for number of subjects, performance at last examination, and hypnotizability. The hypnosis and waking groups attended eight group sessions once a week with general ego- strengthening and specific suggestions for study habits, with a ninth session of age progression and mental rehearsal. Subjects in these two groups practiced self-suggestions (in self-hypnosis or waking respectively) daily for the study period of 9 weeks. The control group experienced sessions of passive relaxation induced by light reading for the same period of time. The hypnosis group improved significantly in coping with examination stress, but there was no significant change in performance on examinations by any of the groups.

Sanders, B.; McRoberts, G.; Tollefson, C. (1989). Childhood stress and dissociation in a college population. Dissociation, 2, 17-23.

Two studies are reported demonstrating that individual differences in dissociation in college students are positively related to differences in self-reported stressful or traumatic experiences in youth. In Study 1, differences in the degree of stress or unpredictable physical violence experienced in childhood or early adolescence were shown to be related to scores on the Dissociative Experiences Scale (DES). Study 2 replicated these relationships and extended them to another dissociation measure, the Bliss

scale. Study 2 also demonstrated that both dissociation measures correlate positively with reported physical and psychological abuse. These findings for a nonclinical population are discussed in relation to the etiology of dissociation in clinical groups.

Soskis, D. A.; Orne, E. C.; Orne, M. T.; Dinges, D. F. (1989). Self-hypnosis and meditation for stress management: A brief communication. International Journal of Clinical and Experimental Hypnosis, 37, 285-289.

In a 6-month follow-up study, telephone interviews were conducted with 31 male executives who were taught either a self-hypnosis or meditation exercise as part of a stress-management program. Use of and problems with the 2 exercises were similar, with the percentage of Ss using the techniques falling over 6 months from 90% to 42%. The exercises were used primarily for physical relaxation, refreshing mental interludes, aiding sleep onset, and stress-reduction. Problems with the exercises chiefly involved difficulty in scheduling even brief uninterrupted practice times and discomfort with the techniques. The incorporation of these issues into the clinical teaching of self-hypnosis may be useful.

Stanton, Harry E. (1989). Hypnosis and rational-emotive therapy--a de-stressing combination: A brief communication. International Journal of Clinical and Experimental Hypnosis, 37 (2), 95-99.

It has been suggested that teacher stress might be reduced through cognitive restructuring which is aimed at improving the rationality of their thinking. To test this hypothesis, 40 high school teachers were paired on their level of reasonable thinking, operationalized in terms of scores on the Teacher Idea Inventory (Bernard, Joyce, & Rosewarne, 1983), and allocated at random to one of 2 groups. They also completed the Face Valid Stress Test. The experimental group participated in 4 weekly treatment sessions involving a hypnotic induction and suggestions derived from key elements of Rational-Emotive Therapy. These focused on the reduction of what Ellis (Ellis & Grieger, 1977), the originator of this treatment, calls "irrational thinking." The control group spent the same amount of time discussing stress reduction methods. Both the Face Valid Stress Test and the Teacher Idea Inventory were re-administered at the end of this period and again 12 months after conclusion of the experiment. Results indicated that both the experimental and control groups significantly reduced their levels of irrational thinking and stress, although the former's improvement was more marked, particularly at the 12-month follow-up.

Wickramasekera, Ian (1989). Enabling the somatizing patient to exit the somatic closet: A high-risk model. Psychotherapy: Theory, Research and Practice, 26 (4), 530-544.

Problems in establishing a therapeutic alliance make somatizing patients poor candidates for psychotherapy. A logical analysis is presented of the conspiracy of silence between the somatizing patient, the medical doctor, and the health insurance industry regarding the psychosocial factors contributing to somatization. Alternatives are sought to repeated biomedical tests and therapies that are clinically unproductive and iatrogenic. Two psychophysiological pathways are proposed that are promising to reduce the distance between the medical doctors' and the psychologists' procedures. The new profile of illness has produced a paradigm shift with implications for an expansion of the definition of the word "physician".

1988

Tsushima, W. T. (1988). Current psychological treatments for stress-related skin disorders. Cutis, 42, 402-404.

Surveys current methods used by psychologists in the management of stress-related skin disorders, including hypnosis, relaxation training, biofeedback, operant conditioning, and cognitive behavioral therapy. These techniques offer promise in the treatment of certain dermatologic conditions, but the limited amount of well-controlled and replicated studies of their use suggests that caution be taken in their application.

1987

Bongartz, Walter (1987, October). Influence of hypnosis on white blood cell count and urinary level of vanillyl mandelic acid. [Paper] Presented at the annual meeting of the Society for Clinical and Experimental Hypnosis, Los Angeles.

#### NOTES

They hypothesized that hypnosis benefits to immunology are due to alterations in white blood cell counts (WBC). Found that (1) blood samples before and after hypnosis with relaxation scenes led to significant decrease in WBCs compared to watching film of Mesmer or doing mental arithmetic, and (2) Vanillyl Mandelic Acid also was reduced.

After physical exercise, video game, or reading, within 20', the WBCs return to pre-relaxation levels, i.e. they hadn't left the bloodstream. Key to understanding this result: only 50% of WBCs are in circulation, and others adhere to vessel walls; the experience of hypnotic relaxation leads to less sympathetic nervous activation and less epinephrine or hormonal response. WBCs also increased over a day period with mental arithmetic, but remained the same with hypnosis.

This research is only preliminary and exploratory.

Katz, Ernest R.; Kellerman, Jonathan; Ellenberg, Leah (1987). Hypnosis in the reduction of acute pain and distress in children with cancer. Journal of Pediatric Psychology, 12, 379-394.

Hypnosis has been used as a behavioral approach to help children tolerate aversive medical procedures more effectively, but empirical longitudinal research evaluating the outcome of such interventions has been limited. In the present study, 36 children with acute lymphoblastic leukemia between the ages of 6 and 12 years of age undergoing repeated bone marrow aspirations (BMAs) were randomized to hypnosis or play comparison groups. Subjects were selected on their behavioral performance on baseline procedures and received interventions prior to their next three BMA procedures. Major results indicated an improvement in self-reported distress over baseline with both interventions, with no differences between them. Girls exhibited more distress behavior than boys on three of four dependent measures used. Suggestions of an interaction effect between sex and treatment group were noted. The role of rapport between patient and therapist in therapeutic outcome was also evaluated. Results are discussed in terms of potential individual differences in responding to stress and intervention that warrant further research.

Shertzer, C. L.; Lookingbill, D. P. (1987). Effects of relaxation therapy and hypnotizability in chronic urticaria. Archives of Dermatology, 123, 913-916.

15 patients with chronic urticaria of 7.8 years' average duration. Compared with baseline and control session values, the hypnosis session provided relief of pruritus as measured by 3 self-report parameters. There was no change in the number of hives. All Ss were given a standard test for hypnotizability. Assuming that the results were not biased by their preceding relaxation sessions, we determined that 6 Ss were hypnotizable and nine were non hypnotizable. Ss in both groups improved symptomatically, but hypnotizable Ss had fewer hives and became more symptomatic during the control (testing and history taking) session. Hypnotizable Ss also more frequently related stress as a

causative factor. At a follow-up examination five to 14 months after the completion of the experimental sessions, six patients were free of hives and an additional seven reported improvement.

1986

Cerny, M. (1986). Hypnosuggestive interventions in emotional stress and in stress disorders. Activitas Nervosa Superior, 2, 141-143.

This paper represents a review of results using the PSA technique (Posthypnotic Suggestion evoked by Autostimulation) as a means of protection against stress. The best results were obtained in Ss with high susceptibility. This fact limits the practical use of the PSA method. However, this method can serve as a model approach in another more exact study of psychophysiological self-regulatory mechanisms in relation to coping with stress.

Miller, Mary E.; Bowers, Kenneth S. (1986). Hypnotic analgesia and stress inoculation in the reduction of pain. Journal of Abnormal Psychology, 95, 6-14.

Investigated the influence of hypnotic ability on 3 methods of reducing cold-pressor pain. Following a baseline immersion, 30 high- and 30 low-hypnotizable undergraduates were randomly assigned to 1 of 3 treatment groups: stress inoculation training, stress inoculation training defined as hypnosis, or hypnotic analgesia. Analysis of pain reports indicated a significant hypnotic ability x treatment interaction. Among Ss receiving hypnotic analgesia, high-hypnotizables reported significantly less intense pain than lows. There was no differential response for high- and low-hypnotizable Ss receiving stress inoculation training, whether or not it was defined as hypnotic. Moreover, Ss in the stress inoculation condition (whether or not defined as hypnosis) reported using cognitive strategies to reduce pain, whereas this was not the case for Ss in the hypnotic analgesia condition. The present findings seem inconsistent with the social psychological account of hypnosis and are discussed from a dissociation perspective, which views hypnosis as involving changes in the way information is processed.

Wickramasakera, Ian (1986). A model of people at high risk to develop chronic stress-related somatic symptoms: Some predictions. Professional Psychology: Research and Practice, 17, 437-447.

Certain measurable high-risk factors that predispose people to develop functionally based somatic disorders are identified. These risk factors compose a multidimensional model that encompasses variables involved in the predisposition, the precipitation, and the buffering of stress-related symptoms. These high-risk factors are (a) high or low hypnotic ability, (b) habitual catastrophizing cognitions and pessimistic belief systems, (c) autonomic lability or neuroticism, (d) multiple major life changes or multiple minor hassles over a short period of time, and (e) a deficit in support systems or coping skills or both.

1985

Eichelman, Burr (1985). Hypnotic change in combat dreams of two veterans with posttraumatic stress disorder. American Journal of Psychiatry, 142 (1), 112-114.

Presents the cases of 2 veterans (aged 57 and 37 yrs) whose recurrent and traumatic combat dreams were dispelled with hypnosis and the dream substitution technique. This technique was based on the hypothesis that incorporation of hypnotically rehearsed dreams into nocturnal dreams would demonstrate to Ss that they had control over nocturnal dream content. Dream substitutions were rehearsed in hypnotic trance and subsequently dreamed at night; afterward, Ss' original traumatic dreams ceased. (8 ref).

Gottschalk, Louis A. (1985). Hope and other deterrents to illness. American Journal of Psychotherapy, 39, 515-524.

Reviews animal and human research demonstrating that events during early development influence vulnerability to physical and mental illness. In addition, effectiveness of coping methods used to deal with problems of living can affect susceptibility to illness. The intervening mechanisms between stressful life experiences and illness appear to involve physiological homeostasis and immune competence.

1984

Holmes, David S. (1984). Meditation and somatic arousal evidence. American Psychologist, 39 (1), 1-10.

The conceptual and methodological issues associated with research on the effects of meditation are reviewed. A summary of the research in which the somatic arousal of meditating subjects was compared to the somatic arousal of resting subjects did not reveal any consistent differences between meditating and resting subjects on measures of heart rate, electrodermal activity, respiration rate, systolic blood pressure, diastolic blood pressure, skin temperature, oxygen consumption, EMG activity, blood flow, or various biochemical factors. Similarly, a review of the research on the effects of meditation in controlling arousal in threatening situations did not reveal any consistent differences between meditating and nonmeditating (no-treatment, antimeditation, or relaxation) subjects. The implications of these findings for research and practice are discussed.

Krenz, Eric W. (1984). Improving competitive performance with hypnotic suggestions and modified autogenic training: Case reports. American Journal of Clinical Hypnosis, 27, 58-63.

Although traditionally trainers of athletes have emphasized physiological refinements for the optimal performance of complex motor skills, research has revealed that heightened levels of stress and anxiety may adversely affect performance. As a result, many athletic training programs, taking into consideration the complex interrelationship of the mind and the body, include "mental training" in an attempt to reduce the negative effects of excess stress. These programs have incorporated various psychological interventions such as post hypnotic suggestions, sensory conditioning, and mental imagery and rehearsal. Modified Autogenic Training, a teaching model based on Standard Autogenic Training, synthesizes the strengths of hypnotic techniques to achieve optimal athletic performance. Athletes trained in these concepts can manage unexpected incidences during competition. The concepts of Modified Autogenic Training are described and four case studies are reported.

Stam, Henderikus J.; McGrath, Patricia A.; Brooke, Ralph I. (1984). The effects of a cognitive-behavioral treatment program on temporomandibular pain and dysfunction syndrome. Psychosomatic Medicine, 46, 534-545.

Sixty-one patients, clearly diagnosed as suffering from temporomandibular pain and dysfunction syndrome (TMPDS), were randomly assigned to one of three groups, (1) hypnosis and cognitive coping skills, (2) relaxation and cognitive coping skills, or (3) a no-treatment control group. All patients were evaluated with a standard hypnotic susceptibility scale prior to treatment. The two treatment groups received four weekly sessions of their respective treatments. Patients in the hypnosis and relaxation groups reported equivalent decrements in pain, abnormal sounds in the temporomandibular joint, and

limitations of jaw mobility. Hypnotic susceptibility was significantly correlated with reductions in reported pain for the treatment groups. Patients' age and the duration of pain prior to treatment were not related to treatment outcome. Patients who dropped out of treatment had fewer limitations in jaw movement but did not differ on any other variable from patients who remained in treatment. These findings are discussed in relation to the hypothesis that TMPDS is a stress related muscular pain and dysfunction.

1982

Hall, Marian D. (1982-83). Using relaxation imagery with children with malignancies: A developmental perspective. American Journal of Clinical Hypnosis, 25 (2-3), 143-149.

Developmental theory has been the foundation for this program of relaxation-imagery therapy with its goal of increasing the efficacy of immune mechanisms, thus increasing the survival rate of children with malignancies and/or improving the comfort and quality of their lives. Three basis constructs--the impact of social stress, the positive development of attachment and the negative effects of separation and loss, and the stages of concept formation relating to the functioning of the human body, the processes of disease and death--are basic approaches to the use of imagery-relaxation as an integral part of a comprehensive care plan.

Stoyva, J. M.; Anderson, C. (1982). A coping-rest model of relaxation and stress management. In Goldberger, L.; Breznitz, S. (Ed.), Handbook of stress: Theoretical and clinical aspects (pp. 745-763). New York: The Free Press.

## NOTES

"Patients with psychosomatic or stress linked disorders are likely to show signs of high physiological arousal, and they are likely, under stress, to react strongly in the symptomatic system and to show evidence of being deficient in the ability to shift from the coping to the rest mode (e.g., slowness of habituation to, and recovery from, stressful stimulation). A corollary inference is that such patients ... show activity in the symptomatic system for a higher percentage of the time that [sic] do normal subjects. We suggest that this defect in the capacity to shift to a rest condition is the principal reason that various relaxation procedures have so often proved successful in the alleviation of stress related symptoms" (p. 748).

The authors refer to a number of different stress management procedures. Among those associated with primary focus on the rest phase they include: Relaxation training (progressive relaxation, autogenic training, EMG feedback, meditation [Zen, TM]), Specific biofeedback (hand temperature, electrodermal response [EDR], EMG from particular muscle group), and Systematic desensitization. Among those associated with primary focus on coping phase are: Assertiveness training, Social skills retraining and motor skills retraining, Self-statements, Imagery (Guided waking imagery, autogenic abreaction, covert reinforcement and covert sensitization, behavior rehearsal). These various procedures may reflect three dimensions or aspects of the stress response, with some addressing physiology and others addressing cognition or behavior change.

"Rachman (1978) ... found it useful to divide the phenomenon of fear into physiological, cognitive, and behavioral components. Similarly, Davidson and Schwartz (1976) conceptualized relaxation as consisting of somatic, cognitive, and attentional components. Phillips (1977) argued that pain, such as headache pain, can be viewed as consisting of cognitive, behavioral, and physiological aspects (and that, consequently, we should not expect high correlations between headache pain and a particular physiological measure such as forehead EMG level). ...

"... In discussing contemporary studies of dreaming, they [Stoyva and Kamiya (1968)] proposed that there is no single, totally valid indicator of dreaming as a mental experience. Instead, there are several

imperfect indicators of the dream experience--verbal report, rapid eye movements, and certain electroencephalographic (EEG) stages. ... Discrepancies among the indicators can serve to generate hypotheses" (p. 749).

The authors discuss different ways of retraining the capacity to rest: relaxation training (including biofeedback, etc.), systematic desensitization; and of reshaping the coping response: assertiveness training, social skills and motor skills retraining, self-statements, imagery techniques; and discuss controllability. These notes cover only a very small part of their extensive review, the material most relevant to hypnosis and suggestion.

"Although imagery techniques are often employed by stress management therapists, one approaches this area with ambivalence. In part, this uneasiness springs from the unsettling awareness that imagery techniques have been embraced by a freewheeling assortment of lay psychologists such as Emil Coue, Dale Carnegie, and Norman Vincent Peale, not to mention a diverse throng of contemporary 'mind controllers' and self-styled healers. A more serious source of uneasiness is ignorance of the specific processes at work. What are the mechanisms by which imagery affects the stress response?" (p. 756).

"There is intriguing recent evidence that simply the illusion of control may exert beneficial effects. Stern, Miller, Ewy, and Grant (1980) noted that subjects who were led to believe by means of bogus information feedback that they were successfully lowering their heart rates showed a reduction in stress type symptoms, especially those of a cardiovascular nature. It seems possible that the feeling of control may be an important part of what we have called 'placebo responding.' Stoyva (1979b) suggested that this phenomenon is probably not a unitary entity but, rather, a cluster of processes, of which the feeling of developing control over factors affecting one's disorder is an important and potentially manipulable component of therapeutic interventions" (p. 758).

Woolfolk, Robert L.; Lehrer, Paul M.; McCann, Barbara S.; Rooney, Anthony J. (1982). Effects of progressive relaxation and meditation on cognitive and somatic manifestations of daily stress. Behaviour Research and Therapy, 20 (5), 461-467.

Compared meditation and progressive relaxation with self-monitoring control as treatments for symptoms of stress. 34 Ss were assigned to either the progressive relaxation, the meditation, or the self-monitoring control group and were given 5 sessions of training. All Ss self-monitored stress symptoms throughout the study and had their behavior rated weekly by a spouse/roommate. Results show that the progressive relaxation and mediation treatments significantly reduced stress symptomatology over time.

1981

Fling, Sheila; Thomas, Anne; Gallaher, Michael (1981). Participant characteristics and the effects of two types of meditation vs. quiet sitting. Journal of Clinical Psychology, 37 (4), 784-790.

Randomly assigned 61 undergraduate volunteers to Clinically Standardized Meditation (CSM), quiet sitting (SIT), or wait list1 and 19 others to Open Focus (OF) or wait list2. Ss were tested before training and again 8 weeks later. All groups but wait list2 decreased significantly on Spielberger's trait anxiety. All groups became nonsignificantly more internal on Rotter's locus of control. On the Myers-Briggs Type Indicator, meditation volunteers were more introverted than extraverted, intuitive than sensing, feeling than thinking, and perceiving than judging. All groups became more intuitive, approaching significance for CSM only. OF became significantly more extraverted than both CSM and SIT, and CSM significantly more so than wait list1. Practice time correlated with anxiety reduction for the combined treatment groups. More evidence was found for correlations of practice time and outcome with growth motivation than with either new experience motivation or expectancy of benefit.

Worthington, Everett L.; Shumate, Michael (1981). Imagery and verbal counseling methods in stress inoculation training for pain control. Journal of Counseling Psychology, 28 (1), 1-6.

Investigated 3 elements of stress inoculation training, a therapeutic package for helping clients control anxiety, anger or pain. 96 undergraduate females were tested twice for ice water tolerance. In a 3 design, the independent variables were the presence or absence of (a) pleasant imagery, (b) a conceptualization of pain as a multistage process, and (c) planned, explicit self-instructions. A multivariate analysis of covariance using the (transformed) pretest tolerance rating and 2 self-ratings of pain. Imagery users (Is) controlled their pain better than nonimagery users (NIs). There was a significant interaction of Imagery and Conceptualization. NIs had longer tolerance and less self-reported pain at withdrawal when they heard no conceptualization. The Is did not derive additional benefit from hearing the conceptualization. Self-instruction did not affect pain control. Results suggest that pleasant imagery effectively relieves pain and may account for much of the effectiveness of stress inoculation training. (23 ref)

1980

Puente, Antonio E.; Beiman, Irving (1980). The effects of behavior therapy, self-relaxation, and transcendental meditation on cardiovascular stress response. Journal of Clinical Psychology, 26 (1), 291-295.

#### NOTES

Compared Behavior Therapy (BT), self-relaxation (SR), transcendental meditation (TM), and a waiting-list control group (WL) on measures of cardiovascular and subjective stress response. Male and female respondents (N = 60) to an ad for therapy were evaluated in assessment sessions before and after treatment. The results indicate that BT and SR were more effective than either TM or WL in reducing cardiovascular stress response. These data were interpreted as resulting from therapeutic suggestion and positively reinforced client progress.

Reiser, Martin; Nielson, Michael (1980). Investigative hypnosis: A developing specialty. American Journal of Clinical Hypnosis, 23, 75-84.

#### NOTES

Author describes his involvement with the Los Angeles Police Department, using hypnosis for "enhancing the recall of key witnesses whose memories of the crime were poor" (p. 75). In 1975, the author and other experts in hypnosis trained 11 lieutenants and 2 captains to use hypnosis. The author describes the training program and a one-year demonstration project, during which volunteer witnesses and victims were interviewed by the hypnotist investigators. "In 77% of cases, important information was elicited that had not been available by routine interrogation. Approximately 16% of cases were solved with the aid of hypnosis" (p. 76). "Follow-up with the involved witnesses and victims has not revealed any instance of ill effects stemming from the hypnosis program, while 39.8% of the hypnosis subjects reported some relief or benefit resulting from the hypnosis session" (p. 77). Jean Holroyd

1978

Parker, Jerry C.; Gilbert, Gary S.; Thoreson, Richard W. (1978). Reduction of autonomic arousal in alcoholics: A comparison of relaxation and meditation techniques. Journal of Consulting and Clinical Psychology, 46 (5), 879-886.

To investigate and compare the effects of progressive relaxation training and meditation training on autonomic arousal in alcoholics, 30 subjects were selected from a population of alcoholics in a Veterans Administration hospital substance-abuse program. The subjects were randomly assigned to one of the following three experimental conditions: (a) progressive relaxation training group, (b) meditation training group, or (c) quiet rest control group. All groups met for 3 weeks during which state anxiety, blood pressure, heart rate, and spontaneous galvanic skin responses were measured. The measures were designed to assess the treatment effects following the first training session and at the end of the total training period. The results indicate that both progressive relaxation training and meditation training are useful for reducing blood pressure in alcoholics. In addition, significant differences between the groups in the effectiveness of the relaxation procedures were found. Meditation training induced blood pressure decreases at an earlier point in the 3-week training period and affected decreases in systolic blood pressure that progressive relaxation training did not. These results support the idea of considerable specificity of response to relaxation techniques.

Shipley, R. H.; Butt, J. H.; Horowitz, B.; Farbray, J. E. (1978). Preparation for a stressful medical procedure: Effect of amount of stimulus preexposure and coping style. Journal of Consulting and Clinical Psychology, 46, 499-507.

Anxiety during the stressful medical procedure of endoscopy was studied as a function of the number of prior viewings of an explicit preparation videotape and of repression-sensitization coping style. Sixty naive patients viewed a videotaped endoscopy either zero, one, or three times. Dependent measures included heart rate, behavioral ratings, tranquilizer required, and self-report. On each dependent measure, three viewings generally resulted in the least distress; one, more distress; and zero, the most distress. Most comparisons reached statistical significance. These results are interpreted as resulting from extinction and/or habituation of anxiety. The repression-sensitization factor interacted with heart rate change. Sensitizers showed a monotonic decrease in heart rate as a function of number of tape exposures. Repressors showed an inverted-U-shaped function, with one viewing producing the highest heart rate; this is interpreted as resulting from a disruption of repressing defenses by one tape exposure followed by extinction of fear by three exposures.

1977

Grant, Guy (1977). The psychophysiology and hypnotherapeutic management of cancer. Australian Journal of Clinical Hypnosis, 5, 35-49.

Reviews research on psychophysiology of cancer, effect of stress on host resistance, cancer prediction from personality traits, psychological theories of cancer aetiology, and psychological characteristics of patients with different types of neoplasms. The hypnotherapy of cancer patients is outlined in terms of its effect upon the malignancy, relief of discomfort, and psyche of the cancer patient. Recommends direction of hypnotherapeutic treatment of cancer patients.

Novaco, Raymond W. (1977). Stress inoculation: A cognitive therapy for anger and its application to a case of depression. Journal of Consulting and Clinical Psychology, 45 (4), 600-8.

Clinical interventions for anger disorders have been scarcely addressed in both theory and research in psychotherapy. The continued development of a cognitive behavior therapy approach to anger management is presented along with the results of its application to a hospitalized depressive with severe anger problems. The treatment approach follows a procedure called "stress inoculation," which consists of three basic stages: cognitive preparation, skill acquisition and rehearsal, and application practice. The relationship between anger and depression is discussed.

1976

Goleman, Daniel J.; Schwartz, Gary E. (1976). Meditation as an intervention in stress reactivity. Journal of Consulting and Clinical Psychology, 44 (3), 456-466.

Meditation and relaxation were compared for ability to reduce stress reactions in a laboratory threat situation. Thirty experienced meditators and 30 controls either meditated or relaxed with eyes closed or with eyes open and then watched a stressor film. Stress response was assessed by phasic skin conductance, heart rate, self-report, and personality scales. Meditators and the meditation condition habituated heart rate and phasic skin conductance responses more quickly to the stressor impact and experienced less subjective anxiety. Meditation can produce a psychophysiological configuration in stress situations opposite to that seen in stress-related syndromes. Research is indicated on clinical applications and on the process whereby meditation state effects may become meditator traits.

Smith, Jonathan C. (1976). Psychotherapeutic effects of transcendental meditation with controls for expectation of relief and daily sitting. Journal of Consulting and Clinical Psychology, 44 (4), 630-637.

Two experiments were conducted to isolate the trait-anxiety-reducing effects of transcendental meditation (TM) from expectation of relief and the concomitant ritual of sitting twice daily. Experiment I was a double-blind study in which 49 anxious college student volunteers were assigned to TM and 51 to a control treatment, "periodic somatic inactivity" (PSI). PSI was carefully designed to match the form, complexity, and expectation-fostering aspects of TM but incorporated a daily exercise that involved sitting twice daily rather than sitting and meditating. In Experiment 2 two parallel treatments were compared, both called "cortically mediated stabilization" (CMS). Twenty-seven volunteers were taught CMS1, a treatment that incorporated a TM-like meditation exercise, and 27, CMS2, an exercise designed to be the near antithesis of meditation. Results show 6 months of TM and PSI to be equally effective and 11 weeks of CMS1 and CMS2. to be equally effective. Differences between groups did not approach significance ( $p > .6$ ). The results strongly support the conclusion that the crucial therapeutic component of TM is not the TM exercise.

1974

Bloom, Richard F. (1974). Validation of suggestion-induced stress.

Sixty college men, divided into three equal groups, each attended two induced stress sessions in which their physiological, psychological and performance reactions were measured. Their responses were compared to determine if valid stress reactions could be induced through suggestion in an altered state (in this case, hypnosis), and also to determine the validity of such reactions if the subject had never before experienced that stress situation. It was demonstrated that valid stress reactions can be induced in an individual with the aid of suggestions, especially if the real stress situation has been experienced before. If no previous experience with that real situation exists, the subject still exhibits stressful reactions; however, the closest resemblance to real stress is found in the subjective or psychological measures, less similarity is found in the physiological measures, and the least similarity is found in the performance measures.

## NOTES

Research and Development Technical Report ECOM-0161-F; AD-913 696L; Contract DAAB07-71-C-0161 with Signatron, Inc. (Lexington, MA). Distribution limited to U.S. Government agencies only; Other requests for this document must be referred to Commanding General, U.S. Army Electronics Command, ATTN: AMSEL-PP-CM-CR4, Fort Monmouth, NJ 07703. NOTES 2: This document reports on a U.S. Army research project using hypnosis to collect high fidelity samples of the voice under "combat stress" conditions in the laboratory. Using hypnotic regression, combat veterans "re-experienced" their own, actual high stress combat situations. Besides subjective reports of stress levels by subjects, physiological stress measures were obtained from polygraph recordings of heart, respiration and GSR activity. The voice samples were later analyzed by spectrographic techniques to determine which factors remain invariant to identify and authenticate the speaker in a military communications situation. Hypnotic techniques were shown to be useful in establishing controlled emotional states for laboratory research purposes. (Richard Bloom)

1971

McAmmond, D. M.; Davidson, P. O.; Kovitz, D. M. (1971). A comparison of the effects of hypnosis and relaxation training on stress reactions in a dental situation. American Journal of Clinical Hypnosis, 13, 233-242.

## NOTES

Compared the effectiveness of relaxation, hypnosis, and a control condition in reducing in dental phobics the reaction to pressure-algometer stimulation and the injection of anesthesia. For subjects with high baseline skin-conductance levels, relaxation was most effective in reducing stress reactions. Hypnosis did not differ from the control condition. For subjects with a medium or low skin-conductance baseline, relaxation was not effective. The hypnosis group rated their treatment as most effective, and the controls rated their treatment as least effective. Five-month follow-up indicated that all subjects in the hypnosis group returned for dental treatment and that 5 of 10 in the control group and only 1 of the relaxation group returned for care.

1970

Bowers, Kenneth S.; Kelly, P. (1970). Stress, disease, psychotherapy, and hypnosis. Journal of Abnormal Psychology, 490-505.

Presents evidence for the importance of suggestion and hypnotic ability in the healing or amelioration of various somatic disorders. It is argued that even in some treatment interventions that are not explicitly hypnotic, suggestion and hypnotic ability may be hidden factors that help to promote successful healing. Consequently, hypnotic ability may be an individual difference variable that influences treatment outcome in a manner not heretofore recognized by many investigators and clinicians involved in helping the psychologically and physically ill.

Evans, Michael B.; Paul, Gordon L. (1970). Effects of hypnotically suggested analgesia on physiological and subjective responses to cold stress. Journal of Consulting and Clinical Psychology, 35 (3), 362-371.

Relative effects of suggested analgesia and hypnotic induction were evaluated with regard to reduction of stress responses (self-report, heart rate, pulse volume) to the physical application of ice-water stress. Four groups (N = 16 each) of undergraduate female Ss, equated on hypnotic susceptibility, were run individually, receiving (a) hypnotic induction plus analgesic suggestion, (b) hypnotic induction alone, (c) waking self-relaxation plus analgesic suggestion, or (d) waking self-relaxation alone. The major findings were that suggestion, not hypnotic induction procedures, produced reductions in the self-

report of distress, and that the degree of reduction was related to hypnotic susceptibility in both "hypnotic and "waking" conditions. Neither suggestion nor hypnotic induction procedures resulted in reduction of the physiological stress responses monitored in this study. Several methodological issues are discussed. Although findings add to the bulk of evidence supporting the "skeptical" view of hypnotic phenomena, results are related to other literature, suggesting that an adequate evaluation of hypnotic analgesia as used clinically has not yet been undertaken.

1968

Nuland, William (1968). The use of hypnotherapy in the treatment of the postmyocardial infarction invalid. International Journal of Clinical and Experimental Hypnosis, 16 (3), 139-150.

DEALS WITH THE PSYCHOLOGICAL ASPECTS OF CONVALESCENCE AND REHABILITATION OF PATIENTS FOLLOWING CORONARY INFARCTION. THE FOCUS IS ON THE SITUATIONAL FACTORS WHICH THE PATIENT ENCOUNTERS DURING CONVALESCENCE THAT SERVE TO PROLONG AND REINFORCE THE INVALIDISM. IT IS CONCERNED ESPECIALLY WITH THE VALUE OF HYPNOTHERAPY AS COMPARED WITH OTHER PSYCHOTHERAPEUTIC METHODS IN TREATING THESE CASES. THE ANXIETY AND EMOTIONAL STRESS WHICH CAN BE RELIEVED THROUGH THE USE OF HYPNOSIS IS DIRECTED PRIMARILY TOWARD REDUCING EMOTIONAL TURMOIL WHICH RESULTS FROM THE CORONARY ATTACK WITH THE CONSEQUENT FEAR OF PHYSICAL ACTIVITY AND OF SUDDEN DEATH. SPECIFICALLY, HYPNOSIS IS USED EFFECTIVELY IN REASSURANCE, REEDUCATION, DESENSITIZATION, GUIDANCE, AND OTHER DIRECT SUPPORT TECHNIQUES IN ACCORDANCE WITH THE PATIENT'S SYMPTOMS AND NEEDS. Duncan, Irma W.; Dressler, Robert L.; Lyon-James, Sara; Sears, Alden B. (1958). The search for an index of hypnosis. Journal of Clinical and Experimental Hypnosis, 6 (2), 95-108.

NOTES

"Blood and urine samples were obtained from 18 university students at the beginning and end of two experimental sessions, one with and one without hypnosis. Some of the subjects relaxed during the sessions; others imagined or hallucinated a traumatic experience.

"Of a variety of measurements made, urinary volumes and 17-ketosteroids, the eosinophil count and psychogalvanometer recordings appear to give useful information about any changes due to the hypnosis. The biochemical changes caused by the experimentally produced emotions seem to depend on the individual and his past experience rather than the hypnosis. The data suggest that if the experience hallucinated is known to the subject, the biochemical changes indicate a relaxed state during the hypnosis. The psycho-galvanometer recordings may indicate an agitated state while the biochemical indices suggest a relaxed state" (pp. 106-107).

Wheeler, William M.; Little, Kenneth; Dorcus, Roy M.; Clemens, Theodore L.; Sternberg, Thomas H.; Zimmerman, Murray C. (1954). The effects of psychological stress as measured by a decrease in the number of circulating eosinophiles. Journal of Clinical and Experimental Hypnosis, 2 (2), 130-135.

NOTES

"Summary and Conclusions. Eight healthy control subjects who had no history of allergic disorders

were run through a series of experimental conditions which were interposed between eosinophile counts taken at 8:00 a.m. and noon. In three of the situations a few additional 'normal' controls were added. Six patients diagnosed as having atopic dermatitis were studied in one of the hypnotic conditions, viz., suggested 'personal stress,' and four other atopics were exposed to a simulated murder.

"An analysis of the results indicated that 'normals' had significant differences in their eosinophile counts before and after a control run and hypnosis. However, direct reference to the raw data revealed an abnormally low average count before one of the intervening stresses which then rose more than 48% on the entire group by noon. The increase, which could hardly have been due to the experimental situation, created such a difference between the means of the hypnotic conditions, that a spurious significance level of greater than .05 but less than .01 was obtained. When the effects of this rather aberrant result were cancelled, we found that hypnosis, regardless of the specific suggestions employed, had some tendency to lower the eosinophile count. The trend was not great enough to be statistically significant.

"'Normals' also displayed a significant drop in eosinophiles in the other experimental situations which was most directly a function of their reaction to simulated murder. The dermatitic patients did not show significant differences in the two psychological stresses where they were studied. There did seem to be a tendency for them to respond in the same direction as the normals, but with less magnitude. Since some atopics did show an eosinophile response to external stress in this study and in another reported previously (3), it is concluded that a defect in the hypothalamus, higher brain centers, or the adrenal medulla could not be characteristic of all dermatitic patients. The behavior of the patient and control groups in the simulated murder condition was discussed" (pp. 134-135).

Conn, Jacob H. (1953). Hypnosynthesis III. Hypnotherapy of chronic war neuroses with a discussion of the value of abreaction, regression and revivication. Journal of Clinical and Experimental Hypnosis, 1, 29-43. (Abstracted in Psychological Abstracts, 53: 6687)

Author's Summary - Three examples of chronic war neuroses which were successfully treated by hypnotherapy are presented. The clinical material would seem to indicate that the patient in the trance state is greatly influenced by the attitude and goal of the therapist and tends to produce the type of material which is expected of him. The protocols reveal that the hypnotized patient responds to a permissive, calm, attitude with relatively little emotional display, and by talking about harrowing war experiences in a matter-of-fact manner.

It would appear that merely to recall the traumatic experience without a personalized, constructive, emotional relation to a supporting, understanding therapist is of little therapeutic value. The crux of the therapeutic problem in every approach, whether it be narcosynthesis, narco-analysis, hypnosynthesis, or the hypnotic intensification of an emotion is to bring about the integration of unbearable experiences which previously had been dissociated and obliterated from memory or which automatically reappear and disrupt smooth ego functioning.

It is postulated that the hypnotic trance state provides a unifying, integrating inter-personal experience which is of value in the treatment of chronic war neuroses.

1947

Kaufman, M. R.; Beaton, L. (1947). A psychiatric treatment in combat. Bulletin of the Menninger Clinic, 11, 1-14.

NOTES

Describes use of hypnosis in treating "combat fatigue" in field conditions during the Pacific campaign

of WWII. Hypnosis was utilized for sleep and rest in tent hospitals in or near combat to avoid chemical sedation as well as for reliving and mastering traumatic events. The milieu was one of expectant recovery with patients pitching tents, digging foxholes and serving as litter bearers. Psychiatric admissions were 12.8% of the total with return to duty rates varying with intensity of combat and duration of campaign with over half returned to combat duty. Four detailed cases are reported.

## **SUBJECTIVE EXPERIENCE**

**2003**

Holroyd, Jean (2003). The science of meditation and the state of hypnosis. American Journal of Clinical Hypnosis, 46 (2), 109-128.

Two aspects of Buddhist meditation -- concentration and mindfulness -- are discussed in relationship to hypnosis. Mindfulness training facilitates the investigation of subjective responses to hypnosis. Concentration practice leads to altered states similar to those in hypnosis, both phenomenologically and neurologically. The similarities and differences between hypnosis and meditation are used to shed light on perennial questions: (1) Does hypnosis involve an altered state of consciousness? (2) Does a hypnotic induction increase suggestibility? It is concluded that a model for hypnosis should include altered states as well as capacity for imaginative involvement and expectations.

Manmiller, Jessica L.; Kumar, V. K.; Pekala, Ronald J. (2002). Hypnotizability, creative capacity, creativity styles, absorption and phenomenological experience. [Paper] Presented at the annual meeting of the American Psychological Association, Chicago.

"The study investigated relationships between creative capacity, styles of creativity, hypnotizability, and absorption. Participants were 429 students enrolled in Introduction to Psychology classes. Students first completed questionnaires pertaining to creative capacity, creativity styles, and absorption (Tellegen's Absorption Scale). They were subsequently hypnotized using the Harvard Group Scale of Hypnotic Susceptibility and completed the Phenomenology of Consciousness Inventory. The pattern of results suggests that creative capacity is more closely related to absorption than hypnotizability. The support for P. G. Bowers' assertion that effortless experiencing while engaged in creative tasks and hypnotic tasks is a process that is common to both high creative and high hypnotizable subjects was weak. Hypnotizability was more strongly and negatively correlated with volitional control for suggestions experienced during hypnosis, than both absorption and creative capacity. Creativity styles of belief in unconscious processes, use of techniques, final product orientation (intrinsic/extrinsic) motivation, environmental control and behavioral self-regulation, and supersition were negatively correlated with volitional control (feeling of effortless experiencing) during hypnosis, but the correlations were small in magnitude" (Bulletin of Division 30, Psychological Hypnosis, Fall, 2002, Vol. 11, No. 3, P. 14).

Gibbons, Don E. (2001). Experience as an art form: Hypnosis, hyperempiria, and the Best Me technique. San Jose CA: Authors Choice Press. ([[available online:] <http://www.iuniverse.com/bookstore/marketplace>))

## **NOTES**

The Best Me Technique is a procedure for constructing suggestions which incorporates many different dimensions of experience -- beliefs, emotions, sensations, thoughts, motives, and expectations -- for

maximum involvement and effectiveness. Best Me suggestions may be used with either hyperempiria, an alert induction based on suggestions of mind expansion and increased alertness and sensitivity, or with more traditional forms of hypnotic induction.

Pekala, Ronald J.; Kumar, V. K. (2001). Operationalizing trance I: Rationale and research using a psychophenomenological approach. American Journal of Clinical Hypnosis, 43 (3-4), 330-.

Reports an error in the article by R. J. Pekala and V. K. Kumar (see record 2000-00739-001). Two references were incorrectly printed: (1) Pekala, R. J., & Kumar, V. K. (1988). 2000

Pekala, Ronald J.; Kumar, V. K. (2000). Operationalizing trance I: Rationale and research using a psychophenomenological approach. American Journal of Clinical Hypnosis, 43 (2), 107-135.

Despite the popularity of the term "trance" among clinicians to describe the subjective effects associated with being hypnotized, heretofore there has been no means to operationalize that definition. The authors present a rationale and psychophenomenological method to operationalize the term "trance" in terms of: (a) hypnotic depth, a quantitative measure of subjective trance assessed via a predicted Harvard Group Scale score, derived from regression analysis; and (b) "trance typology profiles," a qualitative differentiation of empirically derived (via cluster and discriminant analyses) categories of subjective trance experiences. The authors then discuss theoretical and clinical implications of this psychophenomenological approach for developing an operational definition of the concept of trance. 1999

Cardena, Etzel (1999, August). The ways to study anomalous experience. [Paper] Presented at the annual meeting of the American Psychological Association, Boston, Massachusetts.

In recent years, introspective inquiry has become an essential venue to explore states of consciousness and anomalous experience. Many recent reviews have coincided that introspective techniques to examine "one's own mental happenings," rather than to determine the cause of one's behavior, can be valid and reliable. Most limitations of introspective inquiry are also applicable to other content areas in psychology and include: forgetting, reconstruction errors/confabulation, verbal description difficulties, distortion through observation, substitution of inferences for observation, censorship, lack of independent verification, dissembling and social desirability, demand characteristics, and possible inaccessibility due to "state specific" memory. Careful attention to these potential pitfalls is warranted. Various methods (from the Greek etymology methodos for "way" or road) to study the contents of consciousness have been developed, including, phenomenological approaches, concurrent methods (thinking out loud, event recording, thought sampling, and depth ratings) and retrospective methods (diaries; interviews; content analysis; psychological tests; surveys and questionnaires; and case studies and life histories). Because every method has specific areas of application and limitations, an integration of various approaches should yield the most comprehensive view of anomalous experiences.

McConkey, Kevin M.; Wende, Vanessa; Barnier, Amanda J. (1999). Measuring change in the subjective experience of hypnosis. International Journal of Clinical and Experimental Hypnosis, 47 (1), 23-39.

The authors indexed the subjective experience of hypnosis through the use of a continuous behavioral measure of the strength of the participant's experience at the time of the suggestion. Specifically, subjects turned a dial to indicate changes in their experience of the suggested effect during that experience. Thirty-three high, 47 medium, and 28 low hypnotizable subjects were asked to use the dial during the suggestion, test, and cancellation phases of three hypnotic items: arm levitation, arm rigidity, and anosmia. The pattern of ratings differed according to the nature of the suggestion. Also, across the items, subjects who passed according to behavioral criteria experienced the suggested effect to a greater degree than those who failed. Notably, whereas the ratings of highs and mediums did not differ for any item, they differed from lows on all three items. The authors discuss the implications of these findings in terms of the potential for this method to provide insight into the experience of hypnosis.

1998

Eastwood, J. D.; Gaskovski, P.; Bowers, K. S. (1998). The folly of effort: Ironic effects in the mental control of pain. International Journal of Clinical and Experimental Hypnosis, 46 (1), 77-91.

During exposure to pain, participants who were engaged in hypnotic analgesia or stress inoculation provided pain reports every 5 s and 45 s, respectively. It was found that the frequency of pain reporting had a significant effect on participants' level of experienced pain. This finding is discussed in the context of important methodological implications for laboratory investigations of analgesia. Furthermore, preliminary evidence was obtained suggesting that high hypnotizables in hypnotic analgesia remained relatively undisturbed by frequent pain reporting. Based on Wegner's (1994) ironic process theory, it is argued that this pattern of results is inconsistent with theories of hypnosis that propose that hypnotized individuals intentionally engender responses while remaining unaware of their sustained, deliberate effort. The obtained pattern of results was, however, predicted from the dissociated control model of hypnosis (Bowers, 1990, 1992).

Kirsch, Irving; Milling, Leonard S.; Burgess, Cheryl (1998). Experiential scoring for the Waterloo-Stanford Group C Scale. International Journal of Clinical and Experimental Hypnosis, 46 (3), 269-279.

A scale is presented that assesses subjective experiences associated with the test suggestions contained in the Waterloo-Stanford Group C scale (WSGC), a group adaptation of the Stanford Hypnotic Susceptibility Scale: Form [C] (SHSS:C). This scale, along with the standard behavioral scoring system of the WSGC, was given to 926 students at the University of Connecticut. Normative data from this sample indicate that the experiential scoring scale is both reliable and valid as a measure of suggestibility. It is suggested that it may be useful to supplement behavioral scoring with experiential scoring when the WSGC is used.

1997

Hillig, Justine A.; Holroyd, Jean (1997-98). Consciousness, attention, and hypnoidal effects during firewalking. Imagination, Cognition and Personality.

Subjective experiences of individuals who walked on hot coals during a firewalking ceremony were investigated. This study extended and partially

supported an investigation reported by Pekala and Ersek in this Journal [1]. Twenty-three participants completed retrospective questionnaire assessments concerning their subjective experiences while walking on hot coals. Results from twelve participants were compared with the participants' own experiences during a baseline condition. The data suggested that attention during firewalking is significantly more "one-pointed" than during a baseline condition, and that consciousness may be characterized as more "hypnoidal" than during a baseline condition. Walking on hot coals was further characterized by trends toward reporting increased altered awareness, altered experience, and absorbed attention. Participants who developed a greater degree of blistering reported significantly greater hypnoidal effects during the firewalk than those who developed a lesser degree of blistering.

Weitzenhoffer, Andre M. (1997). Hypnotic susceptibility: A personal and historical note regarding the development and naming of the Stanford Scales. International Journal of Clinical and Experimental Hypnosis, 45 (2), 126-143.

Certain misleading, if not inaccurate, allegations that have been made regarding the foundations of the Stanford scales are corrected. No special meaning was intended when the scales were designated susceptibility scales. A retrospective examination, however, indicates that grounds existed for making certain differentiations. SHSS:C and RSPS:I and RSPS:II should more appropriately have been designated as suggestibility and depth scales. On the other hand, whereas SHSS:A and SHSS:B also assess depth of hypnosis, they include a feature that permits using the obtained depth as a measure of hypnotic capacity and a predictor of future hypnotic performance. The possibility of using the same measure, suggestibility, to assess hypnotic responsiveness in dissimilar contexts may have been partially responsible for the confusing variety of labels that have been attached to what in the past has appeared to many to be one and the same thing. Further confusion more recently has been introduced by researchers and clinicians who have used the term depth, previously and conventionally attached to assessments based on observed overt responses, in reference to now certain subjectively based assessments.

1996

Cardena, Etzel (1996). "Just floating on the sky:" A comparison of hypnotic and shamanic phenomena. In Quekelberghe, R. V.; Eigner, D. (Ed.), Yearbook of cross-cultural medicine and psychotherapy 1994 (pp. 85-98).

Despite the vastly different cultural contexts of hypnosis and shamanism, a comparison of the phenomenology of the two is warranted.

The author proposes that the two types of very hypnotizable individuals, one exhibiting vivid imagery and the other showing diminished memory and control, corresponds to the classical distinction between soul journey and spirit possession . Other cognitive traits, developmental histories and alternate experiences of hypnotic virtuosos and shamans imply other similarities. The resemblance between hypnotic and shamanic phenomenology strongly suggests a universal disposition that is independent of culture. Western culture should acknowledge, respect and study the potentials and risks of this ability.

Kumar, V. K.; Pekala, Ronald J.; Cummings, James (1996). Trait factors, state effects, and hypnotizability. International Journal of Clinical and Experimental Hypnosis, 44 (3), 232-249.

This study examined the relationship of 15 trait (e.g., absorption, ego-permissiveness) and 21 phenomenological variables (assessed by the Phenomenology of Consciousness Inventory) with performance on the Harvard Group Scale of Hypnotic Susceptibility, Form A. Factor analyses

suggested three trait factors (absorption-permissiveness, general sensation seeking, and social desirability) and five state factors (dissociated control state, positive affect, negative affect, attention to internal processes, and visual imagery). The factors correlated to hypnotizability were absorption-permissiveness, dissociated control, positive affect, and attention to internal processes. In predicting hypnotizability, the amount of variance accounted for by the trait factors was approximately 9%; an additional 22% was accounted for by state factors. The interactions did not account for any additional variance in predicting hypnotizability.

Pekala, Ronald J.; Forbes, Elizabeth J. (1996, August). Types of hypnotically (un)susceptible individuals as a function of phenomenological experience: Towards a typology of hypnotic types. [Paper] Presented at the annual meeting of the American Psychological Association, Toronto, Canada.

Nursing students (N = 194) experienced the Harvard Group Scale of Hypnotic Susceptibility, in which was embedded a 2-min sitting quietly interval subsequent to the eye catalepsy item but prior to the 'counting out' sequence. After the Harvard Scale subjects completed the Phenomenology of Consciousness Inventory (PCI) in reference to the sitting quietly interval embedded in the hypnotic induction ceremony. Participants were divided into low and high susceptible groups. K-means cluster analysis of the subjects' responses to the PCI revealed three groups of subclusters for the high susceptibles. These results partially replicated two prior studies. Cluster analyses were then completed across all subjects, resulting in nine different cluster groups. These groups had different patterns of phenomenological experiences that cut across individual subjects' actual Harvard Scale scores. Implications of the above for (a) working with clients who may not score that high on standard behavioral measures of hypnotizability (such as the Harvard), or (b) understand how hypnosis 'works,' were discussed. (ABSTRACT from Bulletin of Division 30, Psychological Hypnosis, Fall, 1996, Vol. 5, No. 3.)

1995

Gearan, Paul; Schoenberger, Nancy E.; Kirsch, Irving (1995). Modifying hypnotizability: A new component analysis. International Journal of Clinical and Experimental Hypnosis, 43 (1), 70-89.

The effects of the Carleton Skills Training Program (CSTP) on hypnotizability were compared to those of a modified training program in which instructions for physical enactment of the response were omitted. After training, subjects in the original CSTP reported an increase in the extent to which they intentionally enacted suggested behaviors. In contrast, subjects in the modified training program reported increased fantasy without voluntary physical enactment. Nevertheless, both training programs increased behavioral and subjective responsiveness to suggestion, and there were no significant differences in response enhancement between the two programs. Across conditions, increases in behavioral and subjective responses to suggestion were correlated with increased use of fantasy. In contrast, increases in enactment were correlated only with compliance. The modified training program is recommended as a means of enhancing suggestibility with less likelihood than the original CSTP of engendering compliance.

Repka, Renee J.; Nash, Michael R. (1995). Hypnotic responsivity of the deaf: The development of the University of Tennessee Hypnotic Susceptibility Scale for the Deaf. International Journal of Clinical and Experimental Hypnosis, 43 (3), 316-331.

The purpose of these two studies was to develop and test a measure that assesses the hypnotic responsivity of deaf individuals. The University of Tennessee Hypnotic Susceptibility Scale for the Deaf (UTHSS:D) is a signed, videotaped version of a standard hypnotic induction with 12 standard

suggestions. Experiment 1 compared the behavioral and subjective hypnotic responsivity of deaf and hearing individuals using the UTHSS:D and the Field Depth Inventory (FDI), respectively. As compared to hearing subjects, deaf participants were found to be less responsive to hypnosis when assessed behaviorally (UTHSS:D) and equally responsive to hypnosis when assessed subjectively (FDI). Experiment 2 undertook a more comprehensive examination of the hypnotic responsivity of deaf individuals, using hearing individuals as controls. Three dimensions of hypnosis responsivity were assessed: behavioral (UTHSS:D), subjective (FDI), and interpersonal (Archaic Involvement Measure). Additionally, correlates of hypnotic responsivity (absorption, attitudes, expectations) were examined for the two groups. In Experiment 2, no significant differences were found between the deaf and hearing participant groups on any measures of hypnotic responsivity or on any measure of the correlates of hypnotic responsivity.

Woody, Erik Z. (1995, November). Trying, not trying, and trying not to try. [Paper] Presented at the annual meeting of the Society for Clinical and Experimental Hypnosis, San Antonio, TX.

## NOTES

In the "classic suggestion effect" the behavior of a hypnotized person following a suggestion is experienced as nonvoluntary. So alterations of experience are important to understand. We can think of it as a misattribution: which cues lead subjects to misattribute their behavior, etc.

A different view is to see it as how information is processed (neodissociation theory). There are two views of dissociation to consider: 1. Behavior is voluntary, but that voluntariness is blocked from awareness. (The S is trying but doesn't know it consciously.) This is a barrier model of dissociation. The S lacks information about self agency. Bowers calls it a theory of dissociated experience. 2. Underlying control of behavior is altered (not so governed by executive control) and the subject is correct when they say they are not trying. Bowers called this a theory of dissociated control.

A persistent problem is that these two theories of dissociation are incomplete sketches. But cognitive neuroscientists and experimental psychopathologists have recently become interested also, rapidly developing and independently developing the same two theories.

Bowers and I stated that the theory presented by Norman (Norman?) and Shallice is similar to dissociative control theory. When a response is habitual, a lower system called contention scheduling can do it; if response is more complex, a higher control supervisory system involving unique information like goals is available, modulating the lower control system. Volition and how it is experienced depends on the nature of the supervisory system. When it is not [or when it is?] modulating or monitoring the contention scheduling process, one experiences will.

Thus, hypnosis is in the grey zone where the supervisory system monitors without modulation of contention scheduling--a wide realm. Also, for high hypnotizables hypnosis may weaken the higher level control system associated with the subjective experience of will; this dissociates lower levels of control from higher levels of control. The lower levels cannot be modulated as well at will. This indicates changes of frontal functions.

In psychopathology, Chris Frit argues that schizophrenia can be thought of as disorders of volition: 1. Spontaneous self initiated willed actions are generated by a different route to action from unwilled actions. In schizophrenia there is impoverishment of self initiated action. The patient also shows perseverated action. In contrast, when directly instructed the patient can perform complex tasks. This is close to the dissociated control model of hypnosis. Laboratory procedures for studying perseverative acts in schizophrenia can be applied to hypnosis. (However the theory doesn't explain the positive symptoms of schizophrenia.) 2. There is an internal monitor that keeps track of the self initiated aspects of actions (e.g. inner speech), which schizophrenics lack. Likewise delusions of control, due to a failure to track the self initiated aspect of these actions, resemble the dissociated experience aspect of hypnosis.

The Classic Suggestion Effect is a mild delusion of control. This is very different from the social psychological view. Nisbett & Wilson say people do not introspect about the sources of their behavior. In their view, believing that alien forces are controlling you is due to failure of a mechanism. It is an interesting alternative to social psychological misattribution models to explain the nonvoluntary experience.

Functional brain imaging of normal subjects indicates that willed actions involve different areas of brain than nonvoluntary actions. Current thinking is that what differentiates schizophrenics from normals is in how their separate brain regions interact with each other. (This view is consistent with the research of Crawford and others on brain areas involved in hypnosis.) 3. There is a unifying mechanism of meta-representation or second order representations ("mentalizing") which are distinct from normal representations of reality. Consider the example of the suggestion to hallucinate a fly on the Harvard Form A Group Scale. The hypnotist wants me to believe that a fly is buzzing around me. If the second order representation is not there, only the first order representation is there: "a fly is buzzing around me." This is in Frit's theory's term a dementalized experience. The "dementalized experience" is a bit like Sarbin's believed in imagining. Low hypnotizables are plagued with meta-representation ("trying not to try").

Frit's work even suggests some parts of neodissociation theory may be a better representation of schizophrenia than of hypnosis.

Zamansky, Harold S.; Ruehle, Beth L. (1995). Making hypnosis happen: The involuntariness of the hypnotic experience. International Journal of Clinical and Experimental Hypnosis, 43 (4), 386-398.

The authors tested the hypothesis that hypnotized individuals do not truly experience their responses to suggestions as occurring involuntarily, but instead absorb themselves in imagery that is congruent with the suggestions while avoiding critical thoughts, or even simply comply with suggestions without genuinely experiencing their responses as nonvolitional. Participants were instructed to engage in thoughts and imagery that conflicted with the suggestions given, were urged to pay attention to their behavior, and were questioned regarding the perceived involuntariness of their responses. Simultaneously, electrodermal skin conductance responses provided a measure of the truthfulness of their reports. It was found that responses to all hypnotic suggestions were reported as being involuntary, in spite of the conflicting imagery and increased saliency, and that these reports were truthful. These findings provide disconfirming evidence for the sociocognitive theories of hypnosis.

1994

Varga, Katalin; Banyai, Eva; Gosi-Greguss, Anna C. (1994). Parallel application of the experiential analysis technique with subject and hypnotist: A new possibility for measuring interactional synchrony. International Journal of Clinical and Experimental Hypnosis, 42 (2), 130-139.

The Parallel Experiential Analysis Technique (PEAT), a new method for gathering data on the subjective experiences of both the hypnotist and the subject, is described. The PEAT is an interactional modification of the Experiential Analysis Technique (EAT). Procedural details and methodological observations resulting from the modification of the EAT are discussed. Suggestions on how to characterize the phenomenology of the hypnotic interaction and to determine the degree of interactional synchrony on the subjective level between the hypnotist and subject are made.

1993

Kronenberger, William G.; La Clave, Linda; Morrow, Catherine (1993, October). Assessment of the hypnotic state in the clinical setting: Development of the hypnotic state assessment questionnaire.

[Paper] Presented at the annual meeting of the Society for Clinical and Experimental Hypnosis, Arlington Heights, IL.

## NOTES

We do research, clinical work and teaching. In this setting students ask, how do I know when somebody is hypnotized? We wanted to give them a normative sense of what to expect. Supervisory issues arise--e.g. when student reports that a patient "looked very hypnotized." We also wanted a measure that could track changes from one hypnotherapy session to another. We wanted quantification of hypnotic response (e.g. to use in medical charts).

We looked at self report measures, reviewed by Tart (number ratings) and hypnotizability scales; we reviewed articles, looked at what we teach, etc.. Criteria for the scale we developed were: 1. brief 2. unobtrusive (not introducing something different into the hypnosis process) 3. easy to use 4. have both behavioral and subjective components 5. clinically useful 6. apply to wide age range (we have patients ages 7-60) 7. apply to many different types of inductions (though there is no clinical scale that will apply to all types of inductions). We use a more permissive, relaxation induction ourselves.

We assessed observed behavior during hypnosis as well as immediately following hypnosis, and then asked patients questions about what the experience was like for them. From their responses we developed the Hypnotic State Assessment Questionnaire. The scale has 18 items, as follows: 1.

Hypnotic State Observation (HSO) Items

Noise Factor (e.g. drumming fingers)

Noise

Spontaneous Verbalizations

Behavior Factor

Motoric behavior (spontaneous)

Focused attention (not moving eyes)

Rhythmical Breathing

Relaxed state/Lack of tension Each are coded 1-5 with behavioral anchors at 1, 3, and 5 2. Post Hypnotic Observations

Positive Experience Factor (rated Yes-No)

Smile

Spontaneously Verbalize Positive Experiences 3. Post Hypnotic Inquiry

Automaticity Factor

Thoughts/feelings happen by selves

Thoughts happen without trying to think

PHI Uniqueness/Relaxation Factor

Felt this way before (not hypnosis)

Interrater Reliabilities of Subscales are higher than .9 except for Waking (rubbing eyes and stretching). We studied the HSAQ in 50 patients with a variety of problems (anxiety, depression, eating problems, smoking, somataform problems).

Scores have a floor effect; HSAQ can't determine very high depth from moderate depth, but we don't know if that is clinically meaningful. The HSO behavior factor was significantly correlated with after-hypnosis observations and inquiry. The HSO behavior factors also significantly correlated with the patient's ability to resist unexpected distractions, to comply with therapist requests, and to respond to post-hypnotic suggestions.

Nishith, Pallavi; Barabasz, Areed F.; Barabasz, Marianne (1993, October). Effects of Alprazolam and hypnosis: EEG spectral decomposition and transient experience. [Paper] Presented at the annual meeting of the Society for Clinical and Experimental Hypnosis, Arlington Heights, IL

## NOTES

We wanted to test Hilgard's neodissociation theory and Crawford's and my ideas about theta reflecting processing dissociation where environmental stimuli are ignored.

Hypothesis: highs would show greater EEG theta in hypnosis than lows when exposed to a suggestion to recreate alprazolam (trade name Xanax) effects.

We demonstrated hypnosis to groups, discussed it, administered the Harvard, took highs and lows and then tested them with Stanford C; got 20/group, matched for age, gender, and handedness. Assigned 10/cell, in drug or placebo (double blind) conditions. Tested females to make sure they weren't pregnant. Ingested the placebo or drug, waited 1 hour; took 5' waking EEG while they were asked to focus on "feelings of relaxation brought on by the drug." Interviewed them (see our chapter in Fromm & Nash book) to determine their transient mood states during the 5' period, plus gave them POMS tension/anxiety questions.

Results of first study: analyzed for hypnotizability x placebo x drug condition. EEG Theta was reduced in hypnosis; hypnotic ability showed no effects. Highs maintained higher beta in alprazolam drug condition (vigilance).

Study 2 counterbalanced conditions: Waking Hypnosis Hypnosis with a suggestion to recreate alprazolam effects.

Used Ss who actually had taken Alprazolam participated in the experiment four days later; induction was a tape recorded version of the Stanford Clinical Scale. Suggestion: imagine taking a dose twice as high as you had before. EEG and transient experience data were collected as before. 2 x 3 Manova's were computed. 1. Theta was higher for highs than lows at  $p < .01$  for both the hypnosis and hypnosis with drug effects suggestion conditions. 2. Alpha - had the same findings as for theta. (and same results as in our Antarctica study). 3. Beta was significantly higher for both high and lows in waking vs hypnosis conditions at all but the T4 site where beta was highest in the two hypnosis conditions only for the highs. 4. POMS analysis: mean tension/anxiety scores were significantly lower for highs in both the alprazolam and hypnotic suggestion conditions.

Both highs and lows showed more theta in hypnotized than in waking conditions. Failure to find differences between groups differing in hypnotizability may be because highs were so good at creating the alprazolam effect that they may have desynchronized theta.

Pekala, Ronald J.; Ersek, Barrett (1993). Firewalking versus hypnosis: A preliminary study concerning consciousness, attention, and fire immunity. Imagination, Cognition and Personality, 12, 207-229.

This study assessed the subjective effects associated with firewalking, and compared them with the subjective effects associated with hypnosis and a baseline condition (eyes closed sitting quietly). Twenty-seven subjects, who walked over hot coals during a firewalk ceremony, completed questionnaires about what they subjectively experienced during the firewalk. Their experiences were subsequently compared with those of subjects (n = 246) who experienced hypnosis and a baseline condition. The data suggested that firewalking, as assessed across all subjects, is characterized by high levels of volitional control and rationality, and a very absorbed attentional style wherein the mind is one-pointed, and consciousness is characterized by strong feelings of joy and high levels of internal dialogue. Firewalking was also found to be associated with significantly more joy, one-pointedness of thought, absorption, and internal dialogue than hypnosis or the baseline condition. In addition, a cluster analysis suggested two subgroups of firewalkers based on their subjective experiences of the firewalk. Interestingly, analyzing the attentional experiences among these firewalkers who got slightly burned, versus those who did not, revealed significant differences. A one-pointed and absorbed attentional focus may be the critical variable for the fire immunity observed in firewalking.

## NOTES

About 500 people walked across coals, in 3-4 steps. At end of weekend, 71 said they would complete a questionnaire and it was mailed to them. Of those, 27 responded (25 of 26 in an average of 23 days). Hence, 5% of the population who walked responded to the questionnaire, and it was some time later. Three of 24 reported minor blisters. Those who didn't get burned reported less detachment, less of a feeling of being out of their bodies, and more thoughts than the firewalkers who got slightly burned.

Pekala has defined an altered state of consciousness as associated with the perception of being in an altered state of awareness (the *\_subjective sense\_ of \_altered state\_ --SSAS [30]*), and a change in the patterning or configuration of the subsystems or dimensions of consciousness. A discrete state of consciousness, as defined by Pekala, is associated with a significant pattern change but no perceived alteration in state of consciousness (no SSAS). An identity state of consciousness, on the other hand, is defined as having neither a significantly perceived alteration in state of awareness nor a perceived pattern change among dimensions of consciousness in reference to another state of consciousness. Since the PCI can measure both intensity and pattern effects, it can be used to assess for altered, discrete, and identity states of consciousness.

Using a cluster analysis they found that one group of 16 subjects reported the firewalk experience to be characterized by a significant alteration in awareness and experience (body image, time sense, etc.), and significant intensities of internal dialogue, positive and negative affect, and arousal, while a second group of six subjects reported little alteration in consciousness or experience, little losses in rationality or control, and less internal dialogue, positive and negative affect or arousal than the larger group.

Whereas hypnosis is usually associated with a loss in control (the classic suggestion effect), firewalking was found to be associated with increased control, a more aroused state, and more fear! Firewalking appears to be a more absorbed and one-pointed state than even hypnosis.

The nature of attentional experience is similar across firewalkers (DAQ results).

Both firewalking and hypnosis meet the criteria for altered states of consciousness (different pattern and different subjective experience), but they are not altered states in reference to each other; they are *\_discrete states of consciousness\_* in reference to each other, because there is a significantly different patterning of PCI dimensions between the two conditions, but no significant SSAS. This suggests that the firewalk state is qualitatively different from the hypnotic state (as induced by the induction procedure to the Harvard Scale) and probably represents a different type of state of consciousness than hypnosis. Firewalkers obtained a lower mean hypnoidal state score than hypnosis subjects, so it does not appear that the fire immunity is due to being in a "hypnotized" state.

The fact that there appears to be two groups of successful firewalkers, one of which did not report much alteration in consciousness, calls into question the theorizing concerning the importance of alteration in state of consciousness as being etiologically related to successful firewalking. Since about 25 percent of the firewalkers clustered into what appears to be a nonaltered state of awareness, this suggests a sizable percentage of subjects who did not report any significant alteration in consciousness and experience.

Hence, what may be important is not an alteration in consciousness, but rather an alteration in attention. The cluster analysis revealed a relatively unitary attentional state across all subjects suggesting that attention was deployed in a rather similar manner across all subjects, that is, with very high absorption and one-pointedness. It was also the DAQ dimensions, and not the PCI dimensions, that successfully discriminated a trend between the blistered and nonblistered firewalkers. Hence, high levels of one-pointedness and absorption, that is, how attention is deployed during firewalking may be more critical (than an alteration in consciousness in general) for the fire immunity observed during firewalking.

Spanos, Nicholas P.; Burnley, M. C.; Cross, P. A. (1993). Response expectancies and interpretations as determinants of hypnotic responding. *Journal of Personality and Social Psychology*, 65, 1237-1242.

Subjects rated the extent to which they expected to respond to each of the suggestions on a hypnotizability scale both before and after the administration of the preliminary hypnotic-induction procedure. After the induction, subjects also rated the extent to which they planned to respond actively and passively to each suggestion. Contrary to strong versions of response-expectancy theory, the extent to which subjects planned to adopt an active interpretation predicted behavioral and subjective indexes of hypnotizability even after controlling for the effects of postinduction expectations. In addition, an active interpretation significantly predicted response to suggestion for which subjects held weak and uncertain expectations. The relationship between expectation and hypnotizability was found to be fan-shaped rather than linear. Implications are discussed.

Spinhoven, Philip; Vanderlinden, Johan; ter-Kuile, Moniek M.; Linseen, A. Corry G. (1993). Assessment of hypnotic processes and responsiveness in a clinical context. International Journal of Clinical and Experimental Hypnosis, 41 (3), 210-224.

The present study was designed to investigate in a clinical situation whether differences in measured hypnotizability validly reflect differences in hypnotic processes and to what extent factors deemed extraneous to hypnosis -- such as resistance -- influence hypnotic responding. To answer this question, Dutch versions of relevant scales had to first be developed. The factorial validity and reliability of a Dutch translation of the Resistance Toward Hypnosis Scale (DRHS) and a shortened Dutch version of the Phenomenology of Consciousness Inventory (DPCI) were investigated in a sample of 205 psychiatric patients. The DRHS proved to be factorially valid and reliable, and two subscales, Trance and Reality Orientation, derived empirically from the DPCI showed good to satisfactory reliability. In a second study with a subsample of 99 psychiatric patients, hypnotizability as measured by the Stanford Hypnotic Clinical Scale for Adults was strongly and positively related to DPCI Trance scores and moderately and negatively related to DPCI Reality Orientation and DRHS Resistance scores. It is concluded that hypnotizability as measured in a clinical context under standard conditions is strongly related to hypnotic experiences over and above the moderate effects of resistance toward hypnosis and hypnotic suggestions. Standard hypnotizability assessments appear to be similar in their meaning in an experimental and clinical context.

Szabo, Csaba (1993). The phenomenology of the experiences and the depth of hypnosis: Comparison of direct and indirect induction techniques. International Journal of Clinical and Experimental Hypnosis, 41, 225-233.

The effect of two hypnotic induction styles on subjective experience was measured in an experiment in which 44 subjects participated in both traditional direct hypnosis, induced by the Stanford Hypnotic Susceptibility Scale, Form A, and indirect hypnosis (presented in counterbalanced order), followed by 4 minutes of rest before dehypnosis. The depth of hypnosis was measured retrospectively by a subjective scale, and the structure of experiences was measured by the Phenomenology of Consciousness Inventory. Subjects were subsequently administered the Stanford Hypnotic Susceptibility Scale, Form B, so that awareness of their hypnotizability would not affect their subjective depth reports. No differences were found in a comparison of subjects' structure of experiences in direct and indirect hypnosis. In addition, low and medium hypnotizable subjects reported indirect hypnosis as deeper. This may reflect the possibility that while hypnotized different mechanisms come into play for subjects high in hypnotizability compared to those who are less hypnotizable.

Kirsch, Irving (1992). The state of the altered state debate. Contemporary Hypnosis, 9, 1-6.

The question of whether hypnosis is an altered state of consciousness remains meaningful, despite declarations that it is a dead issue. Reports of its demise were based on a redefinition of the term 'state' which rendered the state hypothesis untestable. However, most state theorists use the term in its more conventional sense. Although these state hypotheses cannot be falsified, they can potentially be confirmed. They also have important implications, which make empirical data on the altered state issue as important now as they were 20 years ago.

Kirsch, Irving; Mobayed, C. P.; Council, J. R.; Kenny, D. A. (1992). Expert judgments of hypnosis from subjective state reports. Journal of Abnormal Psychology, 101, 657-662.

Suggestibility was assessed in 60 student subjects after a traditional hypnotic induction, an alert induction, progressive relaxation training, or instruction in goal-directed imagery. Responsiveness to suggestion did not differ between groups. Subjects also generated open-ended reports of their states of awareness and of their experience of three hypnotic suggestions. A sample of these reports from 24 moderately to highly suggestible subjects was evaluated by 18 experts in the field of hypnosis. Expert ratings of subjects' open-ended reports indicated that (a) traditional hypnotic inductions produce a state of consciousness that is indistinguishable from nonhypnotic relaxation training, (b) the subjective experience of hypnotic suggestions after imagination training is indistinguishable from that after hypnotic inductions, and (c) suggestibility is unrelated to state of consciousness as assessed by experts.

Matthews, William J.; Isenberg, Gail L. (1992). Hypnotic inductions with deaf and hearing subjects - an initial comparison: A brief communication. International Journal of Clinical and Experimental Hypnosis, 40 (1), 7-11.

17 volunteer deaf Ss were compared with 18 volunteer hearing Ss on the Stanford Hypnotic Clinical Scale (SHCS) of Morgan and J. R. Hilgard (1975), and the Indirect Suggestion Scale (ISS) of Matthews and Mosher (1985) in a 2 x 2 ANOVA design. 5 dependent measures: (a) objective scale score; (b) self-report scale score; (c) S rapport with the hypnotist; (d) S resistance to the hypnotist; and (e) overall subjective rating of trance experience were employed to measure any differences between the 2 groups. For SHCS behavioral items, the two-way ANOVA failed to reveal any significant main effect or interaction differences between either group (deaf/hearing) or method of induction (direct/indirect). There was a significant main effect for deaf/hearing groups in level of resistance to the hypnotist. Deaf Ss reported feeling more resistant to the hypnotist than did hearing Ss. This may be due to the mode of communication or the fact that the hypnotist was hearing. Implications and limitations of the study are discussed.

Sheehan, Peter W. (1992). The phenomenology of hypnosis and the Experiential Analysis Technique. In Fromm, Erika; Nash, Michael R. (Ed.), Contemporary hypnosis research (pp. 364-389). New York: Guilford Press.

## NOTES

The problem with behavioral assessment methods such as hypnotizability scales is that similar behavioral responses to hypnotic suggestions may occur for very different reasons. It is important to assess the phenomenological experience of hypnotic Ss. The Experience Analysis Technique (EAT) is a method for assessing the phenomenology of hypnosis. The EAT "consists of gathering the comments of hypnotic subjects about their hypnotic behavior and experience, as they view the video playback of their hypnotic sessions" (p. 372). The EAT draws its origins from Kagan's method of Interpersonal

Process Recall [IPR], in which "counselors in training could review and react to, their contact with clients immediately after therapy sessions. An independent person, present at the review of the session, would inquire into the interaction between the counselor and client by stopping the tape and questioning the client about his or her underlying feelings and thoughts, so facilitating and clarifying the information being recalled" (p. 371). It is important that the interviewer be a different person than the hypnotist.

Hammer, Walker & Diment (1978) applied the IPR to hypnosis, using audiotape. Using the videotape EAT with hypnosis, Sheehan & McConkey (1982; Sheehan, McConkey & Cross, 1978) noted that hypnotic Ss might exhibit any of three different response styles, sometimes related to hypnotic task complexity: 1. Concentrative/cooperative style - S focuses on hypnotist's words, imagining a literal interpretation 2. Independent style - S interprets hypnotist's words in a way that is meaningful to them 3. Constructive style - S considers the communications "from a position of preparedness to process incoming stimuli in a schematic way, so as to structure or re-organize events according to the hypnotist's suggestions"

Some Ss who are high in susceptibility show greater flexibility in the use of cognitive styles than low susceptibility Ss.

Examples of the use of the EAT to evaluate several phenomena observed in experimental and clinical settings are provided: 'duality' during age regression, trance logic, posthypnotic amnesia, pseudomemories, and rapport.

The author reviews the concept of 'countering.' "Countering occurs when a S responds in accord with the wishes of the hypnotist when social influences to respond otherwise are also present in the situation. ... Counterers display a constructive (i.e. active and idiosyncratic) style of cognizing which enables them to make personal sense of the conflicting demands by preserving the integrity of each. ... Counterers, even though they demonstrate a higher degree of involvement with the hypnotist, fail reliably to score as highly on standard tests of susceptibility (e.g. the Stanford Hypnotic Susceptibility Scale, Form C) as subjects who do not counter (Sheehan, 1980). This second finding points to differential effects of rapport on Ss which are not explicable in terms of level of hypnotic susceptibility or simple willingness to comply with anticipated, obvious suggestions. Techniques like the EAT, which are sensitively attuned to detect the personal commitment of subjects to the hypnotist, are needed to detect subtle processes of this kind" (pp. 385- 386).

The author evaluates different reporting techniques used to examine the phenomenological experience of hypnosis (the Chicago Paradigm of Fromm & Kahn, 1990; Shor's phenomenological method; the Field's Inventory Scale of Hypnotic Depth) and evaluates the effects of rapport with the E on the measurement of subjective response. He suggests various experimental controls (e.g. disguising the true aims of the experiment). A measure of rapport or psychodynamic transference to the hypnotist, the Archaic Involvement Measure (AIM) has been developed by Nash and Spinler (1989).

"Experience cannot simply be observed objectively; it may not be reported spontaneously by the experienter; and it may not even be elicited through ordinary forms of interaction" (p. 388).

"What phenomenological research has shown over the last decade is that hypnotic experience is both multifaceted and complex. It has given us a view of the hypnotic subject as a person who participates actively in the hypnotic process, who is susceptible to the influence of motivations and expectations, and who employs a variety of cognitive strategies so as to manage and respond to multiple levels of communication received in the hypnotic setting. Standard techniques of assessment, especially those emphasizing the primacy of behavioral data and those offering structured choices, are not equipped to reveal the full meaning of hypnotic responsiveness" (p. 388).

"If an instrument of assessment assumes a unidimensional underlying process when there are multiple dimensions operating, then that instrument will be deficient in measuring experience by producing equivalent ratings for very different experiences, and thus will be deficient in measuring overall

experience. Measurement of trance-depth poses just such a problem, and measurement of hypnotic experience in its full complexity even more so" (pp. 388-389).

Brown, Jason W. (1991). Self and process: Brain states and the conscious present. New York: Springer-Verlag.

## NOTES

Author, from the Department of Neurology at New York University Medical School, presents a theory about the genetic unfolding of mental content (mind) through stages, from mental state into consciousness or into behavior. He relates the genesis of mind to brain development but avoids assuming that there is a straightforward correlation between brain development (e.g. myelination) and cognitive development or perception. To some degree, the theory is based on subjective report data and psychological symptoms. The author discusses issues that bear on the phenomena of nonvoluntary responding and dissociation that are reported or described by hypnotized persons.

"The nature of the mental state will determine the relation between self and world, and thus the interpretation given to agency and choice. ... The crossing of the boundary from self to world is a shift from one level in mind to another" (pp. 10-11).

"... if we begin with mind as primary and seek to explain objects from inner states and private experience, the discontinuity between inner and outer evaporates: mind is everywhere, a universe. ... Whereas before we thought to perceive objects, now we understand that we think them" (p. 19).

"The concept of a stratified cognition is central to the notion of a mental state .... This entails an unfolding from depth to surface, not from one surface to the next, a direction crucial to agency and the causal or decisional properties of consciousness" (p. 52). By unfolding from depth to surface, he means from Core, through Subconscious, then Conscious Private Events, and finally Extra-Personal Space.

He goes on to provide a definition of mental states. "A mental state is the minimal state of a mind, an absolute unit from the standpoint of its spatial and temporal structure. ... The state also has to include the prehistory of the organism. ... The concept of a mental state implies a fundamental unit that has gestalt-like properties, in that specific contents-- words, thoughts, percepts--appear in the context of mind as a whole (p. 53).

"The entire multitiered system arborizes like a tree, with levels in each component linked to corresponding levels in other components. For example, an early (e.g., limbic) state in language (e.g., word meaning) is linked to an early stage in action (e.g., drive, proximal motility) and perception (e.g., hallucination, personal memory) .... In sum, a description of the spatial and temporal features of a single unfolding series amounts to a description of the minimal unit of mind, the absolute mental state" (p. 54).

The author's discussion of an individual's physical movement relates to the concept of nonvoluntary movement (or movement without awareness of volition) in hypnosis. "More precisely, levels in the brain state constitute the action structure. As it unfolds, this structure generates the conviction that a self-initiated act has occurred. This structure--the action representation--does not elaborate content in consciousness. ... As with the sensory-perceptual interface, the transition to movement occurs across an abrupt boundary. In some manner, perhaps through a translation of cognitive rhythms in the action to kinetic patterns in the movement, levels in the emerging act discharge into motor (physical) events" (p. 57).

"The self has the nature of a global image or early representation within which objects-to-be are embedded. ... The self is the accumulation of all the momentary cognitions developing in a brain configured by heredity and experience in a particular way (p. 70).

"The deposition of a holistic representation ... creates the deception of a self that stands behind and propagates events. The feeling of the self as an agent is reinforced by the forward thrust of the process

and the deeper locus of the self in relation to surface objects. The self appears to be an instigator of acts and images when in fact it is given up in their formation. The self does not cause or initiate, it only anticipates (p. 70).

The foregoing notes cover only the first five chapters, less than half the book. Other chapters relevant to hypnosis would be those titled 'The Nature of Voluntary Action,' 'Psychology of Time Awareness,' 'From Will to Compassion,' and 'Mind and Brain.'

Glicksohn, Joseph; Mourad, Boaz; Pavell, Eyal (1991-92). Imagination, absorption and subjective time estimation. Imagination, Cognition and Personality, 167-176.

We report an exploratory study that investigated the interaction of trait and task in determining duration judgment. High and low absorption subjects (determined by median split along the Absorption Scale) viewed a series of paired slides, and were required to relate to each pair in one of two tasks: A metaphor-production task, and a story-production one. These tasks were carried out for an objective interval of fifteen minutes, following which the subject was required to verbally estimate this duration, retrospectively. In addition, from the individual protocols we measured the average time till response and the average time of response. A significant interaction between absorption and task was obtained for the latter two variables. In addition, a main effect for task was found for the duration estimation. These and other results are assessed in terms of both a cognitive-timer model for time estimation and a contextualistic approach to temporal processing.

## NOTES

The authors used a model for subjective time estimation (STE) that involves a cognitive timer (or internal clock) that encodes temporal information. STE purportedly may be correlated with the amount of attention directed at the passage of time, and negatively correlated with attention paid to other kinds of tasks.

They used tasks that aroused Subjects' imagination--a series of pairs of slides. One group was to produce a metaphor relating the two slides, while the other group was to produce a short story relating the two--theoretically an easier task.

The authors hypothesized that high absorption Ss would be more engrossed in the task than low absorption Ss, and therefore would underestimate the amount of time used for the task irrespective of task difficulty. For the low absorption Ss they predicted that time estimates for the more difficult metaphor task should be longer, because the task itself demanded more attention than the other task. (High absorption Ss would not exhibit such a difference.)

As another measure, Subjects were required to produce four short time intervals (4, 8, 16, and 32 seconds) to assess whether there might be a different rate of the cognitive timer for the two types of Ss, irrespective of nontemporal task involvement.

26 Ss were randomly allocated to one of two conditions (metaphor task or story task). Since this number of Ss is too small for an adequate evaluation of the interaction effect (absorption x task) of particular interest, the authors regard the experiment as exploratory only.

The results suggest that high absorption Ss view the tasks as easy and pleasant relative to the lows, and have larger STE values. Shorter time estimates are associated with the metaphor task than the story task, for both highs and lows--an unexpected finding. While highs take the same amount of time for metaphor production as for story production, lows take longer to produce a metaphor than a story (and of course, the metaphor is shorter in length!)

The high absorption Ss provided larger estimations of time for the task in which they produced a required number of seconds (4, 8, etc.), indicating a slower baseline rate of functioning of the cognitive timer.

The authors in their discussion find the results supportive of the cognitive timer model. They cite the finding that duration estimate was predicted from STE, task, and interaction of absorption with average time to response. (1) remembered duration was positively correlated with baseline functioning of the cognitive timer (STE) (2) remembered duration was negatively correlated with task difficulty (3) remembered duration was an interactive function of absorption and average time to response.

Kinnunen, Taru; Zamansky, Harold S.; Block, Martin L. (1991, August). Is the hypnotized subject lying?. [Paper] Presented at the annual meeting of the American Psychological Association, San Francisco.

To determine whether or not hypnotized subjects misrepresent or lie about their hypnotic experiences, electrodermal skin conductance responses were measured while groups of deeply hypnotized subjects and simulators responded to questions about their experiences to a series of suggestion. 89% of the responses of the hypnotic subjects met the criteria for truthfulness, while 65% of the responses of the simulators indicated deception. Differences between "reals" and simulators were highly significant. The relevance of the results for the nature and theory of hypnosis is discussed. (ABSTRACT from Bulletin of Division 30, Psychological Hypnosis, Provided by former Editor, James Council.)

Pekala, Ronald J. (1991). Hypnotic types: Evidence from a cluster analysis of phenomenal experience. Contemporary Hypnosis, 8, 95-104.

The phenomenological experiences of very-low and very-high, and low, medium and high susceptible individuals were cluster analyzed, attempting to determine if individuals of differing levels of hypnotic susceptibility report experiencing different types of phenomenological experience during hypnosis. Phenomenological experience was assessed by means of a self-report questionnaire called the Phenomenology of Consciousness Inventory (PCI); it allows for quantification of 12 dimensions of phenomenological experience. K-means cluster analysis yielded two relatively distinct clusters of individuals for both low/very-low and high/very-high susceptible individuals. These results suggest at least two types of very-low/low and very-high/high susceptible individuals as determined by their reported experiences during hypnosis.

## NOTES

The author notes that Sheehan and McConkey (1982) found three types of highs: concentrative, independent, and constructive. Spanos, Lush & Gwynn, 1989, found two groups of lows--one capable of learning hypnotic skills and the other less so.

In this study the author did two cluster analyses: (1) Harvard lows (0-1) and highs (11-12), and (2) all subjects divided into lows, mediums and highs, with cluster analyses performed separately for these three groups.

In the first analysis, there were two groups of very low hypnotizable subjects distinguished on the basis of altered state of awareness and rationality; and two very high groups, distinguished on the basis of imagery and positive affect.

One group of very lows reported "little alteration in altered state and altered experience and almost complete volitional control, self-awareness, rationality and memory" (p. 98) and were called 'classic very lows' because they were like refractory subjects in their self reports. The other group of very lows reported "moderate alterations in altered state and altered experience, and major decrements in volitional control, self-awareness, rationality and memory" (p. 98) and were called 'pseudo very lows' because their reports were a little like medium or high hypnotizables.

One group of very high hypnotizables had "great alterations in state of consciousness and moderate altered experiences; a loss of control, self awareness, rationality and memory; and little vivid imagery" (p. 98) and were called 'classic very highs' because their reported experience was like that of somnambules. The other type of highs were called 'fantasy very highs' because they had "moderate

alteration in consciousness and experience, a great deal of vivid imagery, moderate positive affect, and only mild-to-moderate losses in rationality and memory" (p. 100).

When low, medium, and high susceptible subjects' PCIs had separate cluster analyses, the lows had three clusters: classic, dialoging, and pseudo lows. The dialoging group was between the other two in their experiencing yet reported a great deal of internal dialogue. Among the highs, the same two clusters appeared as for the very highs.

Among the mediums there were two groups: high mediums who reported a significant drop in volitional control, self-awareness, rationality, memory, and internal dialogue, and an alteration in state of awareness; and low mediums who had milder changes.

Comparing results to Sheehan and McConkey (1982), the classic highs may correspond to their concentrative type and the fantasy highs to their independent type, because the latter generated imagery without a request to do so.

Regarding the pseudo-lows, "it is intriguing that there appear to be some individuals who make little response on the behaviorally oriented Harvard Scale, and yet report some phenomenological alterations. Are they individuals for whom hypnosis may be somewhat more effective even though they are not that hypnotizable (as measured by the 'direct' Harvard Scale) or could they be Spanos's (Spanos et al., 1989) 'trainable' low susceptibles?" (p. 102).

Richards, D. G. (1991). A study of the correlations between subjective psychic experiences and dissociative experiences. Dissociation, 19, 83-91.

Subjective psychic experiences, such as telepathy, clairvoyance, and out-of-body experiences, are often reported in conjunction with dissociative experiences. This study examined the relationship between the Dissociative Experiences Scale and a variety of psychic experiences in a nonclinical population with a high level of psychic experiences. The DES correlated moderately (.3 to .4) with most but not all of the experiences. The mean DES score was 17.2 (SD = 12.5), substantially above adult norms. Although psychic experiences are correlated with dissociation, they are not necessarily associated with pathology.

Sheehan, Peter W. (1991). Hypnosis, context, and commitment. In Lynn, S. J.; Rhue, J. W. (Ed.), Theories of hypnosis: Current models and perspectives (pp. 520-541). New York: Guilford Press.

## NOTES

"There are several different ways to classify the model that is expounded in this chapter. One may view it ... as an individual-differences model of hypnosis, because it emphasizes the significance of intragroup differences in the pattern of hypnotic performance. Alternatively, one may view it as a phenomenologically based model.... Invariably, however, single categories fail to do justice to the nature of theories, and hence it is perhaps wisest to view this theory as a means of exploring particular hypotheses about hypnotic phenomena that focus primarily on the meaning of suggestion as perceived by susceptible subjects. This model focuses, in a way that most other theories do not, on the motivational implications of the cognitive involvement of the susceptible subject in the events of the hypnotic setting. It offers a variant of contextual theories of psychological functioning, but is experiential in its emphasis rather than simply behavioral" (p. 537).

## 1990

Kirsch, Irving; Council, James R.; Wickless, Cynthia (1990). Subjective scoring for the Harvard Group Scale of Hypnotic Susceptibility, Form A. International Journal of Clinical and Experimental Hypnosis, 38 (2), 112-124.

A scale is presented which assesses subjective experiences associated with the test suggestions contained in the Harvard Group Scale of Hypnotic Susceptibility, Form A (HGSHS:A) of Shor and E. Orne (1962). This scale, along with the standard HGSHS:A self-scoring test booklet, was administered

to 479 students at the University of Connecticut and 618 students at North Dakota State University, and normative data from these samples are reported. Correlational analyses indicated that the scale was both reliable and valid as a measure of hypnotic responsiveness. It is suggested that it may be useful to supplement behavioral scoring of hypnotizability with subjective scoring.

Pekala, Ronald J.; Forbes, Elizabeth J. (1990, Spring). Subjective effects of several stress management strategies: With reference to attention. Behavioural Medicine, 39-43.

This study assessed variations in reported attentional experience associated with several stress management techniques (hypnosis, progressive relaxation, deep abdominal breathing) and baseline (eyes closed) as a function of hypnotic susceptibility. Three hundred nursing students experienced the stress management conditions and afterward completed a self-report inventory, the Dimensions of Attention Questionnaire (DAQ), in reference to each condition. The DAQ quantifies 12 aspects of attentional experience in a reliable and valid manner. The results demonstrated that progressive relaxation, hypnosis, and deep abdominal breathing are characterized by differences in reported attentional experience that are further moderated by an individual's hypnotic susceptibility. The clinical implications of these results are discussed.

#### NOTES

"Significant main effects were found for conditions for perspicacity, absorption, and control, with progressive relaxation associated with increased perspicacity and absorption, but with decreased control vis-a-vis hypnosis.

"Significant main effects for groups were found for perspicacity, locus, direction of attention, absorption, control, and vigilance. ... [Post-hoc comparisons] revealed that high susceptibles (vis-a-vis low susceptibles) reported increased perspicacity, absorption, a more inward-focused attention, more feelings of being out of their bodies, and decreased control and vigilance. High-mediums were also different from lows (in the same direction) for all of the above comparisons except for direction of attention. Low-mediums, along with lows, were different from highs for absorption and control.

"Significant interactions between conditions and groups were found for absorption, control, and vigilance. Whereas low susceptibles reported significantly increased absorption but significantly decreased control and vigilance during progressive relaxation than during hypnosis, high susceptibles reported no significant differences between relaxation and hypnosis for absorption, control, or vigilance" (p. 41).

The authors describe the differences found for deep abdominal breathing on p. 41.

"The interaction effects suggest that the experience of hypnosis and progressive relaxation are moderated by a person's hypnotic susceptibility--low susceptibles experience significantly greater absorption, but decreased control and vigilance during progressive relaxation than during hypnosis, although there are no such differences for high susceptibles. This suggests that progressive relaxation may be a 'better' procedure than hypnosis to use with low susceptibles, at least if one wants to increase absorption and decrease vigilance and control" (p. 42).

The authors also note that "deep abdominal breathing is associated with increased 'calmness of mind,' in reference to a baseline condition, as demonstrated by increased attentional detachment and equanimity, and decreased vigilance and density (the 'amount' of thoughts going through one's mind)" (p. 42).

Richards, D. G. (1990). Hypnotic susceptibility and subjective psychic experiences. Journal of Parapsychology, 54, 35-51. (Abstracted in American Journal of Clinical Hypnosis, 34, 145-146)

Some studies have shown a correlation between hypnotic susceptibility and self-reports of psychic experiences. This study used a population reporting a very high level of psychic experiences and correlated the Harvard Group Scale of Hypnotic Susceptibility with psychic experiences as measured

by two scales. The mean Harvard score (6.31) was approximately the same as published norms, suggesting that the population was not unusual in terms of hypnotic susceptibility. Studies of people with large numbers of psychic experiences who have low hypnotic susceptibility may aid in understanding other factors that are involved.

Spanos, Nicholas P.; Warnock, Sean; de Groot, Hans P. (1990). Cognitive skill training, confirming sensory stimuli, and responsiveness to suggestions in subjects unselected for hypnotizability. Journal of Research in Personality, 24, 133-144.

Subjects unselected for hypnotizability were administered cognitive skill training which taught them to actively generate hypnotic responses or expectancy enhancing procedures that provided them with sensory stimuli aimed at confirming the false belief that they had successfully experienced suggested effects. Subjects were tested for suggestibility / hypnotizability at the end of their experimental treatment session and again in two follow-up posttests. Skill trained subjects exhibited significantly higher scores than subjects in all other treatments on the behavioral and subjective dimensions of the three suggestibility / hypnotizability tests. Subjects who received confirming stimuli showed higher behavioral scores than no treatment controls only on the behavioral dimension of the first suggestibility test, and no differences from controls on the subjective dimensions of any of the theory tests. Theoretical implications are discussed.

Weekes, John R.; Lynn, Steven Jay (1990). Hypnotic suggestion type, and subjective experience - the order-effects hypothesis revisited: A brief communication. International Journal of Clinical and Experimental Hypnosis, 38, 95-100.

In a replication and extension of Field, Evans, and Orne's (1965) research, no support was found for the hypothesis that suggestion order is related to hypnotic responding. Confirming earlier findings, subjects were no more responsive to suggestions ordered from easy-to-difficult than they were to suggestions ordered from difficult-to-easy. Measures of subjective involvement in suggestions, involuntariness, and archaic involvement with the hypnotist were no more sensitive to order effects, nor were order effects more apparent with subjects who received direct versus indirect suggestions. Confirming earlier research, direct suggestions did facilitate suggestion-related involuntariness and response to the hypnotic amnesia item after cancellation, whereas indirect suggestions enhanced fears of negative appraisal by the hypnotist. Thus, authoritative suggestions enhance responding to a cognitive-delusional item relative to more permissive suggestions. Finally, female subjects were more involved in suggestions than were males, particularly in response to more difficult tests items.

1989

Bryant, Richard A.; McConkey, Kevin M. (1989). Hypnotic blindness: A behavioral and experiential analysis. Journal of Abnormal Psychology, 98, 71-77.

## NOTES

"This research examined the influence of visual information on a decision task that subjects were administered during hypnotically suggested blindness. Real, hypnotizable subjects and simulating, un hypnotizable subjects were tested in two experiments. Experiment 1 focused on behavioral responses, and Exper. 2 focused on experiential reactions. In both experiments, the findings indicated that the behavioral responses of reals were influenced by visual info. despite their reported blindness. The behavioral responses of reals and simulators were essentially similar. The experiential data in Experiment 2 provided information about the phenomenal nature of subjects' reported blindness. The experiential reactions of reals and simulators were essentially different. The research is discussed in

terms of the issues that need to be considered in the development of a model of hypnotic blindness" (p. 71).

Bryant, Richard A.; McConkey, Kevin M. (1989). Hypnotic emotions and physical sensations: A real-simulating analysis. International Journal of Clinical and Experimental Hypnosis, 37, 305-319.

Real hypnotizable Ss and simulating un hypnotizable Ss were administered a suggestion for either happiness, emotional neutrality, or sadness. The emotion was assessed through subjective and behavioral measures taken once before, twice during, and once after the emotion. Findings indicated that emotionally congruent changes occurred in both self-report and performance measures. Ss' physical sensations during the emotion were assessed on a 34-item self-report scale. It was demonstrated that Ss in the happy versus sad conditions reported different physical sensations; in particular, they reported different facial sensations. The responses of real hypnotizable subjects, however, were essentially paralleled by those of simulating un hypnotizable subjects. Therefore, the possibility exists that hypnotized subjects may have been responding on the basis of social demands. The findings are discussed in terms of the effects of the emotion suggestions, and the implications of real and simulating Ss displaying similar affective responses.

#### NOTES

Used the real-simulating model in an attempt to eliminate the possibility that hypnotized Subjects in previous studies may have been responding to the demand characteristics of the situation. Used both subjective and behavioral measures. Self-report happiness and sadness, of emotion intensity; behavioral performance measure of speech rate, indexed by counting speed (which has been shown to distinguish between happiness and sadness). Used 34-item self-report Physical Sensations Scale based on Pennebaker, J. W. The psychology of physical symptoms. New York: Springer-Verlag, 1982.

They cite Weiss, et al (1987) who focused on the onset latency, and the fluctuation of muscular contraction associated with facial expression indicated a difference between posthypnotically cued and simulated emotions of anxiety and pleasure.

Kihlstrom, John F.; Register, Patricia A.; Hoyt, Irene P.; Albright, Jeanne Sumi; Grigorian, Ellen M.; Heindel, William C.; Morrison, Charles R. (1989). Dispositional correlates of hypnosis: A phenomenological approach. International Journal of Clinical and Experimental Hypnosis, 37, 249-263.

Attempted to construct and validate a questionnaire measure of hypnotic- like experiences based on Shor's (1979) 8-dimension phenomenological analysis of hypnosis. Separate item pools were developed to measure each disposition: Trance, Nonconscious Involvement, Archaic Involvement, Drowsiness, Relaxation, Vividness of Imagery, Absorption, and Access to the Unconscious. Based on preliminary testing (total Number - 856), a final questionnaire was produced containing 5 items measuring normal, everyday experiences in each domain. Results from a standardization sample (Number - 468) showed that each of the subscales, except for Archaic Involvement, possessed satisfactory levels of internal consistency and test-retest reliability. Factor analysis indicated that 6 subscales loaded highly on a common factor similar to the absorption construct (Tellegen & Atkinson, 1974), while items pertaining to Relaxation and Archaic Involvement formed separate factors. Validation testing on 4 samples receiving the Harvard Group Scale of Hypnotic Susceptibility, Form A (HGSHS:A) of Shor and E. Orne (1962) (total Number = 1855) showed that the Absorption and Trance dimensions correlated most strongly with HGSHS:A; the correlations with Drowsiness, Relaxation, and Nonconscious Involvement approached 0. The scales derived from Shor's analysis, however, did not improve the prediction of hypnotizability over that obtained with the absorption scale (Tellegen & Atkinson, 1974).

Kumar, V. K.; Pekala, Ronald J. (1989). Variations in phenomenological experience as a function of hypnosis and hypnotic susceptibility: A replication. British Journal of Experimental and Clinical Hypnosis, 6, 17-22.

Phenomenological experiences associated with a baseline (eyes closed/open) condition and an hypnotic induction were compared across individuals of differing hypnotic susceptibility. The results indicated individuals of differing hypnotic susceptibility reported different intensities of phenomenological experience during the baseline condition. The induction further augmented intensity differences for low, medium and high susceptible subjects, but more so for high than for low subjects. These results replicate earlier research, are not inconsistent with trait and situational interpretations of hypnotic susceptibility and highlight the importance of the interaction between these factors on the resulting hypnotic experience reported by the subject.

Lynn, Steven J.; Rhue, Judith W.; Weekes, John R. (1989). Hypnosis and experienced nonvolition: A social-cognitive integrative model. In Spanos, N.P.; Chaves, J.F. (Ed.), Hypnosis: The cognitive-behavioral perspective (pp. 78-109). Buffalo, NY: Prometheus.

#### NOTES

The authors present a model to account for the subjective experience of nonvolition. The model rests on four observations: (1) nonvoluntary responses "have all of the properties of behavior that is typically defined as voluntary" (p. 108); (2) "hypnotizable subjects can resist suggestions when resistance is defined as consistent with the role of a 'good' hypnotized subject" (p. 108); (3) "Hypnotic behaviors are neither reflexive/automatic ... nor manifestations of innate stimulus-response connections" (p. 108); (4) "Hypnotic performances consume attentional resources ... in a manner comparable to nonhypnotic performances" (p. 108). They continue, "At the same time, many of the cognitive operations and affective reactions that accompany hypnotic responding are not readily accessible to consciousness" (pp. 108-109).

Matheson, George; Shu, Karen L.; Bart, Catherine (1989). A validation study of a short-form hypnotic-experience questionnaire and its relationship to hypnotizability. American Journal of Clinical Hypnosis, 32, 17-26.

#### NOTES

Investigated the validity of a 16-item scale inquiring about hypnotic experience, drawn from the Hypnotic Experience Questionnaire developed by Kelly (1985) to measure components of hypnotic experience. We administered the HEQ-S and the Harvard Group Scale of Hypnotic Susceptibility: Form A (HGSHS:A) to 198 students. Factor analysis of the scale produced three stable principal components accounting for 70% of the data variance: Dissociation/Altered State (DAS), Rapport (RAP), and Relaxation (REL). Subscales representing these three factors and a composite measure, "General Depth," were constructed. Subscale correlations with HGSHS:A scores were highest for the DAS subscale (.69) and lowest for REL (.41). Applications of the HEQ-S in clinical and research use are considered.

Using the phenomenological studies and theories of J. R. Hilgard (1979) and Shor (1962), Kelly (1985) constructed the Hypnotic Experience Questionnaire (HEQ), a 47- item scale designed to demonstrate the existence of five factors of the hypnotic experience. These factors included dissociation/altered state, relaxation, rapport, visual imagery, and a negatively correlated factor of cognitive rumination measuring the amount of anxious self-reflective, and interfering thought. A composite scale, General

Depth, was also derived to provide a summary measure of the subjective quality of the hypnotic experience. The HEQ was developed as a research instrument.

The HEQ-S was administered immediately after Ss completed the Harvard response record. Items were responded to on a 5-point Likert scale ranging from one (No, none or not at all) to 5 (Yes, a great deal, or almost completely).

Pekala, Ronald J.; Bieber, Stephen L. (1989-90). Operationalizing pattern approaches to consciousness: An analysis of phenomenological patterns of consciousness among individuals of differing susceptibility. Imagination, Cognition and Personality, 9 (4), 303-320. Keywords: arousal, attention, cognition, consciousness, emotion/mood, hypnotizability, imagery, memory, nonvolition/automatism, self, state, subjective experience

Pattern differences in subjective experience, as assessed by a self-report inventory, the Phenomenology of Consciousness Inventory (PCI), were compared across low, low-medium, high-medium, and high hypnotically susceptible individuals during hypnosis and eyes-closed. A hierarchical factor analytic approach was utilized that allowed for the determination of pattern differences among PCI dimensions as a function of hypnotic susceptibility. The factor analyses found that the four susceptibility (sic) groups were 'pattern equivalent' during eyes-closed, partially pattern dissimilar during hypnosis, and partially pattern dissimilar when comparing hypnosis against eyes-closed. The nature of these results support previous analyses (1) which compared pattern structure differences as a function of correlational matrices. The results suggest the complementarity of Bieber's (2) and Pekala's (3) approaches for assessing pattern differences in consciousness and are congruent with the theorizing of Tart (4), Izard (5), and the PDP researchers on the importance of pattern structure changes in understanding states of consciousness.

Pekala, Ronald J.; Kumar, V. K. (1989). Phenomenological patterns of consciousness during hypnosis: Relevance to cognition and individual differences. Australian Journal of Clinical and Experimental Hypnosis, 17 (1), 1-20.

Relationships among phenomenological subsystems of consciousness associated with a baseline condition and an hypnotic induction condition were compared across individuals of differing hypnotic susceptibility. Phenomenological experience on 12 subsystems of consciousness was quantified by means of the Phenomenology of Consciousness Inventory (PCI) and the relationships between dimensions were statistically assessed. The results replicated previous findings and suggested that hypnosis has differential effects upon the reported organization of phenomenological structures of consciousness across subjects of differing susceptibility. The data from the previous and present studies were pooled and the combined data were reanalyzed. The results provided further support for the differential pattern structure across low and high susceptibles during hypnosis. Furthermore, differences in pattern structure were augmented when comparing very low versus very high susceptible individuals.

Van Denberg, Eric J.; Kurtz, Richard M. (1989). Changes in body attitude as a function of posthypnotic suggestions. International Journal of Clinical and Experimental Hypnosis, 37, 15-30.

Hypothesized that highly hypnotizable subjects who remained amnesic for posthypnotic suggestions to improve body attitude would show greater changes than subjects who were not amnesic. Subjects given simulating instructions were used as a comparison group to assess experimental demands. 48 females were screened with the Harvard and assigned to one of 4 conditions: (a) high hypnotizable with amnesia suggestions, (b) high hypnotizable without suggested amnesia, (c) low hypnotizable simulator with amnesia, and (d) low hypnotizable simulator without suggested amnesia. A fifth group was formed of those high hypnotizable subjects who remembered the suggestion despite instructions to

the contrary. The Body Attitude Scale (Kurtz, 1966) was administered prior to and 3 days after the experimental suggestions. Results generally demonstrated that high hypnotizable amnesic subjects manifested the greatest attitudinal and phenomenological changes as a result of the posthypnotic suggestion, although conclusions were tempered by performance of simulating subjects. The implications for hypnosis research and clinical practice are discussed.

#### NOTES

"The hypothesis that hypnotized subjects would report greater positive changes in affect, self-esteem, and social functioning than simulators was tested using a brief structured questionnaire. An analysis of Subjects responses to the questionnaire while with the 'blind' research assistant (simulators in role) revealed number significant differences between groups (N = 48) on six of the seven questions. ... An analysis of Subjects' responses to the questionnaire while being debriefed by the primary investigator (simulators out of role) revealed significant differences among groups (N = 48) on three of the seven questions. ... High hypnotizable subjects with maintained amnesia demonstrated a strong tendency to be the most responsive of all groups of subjects on the first and second assessment. In contrast, the high hypnotizable Ss for whom amnesia 'broke down' reported the fewest phenomenological changes of any of the five groups during the first assessment, and comparatively few during the second assessment. Also of note is that once out of their role, simulators in both conditions dramatically reduced their reporting of positive change" (pp. 23-24).

"Moreover, a closer examination of the data demonstrated that phenomenological and behavioral differences in the groups did appear at several points during the experiment. For example, the 10 high hypnotizable subjects told to explicitly remember the suggestion did so, while 3 of the 10 simulators in this condition claimed to have forgotten it. On debriefing, these Subjects reported they did this because they believed 'really hypnotized subjects wouldn't be able to remember anything, even if they were told they could.' Further, no simulator in the amnesia condition reported they could recall the suggestion, in contrast to the high hypnotizable subjects, 44% of whom said they did remember it. With regard to phenomenological differences, simulators stated during debriefing with the primary investigator that they intentionally faked changes on BAS, and that they experienced no true effects from the suggestion for positive body attitude change. In contrast, high hypnotizability amnesic subjects reported global, pervasive changes in their mood and self-esteem that went beyond specific alterations in attitudes toward their appearance. By comparison, high hypnotizable subjects told to remember the suggestion reported greatly increased self-absorption and acute awareness of the suggestion, 'sort of like a broken record in my head'" (pp. 25-26).

"As shown by the present study, amnesia maintenance can be quite problematic. Of 18 high hypnotizable subjects for whom amnesia was suggested, only 10 remained fully amnesic for the suggestion after 3 days. In addition, those 8 subjects for whom amnesia 'broke down' showed minimal shifts on BAS, or in reports of phenomenological changes. Such frequent amnesia failure has been reported by other researchers, although the effectiveness of the suggestion is not always so compromised" (p. 26).

1988

Cardena, Etzel (1988, November). The phenomenology of quiescent and physically active deep hypnosis. [Paper] Presented at the annual meeting of the Society for Clinical and Experimental Hypnosis, Asheville, NC.

#### NOTES

Twelve highly susceptible undergraduate students participated in three conditions (lying down on a bed, pedaling a stationary bicycle at a comfortable rate, and having a motor do the pedaling at an approximately constant, comfortable rate) in deep hypnosis and non-hypnosis conditions. They were

asked for their expectations about deep hypnotic experience, exposed to a number of traditional hypnotic phenomena before the deep hypnosis and comparison sessions, and given the opportunity to explore their own ways of inducing and deepening their state.

Even without cues or suggestions, participants gave comparable reports of their experiences at light, medium and deep hypnosis. The first one consisted mostly of relaxation and other changes in body sensations. Medium hypnosis was characterized by having complex imaginal experiences. Very deep hypnosis involved experiences of light, emptiness, and other phenomena associated with spiritual experiences.

Council, James R.; Greyson, Bruce; Huff, Kenneth D. (1988, November). Reports of paranormal experiences as a function of imaginative and hypnotic ability. [Paper] Presented at the annual meeting of the Society for Clinical and Experimental Hypnosis, Asheville, NC.

Wilson and Barber (1983) have suggested that some excellent hypnotic subjects ("fantasy prone" persons) may be more likely to report paranormal experiences than the rest of the population. Council and Greyson (1985), studying a sample of subjects who had reported near-death experiences (NDEs), found a significant relationship between fantasy-proneness and NDEs, and a much stronger relationship between fantasy-proneness and reports of paranormal experiences in general. This paper presents new data from the study of NDE reporters and a replication and extension of those findings with a sample not selected for NDEs. These data indicate a strong association between fantasy-proneness and reports of paranormal experiences. Hypnotic susceptibility bears a weaker relationship with such reports that appears dependent upon variance shared with measures of fantasy-proneness. Other data from these studies suggests that both imaginative ability and reports of paranormal experiences may be related to a history of stressful or traumatic childhood experiences.

Kluft, R. P. (1988). The phenomenology and treatment of extremely complex multiple personality disorder. Dissociation, 1, 47-58.

Contemporary reports indicate that the average number of personalities in recently reported patients with MPD is larger than that reported in the older literature. A minority of these recent patients demonstrate extreme complexity. A group of 26 patients with 26 or more personalities and under observation for a minimum of 3 years was studied. Their presentations, the reasons that appeared to underlie their complexity, and their courses of treatment are reviewed. Findings indicate that this group of patients is diverse, with some proving readily treatable, and others proving quite refractory. Observations that appear constructive for the treatment of such patients are offered. The concept of personality is discussed and an alternative description is explored. The usefulness of the paradigms and metaphors of splitting and division as heuristics for the understanding of MPD is challenged, and a paradigm/metaphor of redoubling and reconfiguration is offered for further study.

Kumar, V. K.; Pekala, Ronald J. (1988). Hypnotizability, absorption, and individual differences in phenomenological experience. International Journal of Clinical and Experimental Hypnosis, 36, 80-88.

The phenomenological effects associated with a baseline condition of eyes-closed and a hypnotic induction condition were compared across individuals of differing absorption capacity and hypnotizability. The results indicated that individuals of differing absorption capacity and hypnotizability reported different intensities of phenomenological experience during the baseline eyes-closed condition. The induction further augmented intensity differences for low, medium, and high absorption and hypnotizable Ss, but more so for high (and medium) than low hypnotizable Ss. The results support both a trait and state interpretation of hypnotizability, and highlight the importance of the interaction between these factors on the resulting hypnotic experience of S.

**NOTES:** Based on a review of relevant literature, the authors predicted that (1) during hypnosis and a baseline condition (eyes-closed), high absorption and high hypnotizable Ss will report the phenomenological effects at greater intensity relative to low absorption and low hypnotizable Ss, respectively; (2) hypnotic induction will be associated with increased absorption; greater alterations in awareness and experience; and decreased volitional control, rationality, and memory; (3) phenomenological intensity differences (hypnosis compared to eyes-closed) will be significantly greater for high than for low hypnotizable Ss.

They used the Phenomenology of Consciousness Inventory (PCI) developed by Pekala (1982), which is a 53 item self-report instrument that is completed retrospectively in reference to a preceding stimulus condition. The PCI measures the following dimensions and subdimensions: internal dialogue; self-awareness; state of awareness; imagery (amount, vividness); positive affect (joy, sexual excitement, love); negative affect (anger, fear, sadness); altered experience (time sense, body image, perception, unusual meanings); attention (absorption, direction); memory; rationality; volitional control; and arousal.

The 217 Ss were administered the Tellegen Absorption Scale, then sat quietly with eyes closed for four minutes, then completed the PCI, Form 1, relative to that 4-minute period. They were administered a slightly shortened version of the Harvard Group Scale of Hypnotic Susceptibility, Form A (HGSHS:A); before the posthypnotic suggestion and amnesia suggestion they experienced another 4-minute silent period during which they were told to 'continue to experience the state you are in right now.' After the HGSHS:A they completed PCI, Form 2, in reference to the silent period during the HGSHS:A, before they completed the 11-point questionnaire on the HGSHS:A.

Subjects who did not have reliable PCI response forms were removed from the sample, leaving 173 Ss who were divided into high, medium, and low Absorption groups, and high, medium, and low hypnotizability groups. The statistical analysis employed MANOVA on intensity scores for first the major PCI dimensions and then the 14 subdimensions using Conditions (eyes closed, hypnosis) and Groups. There were significant main and interaction effects. Subsequent ANOVAs for each (sub)dimension, Conditions by Hypnotizability Groups (2 x 3) were then performed.

Hypnosis "was associated with significantly less positive affect (joy, sexual excitement, love); negative affect (anger, sadness); visual imagery (amount, vividness); self-awareness, internal dialogue, rationality, volitional control, and memory; and significantly more altered experience (time sense, perception) and altered state of awareness.

"Significant main effects for Hypnotizability Groups were found for positive affect (joy, love); altered experience (body image, time sense, perception, meaning); attention (direction, absorption); self-awareness; altered state of awareness; rationality; volitional control; and memory.

"Post-hoc comparisons for the eyes-closed condition revealed that high relative to low, hypnotizables reported significantly greater alterations in body image, time sense, meaning, and altered state of awareness. Medium hypnotizable Ss, compared to low hypnotizables, reported significantly increased alterations in body image and state of awareness.

"Post-hoc comparisons for the hypnotic induction condition revealed that high, viz-a-viz low, hypnotizables reported significantly increased absorbed attention; greater altered experience (body image, time sense, perception, meaning); and increased alterations in state of awareness. High hypnotizables also reported significantly less imagery vividness, self-awareness, rationality, volitional control, and memory. Medium hypnotizable Ss, vis-a-vis low hypnotizables, reported significantly more altered experience (body image, time sense, perception, meaning); absorbed attention; and altered state of awareness; and significantly less imagery vividness, self-awareness, rationality, volitional control, and memory. High hypnotizable Ss, relative to medium hypnotizables, reported significantly more altered experience (perception, meaning) and absorption, and significantly less rationality, volitional control, and memory.

"Concerning the significant interactions ( $\alpha = .01$ ), graphs of the means indicated significant ordinal interactions between Conditions and Hypnotizability Groups for altered experience (perception), imagery (vividness), self-awareness, altered state of awareness, rationality, volitional control, and memory. For all of the PCI (sub)dimensions, the hypnotic induction condition (compared to eyes-closed) was associated with a significantly greater increase in altered experience (perception), and altered state of awareness; and a significantly greater decrease in imagery (vividness), rationality, volitional control, and memory for the high (and medium) hypnotizable groups relative to the low hypnotizable group.

"Significant disordinal interactions were found for absorption and unusual meanings. Whereas high hypnotizable Ss reported a more absorbed attentional focus and more unusual meaning during hypnosis, low hypnotizable Ss reported being less absorbed (or more distracted) during the induction than eyes-closed. Low hypnotizables reported more unusual meanings in reference to eyes closed" (pp. 84-85).

Correlations among the major PCI dimensions, absorption, and hypnotizability differ between the two conditions. In hypnosis, the hypnotizability correlations that reached the .001 level were: --Self Awareness -.55 --State of Awareness .60 --Altered Experience .56 --Inward Absorbed Attention .44 --Rationality -.41 --Volitional control -.65 --Memory -.41 --Arousal -.28

In the eyes closed condition, the only PCI variables that Hypnotizability correlated with, at the .001 level, were: --Positive Affect .26 --Altered Experience .32

MANOVAs and ANOVAs were computed for Absorption groups in a similar fashion. Main effects but not interaction effects were significant. Results are not abstracted here.

In their Discussion, the authors note that "The three hypotheses were supported by the results. Several of the absorption group comparisons obtained in previous research (Pekala et al., 1985) involving alterations in subjective experience (body image, perception, meaning); state of awareness; and volitional control were replicated in the present research" (p. 85).

1987

Nash, Michael R.; Lynn, Steven Jay; Stanley, Scott; Carlson, Victor (1987). Subjectively complete hypnotic deafness and auditory priming. International Journal of Clinical and Experimental Hypnosis, 35 (1), 32-40.

The present study examined the cognitive and attentional mechanisms by which auditory information is maintained out of awareness during complete hypnotic deafness. Adopting a methodology from recent work on subliminally presented pattern- masked words and dichotic listening, the study tested whether spoken words presented during complete hypnotic deafness affect lexical decisions concerning subsequently presented word choices. The response of 9 hypnotized and 15 simulating Ss to spoken stimulus words presented following hypnotic deafness instructions was compared to the response of 20 baseline control Ss who never were exposed to the stimulus words. While the response pattern of hypnosis Ss appeared different from that of baseline control Ss, hypnotic Ss showed no evidence of the priming effect found in subliminal perception and dichotic listening studies. Simulator response deviated significantly from hypnotized and baseline control responses.

## NOTES

10 highs capable of hypnotic deafness, screened by Harvard Group and Stanford Profile Scales (Means 11.0 and 24.7, respectively) and 15 lows (means 1.7 and 1.7, respectively) participated in the study; the low hypnotizables being in the simulation group. For the experimental session, a different E administered a standard hypnotic induction and the deafness suggestion, testing for deafness by snapping fingers near S's ear and making loud requests for motor responses.

An experimental trial consisted of tapping an S on the hand, saying the stimulus word out loud, and visually presenting four words for the S to read out loud and circle one. "Of the 18 main experimental trials, the four-word array consisted of two words which were related to the stimulus (one word which was semantically related to the spoken stimulus word and one word which was phonetically related), and two neutral unrelated words" (p. 34). For example, if the spoken word were 'dream,' the word array might include 'cream, tennis, sell, sleep.' There also were "3 phonetically unrelated trials (whose arrays consisted of one phonetically related choice and 3 unrelated choices) and 2 stimulus word-unrelated trials (whose arrays consisted of the stimulus word and 3 unrelated choices) ... [and] 7 dummy trials with 4 unrelated choices only" (p. 34). Ss rated their degree of deafness on a 10-point scale after hypnosis was terminated.

Possible sources of bias were examined by having 20 control Ss respond to blank tachistoscopic slides with the instructions that they were participating in a study of 'subliminal perception.' Another 22 Ss were asked to identify the semantically and phonetically related words from the word array, which for the most part they did successfully.

All Ss rated themselves as '10' on the deafness scale, indicating total deafness. The principal results are seen in Tables 1 and 2.

**Table 1 Mean Number of Related and Unrelated Responses (Percentage of Responses) for all S Groups on the 18 Mean Experimental Trials**

Response Category	S Group	N	Related	Unrelated	Total
Hypnotized	9	7.22	10.78	18	
		(40.13%)	(59.88%)	(100%)	
Simulating	15	12.13	5.87	18	
		(67.43%)	(32.61%)	(100%)	
Baseline	19	8.79	9.21	18	Controls (48.82%) (51.17%) (100%)

**Table 2 Mean Number of Phonetic and Semantic Responses within the Related Response Category on the 18 Main Experimental Trials**

Related Responses	S Group	Phonetic	Semantic
Hypnotized	1.78	5.44	
		(9.89%)	(30.24%)
Simulating	7.07	5.07	
		(39.27%)	(28.16%)
Baseline	4.21	4.58	
		(23.38%)	(25.44%)

Hypnotized Ss were significantly different from simulators (Table 1) in number of related responses. Simulators gave significantly more related responses than baseline controls. Simulators also gave more phonetically related words than either the hypnotized or baseline Ss (Table 2); there was no difference between groups on semantically related words. (Authors performed other useful and detailed analyses.)

In their Discussion section, the authors note that they did not obtain the expected results of hypnotized Ss producing more related responses than baseline Ss. "In fact, internal analyses of hypnotized and baseline responses revealed that the pattern of choices for hypnotic deaf Ss was opposite to the direction predicted by subception. Hypnotic Ss appeared to avoid phonetically related word choices, even for items on which baseline control Ss scored above chance. ...

"This kind of non-baseline performance by hypnotic Ss can be accounted for by either a strategic enactment conceptualization of hypnosis (Spanos, 1982; Wagstaff, 1981) or Hilgard's (1979) neo-dissociation theory. Spanos might emphasize the hypnotic S's active strivings to meet the hypnotist's perceived expectations. ... Neo-dissociation theory might stress the mechanisms by which processing of auditory inputs are maintained outside of awareness via a dissociative barrier.

" ... Given the tendency for simulating Ss to 'overplay' hypnotic phenomena (Levitt & Chapman, 1979), one might have expected simulators to pointedly avoid related responses, thus producing a lower frequency of related words than either the hypnotic Ss or the baseline controls (in effect being more deaf than the deaf). Just the opposite occurred. One possible explanation for this behavior presents itself: In their work with posthypnotic suggestion and the 'disappearing hypnotist' ... M. T.

Orne and others found that simulating Ss may be more alert and responsive to demand cues than are hypnotic Ss. In the present study, the authors' original hypothesis was that hypnotic Ss might reveal a subception effect by above-chance responding on related word choices. If we assume that this expectation was somehow communicated to Ss by some subtle aspect of the experimental procedure, then it is conceivable that simulating Ss were able to detect and act upon these cues, while hypnotized Ss remained relatively unattuned to such subtleties.

"In sum, the priming effect noted in the subliminal perception research does not appear to be a feature of complete hypnotic deafness, at least as measured in this study. The behavior of simulating Ss in the present study should be another caution to researchers that differences between hypnotized and simulating Ss may reflect simulation effects in addition to, or instead of, hypnotic effects" (pp. 37-38).

Pekala, Ronald J.; Kumar, V. K. (1987-88). Phenomenological variations in attention across low, medium, and high susceptible subjects. Imagination, Cognition and Personality, 7 (4), 303-314.

Phenomenological aspects of attention were assessed across 434 subjects in reference to baseline conditions of eyes-open or closed sitting quietly and an hypnotic induction condition. An attention questionnaire, assessing twelve dimensions of attention, was constructed and subjects completed it retrospectively in reference to the baseline condition and hypnosis. Reliability analyses indicated acceptable reliability for most dimensions. Regression and correlational analyses suggested adequate validity. Comparisons between baseline and hypnosis indicated significant phenomenological intensity differences between stimulus conditions on many attention dimensions. Comparisons among low, medium, and high susceptibles in reference to baseline and hypnosis also yielded many significant intensity differences. In addition, significant interactions between conditions and groups for many of the attention dimensions suggest that hypnosis, in comparison to the baseline conditions, potentiated intensity differences in attention for high, vis-a-vis low (and medium), susceptible subjects.

## NOTES

Cited by Wulff, in Cardena, Lynn, & Krippner, 2002 (p. 430). Wulff states, "we may look forward to a genuinely pluralistic mode of inquiry -- what Roth (1987) called \_methodological pluralism\_ -- according to which no point of view is finally privileged over any other, but each is entertained as a potential source of insight. Rather than anchoring ourselves in a particular theory or method, then, we would take our grounding in the phenomena themselves, which are far more likely to yield their secrets to a pluralistic approach" (p. 430 in Cardena et al., 2000).

Laurence, Jean-Roch; Nadon, Robert (1986). Reports of hypnotic depth: Are they more than mere words?. International Journal of Clinical and Experimental Hypnosis, 34, 215-233.

The empirical work relating hypnotizability, the hypnotic situation, and the reports of hypnotic depth is reviewed and evaluated. Asking Ss to assess their hypnotic depth is a complex task involving the interaction of experiential, cognitive, and contextual variables. Accordingly, future experimental work should take into account this multidimensionality; phenomenological, situational, cognitive, and motivational factors implicated in verbal reports should be explored in terms of their respective relationships with both hypnotizability and self-ratings of hypnotic depth. More sophistication in the experimental inquiries of hypnotic depth is required in order to further our understanding of the cognitive and affective structures underlying the hypnotic experience.

## NOTES

In past years, hypnotic susceptibility and hypnotic depth were regarded as the same thing, and depth was inferred from responses to test suggestions on hypnotizability scales (e.g. Davis & Husband, 1931; LeCron, 1953).

There has been little investigation of the relationship between Subjects' subjective experiences and reported "depth." Research suggests that "hypnotic depth reports are usually significantly higher for Ss who have undergone a hypnotic treatment than for those who have received task-motivation (Ham & Spanos, 1974; Spanos & Barber, 1968; Spanos, Stam, D'Eon, Pawlak, & Radtke-Bodorik, 1980); imagination-control; or relaxation-control instructions (Connors & Sheehan, 1978; Gilbert & Barber, 1972; Spanos & Barber, 1968; Spanos, Radtke-Bodorik, & Stam, 1980, Experiment 2)" (pp. 217-218). Others have found that changes in inward experiencing (e.g. feelings of unreality, a sense of disappearance of body parts) could not be attributed simply to sitting quietly with the eyes closed (Barber & Calverley, 1979). [A footnote on p. 218 indicates some studies didn't find this difference between a hypnosis group and a task-motivation control group.]

When Ss are asked to estimate subjective depth after having experienced hypnotizability test items, they are likely to infer depth from whether or not they passed the items (and indeed, early scales promoted that assumption). Reports of subjective depth taken before rather than after the test items still correlate with overall hypnotizability score, though not to as high a degree (E. R. Hilgard & Tart, 1966; Tart, 1970). Although usually depth estimates correlate with hypnotizability in the .50 to .75 range (Perry & Laurence, 1980), the correlations were obtained in the hypnotic context, and Ss may use their own behaviors as one determinant of their estimated depth.

From another line of study it is observed that Ss' subjective depth may be at variance with behavioral performance on hypnosis scales (Bowers, 1981). High hypnotizables judge their own depth from their performance on cognitive items (e.g. amnesia, hallucinations) while mediums and lows judge their own performance based on their responses to motor items and challenge items (Kihlstrom, 1981). In one experiment on amnesia, it appeared that Ss did not judge their own depth by how well they did on the amnesia task (Spanos, Stam, D'Eon, Pawlak, and Radtke-Bodorik, 1980). "M. T. Orne (1966, 1980) has emphasized that although it is necessary to operationalize S's responses to hypnotic suggestions, behavioral concomitants are only valid if they accurately reflect subjective alterations in an individual's experience" (p. 221).

"The social-psychological approach (see Barber, 1969; Radtke & Spanos, 1981, 1982; Spanos, 1982; Wagstaff, 1981) rejects the notion of hypnotic depth as an indicator of a unique state. These authors argue that the reports of having been hypnotized reflect attributions made by Ss when confronted with a hypnotic context. ... Bem (1972) and Kelley (1972) have emphasized the idea that the more ambiguous an experience is, the more a person is likely to base his or her judgment primarily on available external information" (p. 222). In this case, defining the situation as involving "hypnosis" is one of the most potent predictors of Ss' reports of subjective experience (Spanos, Radtke-Bodorik, and Stam, 1980). Other variables that influence subjective depth estimates are the wording of the hypnotizability scale, expectancy, and information provided directly or indirectly. On the other hand, McCord (1961) found that his patients had widely disparate expectations for how they thought they would feel when hypnotized, so expectancy as a predictor would not necessarily determine specific experience.

Direct experimental work on predicting response to hypnosis test items from expectancies (Council, Kirsch, Vickery, & Carlson, 1983; Kirsch, Council, & Vickery, 1984) suggests that expectations may predict test response when people are given a cognitive skill type of induction, but not when given a 'typical trance' type of induction. Also, another study from that laboratory (Council & Kirsch, 1983) established that only when expectancies are assessed after an induction (but before the test items) do they effectively predict hypnotic behaviors. The present authors express the view that these results are

difficult to account for on the basis of social psychology theories that weight heavily the role of expectancy in generating hypnotic response.

When Ss are permitted to use several different descriptors for their experience (being hypnotized, experiencing the effects, being absorbed, and responding to the suggestions), most Ss rated their own experiences as nonhypnotic (Radtke & Spanos, 1982). This was particularly true for medium hypnotizable Ss. Thus, unidimensional scales purporting to measure "depth" actually force Ss to interpret their multi-aspect experience in terms of the investigator's frame of reference, in this case "hypnotic depth." Nevertheless, the highly hypnotizable Ss were the least likely to be swayed from their self description of being "deep" when offered alternative ways of describing their experience. This is concordant with results reported earlier by Barber et al. (1968).

"The attribution literature may provide clues as to why most highly hypnotizability Ss retain their high ratings of experienced depth when confronted with situational manipulations. Self-perception theory strictly applies when Ss' experiences are ambiguous, forcing them to fall back on contextual factors to make self-appraisals. The relationship between expectancies, absorption, effect of scale wording, and hypnotizability scores suggest, however, that high hypnotizable Ss do not rely heavily on contextual factors when assessing their levels of hypnotic depth. Most of these Ss maintain their reports of altered experiences, even when situational determinants are changed (Harackiewicz, 1979; Kihlstrom, 1984; Lepper, Greene, & Nisbett, 1973). Thus, the hypnotizability by depth scale interaction found by Radtke and Spanos (1981) may suggest that experiences reported by high hypnotizable S are not inherently ambiguous. Accordingly, self-perception theory may not apply to them" (pp.226-227).

In their Discussion, the authors state, "Several studies have attempted to relate personal, real-life events to the experience of hypnosis. A number of studies (e.g., As, 1963; Field, 1965; Shor et al., 1962; Wilson & Barber, 1982) have shown that absorption, tolerance of unusual experiences, automaticity, compulsion, and trust are related to the capacity to be hypnotized. Other studies (Bowers & Breneman, 1981; Tellegen & Atkinson, 1974; Van Nuys, 1973) have shown that certain variants of attention are also related to hypnotizability. Extensive work by J. R. Hilgard (1970, 1979) has shown that patterns of personal development relate to hypnotizability in adult life. It appears then that hypnotizable individuals bring a host of experiences and abilities with them to the hypnotic context. It makes intuitive sense which is supported by the available empirical data, that a complex interaction among these experiences and abilities, the hypnotic context, and hypnotic responsiveness is implicated in Ss' assessments of their hypnotic depth. Studies are needed in which all of these potential determinants of hypnotic depth reports are taken into account. Only then will a clearer picture of their respective importance emerge" (p. 228).

Laurence, Jean-Roch; Nadon, Robert; Nogrady, Heather; Perry, Campbell (1986). Duality, dissociation, and memory creation in highly hypnotizability subjects. International Journal of Clinical and Experimental Hypnosis, 34, 295-310.

The present paper reports an initial attempt to create a pseudomemory in a group of highly hypnotizable individuals. It was found that for approximately 50% of Ss tested, recall of a specific event was modified when Ss integrated hypnotically suggested material which then posthypnotically was believed to be veridical. This modification in a previously reported memory was linked to a particular cognitive style found in high hypnotizable Ss, namely dual cognitive functioning. Ss reporting duality in hypnotic age regression, and, to a lesser extent, the hidden observer effect, were found to be the most prone to accept a suggested memory as real. These findings suggest the need to emphasize the importance of a cognitive-phenomenological approach to hypnosis and hypnotizability.

Mitchell, George P.; Lundy, Richard M. (1986). The effects of relaxation and imagery inductions on responses to suggestions. International Journal of Clinical and Experimental Hypnosis, 34, 98-109.

Theoretical attempts to understand the meaning and importance of induction procedures in producing hypnotic phenomena suggest that 2 critical components, relaxation and imagery, should be isolated and their relative effect on hypnotic responding studied. Objectively and subjectively scored responses to 12 hypnotic suggestions, which had followed relaxation, imaginal, or combined inductions, were obtained from 59 Ss, divided into 3 levels of hypnotizability. Regardless of hypnotizability level, the combined induction led to a greater subjective report of hypnotic response than did either the relaxation or the imagery inductions; and the relaxation led to a greater subjective report than the imagery induction. It may follow that the subjective experience of hypnosis is facilitated by inductions which include relaxation. The inductions were equally effective in producing objectively measured behavioral responses. There were no significant interactions found between induction type and hypnotizability level.

#### NOTE

(From the Discussion Section). As suggested by Sacerdote (1970), the combination procedure was the most generally effective in producing hypnotic responses. The difference between combined and imagery inductions reached statistical significance on four dependent variables, and the difference between combined and relaxation reached significance on three. It may also be of interest that Ss receiving the combined procedure scored consistently higher on all nine dependent variables.

A somewhat unexpected finding was that the relaxation induction produced scores on four of the dependent variables that were statistically higher than the imagery induction scores. Considering the difficulty of isolating relaxation and imagery components, it is quite noteworthy that these differences between inductions were found.

The four variables in which the combination and relaxation conditions produced significantly higher scores than the imagery condition were subjective reports--subjective score, degree hypnotized, response volition, and Field Inventory. In contrast to Ss in the imagery induction, Ss in the other two induction conditions believed that they were responding more, felt that their responses were more nonvolitional, and felt that they were more deeply hypnotized.

The fact that relaxation instructions were present in both conditions that were superior to the imagery condition would appear to support Edmonston's (1981) position which posits relaxation as essential for the production of the state of neutral hypnosis. For Edmonston the condition of neutral hypnosis is defined as the relaxed state and precedes other phenomena, such as dissociation and increased suggestibility, which other theoreticians may include in the definition of hypnosis.

However, the statistically significant superior effect of the combined over the relaxation induction on three measures casts doubt on Edmonston's position. The S believes that he or she is more deeply hypnotized and is responding less volitionally when an imagery component is combined with relaxation. The Ss also responded more to the Field Inventory when the combined induction was used. Another explanation for imagery's relatively poor showing may lie in Ss' differential expectations. The Ss, especially those with previous experience with a traditional hypnotic induction, as was the case in the present study, may not expect to be hypnotized when presented with an imagery alone induction. Such expectations, of course, might reduce responses. On the other hand, there is no reason to believe that the reduced expectation in the imagery condition would not affect the behavioral responses as well, and such was not the case.

Thus, we may be left with the explanation that relaxation adds to the subjective experience of hypnosis. This is in keeping with Edmonston's (1981) position as well as with previous research, such as that by Hilgard and Tart (1966), which finds traditional inductions, with their relaxation components, superior to nontraditional inductions, such as fantasy or task-motivational. If future research should

find that bodily involvements such as the physical exertion or repetitive motor behavior (Banyai and Hilgard, 1976) lead to the same level of subjective experience as relaxation did, then we may need to broaden the concept of the somatic component beyond relaxation alone.

In terms of the behavioral compliance of Ss, the results of the present study are in accord with some previous studies in finding all procedures equally effective. Neither imagery, relaxation, nor the combined procedure was superior for the behavioral measure.

Personality factors (social desirability, internality/externality, and absorption) did not affect the basic findings. To the degree that the Tellegen scales measure the ability to engage in imagery there seems to be little basis for believing that imagery ability is related to the general findings.

Sarbin (1983) would call the inductions studied here 'entrance rituals,' and he has recently asked in his review of Edmonston's book, "Which ritual is more suitable... [p. 58]' for preparing S to respond in various hypnotic ways? One answer from the present results is that an entrance ritual should include muscular relaxation if one wants a better subjective response from S. From Sarbin's point of view, the relaxation component may be more ego-involving, producing more subjective experience and meaning for S.

If one wants to produce only a behavioral response, either a relaxation or imagery ritual will serve.

**Pekala, Ronald J. (1986, August). Phenomenological variations in attention across low, medium, and high susceptibility subjects. [Paper] Presented at the annual meeting of the American Psychological Association, Washington, DC.**

Phenomenological aspects of attention were assessed across 434 subjects in reference to baseline conditions of eyes-open or closed sitting quietly and an hypnotic induction condition. An attention questionnaire, assessing 12 dimensions of attention, was constructed and subjects completed it retrospectively in reference to the baseline condition and hypnosis. Reliability analyses indicated acceptable reliability for most dimensions. Regression and correlational analyses suggested adequate validity. Comparisons between baseline and hypnosis indicated significant phenomenological intensity differences between stimulus conditions on many attention dimensions. Comparisons among low, medium, and high susceptibles in reference to baseline and hypnosis also yielded many significant intensity differences. In addition, significant interactions between conditions and groups for many of the attention dimensions suggest that hypnosis, in comparison to the baseline conditions, potentiated intensity differences in attention for high, vis-a-vis (and medium), susceptible subjects.

**Register, Patricia A.; Kihlstrom, John F. (1986). Finding the hypnotic virtuoso. International Journal of Clinical and Experimental Hypnosis, 34, 84-97.**

Measures of hypnotizability based on the Harvard Group Scale of Hypnotic Susceptibility, Form A (HGSHS:A) correlate only moderately with those based on the Stanford Hypnotic Susceptibility Scale, Form C (SHSS:C). Ss (N = 148) scoring in the high range (10-12) on HGSHS:A were classified according to whether they scored in the "virtuoso" range (11-12) or not on a subsequent administration of SHSS:C. Significant group differences were found on items comprising the cognitive distortion subscale of HGSHS:A, whether assessed in terms of overt behavior or subjective impressions of success. The 2 groups also differed on global self-ratings of hypnotic depth and on those subscales of Field's Inventory Scale of Hypnotic Depth concerned with subjective feelings of loss of control, automaticity, transcendence of normal functioning, and fluctuating depth. Assessments of hypnotizability are enhanced when investigators consider subjective involvement as well as behavioral measures of hypnotic response. This is particularly important when the more dissociative aspects of hypnosis are under scrutiny.

NOTES

The correlation between Harvard Group and Stanford Scale scores is usually about  $r = .60$  (Bentler & Roberts, 1963; Coe, 1964; Evans & Schmeidler, 1966). This is much lower than one would expect ( $r = .82$ ), based on the tests' individual reliabilities (Evans & Schmeidler, 1966).

The authors developed a Table to show the cross-classification of Ss in terms of Harvard and SHSS:C. Only a minority (33%) of Ss scoring in the highest range of HGSHS:A also scored in the highest range on the SHSS:C (or 50% if cutting points are different).

The Absorption scale correlated  $r = .38$  ( $p < .001$ ) with the Harvard Scale, which fell to  $r = .31$  ( $p < .01$ ) when corrected for expansion of range. The correlation between Absorption and SHSS:C was  $.35$  ( $p < .001$ ).

The issue of predicting Stanford 'virtuosos' from Harvard 'virtuosos' was addressed. HGSHS:A predictor variables were used to determine which items determined whether or not one of the HGSHS:A 'virtuosos' (the 20% who scored 11-12) would also be a SHSS:C 'virtuoso.' It was found that 70% of the SHSS:C virtuosos, but only 53% of the nonvirtuosos, had reversible posthypnotic amnesia on the HGSHS:A. None of the ideomotor or challenge subscale items demonstrated this ability to predict group association. Although the 'virtuosos' differed from the 'nonvirtuosos' in self reported depth, none of the coding categories associated with the depth variable differentiated the groups; also, judges could not predict who would be a Stanford 'virtuoso' based on subjects' descriptions of depth following the Harvard scale administration.

The Experimenters also could not predict who among the Harvard 'virtuosos' would be classified as a Stanford 'virtuoso' based on either their Absorption Scale score or previous experience with hypnosis. It was found that subjects' subjective experience of the suggestions for hallucinations, amnesia, and posthypnotic behavior (all considered to be cognitive alterations) were the most highly correlated with the subsequent total SHSS:C score. On the Field scale, which measures subjective experience, the most predictive items had to do with feelings of automaticity and loss of control (referred to as nonvoluntary behavior in other literature). Predicting SHSS:C score by 5 items (Harvard behavioral score, Harvard subjective score, Field total score, Tellegen Absorption total score, and self reported depth rating),  $r = .44$ . "The 5-element regression, employing only total scores, explained 17% ... of the variance of SHSS:C; thus, the feelings of subjective success accounted for the vast proportion (79%) of the explainable variance. For the 16 element regression, employing subscales derived from factor analysis of HGSHS:A and Inventory Scale of Hypnotic Depth, the cognitive subscale was dominant, accounting for 65.5% of explainable variance" (p. 92).

A discriminant function analysis employing the same five total score variables correctly classified 63.3% of the virtuosos.

In their Discussion, the authors suggest that investigators use subjective response as well as behavioral response when identifying hypnotic talent (virtuosos) for research. Particularly, the subjective experience of success seems to be important. Little is known, to date, about the determinants of that sense of success with hypnotic suggestions. "In part, they may relate to the 'classic suggestion effect' (K. S. Bowers, 1981; P. G. Bowers, 1982; Weitzenhoffer, 1974): the quasi-automatic, compulsory, involuntary quality which distinguishes hypnotic response from compliance with simple social requests. If so, then a direct assessment of perceived involuntariness might enhance the predictive validity of HGSHS:A even more. This is especially true for the perceptual-cognitive alterations which relate to Ss' capacity for dissociation" (p. 94).

The authors further recommend, "In those situations where HGSHS:A must stand alone for economic reasons, however, and especially where HGSHS:A is employed as a convenient preliminary screening device in the search for hypnotic virtuosos, it would seem that some assessment of the subjective experience of hypnosis would provide useful supplementary information at very little cost" (p. 94).

Stam, Henderikus J.; McGrath, Patricia A.; Brooke, Ralph I.; Cosier, Frances (1986). Hypnotizability and the treatment of chronic facial pain. International Journal of Clinical and Experimental Hypnosis, 34, 182-191.

The Carleton University Responsiveness to Suggestion Scale (CURSS) of Spanos, Radtke, Hodgins, Bertrand and Stam and Spanos, Radtke, Hodgins, Stam, and Bertrand (1983) was individually administered to a sample of 61 facial pain patients. The mean scores on the 3 CURSS suggestibility dimensions were higher than those of the college student norms. As in previous studies using the CURSS, however, objective scores were smaller when experienced involuntariness was taken into account. Observer scores of overt responses were highly related to self-scores of overt responses. The CURSS also proved a good predictor of reductions in clinical pain following a psychologically based treatment program.

NOTES: The CURSS has 7 items: 2 ideomotor (arm-levitation, arms moving apart); 2 motor-challenge (arm rigidity, arm immobility); and 3 cognitive (auditory hallucination, visual hallucination, amnesia). The CURSS yields 3 suggestibility scores: O = Objective (number of suggestions to which S made appropriate overt response; 0-7 range) S = Subjective (the degree to which S reports experiencing the subjective events called for; 0-21 range) O-I = Objective-Involuntariness (number of suggestions that were passed objectively and that were rated as involuntary to either a moderate or great degree; 0-7 range) VC = Voluntary Cooperation; items that are passed objectively and are primarily experienced as voluntary occurrences

They tested 61 patients in facial pain clinic, mean age 26 years, who were diagnosed with temporomandibular pain and dysfunction syndrome (TMPDS). This syndrome includes pain, limitations in mandibular movements, and sounds during condylar movements. 41 of the patients completed a cognitive behavioral pain treatment program (results reported elsewhere, in Stam, H. J., McGrath, P. A., & Brooke, R. I. The effects of a cognitive-behavioral treatment program on temporomandibular pain and dysfunction syndrome. Psychosom. Med., 1984, 46, 534-545).

Patients rated degree they expected to be hypnotized on a visual analog scale. Expectations for becoming hypnotized were not significantly correlated with any of the dimensions, except for the CURSS:O observer-scored dimension ( $r = .29$ ). Age was also related to the CURSS:O observer-scored dimension ( $r = -.25$ ) as well as to the CURSS:S dimension ( $r = -.28$ ).

Several measures of treatment outcome were employed--change scores of weekly self ratings, and post-treatment ratings by the dental surgeon (worse, same, improved, alleviated).

"Whereas the CURSS:V-C dimension is not at all related to any of the outcome measures, the objective, subjective, and objective-involuntariness measures are highly and significantly correlated with the reduction in patients' peak pain scores and the posttreatment pain ratings. The correlations between measures of hypnotizability and pain reductions are not significant for the control group, though these are based on small sample size. Table 3 also indicates a lack of relationship between measures of hypnotizability and the weekly pain ratings. Stam et al. (1984a) point out that it may have been due to the relative instability of the global weekly ratings of pain versus the daily ratings obtained from the home logs that were used to calculate the peak pain scores" (p. 187).

Table 3 Correlation Coefficients between Dimensions of the CURSS and Reductions in Pain Susceptibility Dimension Pain Reduction O S O-I V-C

Measures	O	S	O-I	V-C
Pre-post	.60**(.36)	.51**(.19)	.44*(-.21)	.18(.42)
Peak Pre-post	.19	-.01	.15	.07
Posttreatment	.54**(-.05)	.58**(.26)	.58**(.01)	-.02(.37)
Surgeon's rating				

Note: Correlations in parentheses are for the Waiting List Control group (N = 14; N = 10 for Peak Pain); all others are for combined treatment groups, N = 27.

\* $p < .05$  \*\* $p < .01$

In their Discussion, the authors note that this research is in accord with other studies that indicate that "objective responding and the experience of those responses involuntarily are not necessarily equivalent. ... Ss in both the laboratory and the clinic are almost twice as likely to pass suggestions when assessed overtly than by the combined objective-involuntariness criterion. ... [and] objective scores alone confound responses experienced as voluntary with those experienced as involuntary" (pp. 188-189). They report that earlier studies from their laboratory indicated that "only CURSS suggestibility dimensions, and not the VC dimension, correlated significantly with absorption and Field's (1965) Inventory Scale of Hypnotic Depth. ... [and] correlations between hypnotizability and reductions in pain were not due to compliance factors but were related to each of the other three ways of assessing hypnotizability" (p. 189).

"The objective, subjective, and objective-involuntariness dimensions were all significantly correlated with the reductions in peak pain and posttreatment ratings for the treatment groups but not for the control groups. These results replicate the laboratory demonstrations that hypnotizability is correlated with suggested analgesia regardless of the presence or absence of a hypnotic induction procedure (E. R. Hilgard & J. R. Hilgard, 1975; Spanos, Radtke-Bodorik, Ferguson, & Jones, 1979; Stam & Spanos, 1980). There is some evidence, however, that this depends on the hypnotic induction procedure being defined as a component of the analgesia testing situation (Spanos, Kennedy, & Gwynn, 1984).

"Despite the differential predictions between CURSS dimensions and pain reductions, there were no increases in the predictions of pain reductions when objective scores were corrected for involuntariness or when using subjective scores. (This was apparent for the combined treatment groups as well as for each group examined separately.) The reasons for this are not obvious and await further research" (p. 189).

The authors conclude from their research that the general practice of self-scoring hypnotizability scales that is used in laboratory research appears to be equally reliable in a clinical situation.

Wilson, L.; Kihlstrom, J. F. (1986). Subjective and categorical organization of recall during posthypnotic amnesia. Journal of Abnormal Psychology, 95 (3), 264-73.

Conducted 2 experiments to determine the fate of organization of recall during posthypnotic amnesia. In both studies, amnesia suggestions were administered to undergraduate Ss of low, medium, and high hypnotic susceptibility who had learned a word list by the method of free recall while they were hypnotized. In Exp I (n = 44), words were unrelated to each other, and subjective organization was measured by raw and adjusted pair frequency. In Exp II (n = 59), words were drawn from various taxonomic categories, and category clustering was measured by repetition ratio, modified repetition ratio, and adjusted ratio of clustering. Results indicate that, compared to baseline levels, subjective organization and category clustering did not decrease reliably during the time the amnesia suggestion was in effect. Moreover, these aspects of strategic organization were not significantly correlated with the number of items recalled during amnesia. Both findings contrast with previous results concerning temporal organization of a word list memorized by the method of serial learning. Findings suggest that the disruption of retrieval processes in posthypnotic amnesia may be limited to certain organizational schemes. (43 ref).

Woolson, Donald A. (1986). An experimental comparison of direct and Ericksonian hypnotic induction procedures and the relationship to secondary suggestibility. American Journal of Clinical Hypnosis, 29 (1), 23-28.

Recent studies reporting the disparate effects of direct and indirect suggestion upon hypnotized subjects have indicated that standardized, direct hypnotic susceptibility tests may not accurately predict the suggestibility of subjects exposed to an indirectly worded, albeit similar, test. Historically, primary suggestibility correlates highly with hypnotizability, while secondary suggestibility does not

and has been reported to be a subject's response to indirect suggestion. In this study 56 volunteers for self-hypnosis training were first tested for secondary/indirect suggestibility, then each singly received either a direct standardized [sic] induction or an Ericksonian (indirect) version. While susceptibility scores between groups were close, a greater number of the Ericksonian group subjects were rated as medium or highly susceptible. This occurred regardless of their type of suggestibility. Also, the Ericksonian group subjects appeared to be less aware of their depth of trance, as judged by a comparison of their susceptibility scores and their self-report depth scores. - Journal Abstract

1985

Jupp, James J.; Collins, John K. (1985). Hypnotic responsiveness and depth in a clinical population. Australian Journal of Clinical and Experimental Hypnosis, 13 (1), 37-47.

Two samples of clinical subjects estimated depth during procedures which allowed their estimates to be related to aspects of responsiveness. In Sample 1, subjects estimated depth after they scored their responsiveness and tested their post-hypnotic recall. In Sample 2 subjects estimated depth before they had completed these tasks. Results suggested that subjects use the range of available information in making depth estimates and that they may be more influenced by the more obvious ideomotor challenge performances than by the cognitive distortion responses, aspects of amnesia, or impressions of involuntariness.

Jupp, J. J.; Collins, J. K.; McCabe, M. P. (1985). Estimates of hypnotizability: Standard group scale versus subjective impression in clinical populations. International Journal of Clinical and Experimental Hypnosis, 33 (2), 140-149.

The relationship between hypnotic responsiveness as measured by the Harvard Group Scale of Hypnotic Susceptibility, Form A (HGSHS:A) of Shor and E. Orne (1962) and global depth estimates derived from an 11-point scale were explored in 2 clinical samples. In one case, depth estimates were made just before, and in the other, immediately following the patients' focus on aspects of hypnotic responsiveness. The responsiveness-depth relationship was moderate and consistent across both samples, a finding which in itself is consonant with previous findings employing experimental Ss. When HGSHS:A performance and depth estimates were less proximate, the relationship between them remained significant but was substantially reduced in magnitude. Data suggest that low hypnotizable Ss increase their estimates of depth, and that higher hypnotizable Ss retain relatively stable estimates with increased exposure to hypnosis in a clinical context.

Kelly, Paul James (1985, November). The relationship between hypnotic ability and hypnotic experience (Dissertation). Dissertation Abstracts International, 46 (5), 1690-B.

"This study investigated the relationship between four types of hypnotic experience and hypnotic ability. The types of experiences were: dissociation, the experience of involuntariness, altered state effects, such as perceptual alterations and diminished reality sense rapport, transference-like involvement with the hypnotist, and relaxation. A 47-item scale, the Hypnotic Experience Questionnaire was developed to measure types of hypnotic experience. It was given to 484 subjects and then to a subsample of 272 students. When the scale was factored, four stable factors emerged: Nonconscious/Trance, Rapport, Relaxation, and Cognitive Rumination. A Group Profile Scale was also developed to measure students and when it was factor analyzed four factors were extracted: Hallucinations and Fantasies, Amnesias and Post-Hypnotic Compulsions, Motor Inhibition, and Direct Motor Suggestion. "Two statistical approaches were used to investigate the connections between hypnotic ability and hypnotic experience . Canonical analysis was used to identify the main

relationships between hypnotic ability and hypnotic experience and factor analysis was used to explore the relationship among measures of hypnotizability and hypnotic experience. Two canonical variates from the canonical analysis were significant. The first variate was characterized by a dissociative-imaginative involvement process, and the second variate tapped a rapport-social compliance process. "When 25 variables, representing components of hypnotic ability and hypnotic experience, were factored, five factors were extracted. Imaginative Involvement, Ideomotor Response, Rapport, Cognitive Inhibition, and Relaxation. The results of the factor analysis suggested that dissociative experience and altered state experience are related to hypnotic ability but rapport and relaxation are not. "The results of study, taken as a whole, suggest that relaxation and rapport may happen in the hypnotic situation, but neither experience is related to the condition of being hypnotized in any essential way. The results suggest that the hypnotic condition is characterized by dissociative experience, altered state experience, and by successful performance on hypnotic ability tasks. From a theoretical point of view, the results strongly supported Hilgard's theory, partially supported Shor's theory, and failed to support Edmonston's theory" (p. 1690).

Kirsch, Irving (1985, November). Response expectancy as a determinant of experience and behavior. American Psychologist, 40 (11), 1189-1202.

Response expectancies, defined as expectancies of the occurrence of nonvolitional responses, have generally been ignored in theories of learning. Research on placebos, hypnosis, and fear reduction indicates that response expectancies generate corresponding subjective experiences. In many cases, the genuineness of these self-reported effects has been substantiated by corresponding changes in behavior and physiological function. The means by which response expectancies affect experience, physiology, and behavior are hypothesized to vary as a function of response mode. The generation of changes in subjective experience by corresponding response expectancies is hypothesized to be a basic psychological mechanism. Physiological effects are accounted for by the mindbody identity assumption that is common to all nondualist philosophies of psychology. The effects of response expectancies on volitional behavior are due to the reinforcing properties of many nonvolitional responses. Classical conditioning appears to be one method by which response expectancies are acquired, but response expectancy effects that are inconsistent with a conditioning hypothesis are also documented.

Tkachyk, Mary E.; Spanos, Nicholas P.; Bertrand, Lorne D. (1985). Variables affecting subjective organization during posthypnotic amnesia. Journal of Research in Personality, 19, 95-108.

Subjects learned a list of unrelated words to a criterion of either two successive correct trials (standard criterion), or two successive correct trials plus five additional recall trials (extra criterion). The extra recall trials significantly increased the subjective organization of recall. In the extra criterion group, a posthypnotic amnesia suggestion and a nonhypnotic distraction task produced equivalent decrements both in the amount recalled and in the subjective organization of recall. In the standard criterion group, suggestion and distraction reduced the amount recalled, but not the subjective organization of recall. The implications of these findings for understanding the contradictory results of earlier studies of recall organization during amnesia are discussed. Implications for theories of hypnotic amnesia are also discussed.

Vickery, Anne R.; Kirsch, Irving; Council, James R.; Sirkin, Mark I. (1985). Cognitive skill and traditional trance hypnotic inductions: A within-subjects comparison. Journal of Consulting and Clinical Psychology, 53 (1), 131-133.

Comparison of a traditional trance hypnotic induction and a cognitive skill induction in a within-Ss design with 40 undergraduates showed that the cognitive skill induction enhanced subjective responses to suggestions and produced significant increments in behavioral responses when it was preceded by

the trance induction. The trance procedure led to greater self-reported alterations in consciousness. Findings suggest that skill induction teaches cognitive strategies that enhance responsivity to suggestions in subsequent hypnotic experiences, independent of alterations in consciousness elicited by trance induction.

1984

Kelly, Paul James (1984, December). The relationship between hypnotic ability and hypnotic experience. Newsletter of Division 30, Psychological Hypnosis, of the American Psychological Association, 5.

This study investigated the relationship between four types of hypnotic experience and hypnotic ability. The types of experience were: dissociation, the experience of involuntariness; altered state effects, such as perceptual alterations and diminished reality sense; rapport, transference-like involvement with the hypnotist; and relaxation. A sample of 230 students was given the HGS: A, a group version of the SHSS: C, and the Hypnotic Experience Questionnaire (Kelly, 1984), a 47-item multidimensional scale of hypnotic experience. Items were taken from these tests to form 11 hypnotic ability variables (Positive Hallucinations, Dreams and Regressions, Post-Hypnotic Compulsions, Amnesia (HGS: A), Amnesia (SHSS: C), Arm Rigidity, Arm Immobilization, Other Motor Inhibitions, Head Falling, Moving Hands Together, and Hand Lowering). Fourteen hypnotic experience variables were also formed (Generalized Dissociative Effects, Dissociative Inhibition, Trance, Unawareness, Transference-like Involvement, Trust, Friendliness, Physical Relaxation, Mental Relaxation, Imagery Presence, Imagery Vividness, Imagery Detail, Self Consciousness, and Analytic Thoughts). The 25 variables were intercorrelated and factored with principal axis factoring. Five factors with eigenvalues greater than 1 were extracted and rotated to varimax criteria. These factors, which accounted for 54.4 percent of the variance, were called: Imaginative Involvement, Ideomotor Response, Rapport, Cognitive Inhibition, and Relaxation. Hypnotic ability variables loaded significantly on three of the factors (Imaginative Involvement, Ideomotor Response, and Cognitive Inhibition) and these three factors also tapped some aspect of altered state experience and/or dissociative experience. It was concluded therefore that dissociative experience and altered state experience are related to hypnotic ability. The remaining two factors, Rapport and Relaxation, showed significant loadings only for rapport variables and relaxation variables, respectively. Neither of these two factors were related to any of the traditional measures of hypnotic ability or to the experience of dissociative effects or altered state effects. The results of this study suggest that rapport and relaxation may happen in the hypnotic situation but neither experience is related to the condition of being hypnotized in any essential way. The hypnotic condition is characterized by dissociative experience, altered state experience, and by successful performance on hypnotic ability tasks. The results also raise questions about Edmonston's (1981) theory that relaxation is the essence of hypnotic responsiveness. The finding that the experience of relaxation is unrelated to hypnotic ability is more congruent with Hilgard's (1977) view that relaxation is a nonhypnotic process

Pekala, Ronald J.; Kumar, V. K. (1984). Predicting hypnotic susceptibility by a self-report phenomenological state instrument. American Journal of Clinical Hypnosis, 114-121.

In an attempt to predict hypnotic susceptibility (as measured by the Harvard Group Scale of Hypnotic Susceptibility, HGS) the phenomenological experiences of an hypnotic induction (HI) procedure and a baseline comparison condition (eyes closed, EC, sitting quietly) were assessed. After each experience the subjects (n=217) completed the Phenomenology of Consciousness Inventory (PCI), a self-report phenomenological state instrument, dealing with that condition. Step-wise multiple regression and discriminant analyses were then performed on data using the subject's HGS score as

the dependent variable and the PCI (sub)dimensions as the independent variables. Regression analyses that held up under cross-validation during HI suggest that the PCI may be an appropriate instrument for predicting susceptibility. The possible clinical usefulness of this approach is discussed.

1983

McConkey, Kevin M. (1983). Behaviour, experience, and effort in hypnosis. Australian Journal of Clinical and Experimental Hypnosis, 11, 73-81.

Subjects were administered the Harvard Group Scale of Hypnotic Susceptibility, Form A, and were afterwards asked to rate the degree to which they experienced the items; subjects also scored their behavioural performance on the items. Data were analyzed to explore the relationships among behaviour, experience, and effort. Findings indicated a significant positive relationship between behaviour and experience on all of the HGS: A items, a significant negative relationship between behaviour and effort on the ideomotor items, and a significant positive relationship between behaviour and effort on the cognitive items. A similar pattern was observed between experience and effort. Also, subjects of varying HGS: A responsivity differed in terms of overall experience of the scale but not in terms of the overall amount of effort that they expended. Implications of the data are discussed in terms of the factors influencing subjects' experiential response and behavioural performance as well as the attributions that they make concerning effort during hypnosis.

Nogrady, Heather; McConkey, Kevin M.; Laurence, Jean-Roch; Perry, Campbell (1983). Dissociation, duality, and demand characteristics in hypnosis. Journal of Abnormal Psychology.

Examined hypnotic dissociation (as indexed by the "hidden-observer" method), duality in age regression, and the potential impact of situational cues on these phenomena. 12 high- and 9 low-susceptible undergraduates (as determined by the Stanford Hypnotic Susceptibility Scale) were tested in an application of the real-simulating paradigm of hypnosis; 10 high- to medium-susceptible Ss were also employed. Inquiry into Ss' experiences was conducted through the experiential analysis technique, which involves Ss viewing and commenting on a videotape playback of their hypnotic session. Results demonstrate that neither the hidden-observer effect nor duality could be explained solely in terms of the demand characteristics of the test situation. The hidden-observer effect was observed in high-susceptible Ss only; all Ss who displayed the hidden-observer effect also displayed duality in age regression. High-susceptible Ss were distinctive in their reports of multiple levels of awareness during hypnosis. Findings are discussed in terms of the cognitive skills that Ss bring to hypnosis and the degree to which the hypnotic setting encourages the use of dissociative cognitive processes. (43 ref).

Spanos, Nicholas P.; Dubreuil, Debora L., Saad, Carol L., Gorassini, Donald (1983). Hypnotic elimination of prism-induced aftereffects: Perceptual effect or responses to experimental demands?. Journal of Abnormal Psychology, 92 (2), 216-222.

Two experiments assessed adaptation to displacing prisms in hypnotically limb-anesthetized Ss. Experiment I with 18 college students disconfirmed the hypothesis that the displacement aftereffect is eliminated in limb-anesthetized hypnotic Ss who adapt to prisms in the absence of a visual target. Such Ss showed as large a displacement aftereffect as control Ss who received neither a hypnotic induction procedure nor an anesthesia suggestion. Experiment II with 30 undergraduates demonstrated that under some testing conditions hypnotic Ss complied with experimental demands and eliminated the behavioral but not the perceptual component of the aftereffect.

Wagstaff, Graham F. (1983). Comment on McConkey's "Challenging hypnotic effects: The impact of conflicting influences on response to hypnotic suggestion". [Comment/Discussion] .

## NOTES

"Probably the most consistent finding to emerge from McConkey's review is that hypnotic subjects tend to respond in accordance with what they feel the hypnotist really wants, regardless of conflicting experimental demands" (p. 13).

1982

McConkey, Kevin M.; Sheehan, Peter W. (1982). Effort and experience on the Creative Imagination Scale. International Journal of Clinical and Experimental Hypnosis, 30 (3), 280-288.

158 Ss were administered the Creative Imagination Scale (CIS) of Barber and Wilson (1977) and were asked to rate the degree of effort that they expended in attempting to experience the suggested effects; Ss also routinely rated their experiences of the test items. Results were analyzed to assess the relationship between the ratings of effort and experience on the test items. The data were further analyzed in terms of Ss' CIS total experience score and the average item-effort expended during testing. Results indicated that Ss who experienced the items reported expending more effort than those Ss who did not experience the items on some, but not all, of the items. For Ss who experienced the items, increased vividness of effect was not associated with increased effort; correlational analysis indicated no significant relationship between effort and experience. Ss of varying CIS responsivity also did not differ in the degree of average item-effort they reported expending. Implications of the data are discussed for our theoretical understanding of the imagery-related processes that underlie hypnotic performance.

St. Jean, Richard; MacLeod, Carrie; Coe, W. C.; Howard, M. L. (1982). Amnesia and hypnotic time estimation. International Journal of Clinical and Experimental Hypnosis, 30, 127-137.

Previous research has shown that hypnotic Ss tend to underestimate the duration of the hypnotic interval (Bowers, 1979; Bowers & Brennehan, 1979). Based on Ornstein's (1970) work, the present investigation tested the hypothesis that such underestimation occurs to the extent that Ss are amnesic for the events of the hypnotic session. Two separate studies, in which time estimates were collected in conjunction with administrations of the Harvard, failed to find a relationship between responses to the amnesia suggestion and time estimation. Ss in both studies substantially underestimated the duration of the hypnotic interval, but the degree of such underestimation was not related to hypnotic responsiveness. Thus, Ornstein's hypothesis that underestimation occurs to the extent that Ss are amnesic for the events of the hypnotic session was strongly disconfirmed.

1981

Dosamantes-Alperson, Erma (1981). Experiencing in movement psychotherapy. American Journal of Dance Therapy, 4, 33-44.

Experiencing is a process variable in psychotherapy which deals with the manner with which individuals use their internal, ongoing bodily-felt flow of experience to gain self-awareness and to communicate about themselves. A consistent finding across research process studies in psychotherapy is that successful clients start, continue, and end therapy at higher experiencing levels than do less successful clients. The implication of this finding for all therapists, irrespective of their theoretical framework, is that they need to help their clients process the content they raise in therapy at a high level of experiencing throughout the course of therapy. This paper discusses and demonstrates several body movement based procedures that enhance clients' experiencing level while working within the context of experiential movement psychotherapy, a form of psychotherapy which emphasizes the

acquisition of personal meanings by clients from any of the following three experiential and expressive modalities: body movement, kinetic imagery, or verbal communication.

Fromm, Erika; Brown, Daniel P.; Hurt, Stephen W.; Oberlander, Joab Z; Boxer, Andrew M.; Pfeifer, Gary (1981). The phenomena and characteristics of self-hypnosis. International Journal of Clinical and Experimental Hypnosis, 29 (3), 189-247.

Self-hypnosis and hetero-hypnosis were compared, and self-hypnosis was studied longitudinally. Results indicated that absorption and the fading of the general reality orientation are characteristics of both hetero-hypnosis and self-hypnosis. The differentiating characteristics lie in the areas of attention and ego receptivity. Expansive, free-floating attention and ego receptivity to stimuli coming from within are state-specific for self-hypnosis, while concentrative attention and receptivity to stimuli coming from one outside source--the hypnotist on whom the subject concentrates his attention--are state-specific for laboratory defined hetero-hypnosis. Attempts to produce age regression and positive or negative hallucinations are markedly more successful in hetero-hypnosis. Imagery is much richer in self-hypnosis than in hetero-hypnosis. Self-hypnosis requires adaptation to the state: in the beginning of self-hypnosis there is a good deal of anxiety and self-doubt. As the subject feels more comfortable in the self-hypnotic state, he spends less time worrying about failures in self-suggestion, his ability to enter trance quickly and easily increases, as does the fading of the general reality orientation, trance depth, and absorption. An attempt was also made in the present study to find personality characteristics related to the ability to experience self-hypnosis.

Johnson, L. S. (1981). Current research in self-hypnotic phenomenology: The Chicago paradigm. International Journal of Clinical and Experimental Hypnosis, 29 (3), 247-258.

This paper discusses the research of the Chicago group program (Fromm, Brown, Hurt, Oberlander, Boxer, & Pfeifer, 1981) from several viewpoints: first, as a conceptual and methodological example of what Shor (1977) has called the "phenomenological method" of hypnosis research; second, in terms of its intent and assumptions with respect to some other current self-hypnosis research; third, as potentially plagued with certain demand characteristics which favor finding phenomena unique to self-hypnosis; and fourth, as a most creative and exhaustive effort, clarifying and expanding the field of knowledge of self-hypnosis.

McConkey, Kevin M.; Sheehan, Peter W. (1981). The impact of videotape playback of hypnotic events on posthypnotic amnesia. Journal of Abnormal Psychology, 90 (1), 46-54.

Examined the breakdown of amnesia by showing 48 hypnotic and nonhypnotic undergraduates (Harvard Group Scale of Hypnotic Susceptibility) a videotape of the hypnotic events they had experienced. The extent of the amnesia for these events was defined precisely, and simulating procedures were employed to analyze the cues in the overall test situation. Videotape display of the hypnotic events was presented via the Experiential Analysis Technique and served to optimize conditions for breakdown. Some hypnotic Ss' amnesia could not be broken down even though they were exposed via videotape playback to the events to be recalled and when suggestions for the period of amnesia were quite explicit. Simulators showed breaching of amnesia but attributed their recall to the videotape rather than to the hypnotic session. Hypnotic Ss were distinctive in their inability to recall experiential aspects of their performance even though they could recall behavioral aspects. The data are discussed in relation to the hypothesis that dissociative cognitive mechanisms underlie posthypnotic amnesia. (22 ref).

Orne, Martin T.; McConkey, Kevin M. (1981). Toward convergent inquiry into self-hypnosis. International Journal of Clinical and Experimental Hypnosis, 29 (3), 313-323.

From both theoretical and therapeutic perspectives, there is a need to expand and integrate current lines of research into the phenomenon of self-hypnosis and its clinical application. Some issues and research implications are outlined that concern the need to (a) delineate the phenomenon, (b) convergently assess it through behavioral and phenomenological techniques, and (c) investigate the consequences of its private use. Behavioral, experiential, and consequential measures of self-hypnosis are seen as methodologically distinct ways of convergently assessing the phenomenon. The adoption of multiple strategies of inquiry into the nature and function of self-hypnosis may allow a better understanding of it from the respective viewpoints of those who seek to understand, to teach, and to use the technique.

Singer, Jerome L.; Pope, Kenneth S. (1981). Daydreaming and imagery skills as predisposing capacities for self-hypnosis. International Journal of Clinical and Experimental Hypnosis, 29 (3), 271-281.

A growing body of empirical literature suggests that daydreaming and related forms of waking reverie are natural-occurring, common experiences in normal individuals. Specific experiments relating daydreaming and the stream of ongoing thought as an alternative source of stimulation to external cues are described. It is proposed that everyday waking consciousness has many features of internal absorption in imagery and adaptive but non-sequential processes that resemble fantasy, hypnosis, and night dreaming. Experiments linking daydreaming, imagery vividness, and hypnosis are cited as suggesting that individuals may develop capacities for control over the stream of thought and that such capacities are closely similar to the skills needed for self-hypnosis.

1980

Ericsson, K. Anders; Simon, Herbert A. (1980). Verbal reports as data. Psychological Review, 87 (3), 215-251.

## NOTES

Proposes that verbal reports are data and that accounting for them, as well as for other kinds of data, requires explication of the mechanisms by which the reports are generated, and the ways in which they are sensitive to experimental factors (instructions, tasks, etc.). Within the theoretical framework of human information processing, different types of processes underlying verbalization are discussed, and a model is presented of how ss, in response to an instruction to think aloud, verbalize information that they are attending to in short-term memory (STM). Verbalizing information is shown to affect cognitive processes only if the instructions require verbalization of information that would not otherwise be attended to. From an analysis of what would be in STM at the time of report, the model predicts what could be reliably reported. The inaccurate reports found by other research are shown to result from requesting information that was never directly heeded, thus forcing Ss to infer rather than remember their mental processes. (112 ref)

McConkey, Kevin M.; Sheehan, Peter W. (1980). Inconsistency in hypnotic age regression and cue structure as supplied by the hypnotist. International Journal of Clinical and Experimental Hypnosis, 28 (4), 394-408.

Inconsistency in hypnotic age regression was elicited by asking Ss to write a complex sentence, in contexts that varied appreciably in the extent to which they cued Ss that illogical response was

appropriate. Hypnotically responsive and unresponsive Ss were assigned to a real or simulating group in application of the real-simulating model of hypnosis and tested in 1 of 3 distinct cue conditions. Cue conditions either followed those of previous studies and communicated that no particular response was appropriate, or communicated that an illogical response was appropriate, or inappropriate. It was hypothesized that cue structure would have a significant impact. Data indicated that cues for logical response had a greater influence on the behavior of Ss than did cues for illogical response when compared with the base response condition; at times, real Ss behaved appreciably more illogically than simulating Ss. Also, detailed analysis of the reports of both groups of Ss indicated distinctive properties of experience that point to the importance of recognizing the complexities of consciousness underlying the experiences of highly susceptible Ss.

Perry, Campbell; Laurence, Jean-Roch (1980). Hypnotic depth and hypnotic susceptibility: A replicated finding. International Journal of Clinical and Experimental Hypnosis, 28 (3), 272-280.

A sample of 398 Ss was tested in groups of from 8 to 20 people on the Harvard Group Scale of Hypnotic Susceptibility, Form A (HGSHS:A) of Shor and E. Orne (1962). Retrospective depth reports for each of the 12 HGSHS:A items were taken in order to extend Tart's findings (1970, 1972) on susceptibility and depth. The Ss were tested over 2 successive years in samples of N = 220 and N = 178. Since results were almost identical for each year (thus constituting a replication), the data were pooled for this report.

A remarkable consistency in patterns of subjective depth across the 12 items of HGSHS:A was found, particularly noticeable in Items 7, 8, 9, and 10 for 4 susceptibility groups (high, high-medium, low-medium and low-susceptible Ss) which appeared to reflect differential item difficulties. In addition, all correlations between reported depth and HGSHS:A total scores were high and statistically significant. While the findings are in general accord with those of Tart (1970, 1972), further research is required in order to determine the underlying basis of depth reports, and the degree to which experimental reports of susceptibility and clinical reports of depth reflect similar experiential aspects of hypnosis.

Spanos, Nicholas P.; Radtke-Bodorik, H. Lorraine; Shabinsky, Michael A. (1980). Amnesia, subjective organization, and learning of a list of unrelated words in hypnotic and task-motivated subjects. International Journal of Clinical and Experimental Hypnosis, 28 (2), 126-139.

Hypnotic and task-motivated Ss learned a list of unrelated nouns and were then administered an amnesia suggestion for the list. Hypnotic Ss showed slower learning but more amnesia than task-motivated Ss. Hypnotic and task-motivated Ss showed an equivalent degree of "breakdown" in the subjective organization of their recall following the amnesia suggestion. However, the extent of this breakdown in subjective organization, was unrelated either to Ss' degree of amnesia or to their level of hypnotic susceptibility. A substantial proportion of Ss who failed to recall any words following the suggestion (total nonrecallers) later reported that they remembered but did not say at least some of the words. The theoretical implications of these findings are discussed.

St. Jean, Richard (1980). Hypnotic time distortion and learning: Another look. Journal of Abnormal Psychology, 89 (1), 24.

Conducted 2 studies employing different methodologies with a total of 75 undergraduates to test the hypothesis that hypnotic time distortion facilitates verbal learning. All of the Ss in Exp I and most of those in Exp II were given a modified version of the Stanford Hypnotic Susceptibility Scale-Form C. All Exp II Ss were also given the Harvard Group Scale of Hypnotic Susceptibility. Analysis of previous research indicated that hypnotic susceptibility and the form of time-distortion suggestions might be

important moderator variables in the relationship. The separate and combined effects of these variables were observed in both studies. No combination of hypnotic susceptibility and time-distortion suggestions in either study raised performance level beyond that of the waking- and/or hypnotic-control conditions. Responses to a postexperimental questionnaire in Exp II indicated that high-susceptible Ss reported subjectively convincing changes in experienced time flow following time-distortion suggestions (12 ref)

1979

Dosamantes-Alperson, Erma (1979). The intrapsychic and the interpersonal in movement psychotherapy. American Journal of Dance Therapy, 3, 20-31.

The adaptive function of two states of consciousness and corollary movement experiences is described. Movement in which a relaxed state of attention is maintained on inner kinesthetic sensations and imagery is contrasted with movement which is characterized by conscious, active interacting with the external world of people and events. Clinical examples from individual and group psychotherapy sessions are cited to demonstrate how meaning and conflict resolution may be achieved by clients while moving in either mode.

Johnson, Lynn S. (1979). Self-hypnosis: Behavioral and phenomenological comparisons with heterohypnosis. International Journal of Clinical and Experimental Hypnosis, 27, 240-264.

In a study of behavioral and phenomenological differences between auto- and heterohypnosis, standard autohypnotic and hetero-hypnotic experiences were administered to 48 college students (25 males, 23 females). Total scores of behavioral and phenomenological responses were compared for each experience. The phenomenological scores were also factor analyzed for each type of hypnosis. Behavioral total scores were comparable. Inexperienced Ss were as able to hypnotize themselves as to be hypnotized by another. Scores on "challenge" items were also comparable, whereas items suggesting positive actions showed greater variability. Factor analyses showed that the subjective experiences were generally similar. Heterohypnosis evoked more feelings of unawareness, passivity, and loss of control. Self-hypnosis elicited more feelings of time distortion, disorientation, active direction, and trance variability. The relationship between hypnotic mode and order effects was discussed in terms of Ruch's (1975) facilitatory/inhibitory effects. Conclusions are drawn that self-hypnosis and heterohypnosis are sufficiently similar to be conceptualized under the same label. Data is offered on expectations of self-hypnosis and their effect on later responsiveness.

1978

Coe, William C. (1978). The credibility of posthypnotic amnesia: A contextualist's view. International Journal of Clinical and Experimental Hypnosis, 26 (4), 218-245.

This paper attempts to demonstrate how the contextual view rather than the formist-mechanistic view may be more helpful in understanding posthypnotic amnesia. As a point of departure, the criterion for credible posthypnotic amnesia is defined as Ss' phenomenal experiences which are observed indirectly through their counterfactual statements expressed with a high degree of conviction. To make sense of such self-reports, concepts flowing from contextualism, the view of man as an active person in an everchanging series of contexts, are employed. Concepts such as plots, reinforcement contingencies, trust, belief systems, involvement, ambiguousness, and self-observation may be postulated in understanding how people come to believe in their own counterfactual reports and to convince others of their credibility. Recent research on source amnesia, disrupted retrieval, and breaching

posthypnotic amnesia is also critically evaluated. The conclusion is reached that the data are not compelling and their interpretations have been overstated.

1977

Ryan, M. L.; Sheehan, Peter W. (1977). Reality testing in hypnosis - subjective versus objective effects. International Journal of Clinical and Experimental Hypnosis, 25, 27-51.

90 unselected Ss were assigned to a 2 x 3 (Request for Honesty x Suggestibility Instruction) factorial design to test the hypothesis that hypnotic Ss would show pronounced impairment of reality testing by expressing a degree of conviction substantially out of phase with their objective performance. Barber's operational model of hypnosis was adopted to test the prediction on an unusually distinctive auditory comprehension task. The 2 interdependent measures, confidence and accuracy, were highly positively related indicating that, generally speaking, hypnotic Ss performed adaptively, as did task motivated and control Ss. Results for the difficult aspects of the task were most distinctive. Here, degree of confidence about behavior as expressed by Ss who performed well on the suggestibility tests was relatively greater than the confidence expressed by those who performed poorly; further, hypnotic Ss were distinctively willing to respond on the least intelligible parts of the task. The inconsistent nature of certain features of hypnotic behavior was discussed in some detail.

1976

Miller, Lawrence J. (1976). A comparison of hypnotic susceptibility for internal and external locus of control subjects in hetero- and self-hypnotic treatments (Dissertation). Dissertation Abstracts International, 37, 978-979.

"This study investigated the use of self- and hetero-hypnosis with internal and external locus of control subjects. Fifty-eight subjects, matched on hypnotic susceptibility and internal-external locus of control, were randomly assigned to the self- or hetero-hypnotic treatments. Self reports of their hypnotic behavioral scores and hypnotic subjective responses were obtained for each subject. "The statistical analyses showed there were no significant differences between the internal and external locus of control groups or within groups in regard to self- and hetero-hypnosis total behavioral scores, "challenge" or "non-challenge" items, .... their reported subjective experiences. The results supported the similarity of hetero- and self- hypnosis. Various findings from past research in regard to I-E subjects were also challenged in terms of their generalizability to hypnotic settings" (pp. 978-979).

1975

Barber, Theodore Xenophon (1975). Responding to 'hypnotic' suggestions: An introspective report. American Journal of Clinical Hypnosis, 18 (1), 6-22.

The author first presents an introspective report which describes some of his attitudes, motivations, and expectancies and ongoing thought processes while he is responding to 'hypnotic' suggestions. The introspective report indicates that (a) suggested effects are experienced when a person thinks with and imaginatively focuses on those things that are suggested and (b) a person imaginatively focuses on the suggestions when he sees the test situation as useful and worthwhile and when he wants to and expects to experience those things that are suggested. It is then argued that the responsive subject in a hypnotic situation differs in every important respect from the sleepwalker and closely resembles the person who is involved in reading an interesting novel or in observing an interesting motion picture. Finally, the author outlines a course, now being developed, that aims to teach individuals how to respond to suggestions.

**Mather, Marcia; Degun, Gian S. (1975). A comparative study of hypnosis and relaxation. British Journal of Medical Psychology, 48, 55-63.**

**Hypothesis 2. Learning would be an important variable in the efficacy of post- hypnotic suggestions (n.s.) Hypothesis 3. Suggestions made towards the end of the experimental session would be more effective than suggestions at the beginning; the assumption being that the trance might deepen with the passage of time (n.s.) Hypothesis 4. There would be a significant difference in heart rate between the waking and hypnotic states (n.s.) Hypothesis 5. There would be a shift in attitudes of the subject in favor of hypnosis from pre- to post-experiment due to an increase in susceptibility following training. (p.<.01)**

**The study employed 3 groups, 2 subject groups; there were 1 hypnosis and 1 relaxation session per subject, in a randomized AB, BA design. The relaxation condition only asked the subject to lie on a couch and relax; no relaxation instructions were given, therefore it is not really analogous to relaxation training given in clinical settings. A posthypnotic suggestion was given - to dream on a subject related topic, then to awaken, and to carry out an action.**

**Research and Development Technical Report ECOM-0161-F; AD-913 696L; Contract DAAB07-71-C-0161 with Signatron, Inc. (Lexington, MA). Distribution limited to U.S. Government agencies only; Other requests for this document must be referred to Commanding General, U.S. Army Electronics Command, ATTN: AMSEL-PP-CM-CR4, Fort Monmouth, NJ 07703. NOTES 2: This document reports on a U.S. Army research project using hypnosis to collect high fidelity samples of the voice under "combat stress" conditions in the laboratory. Using hypnotic regression, combat veterans "re-experienced" their own, actual high stress combat situations. Besides subjective reports of stress levels by subjects, physiological stress measures were obtained from polygraph recordings of heart, respiration and GSR activity. The voice samples were later analyzed by spectrographic techniques to determine which factors remain invariant to identify and authenticate the speaker in a military communications situation. Hypnotic techniques were shown to be useful in establishing controlled emotional states for laboratory research purposes. (Richard Bloom)**

**1970**

**Evans, Michael B.; Paul, Gordon L. (1970). Effects of hypnotically suggested analgesia on physiological and subjective responses to cold stress. Journal of Consulting and Clinical Psychology, 35 (3), 362-371.**

**Relative effects of suggested analgesia and hypnotic induction were evaluated with regard to reduction of stress responses (self-report, heart rate, pulse volume) to the physical application of ice-water stress. Four groups (N = 16 each) of undergraduate female Ss, equated on hypnotic susceptibility, were run individually, receiving (a) hypnotic induction plus analgesic suggestion, (b) hypnotic induction alone, (c) waking self-relaxation plus analgesic suggestion, or (d) waking self-relaxation alone. The major findings were that suggestion, not hypnotic induction procedures, produced reductions in the self-report of distress, and that the degree of reduction was related to hypnotic susceptibility in both "hypnotic and "waking" conditions. Neither suggestion nor hypnotic induction procedures resulted in reduction of the physiological stress responses monitored in this study. Several methodological issues are discussed. Although findings add to the bulk of evidence supporting the "skeptical" view of**

hypnotic phenomena, results are related to other literature, suggesting that an adequate evaluation of hypnotic analgesia as used clinically has not yet been undertaken.

Tart, Charles T. (1970). Self-report scales of hypnotic depth. International Journal of Clinical and Experimental Hypnosis, 18, 105-235. Keywords: depth, subjective experience, test/scale

35 male undergraduates scaled their depth of hypnosis on a 10-point scale after each suggestibility test item on the Stanford Hypnotic Susceptibility Scale, Form C. These self-reports were highly correlated with measures of hypnotic behavior and experience. Instructions to report depth immediately and without thinking produced reports which correlated somewhat better with the other measures than instructions to consciously make a best estimate. This self-report scale promises to be highly useful in studies of hypnosis. (Spanish & German summaries) (22 ref.) (PsycINFO Database Record (c) 2003 APA, all rights reserved)

Gendlin, Eugene T. (1969). Focusing. Psychotherapy, 6 (1), 4-15.

## NOTES

This paper presents a therapeutic procedure that involves experiential focusing, described as a bodily method. The paper provides a step by step procedure that has been used in research. "First of all, the method involves a sharp and complete shift in direction. One must cease talking at oneself inside; one must ask: 'What's wrong?' and then keep quiet, and refrain from answering oneself. It is understood that everyone knows a great deal about what is wrong..." (P. 4).

"Whenever the patient is unsure about what he has found (explaining or doubting) the way to deal with it is always again with a fresh start. One needn't decide the verbal issues that arise. 'Focus freshly on it instead, let it come freshly again' - this is almost always the answer to whatever the issue now seems to be" (p. 6).

"In this experiential therapy, it is important that the therapist respond to what is directly felt even while it isn't yet conceptually clear. What patients sense in focusing is often conceptually vague. The patient feels the felt meaning distinctly enough, but if he talks, he often begins by complaining that it isn't possible to think about it clearly. 'There's something funny there, about the way I pull out of relationships ... (He has talked about the problem before, but not about what is 'funny' here, he just focused and encountered that) ... but I can't describe it. It's ... ah ... funny, there.' The therapist must be able to talk to that, even without knowing what it is: 'You got something there, but you don't know what it is, yet. It's a funny something that you find, right there in how you pull out'" (pp. 6-7).

The theory postulates 'felt meaning' as a body sense of the many complexities of a problem, and experiential effect as a kind of body resolution of a problem. Focusing is viewed as "one essential of psychotherapy, desensitization, Jungian imagery, hypnotherapy, free association, and other methods" (p. 9). "Experiential focusing makes specific and synthesizes the steps of those therapeutic methods which systematically seek to engender body change process" (p. 10).

1968

Gendlin, Eugene T. (1968). The experiential response. In Hammer, E. F. (Ed.), Use of interpretation in treatment: Technique and art (pp. 208-227). New York: Grune & Stratton.

## NOTES

The author poses the question, "How can a therapist's response have a concrete experiential effect in the individual?" He notes that therapists do not deal with clear emotions but with more complex experiencing. "What we feel is not an internal object (an 'affective state' as something only inside us), but a felt sense of a whole situation - how we are in that situation, what we bring about, perceive, and

feel we are up against" (p. 209). "Therefore, such a felt sense isn't something only felt, but is also intellectual" (p. 209).

The therapist should draw the patient's attention to the complexity of experiencing. "Only as the client 'focuses' on his felt meaning, can it shift, and only from it can further facets emerge. Some individuals come into psychotherapy with a great ability to engage in this experiential 'focusing'(Gendlin, 1968), while with others the therapist must struggle to draw their attention again and again to the felt sense they concretely have. Sometimes the client acts as though he had no idea that he has access to anything but his words" (p. 211).

The therapy must remain experiential. "A therapeutic response always aims at the client's own directly-felt sense of what he is talking about" (p. 213).

1963

Tart, Charles T. (1963). Hypnotic depth and basal skin resistance. International Journal of Clinical and Experimental Hypnosis, 11, 81-92.

This investigation studied the relationship between a self-report scale for measuring the depth of the hypnotic state and basal skin resistance (BSR). The self-report scale accurately predicted the occurrence of hypnotic dreaming and amnesia, traditional criteria for medium and deep hypnotic states. BSR showed a high, positive correlation with the self-report depth scale. The data suggest that both the self-report scale and BSR may be useful measures for detecting changes in hypnotic depth. Sutcliffe, J. P. (1961). 'Credulous' and 'Skeptical' views of hypnotic phenomena: Experiments on anesthesia, hallucination, and delusion. Journal of Abnormal and Social Psychology, 62, 189-200.

The author distinguishes between 2 interpretations of hypnotic phenomena: the credulous (S does or does not experience what the hypnotist suggests) and the skeptical (S reports what is suggested regardless of the "reality" of his experience). 2 groups of Ss (distinguished with respect to the presence or not of genuine hypnotic behavior and posthypnotic amnesia) were placed in a 3 [control (not under hypnotic trance), hypnotic trance, nontrance acting (S asked to act as if conditions were as suggested)] by 2 (stimulus present or not) design involving paraesthesias, hallucinations, and delusional thinking. Evidence (such as GSR, interference in thinking due to feedback, test measures of delusion) suggests that S does not misperceive the real situation, but misreports it. 1957

Leuba, Clarence (1957). The reality of hypnotic phenomena: A critique of the role playing theory of hypnosis. Journal of Clinical and Experimental Hypnosis, 5 (1), 32-38.

## NOTES

The author describes circumstances that produce paralyzes, hallucinations, and other hypnotic phenomena in normal everyday life, as well as occasionally in hysteria. He suggests that "the phenomena which can be learned and produced in everyday life and are genuine there, can presumably, when conditions are made appropriate under hypnosis, be equally genuine there also" (p. 36). Although the hypnotized and age regressed subject is "taking a part which is different from his ordinary distractible critical self," that is not to imply he is pretending. An hysterical symptom is not malingering. "In the hysterical patient there is a powerful drive to concentrate upon the reality of a useful disability and to exclude contradictory or distracting aspects of the environment. In inducing an

hypnotic state, conducive to the phenomena of hysteria, it is the hypnotist who has somehow to narrow and concentrate his subject's attention and diminish distractions. ... [and] there must be a set or attitude to accept the hypnotist's statements completely and uncritically" (pp. 37-38).

1953

LeCron, Leslie M. (1953). A method of measuring the depth of hypnosis. Journal of Clinical and Experimental Hypnosis, 1 (2), 4-7

Author's Summary - No satisfactory method of ascertaining quickly and accurately the depth of hypnotic trance has heretofore been available. By providing the hypnotized subject with a yardstick of measurement, a reply to the question "how deep are you?" may be obtained from the subconscious mind of the subject himself. This is expressed verbally in percentages of from 1 to 100, with percentage values arbitrarily assigned by the operator to different stages of trance. Indications from testing 30 subjects are that their replies are valid, possibly to an astounding degree of accuracy. (p. 6)

## SUBLIMINAL STIMULATION

1994

Erickson III, James C. (1994). The use of hypnosis in anesthesia: A master class commentary. [Comment/Discussion]

## NOTES

The author answers questions sent by a reader: "When and how can I use hypnosis or hypnotic principles in preparing patients for surgery and while undergoing surgery? Are there studies or experiential evidence to use as guides for the selection of appropriate cases or types of operations?" (p. 8). SUMMARY "There are unequivocal benefits derived from the use of positive suggestion and hypnotic techniques in all patients who must submit to surgical and obstetrical procedures with modern general or regional anesthesia. We must learn, and we must teach our colleagues, the advantages of consistent use of the semantics of positive suggestion. When we help patients focus on the desired comfort, safety, and satisfaction obtained with well-managed modern anesthesia and surgery, they will enjoy great benefit, especially when we use the auditory perception that often exists during general anesthesia. Rather than regarding hypnotic suggestion as a mere adjunct to anesthesia, it should be regarded as an integral part of surgical and obstetrical care" (pp. 11-12).

1992

Bruner, Jerome (1992). Another look at New Look 1. American Psychologist, 47, 780-783.

New Look 1 was not initially about the unconscious. It was the new mentalism on its way to becoming the Cognitive Revolution. Its subsequent concern with "unconscious defense mechanisms," although useful, was not its main theoretical thrust. Its principal questions have always been how and where selective processes operate in perception. Obviously, many such processes are unconscious, for consciously guided attention and search become automatized easily in use. And they are fairly flexible as well. So how smart is "the unconscious"? Not very, but a big help anyway.

Erdelyi, Matthew, Hugh (1992). Psychodynamics and the unconscious. American Psychologist, 47, 784-787.

The original New Look integrated the constructivist-psychodynamic traditions of Bartlett and Freud. The unconscious (Greenwald's "New Look 3") is a logically different idea, although in practice it is often intertwined with constructivist - psychodynamic approaches. The unconscious is a pretheoretic term with a variety of problems: It has multiple and unsettled meanings; null reports need not signify

null awareness; the conscious-unconscious dichotomy implied by the limen may not exist; even "absolute subliminality" (chance-level accessibility) is relative to the time interval of testing, as accessibility can increase to above-chance levels over time (hypermnnesia). Yet, the phenomena that the unconscious sloppily subsumes are not simple or dumb. The capacity of subliminal perception should not be confused with the capacity of subliminal (unconscious) memory and cognition.

Jacoby, Larry L.; Lindsay, D. Stephen; Toth, Jeffrey P. (1992). Unconscious influences revealed: Attention, awareness, and control. American Psychologist, 47, 802-809.

Recent findings of dissociations between direct and indirect tests of memory and perception have renewed enthusiasm for the study of unconscious processing. The authors argue that such findings are heir to the same problems of interpretation as are earlier evidence of unconscious influences--namely, one cannot eliminate the possibility that conscious processes contaminated the measure of unconscious processes. To solve this problem, the authors define unconscious influences in terms of lack of conscious control and then describe a process dissociation procedure that yields separate quantitative estimates of the concurrent contributions of unconscious and consciously controlled processing to task performance. This technique allows one to go beyond demonstrating the existence of unconscious processes to examine factors that determine their magnitude.

Merikle, Philip M. (1992). Perception without awareness: Critical issues. American Psychologist, 47, 792-795.

#### NOTES

This is the introduction to a group of articles. "To a large extent, this entire controversy over perception without awareness has centered on the issue, What constitutes an adequate behavioral measure of conscious perceptual experience? Depending upon one's answer to this question, the evidence for perception without awareness is either overwhelming or nonexistent.

The distinction is much more significant and interesting if conscious and unconscious processes lead to qualitatively different consequences than if unconscious processes are simply quantitatively weaker versions of unconscious processes. Three different qualitative differences have been established: 1. Groeger (1984, 1988) has demonstrated that words are coded differently depending on whether they are perceived with or without awareness. 2. Stroop effect research showed that prediction based on stimulus redundancy only occurs when subjects consciously perceive the predictive stimuli (Cheesman & Merikle, 1986). The fact that the color word predicted the name of the color patch on 75% of the trials was only used by the subjects to facilitate naming of the color patches when the words were clearly visible. 3. Marcel (1980) showed that conscious awareness is necessary for the selection of a context-relevant interpretation of a stimulus.

The important findings are that performance differs qualitatively across the aware and nonaware conditions.

#### 1991

Dixon, Norman F.; Henley, Susan H. (1991). Unconscious perception: Possible implications of data from academic research for clinical practice. Journal of Nervous and Mental Disease, 179 (5), 243-252.

Evidence for the reality of unconscious perception and perceptual defense suggests that the experimental paradigms used to investigate these phenomena might play a role in the understanding and treatment of mental disorders. The literature on applying subliminal stimulation to problems of diagnosis and therapy indicates that data support the view that the meaning of external stimuli of which the recipient is unaware may be responded to and determine emotional responses, lexical

decisions, overt behavior, and subjective experience. Data confirm the reality of psychopathology as a substrate of emotionally colored, stored information with a potential for producing somatic symptoms and disorders of thinking, affect, and behavior. To the extent that psychopathology is screened from conscious scrutiny and thus impervious to supraliminal information, it may be accessed and ameliorated by drive-related stimuli of which the S is not aware.

1990

Bornstein, Robert F. (1990). Critical importance of stimulus unawareness for the production of subliminal psychodynamic activation effects: A meta-analytic review. Journal of Clinical Psychology, **46**, 201-210.

Performed meta-analysis that assessed the magnitude of behavior change produced by subliminal vs supraliminal drive-related stimuli (DRS) on 11 subliminal psychodynamic activation (SPA) studies (published 1966-1989) that employed both types of stimuli. The analysis revealed that subliminal presentation of DRS produced significantly stronger effects on behavior than supraliminal presentation of the same stimuli. Stimulus content, type of outcome measure, and S characteristics influenced the magnitude of subliminal/supraliminal response differences. Results support L. H. Silverman's (1983) hypothesis that DRS must be presented subliminally to produce SPA effects.

Kunzendorf, Robert G.; Jesses, Michael; Dupille, Leonard; Butler, William (1990-91). Subliminal activation of intrapsychic conflicts: Subconscious realms of mind vs subconscious processes of mentation. Imagination, Cognition and Personality, **10**, 117-128.

## NOTES

Cognitive-state monitoring theory asserts that people perceive subliminal stimulation without self-consciously monitoring its external innervation (as opposed to central innervation). Thus monitoring theory predicts that subconsciously perceived discord, in the absence of any 'external location' cues, should be misinterpreted as centrally generated discord and should disrupt self-generated behavior. Consistent with this prediction, mathematical problem-solving in the current experiment was disrupted after mathematically competitive males repeatedly heard the subliminal message IT'S WRONG TO CRUSH DADDY stereophonically localized in the middle of their heads--but not after they repeatedly heard this subliminal 'Oedipal' message binaurally localized on one side of their heads. A subliminal message binaurally localized on one side of the self should not interfere with problem-solving behavior \_because, even though the message's external innervation is not self-consciously 'monitored,' its external location is inferable from subconscious cues.\_

Monitoring theory asserts that subliminal [perceptions] of 'unmonitored' messages are unaccompanied by any self-consciousness that one is perceiving them (rather than imaging them), and that subliminal or 'unmonitored' messages of distress are mistaken for self-generated distress.

Disruption by the 'internal' subliminal word WRONG seems to us consistent with the fact that disruption was limited to mathematically competent males.

Indeed, 'repression' itself is a mode of processing fearful information: a mode in which subjects suspend their self-awareness that they are perceiving fearful stimulation, as research by Kunzendorf and McLaughlin has demonstrated. This selective suspension of monitoring provides immediate relief from fearful stimuli, Freudian or otherwise, but it does so at the risk of turning self-conscious fear into subconscious anxiety (into consciously lingering fear without a self consciously perceived source). No subconscious realm full of lurking fears is implicated in this 'unmonitored' mode of self-protection. All that is implicated is an unconscious storehouse of potentially fearful memories--potentially fearful but sensationless memories, which can be 'suppressed' from conscious sensory representation or

'constructed' into conscious memory images or 'subconsciously represented' as unself-consciously imaged sensations.

McLintock, T. T.; Aitken, H.; Downie, C. F.; Kenny, G. N. (1990). Postoperative analgesic requirements in patients exposed to positive intraoperative suggestions. British Medical Journal, 301 (6755), 788-790.

Sixty-three women undergoing elective abdominal hysterectomy were randomly assigned to a tape of positive suggestions or a blank tape during the operation. Anesthesia was standardized for all of the women. Postoperative analgesia was provided through a patient-controlled analgesia system for the first 24 hours. Pain scores were recorded every 6 hours. The outcome measures were morphine consumption in the first 24 hours and pain scores. Mean morphine requirements were 51.0 mg in women who were played positive suggestions, and 65.7 mg in those played a blank tape ( $p = 0.028$ ). Pain scores were similar in the two groups. It was concluded that intraoperative suggestions seem to have a positive effect in reducing patients' morphine requirements in the early postoperative period.

Weinberger, Joel; Hardaway, Richard (1990). Separating science from myth in subliminal psychodynamic activation. Clinical Psychology Review, 10, 727-756.

This paper reviews subliminal psychodynamic activation (SPA). Eight common criticisms are described and evaluated: (a) SPA data analysis is too liberal; (b) there are enough nonsignificant unpublished SPA studies to offset those showing effects; (c) SPA studies are difficult to replicate; (d) the claims of SPA proponents rely on unpublished studies; (e) SPA stimuli are not really subliminal; (f) experimenter expectancy effects and/or demand characteristics can account for SPA effects; (g) the mediating events said to underlay SPA effects have never been evinced; and (h) alternative explanations for SPA effects are superior to the psychoanalytic ones typically offered. Theoretical and statistical analyses revealed that only the argument concerning mediating events has serious merit. The SPA stimulus for which the most support was found was Mommy and I Are One. Oedipal sanction stimuli were also found to yield reliable effects whereas Oedipal prohibition stimuli did not. Suggestions for future research are offered. Resistance to SPA findings are considered in Kuhnian terms.

Wood, W. E.; Gibson, W.; Longo, D. (1990). Moderation of morbidity following tonsillectomy and adenoidectomy: A study of awareness under anesthesia. International Journal of Pediatric Otorhinolaryngology, 20, 93-105.

In a double-blind study, 67 children, ages 3-10, were randomly assigned to one of three groups: tape recorded therapeutic suggestions repetitively recited in English or in French, and a control of continuous white noise. The English condition was associated with more favorable outcome on all parameters, although statistical significance could not be demonstrated. Favorable outcomes appeared most significant for those patients at highest risk for poor convalescence (i.e., poor status preoperative patients).

1988

Borgeat, Francois; Rezanowicz, Thaddeus; Chaloult, Louis (1988). La stimulation preconsciente et consciente de l'imaginaire erotique. Revue Canadienne de Psychiatrie, 33, 394-398.

The stimulation of erotic fantasies through the association of relaxation and erotic conscious or preconscious suggestions has been evaluated. This study was attempted following positive results in the stimulation of fantasmatic activity in alexithymic subjects with a similar procedure. Thirty female subjects, allocated into three groups practiced relaxation daily for two weeks including three sessions

with psychological measures. During the second week, erotic suggestions, preconscious for one group and conscious for another one were added. The third group (control) received only relaxation throughout. Results have shown an increase of sexual arousal and erotic imagery during the sessions with erotic suggestions. Sexual activities and desire increased in the two experimental groups. There was no difference between the effects of the preconscious and conscious suggestions. Possible clinical applications of such a procedure are discussed.

1987

Nash, Michael R.; Lynn, Steven Jay; Stanley, Scott; Carlson, Victor (1987). Subjectively complete hypnotic deafness and auditory priming. International Journal of Clinical and Experimental Hypnosis, 35 (1), 32-40.

The present study examined the cognitive and attentional mechanisms by which auditory information is maintained out of awareness during complete hypnotic deafness. Adopting a methodology from recent work on subliminally presented pattern- masked words and dichotic listening, the study tested whether spoken words presented during complete hypnotic deafness affect lexical decisions concerning subsequently presented word choices. The response of 9 hypnotized and 15 simulating Ss to spoken stimulus words presented following hypnotic deafness instructions was compared to the response of 20 baseline control Ss who never were exposed to the stimulus words. While the response pattern of hypnosis Ss appeared different from that of baseline control Ss, hypnotic Ss showed no evidence of the priming effect found in subliminal perception and dichotic listening studies. Simulator response deviated significantly from hypnotized and baseline control responses.

#### NOTES

10 highs capable of hypnotic deafness, screened by Harvard Group and Stanford Profile Scales (Means 11.0 and 24.7, respectively) and 15 lows (means 1.7 and 1.7, respectively) participated in the study; the low hypnotizables being in the simulation group. For the experimental session, a different E administered a standard hypnotic induction and the deafness suggestion, testing for deafness by snapping fingers near S's ear and making loud requests for motor responses.

An experimental trial consisted of tapping an S on the hand, saying the stimulus word out loud, and visually presenting four words for the S to read out loud and circle one. "Of the 18 main experimental trials, the four-word array consisted of two words which were related to the stimulus (one word which was semantically related to the spoken stimulus word and one word which was phonetically related), and two neutral unrelated words" (p. 34). For example, if the spoken word were 'dream,' the word array might include 'cream, tennis, sell, sleep.' There also were "3 phonetically unrelated trials (whose arrays consisted of one phonetically related choice and 3 unrelated choices) and 2 stimulus word-unrelated trials (whose arrays consisted of the stimulus word and 3 unrelated choices) ... [and] 7 dummy trials with 4 unrelated choices only" (p. 34). Ss rated their degree of deafness on a 10-point scale after hypnosis was terminated.

Possible sources of bias were examined by having 20 control Ss respond to blank tachistoscopic slides with the instructions that they were participating in a study of 'subliminal perception.' Another 22 Ss were asked to identify the semantically and phonetically related words from the word array, which for the most part they did successfully.

All Ss rated themselves as '10' on the deafness scale, indicating total deafness. The principal results are seen in Tables 1 and 2.

Table 1 Mean Number of Related and Unrelated Responses (Percentage of Responses) for all S Groups on the 18 Mean Experimental Trials

Response Category	S	Group	N	Related	Unrelated	Total
Hypnotized	9	7.22	10.78	18		

(40.13%) (59.88%) (100%)

Simulating 15 12.13 5.87 18

(67.43%) (32.61%) (100%)

Baseline 19 8.79 9.21 18 Controls (48.82%) (51.17%) (100%)

**Table 2 Mean Number of Phonetic and Semantic Responses within the Related Response Category on the 18 Main Experimental Trials**

**Related Responses S Group Phonetic Semantic Hypnotized 1.78 5.44**

**(9.89%) (30.24%) Simulating 7.07 5.07**

**(39.27%) (28.16%) Baseline 4.21 4.58 Controls (23.38%) (25.44%)**

Hypnotized Ss were significantly different from simulators (Table 1) in number of related responses. Simulators gave significantly more related responses than baseline controls. Simulators also gave more phonetically related words than either the hypnotized or baseline Ss (Table 2); there was no difference between groups on semantically related words. (Authors performed other useful and detailed analyses.)

In their Discussion section, the authors note that they did not obtain the expected results of hypnotized Ss producing more related responses than baseline Ss. "In fact, internal analyses of hypnotized and baseline responses revealed that the pattern of choices for hypnotic deaf Ss was opposite to the direction predicted by subception. Hypnotic Ss appeared to avoid phonetically related word choices, even for items on which baseline control Ss scored above chance. ...

"This kind of non-baseline performance by hypnotic Ss can be accounted for by either a strategic enactment conceptualization of hypnosis (Spanos, 1982; Wagstaff, 1981) or Hilgard's (1979) neo-dissociation theory. Spanos might emphasize the hypnotic S's active strivings to meet the hypnotist's perceived expectations. ... Neo-dissociation theory might stress the mechanisms by which processing of auditory inputs are maintained outside of awareness via a dissociative barrier.

" ... Given the tendency for simulating Ss to 'overplay' hypnotic phenomena (Levitt & Chapman, 1979), one might have expected simulators to pointedly avoid related responses, thus producing a lower frequency of related words than either the hypnotic Ss or the baseline controls (in effect being more deaf than the deaf). Just the opposite occurred. One possible explanation for this behavior presents itself: In their work with posthypnotic suggestion and the 'disappearing hypnotist' ... M. T. Orne and others found that simulating Ss may be more alert and responsive to demand cues than are hypnotic Ss. In the present study, the authors' original hypothesis was that hypnotic Ss might reveal a subception effect by above-chance responding on related word choices. If we assume that this expectation was somehow communicated to Ss by some subtle aspect of the experimental procedure, then it is conceivable that simulating Ss were able to detect and act upon these cues, while hypnotized Ss remained relatively unattuned to such subtleties.

"In sum, the priming effect noted in the subliminal perception research does not appear to be a feature of complete hypnotic deafness, at least as measured in this study. The behavior of simulating Ss in the present study should be another caution to researchers that differences between hypnotized and simulating Ss may reflect simulation effects in addition to, or instead of, hypnotic effects" (pp. 37-38).

**1986**

**Kaplan, Rosalind (1985). Further data on the effects of subliminal symbiotic stimulation on schizophrenics. Journal of Nervous and Mental Disease, 173 (11), 658-666.**

Examined the effects of activating unconscious symbiotic fantasies in 128 hospitalized schizophrenic men (aged 18-65 years) who qualified as relatively differentiated on an adjective rating scale and were randomly assigned to 4 groups. Each group was assessed for pathological thinking, pathological nonverbal behavior, and self-esteem before and after the subliminal exposure of an experimental and control stimulus. The control stimulus for all groups were the messages "Mommy and I are one,"

"Mommy is always with me," "Mommy feeds me well," and "I cannot hurt Mommy""(one for each group). One-half of each group was subliminally exposed to verbal messages only and one-half to verbal messages accompanied by congruent pictures. The 1st stimulus ("Mommy and I are one") was intended to activate unconscious symbiotic fantasies that in a number of prior studies reduced pathology in groups of relatively differentiated schizophrenics. The other stimuli were intended to activate reassuring unconscious fantasies about "Mommy" that were not specifically symbiosis-related. Only the "Mommy and I are one" stimulus led to more adaptive behavior and did so on all 3 dependent variables. This supported the supposition that it is specifically symbiosis-related gratifications that are ameliorative for schizophrenics. (23 ref.)

Oliver, J. M.; Burkham, Robert (1985). 'Comments on three recent subliminal psychodynamic activation investigations': Reply to Silverman. Journal of Abnormal Psychology, 94 (4), 644.

Contends that the present authors' (see PA, vol 69:1571) failure to replicate L. H. Silverman's (1976) description of subliminal psychodynamic activation, which was disputed by Silverman (see PA, vol 73:12007), can be traced in part to Silverman's (1978) description of the "symbiotic" stimulus (MOMMY AND I ARE ONE"), 1 of the 2 experimental stimuli used, as a "ubiquitous therapeutic agent". It is suggested that, although Silverman's willingness to modify his theory in light of empirical findings is commendable, modifications that are too frequent and numerous will pose problems for both theory and research. (5 ref)

Porterfield, Albert L.; Golding, Stephen L. (1985). Failure to find an effect of subliminal psychodynamic activation upon cognitive measures of pathology in schizophrenia. Journal of Abnormal Psychology, 94 (4), 630-639.

Replicated the work of L. H. Silverman and colleagues (see PA, vols. 43:14557 and 46:1566) using 30 21-59 year old schizophrenics. Ss were exposed to an aggressive, a merging, and a meaningless lexical stimulus in a within-S design. Dependent variables were inkblot through pathology and form quality, as measured on Rorschach and Holtzman Inkblot Techniques, and performance on the interference task of the Stroop Color-Word Test. Analyses of variance conducted on simple poststimulation scores, rather than on unreliable change scores, revealed no effect of stimulus content. Predicted interactions between stimulus content, Ss self-object differentiation, and temporal position of the assessment tasks did not emerge. Findings do not support Silverman's hypothesis that subliminal tachistoscopic presentations of stimuli with aggressive content temporarily increase thinking disorder in schizophrenics. (44 ref.)

Porterfield, Albert L. (1985). 'Comments on three recent subliminal psychodynamic activation investigations': Reply to Silverman. Journal of Abnormal Psychology, 94 (4), 645-646.

## NOTES

Contends that in defending his nonverbal pathology measure against the claim that it lacks demonstrated validity, L. H. Silverman (see PA, vol 73:12007) painted a misleading picture of its face validity. A correction to that picture is presented, and the impact of the present author and S. L. Golding's (see PA, vol 73:11992) findings on subliminal psychodynamic activation explanations of schizophrenic thought disorder is defended, despite the absence of a nonverbal pathology measure. (5 ref)

Silverman, Lloyd H. (1985). 'Comments on three recent subliminal psychodynamic activation investigations': Rejoinder to Oliver and Burkham and to Porterfield. Journal of Abnormal Psychology, 94 (4), 647-8.

Considers the replies of A. L. Porterfield (see PA, vol 73:11991) and J. M. Oliver and R. Burkham (see PA, vol 73:11985) to the critique of the present author (see PA, vol 73:12007). The original criticisms are seen as valid. A critical deficiency in the design of Porterfield and S. L. Golding's (see PA, vol 73:11992) study is viewed as disqualifying it as a fair attempt at replication. It is suggested that although Oliver and Burkham's (see PA, vol 69:1571) study was well-designed, statements made in their write-up are unwarranted. (12 ref)

Silverman, Lloyd H. (1985). Research on psychoanalytic psychodynamic propositions. Clinical Psychology Review, 5 (3), 247-257.

Discusses a research program in which the present author has been involved that deals with the subliminal psychodynamic activation method. In this method, verbal and/or pictorial stimuli, some of which contain content related to unconscious wishes, fears, and fantasies and other of which are (relatively) neutral, are presented to Ss at 4-msec exposures. A variety of psychoanalytically based hypotheses have been tested on various clinical and nonclinical populations. Two major findings have emerged: (a) a number of clinical groups (e.g., schizophrenics, depressives, stutterers) have shown intensifications of their symptoms after the subliminal exposure of stimuli designed to stir up particular unconscious conflicts; and (b) various clinical and nonclinical groups have manifested enhanced adaptive behavior after the subliminal exposure of the message "Mommy and I are one," conceived as activating unconscious symbiotic fantasies.

1984

Divided 64 10.8 - 19.3 yr old emotionally disturbed residents of a treatment school into an experimental and control group matched for age, IQ, and reading ability. Both groups were seen 5 times/week for 6 weeks for tachistoscopic exposures of a subliminal stimulus. The stimulus for the experimental group was the phrase, "Mommy and I are one," conceived of as activating symbiotic fantasies that in a number of previous studies with varying groups of Ss had led to greater adaptive behavior. The control group was exposed to the phrase, "People are walking." Results show that experimental Ss manifested significantly greater improvement on the California Achievement Tests--Reading than did the controls. On 5 of 6 secondary variables--arithmetic achievement, self-concept, the handing in of homework assignments, independent classroom functioning, and self-imposed limits on TV viewing--the experimental Ss showed better adaptive functioning. It is suggested that activation of unconscious symbiotic fantasies can increase the effectiveness of counseling and teaching. (42 ref)

Frauman, David C.; Lynn, Steven Jay; Hardaway, Richard; Molteni, Andrew (1984). Effect of subliminal symbiotic activation on hypnotic rapport and susceptibility. Journal of Abnormal Psychology, 93 (4), 481-483.

L. H. Silverman's subliminal symbiotic activation paradigm (Silverman, 1982) was used to manipulate unconscious affective factors in hypnosis to determine whether gratification of symbiotic fantasy would enhance hypnotic susceptibility and rapport with the hypnotist. Seventy-two male undergraduates were divided into two groups matched for susceptibility (high, medium, low). The experimental group received symbiotic, MOMMY AND I ARE ONE, subliminal stimulation via tachistoscope in a double-blind design. The comparison group received a psychodynamically neutral stimulus, PEOPLE ARE WALKING. Following subliminal stimulation, subjects were hypnotized individually. Projective tasks that indexed rapport with the hypnotist and the mother were administered during hypnosis. Rapport was also measured by rated intimacy of self-disclosure topics and by valence of topics selected to

disclose to the hypnotist. A significant multivariate group selected more positively valenced topics to disclose on. The effect for symbiotic activation on hypnotic susceptibility was not quite significant ( $p < .056$ , two-tailed).

## NOTES

2350, Frauman, Lynn, Mare, & Kvaal, 1992 NOTES: [Paper presented by Lynn.] A number of observations and conclusions are based on literature reviews done with Brentar (British Journal of Experimental and Clinical Hypnosis; Chapter in Rhue, Lynn, & Kirsch [Eds.] Handbook of Clinical Hypnosis) and 15 years of training students in hypnotherapy. Some of this may seem elementary to some of you.

For half a century there have been reports of negative effects after hypnosis: minor, serious, transient, and chronic. Clinicians need be as wary (but no more wary) of negative effects in hypnosis as in other therapies. There are more negative effects in clinical situations than non clinical situations.

Therapists must be prepared to recognize negative effects and intervene.

Too often hypnosis is seen as a technique divorced from psychotherapy. The hypnotist must be a competent psychotherapist. What makes you a good therapist will make you a good hypnotherapist.

There should be careful assessment of the client for: 1. those with history of unusual experiences following anesthesia or drugs 2. those with a history of dissociation

People may recapitulate a previous bad experience with anesthesia, based on the unusual physiological feelings. The dissociative client must be stabilized before using hypnosis. Depressed clients may also have problems, with the imagery becoming dysphoric. Those vulnerable to psychotic decompensation, with paranoid or borderline character structures, must be evaluated carefully. A lot depends on your comfort zone in therapy.

Life experiences with parents and authority figures may also play into the reaction.

Many clients, and experimental Ss, are ambivalent about hypnosis. This ambivalence must be acknowledged and one must work with the ambivalence before proceeding. One may: - explain hypnosis - reframe in terms of self hypnosis or relaxation - explain as a state of awareness with full consciousness - offer active induction which is just as effective as the passive induction - do induction with eyes open

Research clearly shows that Subjects can monitor events outside the framework of a suggestion--especially if you suggest they can do so with ease.

We do not use ideomotor suggestions because they aren't necessary. We tell them to open their eyes and communicate with us during hypnosis.

We always assess their feelings about hypnosis, have them have a fantasy about what hypnosis would be like, do an informal semantic analysis of the descriptors clients use (and then reframe them), inquire about previous experiences with counseling and psychotherapy, and do a mental status. Don't make assumptions. We want to know about early life experiences to know about transference and form an alliance.

Hypnosis procedures employed must have explicit informed consent (cf MacHovic book), which also provides opportunity to demystify the experience. Our research shows the great majority of Ss find it relaxing, invigorating. Even perceptual distortions can be created without hypnosis. Can create confidence by sharing the research information on hypnosis.

Elicit cooperation with easier suggestions, then use graded suggestions. We want to titrate the demands on clients, move at a pace that keeps anxiety low, promote self efficacy and mastery through ... [missed a few words] and graduated tasks.

Carefully monitor clients for frowns, lack of attention, etc. It is important to ask them what they are experiencing. Rarely, a client appears unable to talk, in which case the therapist can offer hypotheses to the hypnotized client.

Don't terminate hypnosis if there is a problem (Orne also says this); instead, offer reassurance to explore/release the feelings. It is beneficial to work through what is being experienced. There is a somewhat higher risk of emotional reactions with age regression or induced dreams. We simply tell people they can tell us at any time about what they are experiencing, without going through any ritual. When we give suggestions about amnesia, we ask what they would like to remember and suggest that they forget what they would like to forget. The usual permissive suggestion doesn't work; find out what it is, exactly, that they want to forget and then devise strategies for it. Follow for 2 weeks after any abreactive experience that may have occurred. Let them know they can contact you. Forceful suggestions to abandon symptoms can promote resistance and the therapist may generate negative transference. (See their chapter in book edited by Rhue, Lynn, and Kirsch, *Handbook of Clinical Hypnosis*, published by the Amer Psychological Association.)

Palumbo, Robert; Gillman, Irene (1984). Effects of subliminal activation of oedipal fantasies on competitive performance: A replication and extension. *Journal of Nervous and Mental Disease*, 172 (12), 737-741.

Conducted a subliminal psychodynamic activation experiment in which the effects of 5 subliminal stimuli were sought on the dart-throwing performance of 40 male Ss (aged 22-46 years). The stimuli consisted of the following messages, each accompanied by a congruent picture: "beating dad is ok," "beating dad is wrong," "beating him is ok," "beating him is wrong," and "people are walking." The 1st 2 stimuli were intended to activate competitive motives within the context of the Oedipus complex; the next 2, competitive motives outside that context; and the last message was intended as a control stimulus. Findings show that "beating dad is ok" led to greater dart-throwing accuracy than each of the other 4 conditions, which, in turn, did not differ from each other. This finding replicates a result reported by L. H. Silverman et al (1978) and is in keeping with the formulation that the activation of oedipal motives can affect competitive performance (7 ref)

1983

Borgeat, Francois; Goulet, Jean (1983). Psychophysiological changes following auditory subliminal suggestions for activation and deactivation. *Perceptual and Motor Skills*, 56, 759-766.

This study was to measure eventual psychophysiological changes resulting from auditory subliminal activation or deactivation suggestions. 18 subjects were alternately exposed to a control situation and to 25-dB activating and deactivating suggestions masked by a 40-dB white noise. Physiological measures (EMG, heart rate, skin-conductance levels and responses, and skin temperature) were recorded while subjects listened passively to the suggestions, during a stressing task that followed and after that task. Multi-variate analysis of variance showed a significant effect of the activation subliminal suggestions during and following the stressing task. This result is discussed as indicating effects of consciously unrecognized perceptions on psycho-physiological responses.

Silverman, Lloyd H.; Lachmann, Frank M.; Milich, Robert H. (1982). *The search for oneness*. New York: International Universities Press.

## NOTES

This book summarizes research on preconscious activation (subliminal psychodynamic activation) of fantasies of oneness, following tachistoscopic presentation of words like, "Mommy and I are one." It represents an attempt to test and validate, through experimental investigation, psychoanalytic

concepts. The authors show how such fantasies can improve psychosocial adaptation for people with varying kinds of psychopathology.

**1980**

Shevrin, Howard; Dickman, Scott (1980). The psychological unconscious: A necessary assumption for all psychological theory?. American Psychologist, 35 (5), 421-434.

The notion of complex psychological processes operating outside of awareness has traditionally been associated with the concept of the unconscious used by psychodynamically oriented clinicians; it has never found an equivalent place in the mainstream of American experimental psychology. However, mounting evidence from several rather diverse fields of empirical research (e.g., selective attention, cortical evoked potentials, subliminal perception) provides support for such a concept, and, in fact, explanatory constructs of a similar nature have been embodied in several current models of perceptual processing. While there clearly remains an enormous gap between the clinically based conception and the experimentally based conception of the nature of these unconscious processes, they nevertheless seem to provide an interface between two seemingly disparate approaches to the understanding of personality.

**1961**

Pearson, R. E. (1961). Response to suggestion given under general anesthesia. American Journal of Clinical Hypnosis, 4, 106-114.

Employed a double-blind design with placebo control. Audio tapes containing therapeutic suggestions were played to 43 experimental patients during anesthesia. The main theme of the suggestions was that the patient would cope better and recover faster if he could become relaxed. Placebo tapes (music or blank tapes) were played to the 38 control patients. Only E, who had no contact with the patients, knew which tape was played to a given patient. Three postoperative variables were studied: (a) number of doses of narcotics in the first 5 postoperative days; (b) a numerical rating by the surgeon of the postoperative course; and (c) number of postoperative days until release. Although no significant differences were found between the suggestion group and placebo group on need for narcotics or rated course of recovery, patients receiving suggestions were discharged an average of 2.42 days sooner ( $p < .05$ ).

## **SUGGESTABILITY**

**1995**

Eisen, Mitchell L.; Goodman, Gail S.; Qin, Jianjian (1995, November). Child witnesses: Dissociation and memory and suggestibility in abused children. [Paper] Presented at the annual meeting of the Society for Clinical and Experimental Hypnosis, San Antonio, TX.

## **NOTES**

Our study looked at suggestibility and resistance to suggestion. During 5-day hospitalization for investigation of child abuse. The first day patient gets physical exam; 2nd day a genital exam, heart arousal, stress arousal; a later day had mental status, emotional functioning, cognitive functioning--and gross screen of IQ for age 5 and up and the digit span for 6 and up, plus rating of global functioning and provisional diagnosis. On Day 5 each child was given structured interview that included questions about the anal- genital exam, with some misleading questions included.

35 minutes after the psychological examination they were given questions about the exam, for brief memory. Next exam was forensic examination of memory for abuse. Gave memory for sentences, perceptual alterations scale (PAS), adolescent version of Dissociative Experiences Scale (A-DES); gave questionnaire to parents.

Hypotheses: suggestibility would be negatively related to age (more errors when younger). Sexually and physically abused children would show more dissociation or psychopathology. Dissociation or psychopathology should be inversely related to memory ability. IQ should be related to memory and resistance to misinformation. Wanted to reconcile two models of post traumatic stress disorder (PTSD): one says they have poorer memory, and the other says they are hypervigilant.

Over 100 children in the 200 received the questionnaire on Day 5. 39% were 3-5 years old, 41% 6-10 years old. 76% were African American. 22% had no documented abuse or neglect; 13% had experienced physical abuse; 30% sex abuse; 12% both types of abuse; 15% neglect; 8% parental addiction.

Measuring dissociation in kids is problematic. The concept is used to describe a huge range of phenomena. Scores on the DES are more highly correlated with the F Scale on the MMPI than with any other measure (Michael Nash's research). So the DES measures psychopathology. Also, children have healthy kinds of dissociation-- daydreaming, etc. Josephine Hilgard noted that young kids are naturally involved in imagination. Early traumas may lead to this dissociative style. How do we sort out the healthy imaginal involvements of children from the psychopathology? There is not sufficient data at this time.

Available measures are not validated well. The CDC indicates behavior problems in children. The C-PAS conceptualizes dissociation as relating to eating disorders; the A-DES is a self report measure that related to psychopathology.

CDC scores increase, in 3-5 year olds, as the amount of abuse increases. This looks like general psychopathology, and it is a parental rating. The A-DES and C-PAS were not related to abuse or neglect. In the older groups the CDC related to poor performance on memory tests; but only for the 6-10 year olds. (Poorer memories in younger children could have masked the effect in them.)

The main finding for the study was clinician's estimate of Global Adaptive Functioning was significantly related to Resistance to Misleading Information. The effect did not show for the 3-5 yr old group, perhaps because their memory functioning is poor anyway. Also age was related to memory and suggestibility.

1994

Grant, Carolyn (1994). *The Computer-Assisted Hypnosis Scale: Standardization and norming of a computer-administered measure of hypnotic ability (Dissertation)*. Dissertation Abstracts International, 54 (10/B), 5387.

"In a counterbalanced, within-subjects, repeated measures design, 130 subjects were administered both the Computerized Assisted Hypnosis Scale (CAHS) and the Stanford Hypnotic Susceptibility Scale, Form C (Stanford Hypnotic Susceptibility Scale: C). For each hypnotic procedure responsiveness was assessed along three dimensions: behavioral (CAHS, Stanford Hypnotic Susceptibility Scale: C), subjective depth (Field Depth Inventory), and relational involvement (Archaic Involvement Measure). Subjects also completed a Stanford Hypnotic Susceptibility Scale: C self scoring measure and the Tellegen Absorption Scale. The CAHS was shown to be a psychometrically sound instrument for measuring hypnotic ability. The various dimensions of CAHS hypnotic responsiveness were highly positively related, and the CAHS compared favorably with the Stanford Hypnotic Susceptibility Scale: C across the three dimensions assessed. Results are discussed in terms of the theory and practice of clinical assessment, noting directions for future research" (p. 5387).

1993

Balthazard, Claude G. (1993). The hypnosis scales at their centenary: Some fundamental issues still unresolved. International Journal of Clinical and Experimental Hypnosis, 41, 47-73.

Current approaches to the measurement of hypnotic performance can be traced back to the 19th century. In part because of these early origins and in part because of the nature of hypnotic phenomena, the hypnosis scales are unique psychometric instruments. The classic hypnosis scales are based on the notion of a "performance ladder"; items are scored on a pass/fail basis and can be arranged in increasing order of difficulty. Some of the implications on [sic]this "performance ladder" approach are reviewed. The evidence for two-mechanism models of hypnotic performance is reviewed. It is argued that this kind of formulation is at least as plausible as one that argues that the hypnosis scales measure "one thing" or "mostly one thing." If it were the case that the hypnosis scales were tapping two different and distinct processes, the label "hypnotic susceptibility" could not be unambiguously applied to scores on the hypnosis scales. The hypnosis scales would appear well-suited to the investigation of underlying mechanisms, yet no consistent picture of the mechanisms underlying hypnotic performance on the scales has emerged thus far. No resolution is presented, but some of the reasons why such a resolution is so elusive are discussed. The future of hypnosis scales is discussed with respect to multidimensional assessment and alternatives to the "work sample" approach.

#### NOTES

Author discusses the hypnotizability scales' history and psychometric properties, suggesting that they cannot have construct validity if more than one construct is involved. He states that many of the alternative formulations "posit structurally similar two- mechanisms models, where the relative contributions of one and the other mechanism changes gradually with the difficulty of the hypnotic performance--that is, one mechanism is more important for easy items and the other more important in the difficult range. This kind of formulation has been advanced by a number of authors .... Although these formulations are structurally similar, the nature of the mechanisms has been variously conceptualized: nonability and ability components (Shor, Orne & O'Connell, 1962), primary suggestibility and somnambulism (Weitzenhoffer, 1962), minor and major dissociations (Hilgard, 1977), compliance and true hypnosis (Tellegen, 1978-1979), and cooperativeness and expectation at one end and absorption at the other (Spanos, Mah, Pawlak, D'Eon, & Ritchie, 1980). ... In a formulation such as Hilgard's (1977), where both mechanisms are dissociative, it may be that it makes some sense to understand both mechanisms as aspects of the same complex construct. In other formulations... it would appear more cogent to speak of two constructs. Spanos et al. (1980) found that 'cooperativeness and expectation may be particularly important in responding to ideomotor and challenge suggestions, while the ability to convincingly treat imaginings as real (i.e., absorption) becomes increasingly important for more difficult 'cognitive' items" (p. 21). Balthazard & Woody (1992) presented evidence that the more difficult items on hypnotizability scales are related to absorption more than the easier items.

Balthazard & Woody (1989) investigated the proposition that hypnotizability scores are distributed bimodally, and concluded that statistical problems clouded the issue. Furthermore, most analyses previously have been of surface structure, which does not relate directly to the underlying mechanisms of hypnosis, and current psychometric methods cannot address the mechanisms that underlie surface relations. "There are two aspects of hypnotic processes ... that obscure underlying mechanism: synergisms and overdetermination. Synergisms occur when mechanisms potentiate each other in such a way that a combination of processes becomes more than the sum of its parts. Overdetermination occurs when co-occurring mechanisms do not potentiate each other, such that any one of the mechanisms would have been sufficient to produce the observed effect" (p. 63-64).

The author suggests there are two options at present: Corrective Scoring (like the Curss.OI, an objective-involuntary score which, although unreliable on test-retest, appears it could be more a measure of "pure" hypnotizability) and not using the typical "work sample" approach. Balthazard and Woody (1992) suggested the Absorption Scale may provide a better measure of "hypnotizability" than the standard hypnosis scales because absorption scores are more strongly related to difficult hypnotic performances.

Pekala, Ronald J.; Ersek, Barrett (1993). Firewalking versus hypnosis: A preliminary study concerning consciousness, attention, and fire immunity. Imagination, Cognition and Personality, 12, 207-229.

This study assessed the subjective effects associated with firewalking, and compared them with the subjective effects associated with hypnosis and a baseline condition (eyes closed sitting quietly). Twenty-seven subjects, who walked over hot coals during a firewalk ceremony, completed questionnaires about what they subjectively experienced during the firewalk. Their experiences were subsequently compared with those of subjects (n = 246) who experienced hypnosis and a baseline condition. The data suggested that firewalking, as assessed across all subjects, is characterized by high levels of volitional control and rationality, and a very absorbed attentional style wherein the mind is one-pointed, and consciousness is characterized by strong feelings of joy and high levels of internal dialogue. Firewalking was also found to be associated with significantly more joy, one-pointedness of thought, absorption, and internal dialogue than hypnosis or the baseline condition. In addition, a cluster analysis suggested two subgroups of firewalkers based on their subjective experiences of the firewalk. Interestingly, analyzing the attentional experiences among these firewalkers who got slightly burned, versus those who did not, revealed significant differences. A one-pointed and absorbed attentional focus may be the critical variable for the fire immunity observed in firewalking.

## NOTES

About 500 people walked across coals, in 3-4 steps. At end of weekend, 71 said they would complete a questionnaire and it was mailed to them. Of those, 27 responded (25 of 26 in an average of 23 days). Hence, 5% of the population who walked responded to the questionnaire, and it was some time later. Three of 24 reported minor blisters. Those who didn't get burned reported less detachment, less of a feeling of being out of their bodies, and more thoughts than the firewalkers who got slightly burned.

Pekala has defined an altered state of consciousness as associated with the perception of being in an altered state of awareness (the \_subjective sense\_ of \_altered state\_ --SSAS [30]), and a change in the patterning or configuration of the subsystems or dimensions of consciousness. A discrete state of consciousness, as defined by Pekala, is associated with a significant pattern change but no perceived alteration in state of consciousness (no SSAS). An identity state of consciousness, on the other hand, is defined as having neither a significantly perceived alteration in state of awareness nor a perceived pattern change among dimensions of consciousness in reference to another state of consciousness. Since the PCI can measure both intensity and pattern effects, it can be used to assess for altered, discrete, and identity states of consciousness.

Using a cluster analysis they found that one group of 16 subjects reported the firewalk experience to be characterized by a significant alteration in awareness and experience (body image, time sense, etc.), and significant intensities of internal dialogue, positive and negative affect, and arousal, while a second group of six subjects reported little alteration in consciousness or experience, little losses in rationality or control, and less internal dialogue, positive and negative affect or arousal than the larger group.

Whereas hypnosis is usually associated with a loss in control (the classic suggestion effect), firewalking was found to be associated with increased control, a more aroused state, and more fear! Firewalking appears to be a more absorbed and one-pointed state than even hypnosis.

The nature of attentional experience is similar across firewalkers (DAQ results).

Both firewalking and hypnosis meet the criteria for altered states of consciousness (different pattern and different subjective experience), but they are not altered states in reference to each other; they are discrete states of consciousness in reference to each other, because there is a significantly different patterning of PCI dimensions between the two conditions, but no significant SSAS. This suggests that the firewalk state is qualitatively different from the hypnotic state (as induced by the induction procedure to the Harvard Scale) and probably represents a different type of state of consciousness than hypnosis. Firewalkers obtained a lower mean hypnoidal state score than hypnosis subjects, so it does not appear that the fire immunity is due to being in a "hypnotized" state.

The fact that there appears to be two groups of successful firewalkers, one of which did not report much alteration in consciousness, calls into question the theorizing concerning the importance of alteration in state of consciousness as being etiologically related to successful firewalking. Since about 25 percent of the firewalkers clustered into what appears to be a nonaltered state of awareness, this suggests a sizable percentage of subjects who did not report any significant alteration in consciousness and experience.

Hence, what may be important is not an alteration in consciousness, but rather an alteration in attention. The cluster analysis revealed a relatively unitary attentional state across all subjects suggesting that attention was deployed in a rather similar manner across all subjects, that is, with very high absorption and one-pointedness. It was also the DAQ dimensions, and not the PCI dimensions, that successfully discriminated a trend between the blistered and nonblistered firewalkers. Hence, high levels of one-pointedness and absorption, that is, how attention is deployed during firewalking may be more critical (than an alteration in consciousness in general) for the fire immunity observed during firewalking.

Kirsch, Irving; Mobayed, C. P.; Council, J. R.; Kenny, D. A. (1992). Expert judgments of hypnosis from subjective state reports. Journal of Abnormal Psychology, *101*, 657-662.

Suggestibility was assessed in 60 student subjects after a traditional hypnotic induction, an alert induction, progressive relaxation training, or instruction in goal-directed imagery. Responsiveness to suggestion did not differ between groups. Subjects also generated open-ended reports of their states of awareness and of their experience of three hypnotic suggestions. A sample of these reports from 24 moderately to highly suggestible subjects was evaluated by 18 experts in the field of hypnosis. Expert ratings of subjects' open-ended reports indicated that (a) traditional hypnotic inductions produce a state of consciousness that is indistinguishable from nonhypnotic relaxation training, (b) the subjective experience of hypnotic suggestions after imagination training is indistinguishable from that after hypnotic inductions, and (c) suggestibility is unrelated to state of consciousness as assessed by experts.

Spiegel, Herbert; Greenleaf, Marcia (1992). Personality style and hypnotizability: The fix-flex continuum. Psychiatric Medicine, *10*, 13-24.

Since Mesmer, there has been much confusion about the inter-relationship between an individual's degree of hypnotizability, the personality style of the individual, and the importance of the therapeutic strategy. Empirical and experimental research supports the hypotheses that there are: 1) biopsychosocial components of hypnotizability on a continuum ranging from ecologically insensitive (not modifiable by external stimuli) to ecologically sensitive (very modifiable by external stimuli); 2) biopsychosocial components that can be measured to identify an individual's degree of hypnotic capacity and responsivity; 3) distinct personality styles which correlation with low, mid-range and high hypnotizability on a fix (ecologically insensitive) - flex (ecologically sensitive) continuum; and 4) different clinical syndromes which correlation with these categorical distinctions. We propose that measuring hypnotizability and personality style is a way to clarify diagnosis and choose appropriate

treatment strategies to maximize existing biopsychosocial resources of an individual with a specific problem in a particular context.

Spiegel, David (1992, October). Dissociation during trauma. [Paper] Presented at the annual meeting of the Society for Clinical and Experimental Hypnosis, Arlington, VA.

#### NOTES

Spiegel & Spiegel's theory of hypnosis involves: 1. absorption 2. suggestion 3. dissociation

Traumatic memories may be out of consciousness yet may influence consciousness. Thus, rape victim may not be able to continue to enjoy sex with her husband or may hyperventilate when near the place it occurs. This conceptualization is consistent with Kihlstrom's evidence using priming in verbal learning; and Ken Bowers' research on hypnosis for pain control.

Hypnotizability is higher in childhood than in adults, so if children are traumatized they may resort to dissociation more easily.

Certain dissociative disorders may be associated with high hypnotizability (forgetting the causal arrow, as association does not imply causation).

The diagnosis of post traumatic stress syndrome (PTSD) in the current diagnostic manual, DSM III-R, parallels the three characteristics of hypnosis, except that the diagnosis also includes a history of trauma. (In the upcoming revision, DSM IV will remove the language of "beyond the range of normal human experience" when characterizing the trauma in patient's history. The traumas referred to will be physical traumas.)

Holroyd, Jean (1990). How hypnosis may potentiate psychotherapy. In Fass, Margot L.; Brown, Daniel (Ed.), Creative mastery in hypnosis and hypnoanalysis (pp. 125-130). Hillsdale, NJ: Lawrence Erlbaum Associates.

#### NOTES

This chapter is a reprint of an article published in the American Journal of Clinical Hypnosis in 1987. It provides a conceptual framework for understanding psychotherapy processes in the context of a hypnotic state. Based on empirical and theoretical considerations, the author identified nine changes occurring with hypnosis: changes in attention and awareness, imagery, dissociation, reality orientation, suggestibility, mind-body interactions, initiative or volition, availability of affect, and relationship. "This chapter proposes that hypnotherapy exploits hypnotic phenomena-- takes advantage of them--in the service of standard therapy endeavors" (p. 125).

Lynn, Steven Jay (1990). Is hypnotic influence coercive? Invited discussion of Levitt, Baker, and Fish: Some conditions of compliance and resistance among hypnotic subjects. American Journal of Clinical Hypnosis, 32 (4), 239-241.

#### NOTES

Unlike Levitt, Baker, & Fish (1990), Lynn, Rhue, & Weekes (Psychological Review, 1990 in press) concluded that nonvoluntary behaviors in hypnosis are similar to other spontaneous social behaviors (like conversational response to social stimuli). "Hypnotized subjects, like nonhypnotized subjects, act in terms of their aims, according to their point of view, and in relation to their interpretation of appropriate behavior and feelings" (p. 239).

"Research shows that hypnotizable subjects resist and even oppose suggestions as a function of their expectancies and perceptions about appropriate hypnotic behavior (Lynn, Nash, Rhue, Frauman, & Sweeney, 1984; Lynn, Snodgrass, Rhue, & Hardaway, 1987; Lynn, Weekes, Snodgrass, Abrams,

Weiss, & Rhue, 1986; Spanos, Cobb, & Gorassini, 1985). In one study (Spanos et al., 1985), when subjects were informed that deeply hypnotized subjects were capable of becoming involved in suggestions and simultaneously resisting them, subjects resisted 95% of the suggestions. When subjects were told that deeply hypnotized subjects were incapable of resisting suggestions, they passed the majority of suggestions. Thus, knowledge about what constitutes appropriate hypnotic role behavior is a reliable determinant of resistance, apparently more reliable than the monetary lures used by Levitt et al." (P. 240).

These studies by Levitt et al. only used behavioral measures of resistance and hypnotizability, and Ss' perceptions of the resistance instructor and hypnotist. "The ratings of global perceptions are, however, no substitute for measures of subjects' perception of the relationship. ... The failure to measure important variables relevant to the central dimensions of concern--coercion, compliance, involuntariness, and relational factors--precludes meaningful interpretation of the nonresisters' motivation and behavior" (p. 240).

As Orne (1959) has suggested, we should not attribute behavior in the hypnosis context to something unique to hypnosis (such as coercive influence), because other kinds of social context also constrain behavior, e.g. psychotherapy and psychology experiments, with coercive features. Therefore, it seems important in the future to compare the responses of hypnotized subjects with those of subjects in waking-imagination and hypnosis-simulating conditions. In addition to looking at their behavior, it is important to examine their own perceptions of their actions, given the complexity of the social situation entailed in hypnosis.

"Finally, there are statistical grounds to be wary of the authors' conclusions. They assert that 'relational factors in the hypnotic dyad influence hypnotic responsiveness,' yet in three of the studies (I, II, and IV), subjects' ratings of the hypnotist failed to discriminate whether they resisted or responded to the suggestion" (p. 241). Even where Study III was compared with Study II, the difference in the percentage of Ss who resisted failed to reach statistical significance. "In fact, across all studies, differences in overall resistance rates were not documented by statistical tests--despite procedural variations and differing monetary incentives. So contrary to authors' assertion, relational factors in the hypnotic dyad generally had little bearing on resistance behavior. If anything, ratings of the resistance instructor had greater weight" (p. 241).

Sletvold, H.; Jensen, G. M.; Gotestam, K. G. (1990). The effect of specific hypnotic suggestions on blood pressure in normotensive subjects. Pavlovian Journal of Biological Science, 26, 20-24.

Twenty normotensive subjects participated in a study of the effects of specific suggestions on blood pressure (BP). After an induction, the experimental group received suggestions presumed to be relatively nonactivating, although capable of lowering or raising BP. A control group was used to record the BP changes over time. All subjects met for one session. Eight subjects from the experimental group met for a second session. Both adaptation and induction resulted in significant BP decreases. A specific suggestion to increase BP gave a significant result when compared to the induction point. There was no significant change from induction to the BP-decrease suggestion. Both systolic and diastolic BP behaved in the same way. A second experimental session resulted in no significant change compared with the first session. Also, no significant difference was found in suggestibility scores from the first to the second session. The results are in line with previously published studies.

1988

Council, James R.; Loge, D. (1988). Suggestibility and confidence in false perceptions: A pilot study. British Journal of Experimental and Clinical Hypnosis, 5, 95-98.

Subjects received audiotaped instructions implying that they would perceive increases in odor or heaviness while comparing stimuli in a sensory-judgment task. Stimuli were actually indiscriminable. Subjects pretested as higher or lower in hypnotizability performed the task in either hypnotic or non-hypnotic conditions. In both treatments, greater hypnotizability was associated with more perceived changes in the stimuli and greater confidence in the reality of those perceptions. Results support a general factor underlying suggestibility in hypnotic and nonhypnotic situations. The findings are discussed in relationship to false confidence effects reported in hypermnesia research.

Gudjonsson, Gisli (1988). Interrogative suggestibility: Its relationship with assertiveness, social-evaluative anxiety, state anxiety and method of coping. British Journal of Clinical Psychology, 27 (2), 159-166.

Investigated in 30 adults some of the theoretical components related to individual differences thought by the present author and R. Clark (1986) to mediate interrogative suggestibility as measured by a scale developed by the present author (1984). The variables studied were assertiveness, social-evaluative anxiety, state anxiety, and the coping methods generated and implemented during interrogation. Low assertiveness and high evaluative anxiety correlated moderately with suggestibility, but no significant correlations emerged for social avoidance and distress. State anxiety correlated significantly with suggestibility, particularly after negative feedback had been administered. Coping methods (active-cognitive/behavioral vs. avoidance) significantly predicted suggestibility scores. The findings give strong support to the present author's theoretical model.

Gudjonsson, Gisli H. (1988). The relationship of intelligence and memory to interrogative suggestibility: The importance of range effects. British Journal of Clinical Psychology, 27 (2), 185-187.

60 normal adults and 100 adult psychiatric patients completed a suggestibility scale and the Wechsler Adult Intelligence Scale (WAIS). Clear range effects of IQ and memory were evident in their relationship with suggestibility

Lynn, Steven Jay; Rhue, Judith W. (1988). Fantasy proneness: Hypnosis, developmental antecedents, and psychopathology. American Psychologist, 43 (1), 35-44.

This article presents a summary of the findings of our ongoing research program on the fantasy-prone person. In seven studies, nearly 6,000 college students were screened in order to obtain five samples of 156 fantasy-prone subjects. Fantasy-prone subjects (fantasizers) were selected from the upper 2%-4% of the college population on a measure of imaginative involvement and contrasted with nonfantasizers (lower 2%-4%), and medium fantasy-prone subjects (middle range). General support was secured for Wilson and Barber's construct of fantasy proneness: Fantasizers were found to differ from nonfantasizers, and in many cases also from medium-range subjects, on measures of hypnotizability, imagination, waking suggestibility, hallucinatory ability, creativity, psychopathology, and childhood experiences. Differences in hypnotizability were most reliable when subjects participated in a multisession study and were screened not only with the screening inventory, but also with an interview that substantiated their fantasy-prone status. However, our findings indicated that less correspondence between fantasy proneness and hypnotizability exists than Wilson and Barber suggested. Hypnotic responsiveness is possible even in the absence of well-developed imaginative abilities, and not all fantasizers were highly hypnotizable. Fantasizers recollected being physically abused and punished to a greater degree than other subjects did and reported experiencing greater loneliness and isolation as children. Many fantasizers appeared to be relatively well-adjusted; however, a subset of fantasizers were clearly maladjusted based on self-report, Minnesota Multiphasic Personality Inventory (MMPI),

and Rorschach test data. Because of the diversity inherent in the fantasy-prone population, it is misleading to think of individuals at the extreme end of the fantasy-proneness continuum as conforming to a unitary personality type.

1987

De Sano, Christine F.; Persinger, M. A. (1987). Geophysical variables and behavior: XXXIX. Alterations in imaginings and suggestibility during brief magnetic field exposures. Perceptual and Motor Skills, 64, 968-970.

12 male and 12 female volunteers were evaluated for their suggestibility before and after an approximately 15-min. exposure to either sham, 1-Hz or 4-Hz magnetic fields that were applied across their mid-superior temporal lobes. During the field application subjects were instructed to view a green light that was pulsating at the same frequency as the field and to imagine countering an alien situation. Results were commensurate with the hypothesis that weak brain-frequency fields may influence certain aspects of imaginings and alter suggestibility.

#### NOTES

"Subjects who had been exposed to the 4-Hz fields showed a significant decrease ... in heart rate compared to those who had been exposed to either the 1 Hz or sham-field conditions. A significant ... interaction of sex by field ... was noted for the change in HIP [Hypnotic Induction Profile] scales. Whereas both men and women in the sham-field condition tended to show less induction (~ 1 unit) on the second occasion ... women showed much greater (8.4 + 1.1) induction (= 3 units) if they had been exposed to the 1-Hz field while men showed much greater (8.0 + 1.5) induction (= 3 units) if they had been exposed to the 4-Hz fields. On the protocols, women reported significantly more fear responses than men. In addition, subjects who were exposed during the imaginings to the 4-Hz field showed more imaginings ... and more references to vestibular experiences (e.g., self or entity rising or floating) ... than those exposed to the other conditions" (p. 969).

"Dissociation scores on the HIP were correlated significantly ... with vestibular (0.44), imagery (0.43), and fear (-0.45) scores from the transcripts. Floating responses on the HIP were correlated with the amount of imagery. (0.46). There was a significant positive Pearson correlation between the compliance measure and the amount of arm levitation during the second induction only. These results suggest that hypnotic susceptibility may be increased following magnetic-field exposure but that the effective frequency is not the same for each sex. In addition, the amount of the imagery (particular vestibular experiences) increased if the person observed a light that was flashing at the same frequency as a 4-Hz applied magnetic field" (p. 969).

Holroyd, Jean (1987). How hypnosis may potentiate psychotherapy. American Journal of Clinical Hypnosis, 29, 194-200.

Hypnotherapy is defined as doing psychotherapy in the hypnotic state. This article reviews cognitive, affective, and motivational changes associated with hypnotic trance, attempting to demonstrate how the hypnotic state might influence ordinary psychotherapy processes. Nine characteristics of trance probably potentiate psychotherapy: (1) changes in attention and awareness, (2) imagery enhancement, (3) increase in dissociation, (4) decrease of reality orientation, (5) increase in suggestibility, (6) increased accessibility of mind-body interactions, (7) diminution of initiative resulting in a sense of nonvoluntariness, (8) increased availability or manipulability of affect, and (9) development of a fusional relationship (rapport). This article touches upon the psychotherapeutic implications of these hypnosis attributes.

Makarec, K.; Persinger, M. A. (1987). Electroencephalographic correlates of temporal lobe signs and imaginings. Perceptual and Motor Skills, *64*, 1124-1126.

Significant correlations (0.50) were observed between scores for the Wilson-Barber Inventory of Childhood Memories and Imaginings and the experiences that are indicative of temporal lobe lability. In addition, positive correlations (0.42) occurred between temporal lobe EEG measures (scalp electrodes) and numbers of temporal lobe signs. The numbers of alpha seconds per minute from the occipital lobes were correlated (0.57) with the Wilson-Barber cluster that indicated interests in 'altered states'. Scores on the childhood imaginings section of the Wilson-Barber Inventory were correlated (0.44) with the numbers of spikes per minute over the temporal lobes when the eyes were closed.

"Persinger and DeSano (1986) found that people who display temporal lobe signs were also more likely to have more imaginings (as defined by Wilson and Barber's (1983) Inventory of Childhood Memories and Imaginings) and to be more suggestible as indicated by Spiegel's Hypnosis Induction Profile" (p. 1124).

Subjects in this investigation were 12 male and 18 female students, ages 18-39 (M = 25 years) Bipolar measures were taken from just above the ears (approximately T3-T4) and the occipital lobe (01-02). Number of alpha seconds per minute and number of spikes per minute from each lobe was taken for 10 minutes (5 successive pairs of 1 minute eyes- open, 1 minute eyes-closed).

"The total Wilson-Barber score was significantly ( $p < .01$ ) correlated ... with the major (0.46) and minor (0.50) temporal lobe clusters but not with two clusters of control items: normal psychological experiences (0.21) and mundane proprioceptive experiences (0.29). These correlations are similar to those in the Persinger and DeSano study (0.60, 0.50, 0.13, and 0.14, respectively). Like the first study (0.53), the items that were most associated with dissociation (depersonalization) were best correlated with the Wilson-Barber scores (0.60). The Wilson-Barber subcluster: adults' extreme experiences (Items 44 through 52, that indicate physiological changes associated with thinking) was again most strongly correlated with the major (0.55) and minor (0.65) temporal lobe clusters; these values were 0.42 and 0.52 in the first study" (p. 1125).

"The only statistically significant ( $p < .01$ ) correlations between the Wilson-Barber scales and the EEG measures were between the number of alpha seconds from the occipital lobe (with the eyes closed) and the [Wilson-Barber] 'altered state' cluster ( $r = 0.57$ ; Items 33, 41, 42, 43). A weaker correlation (0.36) occurred between the number of alpha seconds per min. (eyes closed condition) and childhood vestibular experiences (items 1, 2, 3, 10, 24)" (p. 1126).

1986

Chertok, Leon (1986). Psychotherapeutic transference, suggestibility. Psychotherapy, *23* (4), 563-569.

Discusses suggestion in psychotherapy and defines it as a body-affective process, an indissociable psychosociobiological entity that acts at an archaic unconscious level far beyond that of transference, mediates the influence of one individual on another, and is capable of producing manifest psychological and physiological changes. Present in all types of therapy, indirect (nondeliberate, nonintentional) suggestion is the element that plays an important role in change and can be observed in hypnotic experimentation. It is further argued that transference and suggestion are phenomena that do not altogether overlap. Suggestion is the condition of transference without which transference could not be established.

1985

Rickard, Henry C.; Crist, Dwayne A.; Barker, Harry (1985). The effects of suggestibility on relaxation. Journal of Clinical Psychology, *41* (4), 466-468.

Studied the influence of personality characteristics of 32 undergraduates on response to relaxation training. Ss were selected on the basis of scores on the Creative Imagination Scale. Eight of the high-suggestibility Ss were assigned randomly to each training mode, progressive relaxation (PR) and suggestions of relaxation (SR). The 16 low-suggestibility Ss were similarly assigned, which resulted in a 2 x 2 factorial design with 1 repeated measure, a pre-post relaxation scale that yields a total score and 3 subscale scores. A significant pre-post relaxation effect emerged. Main effects were found for both suggestibility and mode of training. High-suggestibility Ss performed significantly better regardless of the training mode. PR yielded significantly higher relaxation scores than did SR. An interaction between suggestibility and training mode occurred on the Cognitive Factor scale; Ss who scored low on suggestibility reported relaxing significantly better when the training mode was PR. (15 ref)

Spanos, Nicholas P.; de Groot, Hans P.; Tiller, Dale K.; Weekes, John R.; Bertrand, Lorne D. (1985). 'Trance logic,' duality, and hidden observer responding in hypnotic, imagination control, and simulating subjects: A social psychological analysis. Journal of Abnormal Psychology, 94 (4), 611-623.

Tested the hypothesis that a tolerance for logical incongruity characterizes hypnotic responding and is related to reports of duality experiences during age regression and hidden-observer responding during suggested analgesia. 30 undergraduates (the "reals") with high scores on a responsiveness-to-suggestion scale were randomly assigned to hypnotic or imagination control treatments, while 15 undergraduates with low scores were assigned to a simulation treatment in which they were instructed to fake hypnosis. Ss were assessed on 6 indicators of logical incongruity, given age-regression suggestions and perception tasks, administered a suggestion for analgesia and hidden observer instructions, and interviewed. Results do not support the hypothesis. The differences in responding that did emerge between reals and simulators were accounted for by the different task demands to which Ss were exposed. These behavioral differences, which have been previously interpreted in terms of intrinsic characteristics of hypnosis, may instead reflect a combination of between-treatments differences in demands and between- Ss differences in the interpretation of those demands and in the ability to fulfill them.

1983

Classen, Wilhelm; Feingold, Ernest; Netter, Petra (1983). Influence of sensory suggestibility on treatment outcome in headache patients. Neuropsychobiology, 10, 44-47.

In 45 headache patients the relationship between sensory suggestibility and three measures of treatment effect-ratings on (1) intensity of headaches; (2) efficacy of drugs, and (3) physician's competence - was investigated in a double-blind long-term crossover study. Subjects scoring high on sensory suggestibility clearly showed more relief of headaches upon the analgesic as well as upon the placebo. The physician's competence was rated higher by high-suggestible patients, whereas ratings on drug efficacy were low in all patients. The seemingly controversial behavior of high-suggestible patients was interpreted as a call for continuation of the physician's efforts in spite of the relief the patients already achieved.

McConkey, Kevin M. (1983). Behaviour, experience, and effort in hypnosis. Australian Journal of Clinical and Experimental Hypnosis, 11, 73-81.

Subjects were administered the Harvard Group Scale of Hypnotic Susceptibility, Form A, and were afterwards asked to rate the degree to which they experienced the items; subjects also scored their behavioural performance on the items. Data were analyzed to explore the relationships among behaviour, experience, and effort. Findings indicated a significant positive relationship between behaviour and experience on all of the HGSHS:A items, a significant negative relationship between behaviour and effort on the ideomotor items, and a significant positive relationship between behaviour

and effort on the cognitive items. A similar pattern was observed between experience and effort. Also, subjects of varying HGSHS:A responsivity differed in terms of overall experience of the scale but not in terms of the overall amount of effort that they expended. Implications of the data are discussed in terms of the factors influencing subjects' experiential response and behavioural performance as well as the attributions that they make concerning effort during hypnosis.

1982

Sheehan, Eugene P.; Smith, Howard V.; Forrest, Derek W. (1982). A signal detection study of the effects of suggested improvement on the monocular visual acuity of myopes. International Journal of Clinical and Experimental Hypnosis, 30, 138-146.

2 groups of 8 Ss each, matched for suggestibility and degree of myopia, were assessed by a signal detection method in their ability to make a monocular spatial discrimination, both before and after 15 minutes of listening either to music or to taped suggestions that vision would improve. There was a significantly greater improvement in sensitivity on the part of the group of Ss listening to suggestions, and within this group, but not within the group of Ss listening to music, there was a significant negative correlation ( $r = -.67$ ) between S's initial sensitivity and the amount by which it increased. There was no significant difference between the amounts by which the criterion changed in the 2 groups. In contrast with the results reported by Graham and Leibowitz (1972), there was no evidence in the present study to indicate that the amount of improvement shown by Ss depended upon either their suggestibility as measured by BSS or their refractive error.

Spiegel, David; Detrick, Douglas; Frischholz, Edward (1982). Hypnotizability and psychopathology. American Journal of Psychiatry, 139, 431-437.

Compared hypnotic responsivity of 115 chronically ill psychiatric patients (mean age 44.6 years) with that of 83 nonpatient volunteers (mean age 28.5 years). The Hypnotic Induction Profile was administered, and diagnoses are established for patients according to Research Diagnostic Criteria. Results show that all of the diagnosed Ss (those with thought disorder, affective disorder, generalized anxiety, and miscellaneous disorders) were significantly less hypnotizable than the nonpatient comparison group. This effect was unrelated to age or medication differences. Implications of the findings are discussed in relation to a new model of hypnotic responsivity that takes into account the moderating effects of severe psychopathology. 55 refs.

1977

Albornoz-Ruiz, Jose M. (1977). Suggestibility as a factor in medical treatment. Maryland State Medical Journal, 26, 66-68.

## NOTES

This paper presents the view that a physician must be aware of the great influence, direct and indirect, s/he has with the patient as a result of their relationship. "Here it should be remembered that the power of a suggestion, without the benefit of formalized hypnosis, is directly related to the intensity and nature of the emotional bond between the patient and the doctor, often colored by a marked transference unconscious component, where the doctor stands 'in loco parentis' vis-a-vis the patient, regardless of the age, education or intellectual sophistication of the latter. Whatever the nature of the perception that is eventually presented by the patient as a symptom or identified by the doctor as a sign of illness, such perception will be elaborated upon by the patient's fancy, in lonely reveries where he defines for himself causes, nature and possible course of his disorder, not always in keeping with those established by the doctor as he exposes the same set of phenomena to his learned medical judgment" (p. 68).

Berk, Stephen N.; Moore, Mary E.; Resnick, Jerome H. (1977). Psychosocial factors as mediators of acupuncture therapy. Journal of Consulting and Clinical Psychology, 45 (4), 612-619.

This study investigated a number of psychosocial variables that have been suggested as possible mediating factors in acupuncture therapy. Forty-two volunteers with bursitis and/or tendonitis of the shoulder served as subjects. All were randomly assigned to one of four treatment groups: acupuncture - positive milieu, acupuncture - negative milieu, placebo acupuncture - positive milieu, and placebo acupuncture - negative milieu. Pretreatment and posttreatment subjective pain reports and shoulder motion studies, as well as pretreatment assessments of hypnotic susceptibility and suggestibility, were determined for each subject. Results indicated that (a) acupuncture and placebo acupuncture were equally effective in producing highly significant ( $p < .001$ ) reductions in subjective pain reports; (b) neither treatment effectively improved objective shoulder motion; (c) subjects treated in the positive milieu reported more improvement than those in the negative milieu ( $p < .053$ ); and (d) hypnotic susceptibility, suggestibility, belief in the treatment, and the satisfaction of expectations showed no relationship to treatment outcome. It is concluded that acupuncture therapy provides a powerful placebo. Treatment milieu variables warrant future study in the attempt to understand the acupuncture phenomena.

Connors, J.; Sheehan, P. W. (1976). Analysis of the cue characteristics of task motivational instructions. International Journal of Clinical and Experimental Hypnosis, 24, 287-299.

This study investigated the assumption of Barber's model of hypnosis that its set of task motivational instructions is thoroughly "nonhypnotic" in character. If this assumption is correct, then the cues associated naturally with task motivational instructions should be more compatible with a suggestibility test situation explicitly defined as nonhypnotic than with one defined as hypnotic, and this affinity should be reflected in both Ss' objective and subjective suggestibility test scores. Barber's (1965) Suggestibility Scale data collected from 90 Ss did not confirm the main prediction under test, but results failed to provide unequivocal support for the model; subjective evidence, in particular, supported least well the assumptions of the paradigm.

Naylor, Lynda P. (1976). The relationship of waking pain parameters and suggestibility in hypnosis (Dissertation). Dissertation Abstracts International, 36, 4209.

"Two pain sources, electric shock and ischemic muscle pain, were used with college men to explore the possibility that there is a relationship between waking pain parameters and level of suggestibility in hypnosis. Speculations about the presence of such a pain parameters - suggestibility relationship had arisen from incidental findings of two studies of hypno-algesia. In one study threshold for ischemic muscle pain was higher in highly suggestible subjects than in unsuggestible subjects. In the other study unsuggestible subjects were found to have a higher "tolerance" level for electric shock pain than highly suggestible subjects. "In the current study subjects served as their own controls; that is, each subject was subjected to pain from both sources and was later hypnotized to measure hypnotic suggestibility. Threshold and two tolerance measures were obtained for electric shock. Times to reach "mild", "moderate", "severe", and "intolerable" levels of pain were obtained for ischemic pain. Hypnotic suggestibility was measured by taped individual administration of the Harvard Group Scale and the Classical administration of the Harvard Group Scale and the Classical Suggestion Test. The findings were that there was no linear relationship between any pain measure and the Harvard Scale. There was some evidence that a curvilinear relationship may exist. Subjects who were high on the various pain measures were found to fall into the third quartile of hypnotic suggestibility; that is, they had Harvard Scale scores of 6 to 8. "The presence of a pain parameters-suggestibility relationship

would have raised questions about the suitability of experimental designs in which unsuggestible subjects are used as controls in studies of hypnoanalgesia. While the pain parameters-level of suggestibility data from this study do not raise questions about the suitability of the unsuggestible subject control group as it is now used, other data does. Extremely large variability was found in all the pain data and it is clear that with any small groups, randomly selected, one could easily choose two groups who differ widely in baseline pain parameters. This danger is present in all studies, not just hypnoanalgesia studies. Selection of groups matched on baseline pain parameters, along with the use of large groups, was recommended" (p. 4209).

Slade, P. D. (1976). An investigation of psychological factors involved in the predisposition to auditory hallucinations. Psychological Medicine, 6 (1), 123-132.

Previous research by the author (Slade, 1972, 1973) and others has suggested that psychological stress plays an important role in triggering off the experience of auditory hallucinations. Clearly, however, predispositional factors are involved as well. The present study is an attempt to investigate some of the psychological factors which may predispose the individual to such experiences. A battery of tests involving cognitive, personality and mental imagery variables and the verbal transformation effect was administered to two small groups of psychotic patients differing only in respect of a history of auditory hallucinations and a normal control group. The main conclusion was that the results lend direct support to the proposition of Mintz & Alpert (1972) that a combination of vivid mental imagery and poor reality-testing in the auditory modality provides the basic predisposition for the experience of auditory hallucinations.

1975

Berk, S. N. (1975). The mediating effects of hypnosis, suggestibility and placebo in acupuncture therapy (Dissertation). Dissertation Abstracts International, 36, 3020-3021.

"Results strongly support the contention that variables other than physiological mechanisms are involved in acupuncture therapy. It appears as if patient motivation, models, expectations of relief and the quality of the doctor-patient relationship can influence the outcomes of this ancient therapy. However, additional research is needed to confirm these findings. At present, the data seem to suggest that acupuncture therapy may be largely a placebo phenomenon" (p. 3021).

Tebecis, A. K.; Provins, K. A.; Farnbach, R. W.; Pentony, P. (1975). Hypnosis and the EEG: A quantitative investigation. Journal of Nervous and Mental Disease, 161, 1-17.

A quantitative investigation of the EEG during hypnosis was made by analyzing the analogue power frequency spectrum of one group of subjects in the awake and hypnotized conditions, and another group (random sample) in the awake condition. Individuals of the first group were thoroughly experienced in self-hypnosis and highly hypnotizable, whereas those of the second group had never been hypnotized and were low in waking suggestibility. There were no statistically significant differences in mean power of the whole EEG spectrum between the awake and hypnotized conditions of the experimental group, although a trend toward increased theta (4 to 8 Hz) density during hypnosis was apparent. This group, however, exhibited significantly more theta activity during both the hypnotized and the awake conditions than the random sample of controls in the awake condition, irrespective of whether the eyes were closed or open. We suggest that this increased theta density in the EEG is related to frequent experience of self- hypnosis, high hypnotizability, or both.

Spiegel, Herbert (1974). The grade 5 syndrome: The highly hypnotizable person. International Journal of Clinical and Experimental Hypnosis, 22 (4), 303-319.

On a 0-5 hypnotizability range, as measured by the Hypnotic Induction Profile, the grades 4-5 are identified as highly hypnotizable persons. This group tends to exhibit a clinically identifiable configuration of personality traits. Knowledge of the nature and interplay of these traits can help us to formulate appropriate treatment strategies. The features which together identify the grade 5 syndrome are: the high eye-roll sign; the high intact Hypnotic Induction Profile score; readiness to trust; a relative suspension of critical judgment; an ease of affiliation with new experiences; a telescoped time sense; and easy acceptance of logical incongruities; an excellent memory; a capacity for intense concentration; an overall tractability, and, paradoxically, a rigid core of private beliefs. Role-confusion and a subtle sense of inferiority are often evident. For these persons, treatment strategy requires clarification of central versus peripheral beliefs; increasing sensitivity to positive and negative field-forces; awareness of secondary gain-loss issues; aid in establishing guidelines to implement with action the integrity of their own beliefs, especially their perception of alternatives and their right to use them. Under duress, the grade 5 becomes the so-called hysterical patient. Differential diagnosis is critical because, during acute stress, introspective inquiring therapy can compound their confusion harmfully. "What" therapies are more effective than "why" therapies. If secondary gain is not formidable under appropriate therapy, these patients have a very good health potential.

Shor, Ronald E.; Easton, Randolph (1973). A preliminary report on research comparing self- and hetero-hypnosis. American Journal of Clinical Hypnosis, 16, 37-44.

A method is described for the study of the relationship between self- and hetero-hypnosis and initial findings are presented. A new instrument is described, the Inventory of Self-Hypnosis (ISH) which is a self-hypnosis adaptation of the hetero- hypnotic Harvard Group Scale, Form A (HGS). The new scale permits the making of precise item-by-item quantitative comparisons between the effects of these two scales. Preliminary research with 29 non-motivated college student subjects suggests that mean levels of responsiveness to the two scales are about the same, that item difficulty levels have much in common, but that whatever it is that the ISH measures is largely different from what the HGS measures. The findings help to formulate the need to study what it is that contributes to the similarities and differences. Further studies are in progress.

#### NOTES

Total Score Intercorrelations were reported as follows:

HGS ISHb ISHt

HGS 1.00 ISHb .39 1.00 ISHt .33 .67 1.00

Item Pass Percents Intercorrelations were reported as follows:

HGS ISHb ISHt

HGS 1.00 ISHb .72 1.00 ISHt .70 .82 1.00

ISHb = time calculated by breaths ISHt = time calculated by timer

The Inventory of Self Hypnosis (ISH) consists of 12 items, the same ones as in the Harvard scale with a few minor exceptions. Subjects are told that the inventory "is designed to teach self-hypnosis and that all of the information needed for a person to induce hypnosis in himself and to give himself a series of simple suggestions is contained in the inventory booklet" (p. 40). Therefore, there is more emphasis on hypnosis as an active imagination (cognitive) skill. An example, using a suggestion for Immobilization of the Right Arm, follows.

"This set of instructions is devoted to having it become very difficult for you to lift your right arm. These instructions involve a count of 33 breaths. The first 30 breaths is the \_suggestion phase\_ and the final three breaths is the \_trial phase\_.

"When ready close your eyes and pay close attention to your right arm. Notice how your arm shares in the general feeling of heaviness that you feel all over your body. Throughout the count of 30 breaths

concentrate your thoughts on the idea of how heavy it feels; think about it growing more and more heavy, heavy like lead. Although you should try not to lift it until later, notice how the arm seems to become much too heavy to lift.

"At the end of the 30 breaths take 3 extra breaths. During this new count try to lift your arm to see how heavy it is. Perhaps in spite of being so heavy you will be able to lift it a little, although by then it may be too heavy even for that. You will notice that there is some resistance because of the relaxed state you are in. After the three breaths stop trying and relax. In a few moments your arm will feel normal again, no longer heavy; you can easily lift it if you want to. At that point open your eyes and continue reading below the double lines.

"Summary of instructions:

"Initial actions: Close your eyes. Pay close attention to the feelings in your right arm.

"During count of 30 breaths -- Main Actions: Concentrate on the idea of your arm becoming so heavy that you would not be able to lift it.

"3 breaths -- Try to lift your arm.

"Post actions: Let normal feeling return to your arm. Open your eyes and continue reading" (p. 41).

1972

Sutcliffe, J. P. (1972). Afterimages of real and imaged stimuli. Australian Journal of Psychology, 24 (3), 275-289.

Tested 45 university students and 15 7-10 yr. olds for after-images of images and of real stimuli. 8 different colored stimuli were used and observations made enabled a check on reliability. Real stimuli typically produced negative afterimages in most Ss. Only half the Ss could project images of the stimuli, only 1/3 reported afterimages of those images, and of those images only 7% were negative. Afterimages of images had a longer latency and a shorter duration than afterimages of real stimuli. Thus qualitatively and quantitatively afterimages of images differ from afterimages of real stimuli. Findings are related to individual differences in general vividness of imagery. (18 ref.) 1969

Duke, J. D. (1969). Relatedness and waking suggestibility. International Journal of Clinical and Experimental Hypnosis, 17, 242-250.

Volunteering pairs of Ss took 9 waking tests (WT) of hypnotic susceptibility. Pairs included siblings, friends, and strangers. Concordance correlations from 20 sibling pairs were positive for 7 of the 9 WT, 2 significantly so. For 19 pairs of strangers, correlations were insignificant, 5 positive, 4 negative. Data reopen nature-nurture questions about the origins of individual differences in hypnotic aptitude. For 20 pairs of cross-sex friends, 7 of 9 correlations were negative, 1 significant, and 2 approaching significance. 6 of 9 concordance correlations from 16 spouse pairs were also negative, but none was significant. (Spanish & German summaries) (17 ref.) (PsycINFO Database Record (c) 2002 APA, all rights reserved)

Garmize, L. M.; Marcuse, F. L. (1969). Some parameters of body sway. International Journal of Clinical and Experimental Hypnosis, 17, 189-194.

Investigated the effects of 4 variables on body sway with 160 undergraduates. A 4-dimensional analysis of variance was performed on the body sway scores obtained. None of the main effects were significant. 1 of the interactions was significant, but might have been due to chance. Results are consistent with those of past researchers. (Spanish & German summaries) (16 ref.) (PsycINFO Database Record (c) 2002 APA, all rights reserved)

1968

Barber, Theodore Xenophon; Calverley, David S. (1968). Toward a theory of 'hypnotic' behavior: Replication and extension of experiments by Barber and co-workers (1962-65) and Hilgard and Tart (1966). International Journal of Clinical and Experimental Hypnosis, 16, 179-195.

RESPONSES TO TEST SUGGESTIONS (E.G., HALLUCINATION AND AMNESIA) WERE ASSESSED UNDER THE FOLLOWING TREATMENTS: MOTIVATIONAL INSTRUCTIONS ALONE, HYPNOTIC PROCEDURE WITH MOTIVATIONAL INSTRUCTIONS, AND IMAGINATION-CONTROL. COMPARISONS WERE MADE ACROSS INDEPENDENT GROUPS, EACH TESTED UNDER 1 TREATMENT, AND ALSO WITHIN THE SAME SS TESTED TWICE UNDER VARIOUS COMBINATIONS OF THE TREATMENTS. ALTHOUGH SS WERE SUGGESTIBLE UNDER THE IMAGINATION-CONTROL TREATMENT, BOTH THE MOTIVATIONAL INSTRUCTIONS ALONE AND THE HYPNOTIC PROCEDURE GIVEN TOGETHER WITH THE MOTIVATIONAL INSTRUCTIONS RAISED SUGGESTIBILITY ABOVE THE CONTROL LEVEL. THE HYPNOTIC-MOTIVATIONAL TREATMENT TENDED TO PRODUCE AN INCREMENT IN SUGGESTIBILITY WHICH WENT SLIGHTLY BEYOND THAT ATTRIBUTABLE TO THE MOTIVATIONAL INSTRUCTIONS. THE LATTER INCREMENT IS INTERPRETED AS DUE TO THE SLIGHTLY GREATER EFFECTIVENESS OF THE HYPNOTIC PROCEDURE IN DEFINING THE SITUATION AS ONE IN WHICH UNUSUAL MANIFESTATIONS, SUCH AS HALLUCINATION AND AMNESIA, ARE WITHIN SS' CAPABILITIES AND DEFINITELY EXPECTED BY E. (SPANISH + GERMAN SUMMARIES) (23 REF.) (PsycINFO Database Record (c) 2002 APA, all rights reserved)

Tart, Charles T.; Hilgard, Ernest R. (1966). Responsiveness to suggestions under 'hypnosis' and 'waking-imagination' conditions: A methodological observation. International Journal of Clinical and Experimental Hypnosis, 14, 246-256. (Abstracted in American Journal of Clinical Hypnosis, 1966, 2, 158)

2 groups of Ss were selected, on the basis of previous experimental participation, for a study of hypnotic analgesia. 1 group was highly responsive to suggestions in a waking suggestion condition as well as following a formal hypnotic induction procedure. The other group was unresponsive to suggestions unless given a hypnotic induction, following which they became highly responsive. It was found that the former group was no longer highly suggestible under waking conditions: their self-reports as to how hypnotized they felt strongly suggested that they had been highly responsive to waking suggestion previously because the experimental conditions had allowed them to spontaneously enter hypnosis. The difference in responsiveness when this was not allowed was striking, even with only 11 Ss. Methodological implications of this finding are discussed. (Spanish & German summaries) (16 ref.) (PsycINFO Database Record (c) 2002 APA, all rights reserved)

Das, J. P. (1965). Relationship between body-sway, hand-levitation, and a questionnaire measure of hypnotic susceptibility. International Journal of Clinical and Experimental Hypnosis, 13 (1), 26-33.

67 randomly selected college students were administered the body-sway test, a questionnaire measure of tranceability, and an induction procedure utilizing hand-levitation to determine hypnotic susceptibility. The 6 Es varied in age, sex; 5 of them had little experience as hypnotists. All reference to "hypnosis" was omitted from the induction procedure. Significant phi-coefficients between body-sway and levitation (.52), levitation and tranceability frequency (.28) and intensity (.25), and body-sway and tranceability intensity (.33) were obtained. (16 ref.) (PsycINFO Database Record (c) 2002 APA, all rights reserved)

1964

Anderson, Milton L.; Sarbin, T. R. (1964). Base rate expectations and motoric alterations in hypnosis. International Journal of Clinical and Experimental Hypnosis, 12 (3), 147-158.

Degree of responsiveness to "suggestion" in an experiment which did not utilize hypnotic induction (the Berkeley Sample) was comparable to that obtained in an experiment which did utilize hypnotic induction (the Stanford Sample). Procedural differences between the 2 experiments--self-scoring vs. objective-scoring, and group vs. individual testing--were regarded as not crucial in making a comparison of the 2 experiments. The distribution of responses in the Berkeley Sample may be taken as the base rate. The slightly higher degree of responsiveness over the base rate in the Stanford Sample (on some tests) may be attributed to the "degree of volunteering" that characterized the sample. The importance for experiments in the future to create equal levels of motivation and expectation to perform well under both the hypnotic and the nonhypnotic conditions is stressed, and brief mention is made of a new metaphor to be used in the conceptualization of the problems of hypnosis. (25 ref.) (PsycINFO Database Record (c) 2002 APA, all rights reserved)

Furneau, W. D. (1964). The heat-illusion test and the structure of suggestibility. International Journal of Clinical and Experimental Hypnosis, 12 (3), 169-180.

2 similar forms of the heat-illusion test are shown to correlate to a smaller degree than would be expected if they measure the same attribute. The 2 versions also differ in the way in which they correlate with other suggestibility tests. It is shown that linear regression techniques are not appropriate for analyzing the data concerned. The interaction of various nonlinear relationships with a difference in "difficulty," as between the 2 forms of the illusion, seems to provide an adequate explanation for the results. It is suggested that these nonlinear relationships may indicate the existence of an attribute which prevents some Ss from responding to any suggestibility test, irrespective of what the specific mechanisms of response may be. Evans, Frederick J. (1963). The Maudsley Personality Inventory, suggestibility and hypnosis. International Journal of Clinical and Experimental Hypnosis, 11, 187-200.

An attempt to replicate the claim of Furneau and Gibson (1961) that stable extraverts and neurotic introverts were more susceptible to hypnotic suggestion than neurotic extraverts and stable introverts, using the MPI dimensions, was unsuccessful. Some "trends" are discussed. (PsycINFO Database Record (c) 2002 APA, all rights reserved)

Furneau, W. D. (1963). Neuroticism, Extraversion, answer suggestibility: A comment. International Journal of Clinical and Experimental Hypnosis, 11, 201-202.

#### NOTES

Author develops hypotheses about the relationships between scores on the Maudsley Personality Inventory (MPI) and suggestibility.

"(a) The effective-drive experienced by a S in a suggestibility test, or hypnosis situation, is positively correlated with both neuroticism and with extraversion, as measured by the MPI.

(b) Effective-drive is also a function of the "press" of the test situation, and of the S's previous experience.

(c) Within the range of values of effective-drive lower than the Yerkes-Dodson optimum for the test being studied, the magnitude of response to a suggestibility test (or hypnosis) is a positive function of drive.

(d) For values of effective-drive greater than the Yerkes-Dodson optimum, response is a negative function of drive" (p. 201).

Hoskovec, J.; Svorad, D.; Lanc, O (1963). The comparative effectiveness of spoken and tape-recorded suggestions of body sway. International Journal of Clinical and Experimental Hypnosis, **11**, 163-166.

The relative effectiveness of tape-recorded vs. spoken suggestions of body sway was measured. Both types of suggestion produced increased body sway. Spoken suggestions following recorded suggestions were the most effective. The expectation by Ss of a greater effectiveness of live presentation may have produced this result. (PsycINFO Database Record (c) 2002 APA, all rights reserved)

Gibson, H. B. (1962). Furneaux's discussion of extroversion and neuroticism with regard to suggestibility. International Journal of Clinical and Experimental Hypnosis, **10**, 281-287. (Abstracted in Index Medicus, 63, March, S-676)

Hypotheses suggested by Furneaux (see 36: 4II95F) are criticized on the grounds that his basic assumption that extraverts attend more closely in the interpersonal situation is unwarranted. It is maintained on the contrary that introverts are the less distractible and it is shown that the data published earlier by Furneaux and Gibson (see 36: 3II67F) accord with a theoretical model derived from Spence. The results are also discussed in terms of an alternative interpretation. It is further contended that Furneaux's treatment of the data leads to other inconsistencies. (PsycINFO Database Record (c) 2002 APA, all rights reserved)

Kuhner, Arthur (1962). Hypnosis without hypnosis. International Journal of Clinical and Experimental Hypnosis, **10** (2), 93-99.

The traditional concept of hypnosis that seeks a "sleep" state through employment of formal induction techniques seriously limits its general clinical applicability. It fails to fit the special needs of the patient. An approach designed to counteract this shortcoming manipulates the interpersonal relationship factor. Case illustrations from dental practice support the viewpoint that the proper relationship is akin to the hypnotic one and comparable results obtain without resort to ritualistic induction methods. 1961

Das, J. P. (1961). Body-sway suggestibility and mental deficiency. International Journal of Clinical and Experimental Hypnosis, **13-15**.

50 mental defectives were subjected to the body-sway test of suggestibility. Contrary to expectations the defectives did not differ from each other when taken according to grades of deficiency, nor do they differ, as a group, from normal (college) controls. From Psyc Abstracts 36:02:2JII3D. (PsycINFO Database Record (c) 2002 APA, all rights reserved)

Furneaux, W. D. (1961). Neuroticism, extroversion, drive, and suggestibility. International Journal of Clinical and Experimental Hypnosis, **9**, 195-214. (Abstracted in Psychological Abstracts, 62: 4 II 95F)

In the group studied, the body-sway scores of stable extraverts and neurotic introverts tended to be large, whereas they were smaller for stable introverts and neurotic extraverts. This result was explained in terms of a theoretical model in which the effective drive produced in a S by a test-

situation is a function of both his neuroticism and his extraversion. The author believes that the theoretical model generates a number of predictions and suggestions which can serve to guide future experimental work in this field. From *Psyc Abstracts* 36:04:4II95F. **Klopp, Kirk K. (1961). Production of local anesthesia using waking suggestion with the child patient. International Journal of Clinical and Experimental Hypnosis, 9, 59-62.**

#### **NOTES**

Author describes the use of waking suggestion with children, as opposed to hypnosis. The technique "is simply the presentation of an idea which is sold to the child with such emphasis that when it is communicated to him, he accepts it with conviction. As children reason for the most part paralogically, the absence of logical grounds for the acceptance of the idea is arrived at easier than with the more mature mind of the adult" (p. 59).

**1959**

**Conn, Jacob H. (1959). Cultural and clinical aspects of hypnosis, placebos, and suggestibility. International Journal of Clinical and Experimental Hypnosis, 7 (4), 175-185.**

#### **NOTES**

The author traces the history of hypnosis, suggestion, and placebo, noting that popularity of hypnosis with professionals waxes and wanes over the years. When practitioners lose faith in a drug, it becomes less effective with their patients. The same holds true for hypnosis. Frequently illness is ameliorated or cured by suggestion without hypnosis.

"Hypnosis is nothing more than the suggestive, placebo effect presented in a specific inter-personal setting. It is not just a state of mind, but the end result of various psychologic processes. (2) A patient may be more suggestible when fully awake. ... Another patient may be more suggestible when asleep. There are those who respond best to suggestions in the light stage of hypnosis, while about 10% of subjects are capable of developing the deeper, somnambulistic phase" (p. 181).

**Dittborn, Julio M. (1958). Expectation as a factor of sleep suggestibility. Journal of Clinical and Experimental Hypnosis, 6 (4), 164-170. (Abstracted in *Psychological Abstracts* 61: 2390)**

#### **NOTES**

Authors studied expectation ("the attitude of waiting attentively for something usually to a certain extent defined, however vaguely," as defined by Drever) as a factor of sleep suggestibility. They tested young soldiers in the Chilean army using the postural sway test of suggestibility, repeated twice, to yield 12 Subjects. After a third postural sway test the Subjects were required to respond to a series of visual, then later oral, stimuli. [Experimental instruments are not clearly described in this article.]

The Subjects returned a week later and were asked to respond to the stimuli by using the word "sueno" (dream) for two Ss and "dormir" (sleep) for another two. The word "sleep" was used in the third experiment, following suggestions like "As you read more and more or as you hear yourself repeating the word 'sleep or dream' over and over again you will become more and more sleepy" (p. 166).

Apparently the outcome measure was the number of stimuli to which the Subject responded before lack of response indicated a trance. [Description is unclear.]

**1957**

Solovey, Galina; Milechnin, Anatol (1957). Concerning the induction of the hypnotic state. Journal of Clinical and Experimental Hypnosis, 5 (2), 82-98.

#### NOTES

The hypnotic state has four attributes: "an effect of emotional stabiliztion, a retrogression to an infantile psychological functioning, suggestibility, and transmissibility of the hypnotic relationship" (p. 82). "SUGGESTIBILITY is a special motivation to accept, incorporate within one's self, and execute direct or implicit propositions, which is equivalent to the motvation of a child to accept, assimilate and carry out the propositions of its parents" (p. 84). The authors propose that verbal and non-verbal suggestions are incorporated during the course of education, lasting years and thus becoming in effect post-hypnotic suggestions. "The person will have in the future a \_special responsiveness,\_ that may be more or less pronounced according to the circumstances, \_for those data\_ (coming from books, movies, conversations, etc.) \_which agree with his emotionally-incorporated post-hypnotic suggestions\_" (p. 85). If while in an auto-hypnotic condition he comes in contact with someone "who appears to be the embodiment of the convictions or prejudices that on being stimulated started the process of emotional activation that led to the development of the hypnotic state, \_there may be a transformation of the auto-hypnotic condition into an interpersonal hypnotic relationship\_" (p. 86).

According to the authors, this theory can explain post-hypnotic (negative) sequellae. It also accomodates explantions of both Natural or Direct Orientation inductions and Indirect Orientation inductons, and explains phenomena such as patients entering hypnosis rather automatically while awaiting the appearance of Mesmer in his waiting room.

"To conclude, we will stress that the psychological mechanism of hypnotic induction is exactly \_the same\_ in everyday life and in the experimental environment. The apparent differences like [sic] in the \_behavior\_ of the subject in the hypnotic state, and are due to the motivation that arises from the circumstances and to the convictions, capacities, psychological maturity, and degree of retrogression of the individual" (p. 96).

Solovey, Galina; Milechnin, Anatol (1957). Concerning the nature of hypnotic phenomena. Journal of Clinical and Experimental Hypnosis, 5 (2), 67-76.

#### NOTES

The authors write about the place of the hypnotic state in general psychology: "the study of the \_psychological mechanisms\_ that make the appearance of the phenomenon \_possible, which need not be different from the normal and current psychological mechanisms in everyday life\_" (p. 67). They classify hypnotic phenomena into three groups:

I. Phenomena \_which are a function of the state of psychological\_ retrogression (hypnotic depth), appearing in spontaneously [sic] or when proposed by the operator.

II. Phenomena which appear without any specific suggestion, as \_a side issue of other suggestions,\_ capable of originating emotional states in the subject.

III. Phenomena \_which are independent of all suggestion,\_ being a constituent part of the hypnotic state itself, in its 'positive' or 'negative' forms" (p. 68).

Using this framework, the authors describe several aspects of hypnosis: catalepsy, anesthesia, retrogression, the taking of a role, negativism and resistance, visceral changes, emotional stabilization, psychotherapeutic benefits (indirect). They observe that direct suggestions are often not necessary for therapeutic benefit, and give as an example the tendency for less bleeding when dentists suggest that patients will not feel less pain.

"For the elucidation of this point, the authors carried out an experiment in a dental clinic, taking six easily hypnotizable subjects in whom dental extractions were to be performed. They were given only the suggestions that they would feel the doctor working, but not experience pain ... that they would pay

no attention to it ... or even if they felt a little pain, this would not trouble them and they would bear it perfectly ... Nothing was said about the loss of blood. As a result, in all the cases the loss of blood was slight, practically insignificant, though technically difficult extractions of roots were included" (p. 74). "The explanation of hypnotic phenomena as natural and normal consequences of the hypnotic emotional state, and of the state of psychological retrogression, eliminates the supposed mysterious powers of suggestion. \_Suggestion is thus relegated to the modest role of a litmus paper which reveals the psychological functioning of the individual\_ in an experimental environment. On the other hand, in everyday-life hypnosis, in the principal hypnotic relationships of parents with their children, of teachers with their pupils, etc. (11), suggestibility plays an important role in education or re-education" (p. 75).

1956

Kline, Milton V. (1955). Freud and hypnosis: II. Further observations on resistance and acceptance. Journal of Clinical and Experimental Hypnosis, 3 (2), 124-129.

Freud's rejection of hypnosis in the development of psychoanalytic psychology becomes upon closer examination a two fold process. It involves on the part of Freud the conventional recognition that suggestion plays a basic role in the primitive emotional energy that binds people together and influences the acting out of primary libidinal drives. From an ontogenetic (and presumably phylogenetic) point of view, Freud viewed suggestibility as a repressive element in the organization of behavior and one which in effect had to be dealt with indirectly. To deal with it directly was to create a state within which powerful emotions of an unpredictable nature could emerge. Hypnosis to Freud was a 'condition' which led to general heightened suggestibility and was identical with it. To make use of this condition was in essence an attempt to make use of an individual's energies in a dependent and essentially uninhibited manner. It seemed to Freud that having produced the hypnotic 'condition,' one actually had achieved a state of suspension or ablation of certain critical ego functions and this could lead to an intense and perhaps unmanageable interpersonal relationship. It was almost an 'ethical' rather than a scientific view as Freud discussed it in his thinking and theorizing about a general psychology.

"To a great extent the basic concepts of psychoanalysis were developed as the result of Freud's awareness of the existence of hypnotic phenomena and his need to circumvent and indirectly deal with the ego manifestations of this 'condition.' Thus Freud never really rejected hypnosis as a mechanism of human behavior. His comment of the psychosocial development of man (from which psychoanalytic psychology is influenced) was heavily weighted by his awareness of 'suggestibility' and the 'condition' descriptively called hypnosis.

"The simple equation of hypnosis with suggestibility is now scientifically outmoded and incorrect. The role of suggestion and its psychosomatic equations has taken on a drastically changed perspective in social psychology, particularly with regard to the early concepts of Le Bon, Freud and McDougall (5). For these reasons alone, Freud's circumvention of hypnosis becomes increasingly unsound scientifically and adherence to such a perception of hypnosis serves only to obscure theoretical research in psychology and to maintain a rigidity born essentially of emotional ties and ethics alien to the nature of scientific inquiry" (pp 128-129).

## SUGGESTION

1995

Lee DY. Barak A. Uhlemann MR. Patsula P. Effects of preinterview suggestion on counselor memory, clinical impression, and confidence in judgments. *Journal of Clinical Psychology* 1995;51(5):666-75 This study examined the effects of schematic preinterview suggestion on counselors' (a) recognition

memory of the information presented by the client; (b) clinical impression rating of the client; and (c) confidence in rating clinical impression. Fifty-two Master's-level counselor-trainees were assigned randomly to two conditions of preinterview suggestion about the status of the client (i.e., depression and no depression). After subjects had received appropriate preinterview information (i.e., depression or no-depression content) and had viewed a videotaped counseling interview, information was gathered from them. The results indicated that the preinterview suggestion (a) did not affect counselor-trainees' clinical impression rating of the client; (b) did not affect confidence of rating; and (c) yielded a weak, but significant, confirmatory memory. Implications for the interview setting are discussed.

**Barnier, Amanda J.; McConkey, Kevin M. (1995, November). Posthypnotic suggestion: Knowing when to stop helps to keep it going. [Paper] Presented at the annual meeting of the Society for Clinical and Experimental Hypnosis, San Antonio, TX.**

## **NOTES**

Posthypnotic suggestion sometimes leads to compulsive and involuntary responding, but we have little information about the parameters of such a response. In some research in our laboratory, we found that subjects who were given a posthypnotic suggestion that encouraged them to experience a desire to respond, showed a different pattern of response from those simply told to make a specific behavioral response. In another study, we gave subjects a posthypnotic suggestion to mail a postcard every day to the experimenter; some subjects were told to respond until they saw the hypnotist again (termination), others were given no specific information about how long they should respond (no termination). Those expecting a termination to the suggestion showed a different pattern of response across 16 weeks of testing. Thus, the information included in the suggestion about how or when to respond influences posthypnotic responding.

**Present Experiment:** Laboratory test of including specific information in the posthypnotic suggestion about how long to respond - cancellation cue vs. no cancellation cue. Responding indexed on four different tests: formal, embedded, informal, postexperimental. Also used real/simulating methodology. We expected that responding would decline across the four tests, but that the decline would be slowest for those expecting a cancellation cue.

**Methodology:** High hypnotizable subjects scored 8-10 on SHSS:C, lows scored 0- 3 on SHSS:C. Given real/simulating instructions (Orne, 1959). Formal test was given immediately after deinduction; embedded test was given during an inquiry question; informal test was given as the hypnotist appeared to terminate the experiment and leave the room; postexperimental test was given by another experimenter during a postexperimental inquiry. The suggestion was to cough when Ss heard a particular response cue.

**Results:** On the formal test, there was no difference between reals or simulators in either the cue or no cue condition, although simulators in the cue condition tended to overplay their response. Across the tests, responding declined. In particular, the majority of reals and simulators in the no cue condition stopped responding after the formal test. In the cue condition, reals and simulators responded similarly on the embedded test, but differently on the informal test; more reals than simulators continued to respond across the tests. Few subjects responded on the postexperimental test. Subjects' postexperimental comments indicated that reals and simulators in the no cue condition believed that one response was sufficient; simulators in the cue condition were confused about whether to keep responding, and reals in the cue condition responded compulsively across the test.

**Conclusions:** The inclusion of a cancellation cue in a posthypnotic suggestions maintains responding for a longer period. Responding posthypnotically is not explained solely by demand characteristics. Rather, individuals respond on the basis of their interpretation of the implied intent of the hypnotist's message (c.f., Sheehan, 1971). Responding changes across test types. These findings contribute to a

model of posthypnotic responding. They point to the active responding of hypnotized individuals (c.f., Kihlstrom: experimental subjects try to make sense of the message of the suggestions and instructions they receive).

**1994**

**Barber, Joseph (1994, October). How to use and abuse boundaries with hypnosis. [Paper] Presented at the annual meeting of the Society for Clinical and Experimental Hypnosis, San Francisco.**

#### **NOTES**

**(for only part of the presentation) I would like to focus on how we can productively use boundaries. Hypnosis experience reactivates archaic experiences with parents; if therapist can evoke trust, the patient can feel increasingly that they can relax into the experience.**

**Bejenke, Christel J. (1993, October). A clinician's perspective. [Paper] Presented at the annual meeting of the Society for Clinical and Experimental Hypnosis, Arlington Heights, IL.**

#### **NOTES**

**Presents point of view of a private practice anesthesiologist in Santa Barbara, California. Used hypnosis for 20 years.**

**Use of hypnosis as hypnoanesthesia is rare since Esdaile, with brief resurgence in 50's, because surgery techniques advanced before anesthetics did in areas that were very risky. Now it is a matter of choice, and may be undertaken because of a patient's extreme fear of anesthesia, previous bad experience with anesthesia, fervent belief in holistic method, allergy, or previous experience with hypnosis. Still advised to use hypnosis for MRIs, radiation procedures, former drug addicts (who may have problems with drugs), burn patients, release of neck contractions, and medical procedures--especially with children--like lumbar puncture.**

**She disagrees with Kroger's estimate of only 10% of patients being able to use hypnoanesthesia; she does not believe it requires a lot of training, or profound muscle relaxation.**

**There is no indication of how many cases are actually done with hypnosis. Also, published cases are not representative of the quantity or complexity of cases; most published cases have a few extraordinary characteristics. The Irish surgeon Jack Gibson has done more than 4000 cases, some very complicated.**

**I have used it for D & Cs, and complex cases that were not published. Most of my patients elected to be alert during the hypnosis and conversed with their surgeons. The most common benefit is that recovery from anesthesia is not necessary; but these days with newer anesthetics recovery from anesthesia is rapid anyway. However, if as we suspect anesthesia affects immune function, that would be another reason to use hypnosis.**

**Preparation for surgery may be of three types: 1. formal hypnosis techniques 2. "hypnoidal" techniques that aren't formal 3. unprepared patients in whom hypnosis is used at last moment.**

**Examples. 1. Formal hypnosis: This symposium deals with this type of approach. Three groups derive particular benefit -- those requiring prolonged artificial ventilation postoperatively (because otherwise sedation must be used, which leads to complications), where prepared patients tolerate interventions calmly and comfortably -- cancer patients, for whom this can be first experience of patient to see self as active participant in care rather than a victim of the illness and of complicated technology -- pediatric patients. 2. Hypnoidal (hypnosis like) techniques: This is the most important application. Time doesn't permit much discussion here. Patients are in an altered state when they come for surgery, highly suggestible, and suggestions appear to be as effective as during formal trance state. The doctor can elicit positive responses during "casual conversation" while seemingly giving information to the**

patient. (The reverse is true also, with inadvertent negative suggestions, to the detriment of the patient.) Scrupulous adherence to medical facts is important during this type of conversation. Operating room fixtures are useful for focus of attention, and I have published this information in an article.

Recovery room also is place where case specific information and appropriate suggestions can be given. Patient can experience his ability to alter sensations, for the first time, following suggestions.

Remainder of the hospitalization offers opportunity for reinforcing case specific positive suggestions.

Bennett, Henry L. (1993, October). Hypnosis and suggestion in anesthesiology and surgery. [Paper] Presented at the annual meeting of the Society for Clinical and Experimental Hypnosis, Arlington Heights, IL.

## NOTES

He began by saying that he is opposed to using hypnosis for surgery, though he favors a theory of how hypnosis effects physiological change, and cites T. X. Barber's classic "Changing Unchanging Bodily Processes."

Relaxation puts patient in a "psychological strait jacket" because surgery is so highly stressful. He gives information "about how to go through the surgery more comfortably," gets across the idea about coping style, tells them surgery is exertional and that they are tired afterward, that he can help them "using things you already know how to do," and specifies exactly what they can do--using model of himself as a trainer.

In some recent research he used pairs of pictures, some of which lead to pupillary constriction (blood pressure goes down) or dilation (blood pressure goes up). Instructing them to look, patients looked twice as long at the pictures than they did during free gaze. When not instructed to look, heart rate went down; when told to look, heart rate went up. So the researchers went back to free gaze. He uses this as a metaphor for many of the pre- surgery preparation activities that encourage relaxation "inappropriately."

He cites Cohen & Lazarus re vigilant copers, Price et al (1957), and some other studies on epinephrine effects. He uses examples of work patients may have done (e.g. planting a garden) when talking with patients prior to surgery, that gives them a sense of accomplishment later.

You have to give specific instructions or suggestion, not general relaxation suggestions.

Question from the audience: Can preoperative instructions (not hypnosis) diminish blood loss.

In Bennett's answer he seems to be reporting the earlier study: they found 150- 4000 cc blood loss, high variability. Extent of blood loss was determined by extent of surgery, by instructions to patients vs no instructions.

This study was replicated by Enqvist, Bystedt, & von Konow in the Anesthesia conference at Emory University in 1992.

May 1993 Western Journal of Medicine article, Disbrow, Bennett, & Owinos, with 40 lower abdominal surgery patients who got specific instructions or not. The SHCS was used to measure hypnotizability: highs resolved quicker than low hypnotizable patients. They also found that instructed patients did better than those who did not get specific instructions.

There are now 3 replications of McClintock's study: people use less medications after surgery, when tapes about rapid recovery are played \*during\* surgery.

Bennett is now using tapes with suggestions for recovery during surgery.

Blankfield, Robert P. (1993, October). Suggestion, hypnosis, and relaxation as adjuncts for surgery patients: Lessons from studies involving cardiac surgery patients. [Paper] Presented at the annual meeting of the Society for Clinical and Experimental Hypnosis, Arlington Heights, IL

## NOTES

The author stated that his research and the few other studies of cardiac surgery patients do not support idea that cardiac surgery patients benefit from hypnosis and suggestion.

Types of intervention have varied: hypnosis, suggestion, relaxation; pre-op, during, or post-op; with many different outcome variables.

Aiken & Henrichs (1971) study was nonrandomized, nonblinded, for 30 patients getting open heart surgery. Treated patients had benefits.

Surman, Hackett, Silverberg, & Behrendt (1974) had a randomized, single-blind design for 40 patients taught Self Hypnosis (S-H), for elective mitral valve surgery. No difference in benefits. But 45% of patients taught S-H reported a subjective sense of benefit (though objective indicators didn't support that). [He says the difference between subjective/objective outcome ratings is important.]

Hart (1980) used randomized, single-blind design for 40 patients who had open heart surgery. No differences found except initial 3 days post surgery.

Greenleaf et al (1992) - see her paper presentation of this date.

Blankfield et al (presented at Society of Clinical and Experimental Hypnosis meeting in 1992) used a randomized, single-blind design for 95 patients, who were randomly assigned to taped suggestions, music, or controls. No differences were found in benefits.

Our data were re-analyzed: patients who felt tape was helpful were compared to the remaining 62 patients, but there again were no differences in amount of narcotics used for pain, though there was a trend in the right direction; nursing assessments failed to identify less anxiety.

The point is, whereas the bulk of publications suggest benefits, there is little evidence with this population. Could these patients be different in personality, ability to respond to intervention, amount of external stimuli? They should be studied because there are a lot of these patients with only a few surgeons and you don't have to gain the cooperation of a lot of different surgeons to do this kind of research. Also, there is uniformity in cardiac surgery whereas standard operating surgery is in a state of flux in other areas (e.g. movement from generous incisions to micro procedures, and patients receiving this type of surgery remain in hospital for a week whereas this opportunity to study them during inpatient post-surgical period is disappearing in other areas). It is my opinion that cardiac patients may not be highly receptive to suggestion.

Curiously, according to Surman and my research, 1/2 the subjects report benefits. Either some benefits are subtle, or they are reporting a placebo effect.

Future studies need more patients, and the investigators must stratify on personality inventory variables such as Type A personality, hypnotizability, motivation, anxiety, depression, family support, social support systems. This is labor intensive, to determine which characteristics determine differing outcomes. The patients used in this type of research require more presurgery evaluation than previously has occurred.

The MMPI can be self administered and is widely acceptable, but is cumbersome, not well suited to people who are acutely ill. Assessment of Type A personality is important because Type A's might be less receptive to suggestion. Structured interview is time consuming, but a 52-item questionnaire can be self administered. Other factors listed above are important.

Bruehl, Stephen; Carlson, Charles R.; McCubbin, James A. (1993). Two brief interventions for acute pain. Pain, 54, 29-36.

This study evaluated two brief (3-5 min) interventions for controlling responses to acute pain. Eighty male subjects were randomly assigned to 1 of 2 intervention groups (Positive Emotion Induction (PEI) or Brief Relaxation (BR)) or to 1 of 2 control groups (No-instruction or Social Demand). The PEI focused on re-creating a pleasant memory, while the BR procedure involved decreasing respiration rate and positioning the body in a relaxed posture. All subjects underwent a 60-sec finger pressure pain trial. Analyses indicated that the PEI subjects reported lower ratings of pain, fear, and anxiety, and experienced greater finger temperature recovery than controls. The BR procedure resulted in

greater blood pressure recovery, but did not alter ratings of pain or emotion relative to controls. Further research is needed to explore the clinical use of the PEI for acute pain management.

De Pascalis, Vilfredo (1993). EEG spectral analysis during hypnotic induction, hypnotic dream and age regression. International Journal of Psychophysiology, 15, 153-166.

EEG was recorded monopolarly at frontal (F3, F4), central (C3, C4) and posterior (in the middle of O1-P3-T5 and O2-P4-T6 triangles) derivations during the hypnotic induction of the Stanford Hypnotic Clinical Scale (SHCS) and during performance following suggestions of hypnotic dream and age-regression as expressed in the before-mentioned scale. 10 low-hypnotizable and 9 highly-hypnotizable and right-handed female students participated in one experimental session. Evaluations were Fast-Fourier spectral analyses during the following conditions: waking-rest in eyes-open and eyes-closed condition; early, middle, and late phases of hypnotic induction; rest-hypnosis in eyes closed condition; hypnotic dream and age regression. After spectral analysis of 0 to 44 Hz, the mean spectral amplitude estimates across seven Hz bands (theta 1, 4-6 Hz, theta 2, 6-8 Hz; alpha 1, 8-10 Hz; alpha 2, 10-13 Hz; beta 1, 13-16 Hz; beta 2, 16-20 Hz; beta 3, 20-36 Hz) and the 40-Hz EEG band (36-44 Hz) for each experimental condition were extracted. In eyes-open and -closed conditions in waking and hypnosis highly-hypnotizable subjects produced a greater 40-Hz EEG amplitude than did low hypnotizable subjects at all frontal, central and posterior locations. In the early and middle hypnotic induction highly-hypnotizables displayed a greater amount of beta 3 than did low hypnotizables and this difference was even more pronounced in the left hemisphere. With posterior scalp recordings, during hypnotic dream and age regression, high hypnotizables displayed, as compared with the rest-hypnosis condition, a decrease in alpha 1 and alpha 2 amplitudes. This effect was absent for low hypnotizables. Beta 1, beta 2 and beta 3 amplitudes increased in the left hemisphere during age regression for high hypnotizable; low hypnotizables, in contrast, displayed hemispheric balance across imaginative tasks. High hypnotizables during the hypnotic dream also displayed in the right hemisphere a greater 40-Hz EEG amplitude as compared with the left hemisphere. This difference was even more evident for posterior recording sites. This hemispheric trend was not evidenced for low hypnotizable subjects. Theta power was never a predictor of hypnotic susceptibility, 40-Hz EEG amplitude displayed a very high main effect ( $p < 0.004$ ) for hypnotizability in hypnotic conditions by displaying a greater 40-Hz EEG amplitude in high hypnotizables with respect to lows. NOTES 1:

#### NOTES

In the Discussion section, the authors indicate that they have no idea why they didn't replicate results of other theta studies, including their own, except maybe due to complex interaction among personality, subject selection, situation-specific factors, and hypnotizability.

They observe that the alpha results conform with previous findings (p. 163). Beta bands were sensitive. Highs showed left-hemisphere prevalence in all beta bands during age regression; they also showed hemispheric balance in the hypnotic dream condition. Beta 3 amplitude was also greater among highs than lows. "among high hypnotizables, beta 3 amplitude in the early hypnotic condition was greater in the left hemisphere as compared to the right and as the hypnotic induction proceeded hemisphere balancing, with reduced beta 3 amplitude, was displayed. This result appears in agreement with the predictions of the neurophysiological model proposed by Gruzelier et al. (1984) and Gruzelier (1988) as well as with other studies in which beta rhythm was found to discriminate performances between high and low hypnotizables (e.g., Meszaros et al., 1986, 1989; Sabourin et al., 1990)" (p. 163-164).

40 Hz amplitude was higher in highs and increased in right hemisphere during the hypnotic dream, especially in posterior areas. "This pattern of hemispheric activation may be interpreted as an expression of the greater right-hemisphere activation and of the release of posterior cortical functions during the hypnotic dream and is compatible with the predictions of the Gruzelier model of hypnosis,

however, the results obtained in this study for 40-Hz EEG amplitude failed to reveal an inhibition of the left-hemisphere activity with the progress of the hypnotic induction" (p. 164). (They note that De Pascalis & Penna, 1990, agreed with the Gruzelier 1988 model: highs in early induction had increase of 40-Hz in both hemispheres, but as induction proceeded they had inhibition of left and increase in right hemisphere activity. In this current experiment, only beta 3 showed the hemispheric trend of Gruzelier's model. They cite other details of current study, p. 164, not consonant with Gruzelier.)

"The 40-Hz EEG rhythm, which according to Sheer (1976) is the physiological representation of focused arousal, appeared to discriminate between differential patterns of high and low hypnotizables. Both during hypnotic induction and during hypnotic dream and age regression highly hypnotizables exhibit greater 40-Hz EEG amplitude with respect to the lows. These findings support the validity of the assumption that hypnosis is characterized by a state of focused attention (Hilgard, 1965) and that 40-Hz EEG activity reflects differential attentional patterns among subjects high and low in hypnotizability. On the basis of these findings it would appear that 40-Hz EEG and beta 3 spectral amplitudes may prove to be useful measures of individual hypnotizability" (p. 164).

1992

Anonymous (1992, May). Studies: Learning can occur while under anesthesia. Daily Breeze (South Bay, Los Angeles County).

## NOTES

"Surgical patients can absorb information while they're knocked out, and even learn tips that help with recovery, researchers reported Friday at a symposium on memory and anesthesia.

"Researchers at Papworth Hospital in Cambridge, England, studied 51 cardiac patients, one-third of whom heard a tape of positive 'therapeutic suggestions' during surgery. Another third heard batches of word associations; the rest heard a blank tape.

"Patients who were played the suggestion tape - which told them they were doing well, or wouldn't feel much pain - left the hospital 1 1/2 days earlier on average than other patients.

"Another study, from the University of Arizona College of Medicine, found that surgical patients who heard specific pain-relief suggestions recovered more easily than those hearing vague advice such as, 'Think of being well.'

"These are still early days to invest in every operating suite buying a tape recorder to play for the patients,' said Dr. Sunit Ghosh, a researcher with the Papworth team. 'But this definitely does hold promise.'

"Scholars at the second annual Symposium on Memory and Awareness in Anesthesia said patients rarely wake up recalling - unprompted - something that happened during anesthesia.

"But several studies showed subconscious learning while the patients were out cold.

"Not everyone accepted the findings.

"It shows an enormous sensitivity on the part of the brain, if it can be shown,' said Eugene Winograd, an Emory University psychologist and organizer of the Emory-sponsored conference. 'I'm not confident it has been shown yet.'

"Some researchers in other studies found no association between messages heard during anesthesia and learning.

"Dr. Alan Aitkenhead, professor of anesthesia at the University of Nottingham in England, found no significant difference between patients who heard recuperative suggestions and patients who were treated to a deliberately dull history of the hospital where they were.

"Aitkenhead said his study kept all patients quite deeply anesthetized, and that may be why they might not have learned as much as patients in other studies.

"By far, most likely, it's a difference in levels of anesthesia,' he said.

"The Papworth researchers, in another study, found that some patients showed strong word associations after hearing tapes of groups of words during surgery; but other patients under a different anesthesia didn't.

"'There needs to be standardization of our testing,' Ghosh said. 'I think it's partly related to the anesthesia technique and partly related to the way in which material is presented to the patient.'

"Dr. Peter Sebel, an Emory anesthesiologist and conference organizer, said that if patients can retain information about a speedy recovery, they probably retain other information, too - for example, a surgeon's discouraging operating-room assessment of their prognosis."

Burish, Thomas G.; Snyder, Susan L.; Jenkins, Richard A. (1991). Preparing patients for cancer chemotherapy: Effect of coping preparation and relaxation interventions. Journal of Consulting and Clinical Psychology, 59 (4), 518-525.

60 cancer chemotherapy patients were randomly assigned to 1 of 4 treatments: (a) relaxation training with guided relaxation imagery (RT), (b) general coping preparation package (PREP), (c) both RT and PREP, or (d) routine clinic treatment only. All patients were assessed on self-report, nurse observation, family observation, and physiological measures and were followed for 5 sequential chemotherapy treatments. Results indicate that the PREP intervention increased patients' knowledge of the disease and its treatment, reduced anticipatory side effects, reduced negative affect, and improved general coping. RT patients showed some decrease in negative affect and vomiting, but not as great as in past studies. The data suggest that relatively simple, 1-session coping preparation intervention can reduce many different types of distress associated with cancer chemotherapy and may be more effective than often-used behavioral relaxation procedures.

DeKoninck, J.; Brunette, R. (1991). Presleep suggestion related to a phobic object: Successful manipulation of reported dream affect. Journal of General Psychology, 118, 185-200.

When compared with subjects who received presleep suggestions for negative affect, subjects who received positive affect suggestions had significantly higher levels of positive emotions in their dreams, rated their own dreams as more pleasant, and had significantly lower levels of anxiety, sadness, and aggression. This supports the hypothesis that presleep suggestion can be an effective technique in influencing the affective dimension of the dream.

Barber, Theodore Xenophon (1990, August). Some things I've learned about hypnosis after 37 years. [Audiotape] Presented at the annual meeting of the American Psychological Association, Boston.

NOTES

"We are a unity of cells. Every cell is a citizen with it's own jobs, communicating all the time; cells send messages; the way we communicate with them is by suggestions. Each \_cell\_ is a mind-body.... When I do it now [hypnotic inductions], I say, 'We're going to go into hypnosis, we're \_both\_ going to go into hypnosis. I'm going to close my eyes (etc.)' - modeling hypnosis for them."

Biasutti, M. (1990). Music ability and altered states of consciousness: An experimental study. International Journal of Psychosomatics, 37, 82-85.

The relationship between music and altered states of consciousness was studied with 30 subjects divided into hypnosis and control groups. The "Test di abilita musicale" was applied. The hypnosis group did the retest after posthypnotic suggestions and the second in waking conditions. The hypnosis group had better results than the control group, especially in the rhythm test ( $p < 0.0001$ ).

1989

Baker, Elgan L.; Levitt, Eugene E. (1989). The hypnotic relationship: An investigation of compliance and resistance. International Journal of Clinical and Experimental Hypnosis, 37, 145-153.

The purpose of this investigation was to assess the ability of hypnotic Ss to voluntarily resist a neutral suggestion when a monetary reward was offered for resistance. 19 of 40 Ss (47.5%) successfully resisted after money was offered by the "resistance instructor." The correlation between resistance/compliance and hypnotizability was  $-.44$  (high hypnotizables were more likely to comply). Ss' impressions of the hypnotist tended to be positive; impressions of the resistance instructor tended to be neutral. There was a tendency for nonresistors to have a more positive view of the hypnotist but it is not as marked as was found in an earlier study (Levitt & Baker, 1983).

#### NOTES

Twelve (75%) of the high hypnotizables did not resist; two (16.7%) of the low hypnotizable Ss did not resist.

In their discussion, they state that "these data support the conclusion that hypnotizability or talent accounts for a significant portion of the variance in determining compliance with suggestions during trance. ... [Further], this research may be conceptualized as examining the contributions of a trait variable (hypnotizability) as compared with a variety of situational or state variables (motivation, social perception, environmental contingencies) in determining compliance and suggestibility. Inherent in this model of research is the assumption that many observed hypnotic phenomena (such as suggestibility) are interactive in nature, representing the outcome of the interplay between trait and state variables and between historically determined and contemporary forces. Such a perspective is consistent with the emerging view of trance behavior and experience and validly parallels the phenomenology of experimental and clinical hypnosis which describe both consistency and variability in hypnotic responsiveness for a specific subject or patient across varying conditions and time" (p. 151).

"This study also serves to clarify the important role of positive social perception and a positive sense of alliance with the hypnotist as a correlate of compliance with suggestion. It is clear that Ss who complied despite inducements to resist reported a more positive perception of the hypnotist and a more gratifying sense of relatedness with him than did their counterparts who resisted in response to financial inducement. These data do not indicate whether the positive perceptions contributed to compliance, as transference theories of trance involvement would predict, or whether they were consolidated after the fact due to other variables such as management of potential cognitive dissonance. It does seem reasonable to conclude, however, that the relationship is influential in the process of suggestibility and compliance" (p. 151).

1988

Azuma, Nagato; Stevenson, Ian (1988). 'Psychic surgery' in the Philippines as a form of group hypnosis. American Journal of Clinical Hypnosis, 31, 61-67.

Psychic surgeons and their patients were observed in the Philippines during a variety of procedures of 'minor surgery.' In six cases, subcutaneous tissues (cysts and benign tumors) were removed. Histological examination confirmed the gross diagnoses and left no doubt that the skin had been penetrated. Although the psychic surgeons used no analgesics or anesthetics, the patients appeared to experience little or no pain and only slight bleeding. The authors believe that a supportive group 'atmosphere' enables the patients to enter a quasi-hypnotic state that reduces pain and facilitates healing.

Council, James R.; Loge, D. (1988). Suggestibility and confidence in false perceptions: A pilot study. British Journal of Experimental and Clinical Hypnosis, 5, 95-98.

Subjects received audiotaped instructions implying that they would perceive increases in odor or heaviness while comparing stimuli in a sensory-judgment task. Stimuli were actually indiscriminable. Subjects pretested as higher or lower in hypnotizability performed the task in either hypnotic or non-hypnotic conditions. In both treatments, greater hypnotizability was associated with more perceived changes in the stimuli and greater confidence in the reality of those perceptions. Results support a general factor underlying suggestibility in hypnotic and nonhypnotic situations. The findings are discussed in relationship to false confidence effects reported in hypermnesia research.

1986

Chertok, Leon (1986). Psychotherapeutic transference, suggestibility. Psychotherapy, 23 (4), 563-569.

Discusses suggestion in psychotherapy and defines it as a body-affective process, an indissociable psychosociobiological entity that acts at an archaic unconscious level far beyond that of transference, mediates the influence of one individual on another, and is capable of producing manifest psychological and physiological changes. Present in all types of therapy, indirect (non deliberate, nonintentional) suggestion is the element that plays an important role in change and can be observed in hypnotic experimentation. It is further argued that transference and suggestion are phenomena that do not altogether overlap. Suggestion is the condition of transference without which transference could not be established.

1985

Bennett, Henry L.; Davis, H. S.; Giannini, Jeffrey A. (1985). Non-verbal response to intraoperative conversation. British Journal of Anesthesiology, 57, 174-179.

In a double-blind study, 33 patients (herniorrhaphy, cholecystectomy and orthopedic) were randomly assigned to either suggestion or control groups. Under known clinical levels of nitrous oxide and enflurane or halothane anesthesia, suggestion patients were exposed to statements of the importance of touching their ear during a postoperative interview. Compared with controls, suggestion patients did touch their ear (tetrachoric correlation 0.61,  $P < 0.02$ ). test, U (Mann-Whitney frequently more so did they and

Bolocofsky, David N.; Spinler, Dwayne; Coulthard-Morris, Linda (1985). Effectiveness of hypnosis as an adjunct to behavioral weight management. Journal of Clinical Psychology, 41 (1), 35-41.

109 17-67 year olds completed a behavioral treatment for weight management either with or without the addition of hypnosis. Results show that, at the end of the 9-week program, both interventions resulted in significant weight reduction. However, at 8-month and 2-year follow-ups, the hypnosis Ss showed significant additional weight loss, while those in the behavioral-treatment-only group exhibited little further change. More Ss who used hypnosis also achieved and maintained their personal weight goals. It is suggested that hypnosis may have been an effective motivator for Ss to continue practicing the more adaptive eating behaviors acquired during treatment. Findings support the utility of employing hypnosis as an adjunct to a behavioral weight management program. (25 ref)

1984

Bryant-Tuckett, Rose; Silverman, Lloyd H. (1984). Effects of the subliminal stimulation of symbiotic fantasies on the academic performance of emotionally handicapped students. Journal of Counseling Psychology, 31 (3), 295-305.

Divided 64 10.8 - 19.3 yr old emotionally disturbed residents of a treatment school into an experimental and control group matched for age, IQ, and reading ability. Both groups were seen 5 times/week for 6 weeks for tachistoscopic exposures of a subliminal stimulus. The stimulus for the experimental group was the phrase, "Mommy and I are one," conceived of as activating symbiotic fantasies that in a number of previous studies with varying groups of Ss had led to greater adaptive behavior. The control group was exposed to the phrase, "People are walking." Results show that experimental Ss manifested significantly greater improvement on the California Achievement Tests--Reading than did the controls. On 5 of 6 secondary variables--arithmetic achievement, self-concept, the handing in of homework assignments, independent classroom functioning, and self-imposed limits on TV viewing--the experimental Ss showed better adaptive functioning. It is suggested that activation of unconscious symbiotic fantasies can increase the effectiveness of counseling and teaching. (42 ref)

Critelli, Joseph W.; Neumann, Karl F. (1984). The placebo: Conceptual analysis of a construct in transition. American Psychologist, 39, 32-39.

The placebo in psychotherapy has unfortunately retained the negative connotation of an inert "nuisance variable," a label that it originally incurred in the field of medicine. In addition, the transition toward more cognitive models of psychotherapy, particularly Bandura's theory of self-efficacy, has led to problems in defining the placebo within psychology. This transition has resulted in an awkward interface between certain preferred cognitive metaphors and the negative connotations of a presumably cognitive placebo construct. As a result, suggestions have recently been made to dismiss the placebo construct from psychology and to do away with the use of true placebo controls in outcome research. The present analysis maintains that (a) the placebo can be adequately defined within psychology, (b) the negative connotation of the placebo label is largely undeserved, (c) the placebo retains a continuing conceptual and empirical utility for evaluating psychotherapy, and (d) the therapeutic efficacy of current therapies is well established even though they have not generally been shown to be more effective than nonspecific treatment.

1983

Borgeat, Francois; Goulet, Jean (1983). Psychophysiological changes following auditory subliminal suggestions for activation and deactivation. Perceptual and Motor Skills, 56, 759-766.

This study was to measure eventual psychophysiological changes resulting from auditory subliminal activation or deactivation suggestions. 18 subjects were alternately exposed to a control situation and to 25-dB activating and deactivating suggestions masked by a 40-dB white noise. Physiological measures (EMG, heart rate, skin-conductance levels and responses, and skin temperature) were recorded while subjects listened passively to the suggestions, during a stressing task that followed and after that task. Multi-variate analysis of variance showed a significant effect of the activation subliminal suggestions during and following the stressing task. This result is discussed as indicating effects of consciously unrecognized perceptions on psycho-physiological responses.

Classen, Wilhelm; Feingold, Ernest; Netter, Petra (1983). Influence of sensory suggestibility on treatment outcome in headache patients. Neuropsychobiology, 10, 44-47.

In 45 headache patients the relationship between sensory suggestibility and three measures of treatment effect-ratings on (1) intensity of headaches; (2) efficacy of drugs, and (3) physician's competence - was investigated in a double-blind long-term crossover study. Subjects scoring high on

sensory suggestibility clearly showed more relief of headaches upon the analgesic as well as upon the placebo. The physician's competence was rated higher by high-suggestible patients, whereas ratings on drug efficacy were low in all patients. The seemingly controversial behavior of high-suggestible patients was interpreted as a call for continuation of the physician's efforts in spite of the relief the patients already achieved.

1982

Belicki, Kathryn; Bowers, Patricia (1982, October). Dimensions of dissociative processing, absorption and dream change following a presleep instruction. [Paper] Presented at the annual meeting of the Society for Clinical and Experimental Hypnosis, Indianapolis, IN.

#### NOTES

Subjects' tendency to have things pop into their mind when asked to imagine, image them, or to do a divergent thinking task is correlated with behavior change out of awareness (dissociated), change in dream content in response to indirect suggestion - the request to pay attention to a certain element in their dreams. Effortless imagining (as opposed to working at it), a particular type of dissociative phenomenon, is associated with dream change.

Bowers, Patricia G. (1982). The classic suggestion effect: Relationships with scales of hypnotizability, effortless experiencing, and imagery vividness. International Journal of Clinical and Experimental Hypnosis, 30 (3), 270-279.

How well the Stanford Hypnotic Susceptibility Scales assess what Weitzenhoffer (1978) terms the "classic suggestion effect" is addressed by developing an index of nonvolitional behavior (N-VB) for a group form of the Stanford Hypnotic Susceptibility Scale, Form C of Weitzenhoffer and Hilgard (1962) given to 43 Ss. The N- VB index, reflecting the classic suggestion effect's dual criteria of both behavioral responsiveness to suggestion and nonvolition ratings, was correlated highly with the traditional scoring of the group SHSS:C and moderately with the Harvard Group Scale of Hypnotic Susceptibility, Form A. Effortless experiencing of imagination and imagery vividness relate similarly to traditional and N-VB scores of hypnotizability. In addition, the relationship between involuntary ratings and passing and failing an item of the group SHSS:C was examined for each of the 10 items. There was a significant relationship for 7 of the items.

1980

Bauer, Herbert; Berner, Peter; Steinringer, Hermann; Stacher, Georg (1980). Effects of hypnotic suggestions of sensory change on event-related cortical slow potential shifts. Archiv fur Psychologie, 133 (3), 161-169.

"The purpose of this study was to evaluate whether cortical slow potentials related to a S1-S2 paradigm are influenced by hypnotic suggestions of sensory change. Five healthy subjects susceptible to hypnosis participated each in two identical experiments with three conditions. In condition (1) and (2) each three intensities of 800 and 4000 Hz tones were presented. Preceding condition (2) hypnosis was induced and the subjects received the suggestion to hear the 800 but not the 4000 Hz tones. In condition (3), the tones were presented as S1 and a flash as S2. The subjects received the same suggestions as in (2) and a motor response to S2 was required. EEG was recorded from Cz. In (1) 800 and 4000 Hz tones caused negativities of equal amplitude, in (2) only minute negativities developed, possibly due to hypnosis induced deactivation. In (3) the S1-S2 related negativities were significantly smaller in amplitude during 4000 Hz tones than during 800 Hz tones, while the negativities preceding

S2 differed only after the most intense S1. Hypnotic suggestions attenuate S1-S2 related negative potentials, possibly by affecting cognitive functions.

1979

Barber, Joseph; Donaldson, David; Ramras, Susan; Allen, Gerald D. (1979). The relationship between nitrous oxide conscious sedation and the hypnotic state. Journal of the American Dental Association, **99**, 624-626.

#### NOTES

Nitrous oxide-oxygen produces a state of consciousness in the patient that is reported to be similar to the hypnotic state. In this investigation, the authors test the hypothesis that nitrous oxide-oxygen heightens a patient's responsiveness.

This study apparently did not have a control group receiving nitrous oxide but no suggestions, to evaluate the amnesia and analgesic effects of the drug alone.

1978

Connors, J. R.; Sheehan, P. W. (1978). The influence of control comparison tasks and between-versus within-subjects effects in hypnotic responsivity. International Journal of Clinical and Experimental Hypnosis, **26**, 104-122.

Type of experimental design (between- versus within-subjects) and type of control task were examined for their differential effects on the magnitude of objective and state report test scores associated with response to items on the Stanford Hypnotic Scale of Susceptibility, Form C (Weitzenhoffer & Hilgard, 1962). In an integrated program of work exploring design effects in hypnotic research, Ss in each of 7 comparison conditions that involved hypnosis and 4 separate comparison conditions that did not involve hypnosis were tested twice on successive occasions. Three of the control tasks used (waking, imagination, and imagination [alert] instruction) were counterbalanced with hypnosis to analyze possible order effects associated with hypnotic test conditions. Data indexed the patterns of between-versus within-subjects effects associated with standard control tasks and also highlighted the order effects that accompanied them. Imagination instructions, in particular, pose specific difficulties that require attention when Ss are tested as their own controls.

1977

Anderson, J. W. (1977). Defensive maneuvers in two incidents involving the Chevreul pendulum: A clinical note. International Journal of Clinical and Experimental Hypnosis, **25**, 4-6.

#### NOTES

"Hypnosis frequently facilitates increased access to the unconscious. In both of these cases, the hypnotized subject gained contact with a thought which otherwise would likely have remained out of awareness. Then the ego quickly resorted to defensive maneuvers in order to deny the thought" (p. 6).

1976

Chaves, John F.; Barber, Theodore Xenophon (1976). Hypnotic procedures and surgery: A critical analysis with applications to 'acupuncture analgesia'. American Journal of Clinical Hypnosis, **18** (4), 217-236.

Although hypnotic procedures are useful for reducing the anxiety of surgery and helping patients tolerate surgery, they do not consistently eliminate pain. Six factors that are part of or associated with hypnotic procedures help patients tolerate surgery. These factors pertain to patient selection, the

patient-physician relationship, the preoperative 'education' of the patient, the adjunctive use of drugs, and the use of suggestions of analgesia and distraction. It appears that the same factors account for the apparent successes of 'acupuncture analgesia' as well. A frequently-overlooked fact, that most internal tissues and organs of the body do not hurt when they are cut by the surgeon's scalpel, is also important in understanding how surgery can be performed with either 'hypnoanesthesia' or 'acupuncture analgesia.'

**1975**

**Barber, Theodore Xenophon (1975). Responding to 'hypnotic' suggestions: An introspective report. American Journal of Clinical Hypnosis, 18 (1), 6-22.**

The author first presents an introspective report which describes some of his attitudes, motivations, and expectancies and ongoing thought processes while he is responding to 'hypnotic' suggestions. The introspective report indicates that (a) suggested effects are experienced when a person thinks with and imaginatively focuses on those things that are suggested and (b) a person imaginatively focuses on the suggestions when he sees the test situation as useful and worthwhile and when he wants to and expects to experience those things that are suggested. It is then argued that the responsive subject in a hypnotic situation differs in every important respect from the sleepwalker and closely resembles the person who is involved in reading an interesting novel or in observing an interesting motion picture. Finally, the author outlines a course, now being developed, that aims to teach individuals how to respond to suggestions.

**1974**

**Chaves, John F.; Barber, Theodore Xenophon (1974). Acupuncture analgesia: A six-factor theory. Psychoenergetic Systems, 1, 11-21.**

The dramatic successes claimed for acupuncture suggest that Western medicine has failed to identify important factors that pertain to the nature of pain and its control. This may not be the case, as there are at least six factors which are often overlooked by writers describing the absence of pain (i.e., analgesia) during acupuncture: (a) the patients accepted for surgery under acupuncture usually believe that it will work, (b) drugs are frequently used in combination with acupuncture, (c) the pain associated with surgical procedures is less than is generally assumed, (d) the patients are prepared in special ways for surgery under acupuncture, (e) the acupuncture needles distract the patient from the pain of surgery and, (f) suggestions for pain relief are present in acupuncture treatment. It is concluded that more research is needed to determine whether additional factors are needed to help explain the phenomenon of acupuncture analgesia.

**1973**

**Brown, H. Alan (1973). Role of expectancy manipulation in systematic desensitization. Journal of Consulting and Clinical Psychology, 41 (3), 405-411.**

Expectancy, relaxation, and hierarchy content were manipulated in a 2X2 factorial design with two additional control groups. It was hypothesized that a major portion of therapeutic change following desensitization could be accounted for by the subjects' responses to positive feedback inherent in the paradigm. Spider-phobic subjects saw either photographs of spiders or blank slides that they believed to be tachistoscopically presented pictures of spiders. In the factorial part of the design, half of the subjects believed their progress through the hierarchy to be contingent on autonomic responses; the others believed rate of progress to be random. Findings did not support the hypothesis that expectancy

was the only factor in desensitization, but they did serve to clarify the role of expectancy vis-a-vis the counterconditioning elements typically discussed in the literature.

1972

Barber, Theodore Xenophon; de Moor, Wilfried (1972). A theory of hypnotic induction procedures. American Journal of Clinical Hypnosis, 15 (2), 112-135.

The first part of the paper delineates nine variables in hypnotic induction procedures that give rise to heightened responsiveness to test-suggestions: (a) defining the situation as hypnosis; (b) removing fears and misconceptions; (c) securing cooperation; (d) asking the subject to keep his eyes closed; (e) suggesting relaxation, sleep, and hypnosis; (f) maximizing the phrasing and vocal characteristics of suggestions; (g) coupling suggestions with naturally-occurring events; (h) stimulating goal-directed imagining; and (i) preventing or reinterpreting the failure of suggestions. Data are presented to support the theory that the nine variables augment responsiveness to test-suggestions by giving rise to positive attitudes, motivations, and expectancies which, in turn, tend to produce a willingness to think with and vividly imagine those things that are suggested. The second part of the paper specifies situational variables and variables involved in induction procedures that produce a trance-like appearance, changes in body feelings, and reports of having been hypnotized.

Bowers, Kenneth S.; Kelly, P. (1970). Stress, disease, psychotherapy, and hypnosis. Journal of Abnormal Psychology, 490-505.

Presents evidence for the importance of suggestion and hypnotic ability in the healing or amelioration of various somatic disorders. It is argued that even in some treatment interventions that are not explicitly hypnotic, suggestion and hypnotic ability may be hidden factors that help to promote successful healing. Consequently, hypnotic ability may be an individual difference variable that influences treatment outcome in a manner not heretofore recognized by many investigators and clinicians involved in helping the psychologically and physically ill.

Bartlett, Edmund E.; Faw, Terry T.; Liebert, Robert M. (1967). The effects of suggestions of alertness in hypnosis on pupillary response: Report on a single subject. International Journal of Clinical and Experimental Hypnosis, 15 (4), 189-192.

THE PUPIL SIZE OF A SINGLE S WAS RECORDED UNDER 2 TYPES OF HYPNOTIC SUGGESTION: ALERTNESS INSTRUCTIONS AND TRADITIONAL RELAXATION INSTRUCTIONS. IT WAS FOUND THAT THE SIZE OF THE PUPIL INCREASED SIGNIFICANTLY UNDER ALERTNESS INSTRUCTIONS. THIS RESULT WAS TAKEN AS FURTHER CORROBORATION OF THE HYPOTHESIS THAT CHANGES IN VARIOUS PARAMETERS OF AROUSAL APPARENTLY ASSOCIATED WITH HYPNOSIS MAY BE ATTRIBUTED TO SPECIFIABLE CHARACTERISTICS OF THE INSTRUCTIONS USED RATHER THAN TO STABLE CHARACTERISTICS OF THE "STATE" OF HYPNOSIS. 1965

Agosti, E.; Camerota, G. (1965). Some effects of hypnotic suggestion on respiratory function. International Journal of Clinical and Experimental Hypnosis, 13 (3), 149-157.

Several respiratory indices were measured in 10 Ss in 3 states: at rest, with hypnotic suggestion of relaxation, and with hypnotic instructions to imagine muscular work. The same suggestions were given to 10 control Ss in the waking state. The suggestion of relaxation produced a decrease in pulmonary ventilation in both groups, although it was substantial only in the hypnotic group which started from a

higher baseline level. The imagined work produced an increase in ventilation, especially in the hypnotic group. However, in both instances because of compensatory changes in respiratory efficiency the actual uptake of oxygen remained almost unaffected. (PsycINFO Database Record (c) 2002 APA, all rights reserved)

Barber, Theodore Xenophon (1965). Physiological effects of 'hypnotic suggestions': A critical review of recent research (1960-64). Psychological Bulletin, 201-222.

Recent studies are reviewed which were concerned with the effectiveness of suggestions given under "hypnosis" and "waking" experimental treatments in alleviating allergies, ichthyosis, myopia, and other conditions and in eliciting deafness, blindness, hallucinations, analgesia, cardiac acceleration and deceleration, emotional responses, urine secretion to sham water ingestion, narcotic-like drug effects, and other phenomena. The review indicates that a wide variety of physiological functions can be influenced by suggestions administered under either hypnosis or waking experimental treatments, and direct and indirect suggestions to show the particular physiological manifestations are crucial variables in producing the effects.

Das, J. P. (1965). Relationship between body-sway, hand-levitation, and a questionnaire measure of hypnotic susceptibility. International Journal of Clinical and Experimental Hypnosis, 13 (1), 26-33.

67 randomly selected college students were administered the body-sway test, a questionnaire measure of tranceability, and an induction procedure utilizing hand-levitation to determine hypnotic susceptibility. The 6 Es varied in age, sex; 5 of them had little experience as hypnotists. All reference to "hypnosis" was omitted from the induction procedure. Significant phi-coefficients between body-sway and levitation (.52), levitation and tranceability frequency (.28) and intensity (.25), and body-sway and tranceability intensity (.33) were obtained. (16 ref.) (PsycINFO Database Record (c) 2002 APA, all rights reserved)

1964

Anderson, Milton L.; Sarbin, T. R. (1964). Base rate expectations and motoric alterations in hypnosis. International Journal of Clinical and Experimental Hypnosis, 12 (3), 147-158.

Degree of responsiveness to "suggestion" in an experiment which did not utilize hypnotic induction (the Berkeley Sample) was comparable to that obtained in an experiment which did utilize hypnotic induction (the Stanford Sample). Procedural differences between the 2 experiments--self-scoring vs. objective-scoring, and group vs. individual testing--were regarded as not crucial in making a comparison of the 2 experiments. The distribution of responses in the Berkeley Sample may be taken as the base rate. The slightly higher degree of responsiveness over the base rate in the Stanford Sample (on some tests) may be attributed to the "degree of volunteering" that characterized the sample. The importance for experiments in the future to create equal levels of motivation and expectation to perform well under both the hypnotic and the nonhypnotic conditions is stressed, and brief mention is made of a new metaphor to be used in the conceptualization of the problems of hypnosis. (25 ref.) (PsycINFO Database Record (c) 2002 APA, all rights reserved)

Black, Stephen (1964). Mind and body. London: Kimber.

## NOTES

Defines psychosomatic disease as one that responds to psychotherapy. Believes only 5% are highly hypnotizable, that hypnosis is learnable in 1/2 hour, that hypnosis is not a useful treatment for

psychosomatic disorders because you can't use interpretation [of unconscious]. The 'unconscious' is "... a complex of informational systems derived from such primaevial mechanisms" (p. 133). "Primaevial mind is involved in these mechanisms of genetics and immunology" (p. 133). "There is thus a 'somatic mind' which is unconscious and presumably without any means of verbalization of experience--and a 'cerebral mind' which is conscious" (p. 133). The dividing line is not clear.

Rapport is discussed on pp. 160, 169 as one of the spontaneous characteristics of hypnosis, in the absence of suggestion. The same for posthypnotic suggestion (rapport and amnesia). Spontaneous physiological changes in hypnosis relate to mind-body relationships (p. 169)

Conditioned reflex is discussed on p. 161

"...the subjective evidence indicates that a perceptual change involving any sensory modality can be produced by DSUH" [direct suggestion under hypnosis] p. 178. Suggestion can selectively affect different parts of the body p. 197.

Research: "Hypnosis is not only the most important and practical way of proving the existence of the unconscious--which is still in doubt in some circles--but is in fact the only way in which unconscious mechanisms can be manipulated under repeatable experimental conditions for purposes of investigation" (p. 152).

Mind-body is "amenability to control" Catatonia, which characterizes both animal and human hypnosis, seen in hypnosis, is induced by constriction (i.e. disorientation). The Cartesian concept of mind and body tends to confuse the issue p. 157.

Rapport is discussed (p. 157).

Suggestion (p. 159) "It was this concept of 'suggestion'--which so obviously parallels 'amenability to control' in animals--that eventually established hypnosis in the French schools of psychiatry as a state of increased suggestibility. ... still the standard definition of hypnosis in most medical psychiatric textbooks and in lay dictionaries" (p. 159).

Black (1969) did some biochemical sleuthing to learn how information transmitted by words becomes information encoded somatically, as when psychosomatic allergies flare and recede or disappear. What accounts for suggestion "curing" an allergic skin reaction in one part of the body while another part not included in the suggestion remains reactive? What accounts for the instantaneous skin allergy cure which sometimes occurs with suggestion (in 24 hours)?

Skin sensitivity tests in highly hypnotizable Ss who were also very allergic were inhibited by direct suggestion under hypnosis under highly controlled experimental conditions--and in one subject the effect (inhibition) was relatively permanent--ruling out (he suggests) a neurological mechanism. He did further experiments to examine whether the result was due to an instant neurological mechanism and a long-term endocrinal mechanism.

p. 212 He ruled out peripheral blood flow as the cause of diminished skin sensitivity (there was no change in blood flow with suggestions of heat or cold). Therefore decrease in blood flow couldn't explain in neurovascular terms the 'instant' inhibition of skin sensitivity (allergy) tests. Was it due to systemic--especially adrenal-- changes? He demonstrated increases in plasma cortisol under hypnosis with suggestions of fear. On p. 230 he summarizes the facts he established by skin sensitivity tests, plasma- cortisol studies, and histology - endocrinological.

Black, Stephen; Edholm, O. G.; Fox, R. H.; Kidd, D. J. (1963). The effect of suggestion under hypnosis on the peripheral circulation in man. Clinical Science, 26, 223-230.

Summary.

1. The effects on the circulation in the forearm and hand of both direct and indirect suggestion under hypnosis of thermal stimuli have been studied. 2. The induction of hypnosis did not significantly alter the forearm blood flow, but a small reduction in hand blood flow was usually observed. Pulse rate in general slowed slightly as did respiration rate. 3. The effect of body heating on forearm and hand

blood flow was not modified by hypnosis. 4. Direct suggestion under hypnosis of body heating or body cooling, with and without body heating, produced only small changes. 5. The changes associated with suggestion were not related to the thermal suggestion. Whatever the suggestion, the usual response was a reduction in hand blood flow and an increase in forearm blood flow. 6. The rise of body temperature with heating was not modified by direct suggestion, under hypnosis, of body cooling. 7. No change in body temperature could be elicited by suggestion. 8. In a few experiments marked changes in forearm blood flow occurred. These appeared to resemble the changes in the circulation produced by emotional stimuli. 9. The smaller changes more frequently observed were also similar to those produced by mild emotional stimuli" (p. 229). [N.B. The Subjects were normal, healthy adults, N = 9, between 21-45 years old; highly hypnotizable, amnesic for trance.]

1959

Conn, Jacob H. (1959). Cultural and clinical aspects of hypnosis, placebos, and suggestibility. International Journal of Clinical and Experimental Hypnosis, 7 (4), 175-185.

Observation that student subjects often go into a deeper level of hypnosis after suggestions have been given for ending the session has led the writer to explore the reactions of subjects to this phenomenon and to set up a simple experiment using ideomotor responses in ten gynecological patients who needed hypnosis for therapy. In each of the ten patients there was a deepening of the trance after the suggestion to awaken had been given. It was the opinion of the subjects that they deepened the trance in rebellion against the direction for terminating a pleasant experience" (p. 227).

1956

Barber, Theodore Xenophon (1956). 'Sleep' and 'hypnosis': A reappraisal. Journal of Clinical and Experimental Hypnosis, 4, 141-159.

## NOTES

"Some recent experiments and a reevaluation of the electroencephalographic findings indicate that the term 'hypnosis' has subsumed at least two more or less distinct phenomena: (a) 'hypnosis' preceded by 'trance-inducing suggestions' which is closely related to 'light sleep' and (b) 'hypnosis' without 'trance-inducing suggestions' which is often a 'waking' state.

"From this viewpoint we can begin to reevaluate the contradictory physiological experiments comparing sleep and hypnosis, the most favorable conditions for producing hypnosis, amnesia and decreased suggestibility in very deep hypnosis, and the reports of waking and sleeping hypnosis. We can also reappraise such thorny problems in hypnotic theory as the production of hypnosis by artificial means, autohypnosis, and animal hypnosis.

"The argument presented calls for further research. We should investigate (a) suggestibility during extreme relaxation; (b) response on hypnotic tests when the subject is told, "Go to sleep and I'll be back later to give you some tests"; (c) deep trance phenomena during sleep; (d) hypnotizability of good sleepers and insomniacs; (e) beneficial suggestions during sleep; (f) physiological functions during 'light sleep' and hypnosis; (g) the response of 'sleep-walkers' to standard hypnotic tests; (h) the relationship of 'light sleep' dreams to hypnotically induced dreams; and (i) the relationship of sleep amnesia to hypnotic amnesia" (pp. 153-154).

## SURGERY

1995

Lang, Elvira V.; Joyce, Janet S.; Spiegel, David; Hamilton, Donna; Lee, Kelvin K. (1995, November). Self-hypnotic relaxation: Effect on use of intravenous medication during invasive procedures. [Paper] Presented at the annual meeting of the Society for Clinical and Experimental

#### NOTES

I'm an interventional radiologist. Interventional radiologists do things like placing needles into the body, putting guide wires through them, advancing instruments (to get into vessels, to treat blockages, make diagnoses, drain urine, drain pus, remove gall stones) while progress is imaged. Procedures are usually performed on awake patients and may take 1-5 hours. Traditionally intravenous drugs are given for these procedures, most commonly a mixture of morphine derivatives and sedatives. Annually about 10 million invasive procedures are performed in the U.S. Among those 47,000 patients per year are estimated to be at risk of serious cardiovascular complications and 2,600 patients per year are estimated to die as a direct consequence of sedation. Hospital regulations also require a dedicated observer to be with the patient throughout the entire procedure and for extended times afterwards, when any intravenous drugs are given. This becomes very expensive.

We started self-hypnotic relaxation with patients because of a nursing shortage. We used rapport techniques, relaxation training, imagery (neutralizing distressing imagery, enhancing pleasant imagery) and suggestions. Members of the procedure team apply these methods while the procedure takes place. During the time patients are prepared for the procedure, induction can be performed. Hypnosis can also be initiated in the procedure room, and a nurse or assistant reads a script. We give patients control over what happens, over the whole process, including even rejection of the self-hypnotic process.

We did a randomized study with male veterans. Sixteen were attributed to a self-hypnotic relaxation group, 14 served as a control group. All patients had access to patient control intravenous analgesia. We assessed pain and anxiety on visual analogue self rating scales giving intensities between 0 (none at all) to 10 (maximum). We also recorded increases in blood pressure and heart rate, side effects that could be attributed to drugs or overexcitation. In the self-hypnotic relaxation group 50% of the patients reported distressing imagery at the onset. We helped them transform this negative imagery into imagery with neutral content, then enhanced the pleasant imagery, (often a pleasant scene at home). Twelve of 16 patients in the self-hypnosis group did not request medication at all; and only 1 in the control group did not request medication. The maximum pain perception was significantly less (2 vs 5) and procedural interruptions were fewer (2 vs 7) for the self-hypnosis group. There was no difference in the increases in blood pressure and heart rate.

We concluded that use of self-hypnotic relaxation is a valuable adjunct for invasive procedures.

#### NOTES

Presents point of view of a private practice anesthesiologist in Santa Barbara, California. Used hypnosis for 20 years.

Use of hypnosis as hypnoanesthesia is rare since Esdaile, with brief resurgence in 50's, because surgery techniques advanced before anesthetics did in areas that were very risky. Now it is a matter of choice, and may be undertaken because of a patient's extreme fear of anesthesia, previous bad experience with anesthesia, fervent belief in holistic method, allergy, or previous experience with hypnosis. Still advised to use hypnosis for MRIs, radiation procedures, former drug addicts (who may have problems with drugs), burn patients, release of neck contractions, and medical procedures--especially with children--like lumbar puncture.

She disagrees with Kroger's estimate of only 10% of patients being able to use hypnoanesthesia; she does not believe it requires a lot of training, or profound muscle relaxation.

There is no indication of how many cases are actually done with hypnosis. Also, published cases are not representative of the quantity or complexity of cases; most published cases have a few extraordinary characteristics. The Irish surgeon Jack Gibson has done more than 4000 cases, some very complicated.

I have used it for D & Cs, and complex cases that were not published. Most of my patients elected to be alert during the hypnosis and conversed with their surgeons. The most common benefit is that recovery from anesthesia is not necessary; but these days with newer anesthetics recovery from anesthesia is rapid anyway. However, if as we suspect anesthesia affects immune function, that would be another reason to use hypnosis.

Preparation for surgery may be of three types: 1. formal hypnosis techniques 2. "hypnoidal" techniques that aren't formal 3. unprepared patients in whom hypnosis is used at last moment.

Examples. 1. Formal hypnosis: This symposium deals with this type of approach. Three groups derive particular benefit -- those requiring prolonged artificial ventilation postoperatively (because otherwise sedation must be used, which leads to complications), where prepared patients tolerate interventions calmly and comfortably -- cancer patients, for whom this can be first experience of patient to see self as active participant in care rather than a victim of the illness and of complicated technology -- pediatric patients. 2. Hypnoidal (hypnosis like) techniques: This is the most important application. Time doesn't permit much discussion here. Patients are in an altered state when they come for surgery, highly suggestible, and suggestions appear to be as effective as during formal trance state. The doctor can elicit positive responses during "casual conversation" while seemingly giving information to the patient. (The reverse is true also, with inadvertent negative suggestions, to the detriment of the patient.) Scrupulous adherence to medical facts is important during this type of conversation.

Operating room fixtures are useful for focus of attention, and I have published this information in an article.

Recovery room also is place where case specific information and appropriate suggestions can be given. Patient can experience his ability to alter sensations, for the first time, following suggestions.

Remainder of the hospitalization offers opportunity for reinforcing case specific positive suggestions.

Bennett, Henry L. (1993, October). Hypnosis and suggestion in anesthesiology and surgery. [Paper] Presented at the annual meeting of the Society for Clinical and Experimental Hypnosis, Arlington Heights, IL.

## NOTES

He began by saying that he is opposed to using hypnosis for surgery, though he favors a theory of how hypnosis effects physiological change, and cites T. X. Barber's classic "Changing Unchanging Bodily Processes."

Relaxation puts patient in a "psychological strait jacket" because surgery is so highly stressful. He gives information "about how to go through the surgery more comfortably," gets across the idea about coping style, tells them surgery is exertional and that they are tired afterward, that he can help them "using things you already know how to do," and specifies exactly what they can do--using model of himself as a trainer.

In some recent research he used pairs of pictures, some of which lead to pupillary constriction (blood pressure goes down) or dilation (blood pressure goes up). Instructing them to look, patients looked twice as long at the pictures than they did during free gaze. When not instructed to look, heart rate went down; when told to look, heart rate went up. So the researchers went back to free gaze. He uses this as a metaphor for many of the pre- surgery preparation activities that encourage relaxation "inappropriately."

He cites Cohen & Lazarus re vigilant copers, Price et al (1957), and some other studies on epinephrine effects. He uses examples of work patients may have done (e.g. planting a garden) when talking with patients prior to surgery, that gives them a sense of accomplishment later.

You have to give specific instructions or suggestion, not general relaxation suggestions.

Question from the audience: Can preoperative instructions (not hypnosis) diminish blood loss.

In Bennett's answer he seems to be reporting the earlier study: they found 150- 4000 cc blood loss, high variability. Extent of blood loss was determined by extent of surgery, by instructions to patients vs no instructions.

This study was replicated by Enqvist, Bystedt, & von Konow in the Anesthesia conference at Emory University in 1992.

May 1993 Western Journal of Medicine article, Disbrow, Bennett, & Owinos, with 40 lower abdominal surgery patients who got specific instructions or not. The SHCS was used to measure hypnotizability: highs resolved quicker than low hypnotizable patients. They also found that instructed patients did better than those who did not get specific instructions.

There are now 3 replications of McClintock's study: people use less medications after surgery, when tapes about rapid recovery are played \*during\* surgery.

Bennett is now using tapes with suggestions for recovery during surgery.

Blankfield, Robert P. (1993, October). Suggestion, hypnosis, and relaxation as adjuncts for surgery patients: Lessons from studies involving cardiac surgery patients. [Paper] Presented at the annual meeting of the Society for Clinical and Experimental Hypnosis, Arlington Heights, IL.

## NOTES

The author stated that his research and the few other studies of cardiac surgery patients do not support idea that cardiac surgery patients benefit from hypnosis and suggestion.

Types of intervention have varied: hypnosis, suggestion, relaxation; pre-op, during, or post-op; with many different outcome variables.

Aiken & Henrichs (1971) study was nonrandomized, nonblinded, for 30 patients getting open heart surgery. Treated patients had benefits.

Surman, Hackett, Silverberg, & Behrendt (1974) had a randomized, single-blind design for 40 patients taught Self Hypnosis (S-H), for elective mitral valve surgery. No difference in benefits. But 45% of patients taught S-H reported a subjective sense of benefit (though objective indicators didn't support that). [He says the difference between subjective/objective outcome ratings is important.]

Hart (1980) used randomized, single-blind design for 40 patients who had open heart surgery. No differences found except initial 3 days post surgery.

Greenleaf et al (1992) - see her paper presentation of this date.

Blankfield et al (presented at Society of Clinical and Experimental Hypnosis meeting in 1992) used a randomized, single-blind design for 95 patients, who were randomly assigned to taped suggestions, music, or controls. No differences were found in benefits.

Our data were re-analyzed: patients who felt tape was helpful were compared to the remaining 62 patients, but there again were no differences in amount of narcotics used for pain, though there was a trend in the right direction; nursing assessments failed to identify less anxiety.

The point is, whereas the bulk of publications suggest benefits, there is little evidence with this population. Could these patients be different in personality, ability to respond to intervention, amount of external stimuli? They should be studied because there are a lot of these patients with only a few surgeons and you don't have to gain the cooperation of a lot of different surgeons to do this kind of research. Also, there is uniformity in cardiac surgery whereas standard operating surgery is in a state of flux in other areas (e.g. movement from generous incisions to micro procedures, and patients receiving this type of surgery remain in hospital for a week whereas this opportunity to study them

during inpatient post-surgical period is disappearing in other areas). It is my opinion that cardiac patients may not be highly receptive to suggestion.

Curiously, according to Surman and my research, 1/2 the subjects report benefits. Either some benefits are subtle, or they are reporting a placebo effect.

Future studies need more patients, and the investigators must stratify on personality inventory variables such as Type A personality, hypnotizability, motivation, anxiety, depression, family support, social support systems. This is labor intensive, to determine which characteristics determine differing outcomes. The patients used in this type of research require more presurgery evaluation than previously has occurred.

The MMPI can be self administered and is widely acceptable, but is cumbersome, not well suited to people who are acutely ill. Assessment of Type A personality is important because Type A's might be less receptive to suggestion. Structured interview is time consuming, but a 52-item questionnaire can be self administered. Other factors listed above are important.

Don, Norman S. (1993, October). Trance surgery in Brazil. [Paper] Presented at the annual meeting of the Society for Clinical and Experimental Hypnosis, Arlington Heights, IL.

#### NOTES

Showed a videotape of a Brazilian trance surgeon, who cuts without analgesia or asepsis. Patients later report no pain, infections, etc. The healer/surgeon is believed by everyone to be in a trance state, and the body is believed to be taken over by a spiritual doctor. The people involved deny that the patient is in trance.

Greenleaf, Marcia; Fisher, Stanley; Miaskowski, Christine; Du Hamel, Katherine (1993). Hypnotizability and recovery from cardiac surgery. American Journal of Clinical Hypnosis, 35, 119-128.

#### NOTES

Notes were taken from author's presentation of this material at the Annual Meeting of the Society of Clinical and Experimental Hypnosis, Arlington Heights, Illinois. The paper presentation was part of a Symposium: Towards a Theory of Surgery: Hypnosis, Suggestion, Anesthesiology and Surgery, Methodological and Theoretical Issues and Dilemmas.

Authors outlined the reported advantages of using hypnosis. Their review found problems in much of the research on this topic published to date: many single subject studies, subjects were often selected and trained by the investigator, hypnotizability wasn't evaluated.

Used the Hypnotic Induction Profile (HIP) before assignment of patients to groups, and also equated groups for age. Groups 1 & 2 had formal hypnosis and then either relaxation-imagery (Janck's autogenic training) or specific outcome suggestions (e.g. to have a clean dry wound, and to look forward to being able to function well); Group 3 were controls.

No differences were found in outcome measures of length of time in ICU, time on respirator, length of stay, and cumulative index of recovery. Didn't publish our data on pain medications because learned it was poorly charted.

Only difference found was: the relaxation imagery group got more wound drainage. It was degree of hypnotizability, independent of group, that made a difference in total number of hours on Nipride - highs were on it almost twice as long. On cumulative stability (having need of medications or respirator) the mid-range people did better. Not statistically significant but nevertheless clinically important, the lows were in the hospital 5 days longer.

This was counter-intuitive though it supports Herbert Spiegel's theory. We, as experimenters, were independent of the treatment team. We didn't have DRGs then and now we may have hit a ceiling

effect in the amount of time people stayed in the hospital, because they had excellent pre-surgery education.

We had difficulty continuing the study because the intervention seemed to other staff to be so useful: after 6 months the surgeons began requesting hypnosis for their anxious patients; the chief anesthesiologist had started using it routinely.

Sample size is problematic. They were patients who were actively recruited, not people who sought hypnosis.

**CONCLUSIONS.** High hypnotizables in the hospital intensive care unit (ICU) demonstrate sensitivity to external stimuli without critical ability to screen; we see this reversed in the postoperative period. Mid range hypnotizables can decide which external cues to pay attention to. Lows are less able to incorporate new suggestions. They are bound by pre-existing views and also vigilance.

Hypnosis = Dissociation + Absorption + Suggestibility (Spiegel's theory)

We must focus more on the state-trait phenomena, the context, and then select the treatment.

**Kessler, Roger S. (1993, October). Suggestion and hypnosis in anesthesiology and surgery: A simple and complicated analysis. [Paper] Presented at the annual meeting of the Society for Clinical and Experimental Hypnosis, Arlington Heights, IL.**

## NOTES

Cites three reviews: Blankenfield; Rogers & Reich; and Mumford. These reviews leave us with several questions: - What does the addition of hypnosis add? - What is importance of hypnotic ability? - What techniques are most effective? - How useful are standardized tailored interventions? - What are psychological, physiological, and biochemical markers?

We lack a general theoretical framework (see H. Bennett), and there are a broad variety of pre-surgical interventions, which may influence different aspects of functioning.

Evans & Richardson found no differences between people with and without preparatory interventions. Bonke & colleagues found no differences in length of hospitalization for people with and without preparatory interventions (except for people 55 and over). Relaxation training for surgery finds mixed results.

Blankenfield obtained negative findings in cardiac surgery. His recent IJCEH article reports those negative results.

What does presurgical intervention influence? - Psychological dimensions - Biochemical & physiological dimensions - Time/cost dimensions

Correspondence across these dimensions has not been consistently demonstrated, e.g. there is a lack of correlation between cortisol (physiological dimension) and anxiety (psychological dimension).

Why are there conflicting findings? 1. Possibly patient's coping style is responded to inappropriately, e.g. people who deny vs those who sensitize seem to require different interventions. Must assess the patient's idiosyncratic coping style. 2. Four studies suggest hypnotic ability may be a factor in recovery.

a. Disbrow, Bennett, & Owings (1993)

b. Rondi et al. (high hypnotizables use less morphine via Patient Controlled Analgesia)

c. Greenleaf et al. (hypnotizability predicts recovery independently)

d. Rapkin, Straubing, & Holroyd (high hypnotizables had less blood loss during surgery) 3. Is hypnosis per se necessary?

Comparative evaluation of strategies has been ignored. Enquist found hypnosis had a greater effect than non-hypnotic treatment in blood loss. Another study of bone marrow transplant patients found the hypnosis treatment superior.

When it comes to clinical interventions, we need to assess the patient's historic and current beliefs, their experience with medical procedures, their coping style, and then form a brief tailored intervention.

1992

Adams, P. C.; Stenn, P. G. (1992). Liver biopsy under hypnosis. Journal of Clinical Gastroenterology, 15, 122-124.

Two patients underwent outpatient percutaneous liver biopsy under hypnosis without complications. One patient had severe anxiety about the procedure because of a previous adverse experience with liver biopsy, and the other had a history of severe allergy to local anesthesia. Both patients had undergone a session of hypnosis at least once prior to the biopsy. One received no local anesthesia, and the other received 1% lidocaine as a local anesthetic. Both patients were completely cooperative during the procedure with the required respiratory maneuvers. Both patients stated that they were aware of the procedure under hypnosis but described no pain and would be most willing to have the procedure done under hypnosis in the future.

Alden, Phyllis (1992, October). The use of hypnosis in the management of pain on a spinal injuries unit. [Paper] Presented at the annual meeting of the Society for Clinical and Experimental Hypnosis, Arlington, VA.

#### NOTES

[Author is at Royal National Hospital in England]

To have a spinal injury is one of the most devastating injuries that can happen, reducing you suddenly from a normal life to situation of loss of control, helplessness, etc.- -with nothing to say about what is being done in surgery or other aspects of treatment.

In UK patients come for acute care and rehabilitation all in one place. Over 2 1/2 yrs we had 46 referrals. 7 refused hypnosis ("witch doctoring"). 30 benefitted

Anonymous (1992, May). Studies: Learning can occur while under anesthesia. Daily Breeze (South Bay, Los Angeles County).

#### NOTES

Surgical patients can absorb information while they're knocked out, and even learn tips that help with recovery, researchers reported Friday at a symposium on memory and anesthesia.

"Researchers at Papworth Hospital in Cambridge, England, studied 51 cardiac patients, one-third of whom heard a tape of positive 'therapeutic suggestions' during surgery. Another third heard batches of word associations; the rest heard a blank tape.

"Patients who were played the suggestion tape - which told them they were doing well, or wouldn't feel much pain - left the hospital 1 1/2 days earlier on average than other patients.

"Another study, from the University of Arizona College of Medicine, found that surgical patients who heard specific pain-relief suggestions recovered more easily than those hearing vague advice such as, 'Think of being well.'

"These are still early days to invest in every operating suite buying a tape recorder to play for the patients,' said Dr. Sunit Ghosh, a researcher with the Papworth team. 'But this definitely does hold promise.'

"Scholars at the second annual Symposium on Memory and Awareness in Anesthesia said patients rarely wake up recalling - unprompted - something that happened during anesthesia.

"But several studies showed subconscious learning while the patients were out cold.

**"Not everyone accepted the findings.**

**"It shows an enormous sensitivity on the part of the brain, if it can be shown,' said Eugene Winograd, an Emory University psychologist and organizer of the Emory- sponsored conference. 'I'm not confident it has been shown yet.'**

**"Some researchers in other studies found no association between messages heard during anesthesia and learning.**

**"Dr. Alan Aitkenhead, professor of anesthesia at the University of Nottingham in England, found no significant difference between patients who heard recuperative suggestions and patients who were treated to a deliberately dull history of the hospital where they were.**

**"Aitkenhead said his study kept all patients quite deeply anesthetized, and that may be why they might not have learned as much as patients in other studies.**

**"By far, most likely, it's a difference in levels of anesthesia,' he said.**

**"The Papworth researchers, in another study, found that some patients showed strong word associations after hearing tapes of groups of words during surgery; but other patients under a different anesthesia didn't.**

**"There needs to be standardization of our testing,' Ghosh said. 'I think it's partly related to the anesthesia technique and partly related to the way in which material is presented to the patient.'**

**"Dr. Peter Sebel, an Emory anesthesiologist and conference organizer, said that if patients can retain information about a speedy recovery, they probably retain other information, too - for example, a surgeon's discouraging operating-room assessment of their prognosis."**

**Blankfield, Robert; Scheurman, Kathleen; Bittel, Sue; Alemagno, Sonia; Flocke, Sue; Zyzanski, Stephen (1992, October). Taped therapeutic suggestions and taped music as adjuncts in the care of coronary artery bypass graft patients. [Paper] Presented at the annual meeting of the Society for Clinical and Experimental Hypnosis, Arlington, VA.**

## **NOTES**

**18 studies have explored the issue with an experimental design; half used tapes, half didn't; majority of studies found benefits; 2 were of heart surgery patients.**

**This study used taped suggestions with coronary bypass patients. Used tape recorder rather than person delivering suggestions because it was more convenient; used tape intra-surgery and post-operatively for more impact.**

**We hypothesized: shorter length of stay, less narcotic analgesia, less anxiety, faster recovery, more positive mental outlook, resume activities sooner, have less symptoms postoperatively, etc.**

**Used a prospective, randomized, single-blind trial in 2 community hospitals in Cleveland with coronary artery bypass graft surgery patients. Study was done between Dec 1989 - Feb 1992.**

**3 groups were involved: (1) Suggestion, (2) music, and (3) tape. Control subjects had a blank tape. Tapes were played continuously and repeatedly with headphones. Postoperatively, a different tape was played.**

**Excluded: Patients with emergent surgery, hearing impairment, poor comprehension of English, patients who died in hospital, patients whose hospital stay lasted longer than 14 days (3 of them). 5% of sample were eliminated for last 2 reasons.**

**Music: Herb Ernst, Dreamflight II. Suggestions: Music background, permissive, based on Evans & Richardson's study.**

**Outcome Measures: Nurse assessment of anxiety and progress post operatively, Symptom scale, Depression scale.**

**Mean age 62, 3/4 men, 92% white, 75% married. The groups were same on a variety of preoperative variables (status of heart and arteries). Length of stay was 6.5 in all 3 groups. No difference in**

narcotics use, in nurse assessment of anxiety or of progress; of depression scale, or activities of daily living.

Recategorized data into patients who said the tapes were helpful (both music and suggestion) N = 33 vs the other patients N = 62. No difference in the variables evaluated.

Kostka, Marion (1992). Personal experience with 'Use of Hypnosis Before and During Angioplasty' [Letter]. American Journal of Clinical Hypnosis, 34, 281-282.

#### NOTES

Author read the article referred to after his/her heart attack and before angioplasty. Goal was to control preprocedure anxiety and assist by being relaxed and cooperative; also to be able to tolerate inflations of the balloon for as long as needed. Used self-hypnosis "and by the time I entered the laboratory my anxiety was under control. ... None of the physiological responses that can occur (i.e., nausea, pain, etc.) did occur and, for the most part, my postprocedure recovery was uneventful. ... Had two procedures because the artery again occluded. ... My cardiologist commented later that the time of inflation was longer than he had even attempted with any of his patients and he attributed this to my lack of symptoms. I felt this was due in part to the use of self- hypnosis. .... my subjective feeling was that both my discomfort and anxiety were minimal" (Pp. 281-82). No blood was sampled to measure catecholamine levels.

Levitan, Alexander A.; Harbaugh, Thomas E. (1992). Hypnotizability and hypnoanalgesia: Hypnotizability of patients using hypnoanalgesia during surgery. American Journal of Clinical Hypnosis, 34, 223-226.

Administered Stanford Hypnotic Suggestibility Scale (Form A) to 10 patients from a population of 20 who had undergone surgery in the previous 10 years using hypnoanalgesia as the sole or principal analgesic agent. Time since surgery ranged from 2 days to 10 years. Scores on the SHSS ranged from 5 (medium susceptibility) to 12 (high susceptibility) with a mean of 8.6, significantly higher than the SHSS:A normative group ( $p < .001$ ). The relationship between severity of surgery and the use of hypnoanalgesia as the sole or principal analgesia was significant for our patient population (N = 20) but not for our patient sample (N = 10).

#### NOTES

No referrals were rejected or dissuaded from the use of hypnoanalgesia. The medical reasons for referral included (1) the presence of anatomic abnormalities precluding use of inhalation anesthesia, (2) a history of cardiac arrest accompanying prior use of chemoanesthesia, and (3) excessive bleeding associated with previous attempted surgery. Self-referred patients had previous experience with meditation or self hypnosis and wished to avoid the potential complications associated with the use of chemoanesthesia" (pp. 223- 224).

The second author, who was unknown to the patients, administered the SHSS:A. "Those four patients using hypnoanalgesia alone achieved a mean SHSS:A score of 8.25. Those [five patients] using a combination of hypnosis and chemoanesthesia achieved a mean SHSS:A score of 8.80" (p. 224). (One did it both ways, in two surgeries, and is not included in this analysis.)

"Hypnoanalgesia alone was unlikely to be used for major surgery [as rated by independent rater, on major vs minor surgery] and, for whatever reasons, is most likely to be employed alone during minor surgery" (p. 224). 64% of the major surgical procedures (in their 10 patients) used combination of hypnoanalgesia and chemoanesthesia; 69% of procedures that used only hypnoanalgesia were minor surgeries.

This suggests that "the use of hypnoanalgesia as the sole analgesic agent during major surgical procedures is an option seldom taken in the presence of reliable chemoanesthetics. Hypnoanalgesia as the sole analgesic agent may be a practical alternative for patients of moderate to high hypnotic susceptibility during minor surgical procedures. Hypnoanalgesia used as the principal or adjunctive analgesic may be useful to patients of moderate to high hypnotic susceptibility during major surgical procedures" (pp. 225-226).

1991

Blankfield, Robert P. (1991). Suggestion, relaxation, and hypnosis as adjuncts in the care of surgery patients: A review of the literature. American Journal of Clinical Hypnosis, 33, 172-186.

#### NOTES

He notes that the authors provide little information re complications, and length of stay (LOS) is one of the most sensitive response measures used in these studies. The mean difference in LOS for 5 studies that have randomized assignment is 1.3 days. The N's are 80-100 for 3 of the studies, 39 and 60 for others. For two well controlled studies that did not achieve significance, the N's were 40 and 45. Many studies mixed the diagnosis and types of surgeries, making it difficult to interpret the results.

Block, Robert I.; Ghoneim, M. M.; Sum Ping, S. T.; Ali, M. A. (1991). Efficacy of therapeutic suggestions for improved postoperative recovery during general anesthesia. Anesthesiology, 75, 746-755.

There have been claims that the postoperative course of patients may be improved by presentation during general anesthesia of therapeutic suggestions which predict a rapid and comfortable postoperative recovery. This study evaluated the effectiveness of such therapeutic suggestions under double-blind and randomized conditions. A tape recording predicting a smooth recovery during a short postoperative stay without pain, nausea, or vomiting was played during anesthesia to about half the patients (N = 109), while the remaining, control patients were played a blank tape instead (N = 100). The patients were primarily undergoing operations on the fallopian tubes, total abdominal hysterectomy, vertical banding gastroplasty, cholecystectomy, and ovarian cystectomy or myomectomy. The anesthesia methods consisted of either isoflurane with 70% nitrous oxide in oxygen to produce end-tidal concentrations of 1.0, 1.3, or 1.5 MAC; or 70% nitrous oxide in oxygen combined with high or low doses of opioids. Assessments of the efficacy of the therapeutic suggestions in the recovery room and throughout the postoperative hospital stay included: the frequency of administration of analgesic and antiemetic drugs; opioid doses; the incidence of fever; nausea, retching, and vomiting; other gastrointestinal and urinary symptoms; ratings of pain; ratings of anxiety; global ratings of the patients' physical and psychological recoveries by the patients and their nurses; and length of postoperative hospital stay. There were no meaningful, significant differences in postoperative recovery of patients receiving therapeutic suggestions and controls. These negative results were not likely to be due to insensitivity of the assessments of recovery, as they showed meaningful interrelations among themselves and numerous differences in recovery following different types of surgery. Widespread utilization of therapeutic suggestions as a routine operating room procedure seems premature in the absence of adequate replication of previously published positive studies. (Key words: Anesthesia, depth: Awareness, Memory, Recall, Learning.)

#### NOTES

Patients ages 19-55 were accepted into the study and they were paid for participation. (Older patients were excluded to guard against memory or hearing problems.) Other criteria for exclusion were: ASA physical status 4 or 5 indicating significant systemic disease, visual or hearing problems, middle ear

disease (because it increases probability of nausea and vomiting), if their condition might require heavy sedation, if they were currently taking medication that interferes with memory (e.g. benzodiazepines, if there were intolerance to opioids, or if there were a likelihood of using postoperative pain treatment other than opioids).

The Spielberger State-Trait Anxiety Inventory was administered before surgery. Either suggestions (lasting 6 minutes) or a blank tape were played through headphones, starting 5 minutes after the surgical incision. The tape was played once for the first 59 patients, continuously for the remaining 150 patients. The first 139 patients received additional verbal materials on the tape, for memory tests to test possibility of learning under anesthesia. Operating room sounds were recorded by a tape recorder near the patient's head, throughout period of unconsciousness (except when tape was being played).

After the first 25% of cases, the team decided that lack of effect on therapeutic suggestions attributable to type of anesthesia did not warrant restriction to a single anesthetic method; also, multiple presentations of the suggestions on tape did not show an effect different from a single presentation.

After the patient regained consciousness and was reoriented, pain, nausea, retching, and vomiting were assessed every 30 minutes. Pain was rated orally on a scale from 1 to 10 in the recovery room, then on visual analogue scales every 2 hours on the day of surgery and the second day, and every 4 hours on subsequent hospital days during waking hours. Variables that were rated by staff every 24 hours included: opioids, other analgesics, antiemetics, nausea, vomiting, retching, presence or absence of nasogastric tube, passage of flatus, bowel movement, fluid intake, solids intake, urination. Temperature was recorded every 4 hours for the first 2 days after surgery, and after that less often. The anxiety measures were repeated on Day 3 postsurgery, as well as self ratings and nurse ratings on physical and psychological recovery. Staff recorded length of postoperative hospital stay and reasons for any delay of discharge. Separate analyses were performed for patients receiving opioids via patient-controlled analgesia (52%) vs traditional administration (48%), but no differences were found for effects of therapeutic suggestions except on postoperative Day 8.

"The inability to detect beneficial effects of therapeutic suggestions probably was not due to insensitivity of the measures of recovery. These measures were sensitive enough to show numerous significant differences in recovery after different types of surgery" (p. 751). The authors supported their contention that the measures were sufficiently sensitive by demonstrating meaningful correlations among the measures themselves; and by demonstrating adequate statistical power for detecting the effects of theoretical interest--at least 1 day in postoperative hospital stay or one half day in fever.

**Discussion:** The authors note that a recent investigation that found positive results in a double-blind, randomized design with 39 hysterectomy patients (Evans & Richardson, 1988. Improved recovery and reduced postoperative stay after therapeutic suggestions during general anaesthesia. *Lancet*, 2:491-493) may not have controlled for variables such as presence of malignancy, physical status of patients before surgery, or ethnicity. Authors note that Evans and Richardson observed shorter periods of pyrexia despite there being no relevant suggestions, but no differences in pain intensity, nausea, vomiting, or urinary difficulties despite there being suggestions relating to those symptoms. There also were no differences in mood and anxiety test scores postoperatively for the experimental and control groups.

The authors note that McLintock, Aitken, Downie, & Kenny (Postoperative analgesic requirements in patients exposed to positive intraoperative suggestions. *Br M J* 301:788-790. 1990) reported a 23% reduction in opioids by patients receiving suggestions, but no reduction in pain, nausea, or vomiting. They contrast the present study with these earlier studies that had obtained positive results.

"We studied patients who had more than one type of surgery to obtain a large sample size and to assess the possibility that beneficial effects of therapeutic suggestions would be restricted to certain types of operations. Had this been the case, interactions of therapeutic suggestions with type of surgery would have been significant in the overall analyses, and follow-up analyses would have indicated that

they were attributable to beneficial effects of therapeutic suggestions for certain surgeries. This did not occur. The two types of surgeries involving the largest numbers of patients seemed particularly promising for demonstrating beneficial effects. It has been reported that therapeutic suggestions presented during anesthesia are likely to be less successful with major and extensive surgery. Certainly, surgery on the fallopian tubes and gastric stapling did not involve a great deal of tissue trauma and blood loss. Patients were motivated to have the surgery and to recover quickly; particularly motivated were those having operations on the fallopian tubes, who were very eager to become pregnant, and those having vertical banding gastroplasties, who wanted desperately to lose weight" (pp. 753-754).

"In practice, we observed no beneficial effects of therapeutic suggestions, and there was no hint that anesthesia methods influenced the efficacy of the therapeutic suggestions. Interestingly, anesthetic methods also did not influence learning under anesthesia in the implicit memory tests we have used previously. Patients anesthetized with nitrous oxide and opioids did not differ from those anesthetized only with inhalational agents. In general, implicit or unconscious memory occurs in patients regardless of anesthesia methods or dosages of drugs" (p. 754).

"The few significant effects of therapeutic suggestions in our study did not point toward a beneficial influence of these suggestions. We found, in fact, an increased frequency of retching (but not nausea or vomiting) in the experimental group. The multiple variables examined in this study increased the likelihood of significant differences arising by chance, such that the null hypothesis was rejected when it should have been accepted. This is the way we interpret the effect on retching---i.e., as a type I error. We used in our therapeutic suggestions one negative or exclusionary sentence, 'You won't feel nauseous or have to vomit', among several positive or affirmative statements, e.g., 'You will enjoy eating, drinking...You will swallow to clear your throat and everything will go one way, straight down. . . The food will taste good....Your stomach will feel fine.' We do not think that the negative sentence led to paradoxical results. Evans and Richardson (personal communication) used in their therapeutic suggestions a negative sentence ('You will not feel sick'), which they repeated, yet the reported incidence of nausea and vomiting did not differ between the experimental and control groups" (p. 754).

**Brown, Peter (1991). The hypnotic brain: Hypnotherapy and social communication. New Haven, CT: Yale University Press.**

## NOTES

Notes are taken from a review of this book: Diamond, Michael (1993). Book review. *Bulletin of the Menninger Clinic*, 57 (Winter), 120-121.

Brown "posits that because the fundamental matrix of the human brain is metaphoric, hypnosis results from skillful matching of metaphorical communication with the brain's biological, rhythmic alterations. The most significant feature of trance experience is thereby located in the hypnotist-subject interaction" (p. 120).

"The middle section [of the book is comprised largely of] literature reviews in support of Rossi's (1986) ultradian rhythm theory of hypnosis and Lakoff and Johnson's (Johnson, 1987; Lakoff & Johnson, 1980) experientialist theory of conceptual thought" (p. 120). The final section includes "research evidence on medical uses of hypnosis, a theory of dissociation and multiple personality disorders, and an uncritical discussion of Milton Erickson's naturalistic hypnotherapeutic approach ... [and also] a brief discussion of the social-cultural functions of possession states among the Mayotte culture" (p. 120).

**Cochrane, Gordon J. (1991). Client-therapist collaboration in the preparation of hypnosis interventions: Case illustrations. American Journal of Clinical Hypnosis, 33, 254-262.**

Therapists can use hypnosis in a variety of situations to help clients utilize their own resources effectively. In both heterohypnosis and tape-assisted self-hypnosis, the respectful collaboration of therapist and client in the development of specific intervention strategies can be effective. I have described four cases to illustrate the collaborative aspect of heterohypnosis in a surgical setting and tape-assisted self-hypnosis for anxiety, tinnitus, and situational depression. In each case the clients were willing and able participants.

#### NOTES

Hypnotic interventions as adjunctive therapeutic modalities for a variety of surgical procedures have been well documented (Frankel, 1987; Gravitz, 1988; Nathan, Morris, Goebel, & Blass, 1987). The availability, relative safety, dependability, and ease of use have made chemical agents the anesthetic of choice in the majority of surgical situations, but hypnosis, either alone or in conjunction with chemical agents, can have a number of advantages for some patients (Udolf, 1987, p. 248). Some patients who have extreme preoperative pain and anxiety can learn to use self-hypnosis (Frankel, 1987); others may use hypnosis when experiencing postoperative nausea and other uncomfortable side effects of chemical anesthetics. Some may fear death under general anesthesia or react to a previous trauma arising from general anesthesia and the operating room procedures in general (Udolf, 1987, p. 250) and therefore choose hypnotic strategies. In the following case illustration the patient feared general anesthesia because of a previous negative postoperative experience" (p. 255).

While collaboratively planned hypnosis often empowers the patient, contributing to a sense of personal control and well being, some patients are not able to participate in that manner. Cochrane cites patients who are severely depressed or "who struggle with narcissism and other severe pathologies" (p. 260). He notes that audiotapes are useful for supplementing in-session therapy, contributing to skill development, attitude change, and a sense of self-worth. He cites Eisen and Fromm (1983) as indicating that self hypnosis is also useful for clients "who struggle with issues of control and intimacy" (p. 260).

**Kleinhauz, Moris (1991). Prolonged hypnosis with individualized therapy. International Journal of Clinical and Experimental Hypnosis, 39 (2), 82-92.**

A therapeutic approach is presented which involves the use of prolonged hypnosis for the treatment of diverse medical and/or psychological conditions, including intractable pain. This approach may be indicated either as a complementary tool used in conjunction with other treatment approaches or as the only method of intervention. The technique is based on achieving a prolonged hypnotic response, during which hypno- relaxation serves as the foundation for the delivery of an individualized therapeutic plan which includes self-hypnosis, suggestive procedures, metaphors, and constructive imagery techniques. In debilitated patients, medical supervision and nursing care are essential, and hospitalization is recommended if necessary. Theoretical assumptions underlying this approach are presented, and clinical implications are discussed. The method is illustrated through case presentations.

#### NOTES

The general procedure involves: 1. A flexible plan concerning the duration of treatment: days, weeks, or longer. 2. Information is given to the patient, the family and the medical staff if in hospital. Emphasize that while the patient may be in a 'twilight-like' state, most of the time he/she is able to fulfill his or her basic physiological needs, (drinking, eating, taking care of personal cleanliness, etc.). 3. The method of hypnotic induction is individualized. 4. The patient is trained in self- hypnosis, and for using signals for induction and dehypnotization either for self hypnosis or for the hypnotist to use. Thus if there is a physiological or emotional need for self-hypnosis the patient can do it. Suggestions and training are given and reinforced concerning the patient's capability to fulfill his/her basic

physiological needs. 5. The family and/or the medical staff are instructed and trained in induction and dehypnotization, until the patient responds to them satisfactorily. 6. At this stage, therapeutic suggestions aimed at ego-boosting and a change of attitudes and meanings towards the symptom and symptom removal/amelioration/substitution are added. 7. Metaphoric constructive imagery is introduced when indicated. 8. If required, other hypnotic phenomena are elicited and used (e.g. dissociation, time distortion, age regression, rehearsal, hypno/analgesia, change of muscular tonus, displacement of emotions, abreaction, etc.). 9. An audio cassette which contains the wording of the therapeutic intervention is used with some patients. 10. The family and/or the medical staff are instructed to supervise the patient properly and to avoid potential complications. 11. Termination of prolonged hypnosis with individualized therapy is gradual to permit appropriate re-orientation towards reality. 12. Treatment is evaluated and a posttreatment plan is outlined.

They provide case reports and discuss precautions. All the cases reported were treated while the patients were hospitalized for their physical condition (although in Case 3, prolonged hypnosis with individualized therapy was also continued at home after the patient's discharge from the hospital), and the patients were monitored by the medical staff. In very debilitated patients, special care should be taken to avoid potential complications arising from their passivity, mainly the development of decubitus ulcer and of aspiration/choking while drinking or eating. Although precaution is taken routinely with these patients, these measures should be emphasized while the patient is in a state of prolonged hypno-relaxation.

Morse, Donald R.; Martin, John; Moshonov, Joshua (1991). Psychosomatically induced death: Relative to stress, hypnosis, mind control, and voodoo: Review and possible mechanisms. Stress Medicine, 7, 213-232.

A common denominator in psychosomatically induced death is stress. Death can occur slowly, as from the preponderance of chronic stressor, or it can come on suddenly, as from an acute stressor. Sudden death is more likely in an individual with preexistent serious medical conditions, which were outlined. Seven types of individuals more prone to sudden death were outlined. Most cases of sudden death are related to the presence of a severely stressful situation in which there appears to be no means of control or escape. With mind control, hypnosis, and voodoo curses, circumstances can be manipulated to achieve severe stress and uncontrollability.

1990

Evans, Frederick J.; Stanley, R. O. (1990). Psychological interventions for coping with surgery: A review of hypnotic techniques. Australian Journal of Clinical and Experimental Hypnosis, 18, 97-105.

Illness, hospitalization, and surgery pose many severe stresses for many patients, to the extent that their ability to understand and cope with what is happening may be significantly reduced. Many of these stresses result from the nature and significance of patients' surgical procedures and post-operative treatment. This paper reviews the range of psychological interventions aimed at helping patients cope with pre- and post-operative treatment regimens. The range and content of hypnotic interventions are examined in detail. It is concluded that more rigorous research studies are required to determine the relative effectiveness of different types of interventions and to evaluate the effects of patients' psychological characteristics on the effectiveness of these interventions.

Gauld, Alan (1990). Mesmeric analgesia and surgery: A reply to Spanos and Chaves. British Journal of Experimental and Clinical Hypnosis, 7, 171-174.

NOTES

Spanos and Chaves' criticisms of the author's paper in this journal (vol. 5, 1988, pp 17-24) on mesmeric analgesia are considered. Spanos and Chaves are unnecessarily dismissive of nineteenth century reports of mesmeric analgesia and, in order to bring these cases within the compass of their theory, they make assumptions about them that are not supported by the facts.

Kaye, J. M.; Schindler, B. A. (1990). Hypnosis on a consultation-liaison service. General Hospital Psychiatry, 12, 379-383.

Studied the use of hypnosis on a consultation-liaison service with a broad spectrum of medically hospitalized patients. Autohypnosis tapes were used for reinforcement. Twenty-nine women and eight men from 24-75 years of age were hypnotized for relief of depression, pain, anxiety, or side effects of chemotherapy. Results were excellent (total to almost total relief of symptoms) in 68%, fair in 22%, and poor in 11%, with no differences among the results with the various conditions. This demonstrates that hypnotherapy is an extremely useful tool in medical management of patients in consultation-liaison psychiatry.

Kihlstrom, John F.; Schaecter, Daniel L.; Cork, Randall C.; Hurt, Catherine A.; Behr, Steven E. (1990). Implicit and explicit memory following surgical anesthesia. Psychological Science, 1, 303-306.

Paired associates were presented to 25 surgical patients following the induction of anesthesia by thiopental, vecuronium, and isoflurane. Postoperative testing (immediately or after two weeks) showed no free recall for the list; nor was there significant cued recall or recognition, compared to a matched control list. However, a free-association task showed a significant priming effect on both immediate and delayed trials. At least under some conditions, adequate surgical anesthesia appears to abolish explicit, but not implicit, memory for intraoperative events.

Kraft, Tom (1990). Use of hypnotherapy in anxiety management in the terminally ill: A preliminary study. British Journal of Experimental and Clinical Hypnosis, 7, 27-33.

The aim of this project was to give some preliminary information about the possible value of hypnotherapy in the management of terminally ill patients suffering from widespread cancer. The five phases of the dying process are described, and the case illustrations would suggest that, apart from severely obsessional patients, the terminally ill seem to benefit quite considerably from hypnotherapy. Matheson, G.; Drever, J. M. (1990). Psychological preparation of the patient for breast reconstruction. Annals of Plastic Surgery, 24, 238-247.

#### NOTES

Reviews over 100 women who had undergone rectus abdominis musculocutaneous flap reconstruction, the psychological issues motivating the patient for surgery, and psychological problems to be considered by the surgeon. A method of psychological preparation that was used and a report on the evaluative study of the program is included, and a protocol and verbalization for hypnotic relaxation is included.

McLintock, T. T.; Aitken, H.; Downie, C. F.; Kenny, G. N. (1990). Postoperative analgesic requirements in patients exposed to positive intraoperative suggestions. British Medical Journal, 301 (6755), 788-790.

Sixty-three women undergoing elective abdominal hysterectomy were randomly assigned to a tape of positive suggestions or a blank tape during the operation. Anesthesia was standardized for all of the

women. Postoperative analgesia was provided through a patient-controlled analgesia system for the first 24 hours. Pain scores were recorded every 6 hours. The outcome measures were morphine consumption in the first 24 hours and pain scores. Mean morphine requirements were 51.0 mg in women who were played positive suggestions, and 65.7 mg in those played a blank tape ( $p = 0.028$ ). Pain scores were similar in the two groups. It was concluded that intraoperative suggestions seem to have a positive effect in reducing patients' morphine requirements in the early postoperative period.

1989

Jirout, J. (1989). Reaction of the cerebral vertebrae in imagined changes in the shape of the cervical spine. Ceskoslovenska Neurologie a Neurochirurgie, 52, 75-77.

Postural reaction of the cervical vertebrae on imagined, but actually not performed, changes in the shape of the cervical spine in the sagittal plane are described. The percentage of reacting vertebrae is relatively high. The findings seem to indicate that, (1) the described phenomena belong to the constant features of the spinal dynamics, (2) that there probably exist residual traces of preceding activities, and (3) that these changes are due to the activation of the polymetameric system of the intrasegmental muscles. Abstracted in *American Journal of Clinical Hypnosis*, 1990, v. 32, p. 213.

Peebles, M. J. (1989). Through a glass darkly: The psychoanalytic use of hypnosis with post-traumatic stress disorder. International Journal of Clinical and Experimental Hypnosis, 37, 192-206.

A severe case of post-traumatic stress disorder stemming from consciousness (with auditory and pain perception) during surgery was treated with 8 sessions of hypnosis. Abreaction and revivification used alone initially retraumatized the patient, and her symptoms worsened. Ego-mastery techniques were then added; emphasis was placed on the role of the therapist as a new object presence to be internalized in restructuring the traumatic memory; memory consolidation and working-through techniques were instituted. The patient's symptoms abated and her condition remitted. The similarities between hypnotic and analytic work are highlighted. In addition, the case material provides a clinical example of the existence and potential traumatic effects of conscious awareness during surgery.

1988

Azuma, Nagato; Stevenson, Ian (1988). 'Psychic surgery' in the Philippines as a form of group hypnosis. American Journal of Clinical Hypnosis, 31, 61-67.

Psychic surgeons and their patients were observed in the Philippines during a variety of procedures of 'minor surgery.' In six cases, subcutaneous tissues (cysts and benign tumors) were removed. Histological examination confirmed the gross diagnoses and left no doubt that the skin had been penetrated. Although the psychic surgeons used no analgesics or anesthetics, the patients appeared to experience little or no pain and only slight bleeding. The authors believe that a supportive group 'atmosphere' enables the patients to enter a quasi-hypnotic state that reduces pain and facilitates healing.

Boeke, S.; Bonke, B.; Bouwhuis-Hoogerwerf, M. L.; Bovill, J. G.; Zwaveling, A. (1988). Effects of sounds presented during general anaesthesia on postoperative course. British Journal of Anaesthesia, 60, 697-702.

In a double-blind, randomized study, patients undergoing cholecystectomy were administered one of four different sounds during general anaesthesia: positive suggestions, nonsense suggestions, seaside sounds or sounds from the operating theatre. The effect of these sounds on the postoperative course

was examined to assess intraoperative auditory registration. No differences were found between the four groups in postoperative variables.

## NOTES

Postoperative course was evaluated by 5 variables: pain, nausea and vomiting, evaluation by nursing staff, subjective well-being, and duration of postoperative hospital stay. From the chart they used amount of postoperative analgesia, volume of nasogastric suction or drainage and fluid lost through vomiting over 6 days post-operatively; duration of postoperative hospital stay was registered after discharge. See p. 699 for details, including wording of questions. They cite their own earlier study that got positive results, and explain the difference as possibly due to use of only male voices on tapes, lack of difference in the sounds on tapes in this study, insensitivity of outcome measures (patients stayed longer in first study than in this one), and sample too small in this study (106).

Boeke et al. (1988) report that this double-blind, randomized study of positive suggestions, noise or sounds from the operating theatre presented to 3 groups of patients undergoing cholecystectomy during general anaesthesia had positive results for older patients. patients > 55 years who received positive suggestions had a significantly shorter postoperative hospital stay than the other patients in this age category.

Evans, C.; Richardson, P. H. (1988). Improved recovery and reduced postoperative stay after therapeutic suggestions during general anesthesia. Lancet, 2 (8609), 491-493.

The clinical value of suggestions during general anesthesia was assessed in a double-blind randomized placebo-controlled study. 39 unselected patients were allocated to suggestion (N = 19) or control (N = 20) groups who were played either recorded suggestions or a blank tape, respectively, during hysterectomy. The patients in the suggestion group spent significantly less time in the hospital after surgery, suffered from a significantly shorter period of pyrexia, and were generally rated by nurses as having made a better-than-expected recovery. Patients in the suggestion group, unlike the control group, guessed accurately that they had been played an instruction tape.

Goldmann, Les; Ogg, T. W.; Levey, A. B. (1988). Hypnosis and daycase anaesthesia. A study to reduce preoperative anxiety and intraoperative anesthesia requirements. Anesthesia, 43, 466-469.

52 female patients having gynecological surgery as day cases received either a short preoperative hypnotic induction or a brief discussion of equal length. Hypnotized patients who underwent vaginal termination of pregnancy required significantly less methohexitone for induction of anesthesia and were significantly more relaxed as judged by their visual analogue scores for anxiety. Less than half the patients were satisfied with their knowledge about the operative procedure even after discussions with the surgeon and anesthetist. A significant correlation was found between anxiety and perceived knowledge of procedures. Results suggest that preoperative hypnosis can provide a quick and effective way to reduce preoperative patient anxiety and anesthetic requirements for gynecological daycase surgery.

Hawkins, Russell; Le Page, Keith (1988). Hypnotic analgesia and reflex inhibition. Australian Journal of Clinical and Experimental Hypnosis, 16, 133-139.

The major change in thinking about models of analgesia over the last decade or so may be seen as a shift away from the earlier emphasis on a one-way afferent transmission sequence. Analgesia was effected, according to the older models, by a simple blocking of afferent impulses at some level (as achieved by local anaesthesia). Recent models suggest that there are at least two CNS analgesia control systems, each operating via an active mechanism for the inhibition of nociception which includes reciprocal \_efferent\_ impulses able to respond to input from lower centres by sending control signals

which modify their output. One CNS analgesia system has now been quite well described. This "opiate" analgesia system has proved to be naloxone reversible and seems to be mediated by reciprocal pathways between brain stem structures and the dorsal horn and trigeminal caudalis. This is not likely to be the system responsible for all cases of hypnotic analgesia, since the common experience of continued awareness of some elements of a normally painful stimulus, in spite of a freedom from pain, implicates a higher level involvement such as input from the prefrontal cortex.

## NOTES

The authors present a surgery case (of a cystoscopy and urethrotomy performed under hypnotic analgesia, with a highly hypnotizable patient) as an illustration of their position. The patient grimaced when the urethrotome was inserted into the urethra and dilated, but she denied discomfort and did not exhibit a reflex adduction of the thighs that is often observed even under standard general anaesthesia. She had spontaneous amnesia for the entire surgery. Later, under hypnosis, the patient could remember "discomfort and a sharp pain" which lasted for "seconds, if that" (p. 134).

The authors refer to Melzack and Wall's (1965) gate control theory as well as Hilgard's (1973) neodissociation interpretation of pain reduction in hypnosis. They review research by Hardy and Leichnetz (1981) with monkeys, in which they "traced the projections of the periaqueductal gray (PAG) to determine the extent of any possible cortical involvement in the endogenous analgesic system. Their work showed that the prefrontal cortex was the principal source of projections to the PAG" (p. 136). They quote the latter as writing that, "Patients who have had prefrontal lobotomies for relief of chronic pain report that while they still feel the pain they are no longer bothered by it ... the prefrontal cortex by virtue of its projections to the PAG may play a role in modulating nociception at the spinal level" (Hardy & Leichnetz, 1981, p. 99).

"Hardy and Leichnetz have also suggested that there may be more than one analgesic system within the CNS. The first system is a naloxone-reversible mechanism which can be activated by opiates (presumably both endogenous and exogenous) and by acupuncture. Since hypnotic analgesia has shown itself not to be naloxone-reversible (Goldstein & Hilgard, 1975) it may have little to do with the opiate reception analgesia system. Instead the mechanism of hypnotic analgesia may lie in Hardy and Leichnetz's second system which is sensitive to affective and cognitive influences" (pp. 136-137).

The authors include a review of the work by Mayer and Price (1976) which established the importance of brain stem structures in analgesia, especially for eliciting stimulation-produced analgesia. They cite Mayer and Price as drawing a distinction between "analgesia achieved by incapacitating a component in a pain transmission system or by activating a pain inhibition system" (p. 137). They also report that Mayer and Price conclude that stimulation-produced analgesia does not result from a "functional lesion" in the brain stem, but results from stimulation of a pain-inhibiting mechanism, suggesting the dorsal horn and trigeminal nucleus caudalis may be involved. This would be consistent with the inhibition of spinal reflexes (the adductor reflex) observed in their urethrotomy case, and the spinal reflex to nociception has also been reported by Finer (1974).

"The concomitant inhibition of reflexes in humans during hypnotic analgesia can be interpreted as evidence that nociception is probably not ascending to the cerebral cortex and that therefore the source of analgesia can be localized to the brain stem areas. It may be the case, however, that the locus of effect of hypnotic analgesia is not uniform across cases and may be identified by the overall pattern of subjective reports and physiological responses. Hypnotic analgesia may be experienced in more than one way subjectively and these differences may be attributable to differing underlying physiological mechanisms. On some occasions the relevant body part may be experienced as totally anaesthetised and all sensation (not only painful sensation) may be lost. This experience matches well with a brain stem involvement, which presumably inhibits any further afferent action. On other occasions, however, and more commonly, patients are still aware of a variety of sensations, which might include pressure in the case of childbirth or even cutting in the case of surgery, but these sensations are not

described as painful. This is reminiscent of the effect of frontal lobotomy and it is tempting to focus on the frontal lobe as the locus of hypnotic analgesia effects in such instances" (p. 138).

Houge, Donald R.; Hunter, Robert E. (1988). The use of hypnosis in orthopaedic surgery. Contemporary Orthopaedics, **16**, 65-68.

Some patients postpone or refuse indicated orthopaedic surgery because of fear or a medical contraindication to anesthesia. Clinical hypnosis previously has been used mainly as an adjunct to chemical anesthesia. However, hypnosis was shown to be entirely effective when used as the sole anesthesia in three of four orthopaedic cases. These four procedures included a radical head resection, the removal of a sideplate and Richard's screw from the hip, and two cases of arthroscopic knee surgery. The preparation required for the surgery and the experiences of the patients during these procedures are described, and the kinds of patients most likely to benefit from the use of hypnosis in orthopaedic surgery are reviewed.

1987

Frankel, Fred H. (1987). Significant developments in medical hypnosis during the past 25 years. International Journal of Clinical and Experimental Hypnosis, **35**, 231-247.

Selected significant investigative studies on the use of hypnosis in the medical context over the past 25 years are discussed. The topics covered include anxiety and pain, asthma, migraine, skin disease, burns, nausea and vomiting, surgery, haemorrhagic disorders, and cancer and immunity. The importance of hypnotizability ratings in the methodology is emphasized.

Goldmann, Les; Shah, M. V.; Hebden, M. W. (1987). Memory of cardiac anesthesia: Psychological sequelae in cardiac patients of intra-operative suggestion and operating room conversation. Anesthesia, **42** (6), 596-603.

Thirty elective cardiopulmonary by-pass surgery patients were interviewed pre- and postoperatively. A random selection of patients heard a prerecorded audio tape toward the end of surgery after they were rewarmed to 37 degrees C. The tape contained suggestions for patients to touch their chin during the postoperative interview, to remember three sentences, and to recover quickly. The interviewers were blind to the experimental conditions. The experimental group touched their chins significantly more often than the control group ( $p = .015$ ). Sentence recognition did not reach significance, perhaps due to the small numbers and low salience of the stimuli. Seven patients (23%) recalled intraoperative events, five with the aid of hypnosis. Three reports (10%) were corroborated. Preoperative medication ( $p < .01$ ) and postoperative anxiety ( $p < .05$ ) were significant predictors of those patients who reported recall.

Jay, Susan M.; Elliott, Charles H.; Katz, Ernest; Siegel, Stuart E. (1987). Cognitive-behavioral and pharmacologic interventions for children's' distress during painful medical procedures. Journal of Consulting and Clinical Psychology, **55**, 860-865.

This study evaluated the efficacy of a cognitive-behavioral intervention package and a low-risk pharmacologic intervention (oral Valium), as compared with a minimal treatment-attention control condition, in reducing children's distress during bone marrow aspirations. The subjects were 56 leukemia patients who ranged in age from 3 years to 13 years. The three intervention conditions were delivered in a randomized sequence within a repeated-measures counterbalanced design. Dependent outcome measures included observed behavioral distress scores, self-reported pain scores, pulse rate,

and blood pressure scores. Repeated-measures analyses of variance indicated that children in the cognitive-behavior therapy condition had significantly lower behavioral distress, lower pain ratings, and lower pulse rates than when they were in the attention- control condition. When children were in the Valium condition, they exhibited no significant differences from the attention control condition except that they had lower diastolic blood pressure scores.

#### NOTES

Lonnie Zelzer, M.D., in a UCLA Hypnosis Seminar lecture in 1992, stated that in pre-treatment with Valium the patients did worse during the procedure, vs no pretreatment with Valium, because the medicated patients didn't have clarity of attention during the cognitive behavioral learning.

Katz, Ernest R.; Kellerman, Jonathan; Ellenberg, Leah (1987). Hypnosis in the reduction of acute pain and distress in children with cancer. Journal of Pediatric Psychology, 12, 379-394.

Hypnosis has been used as a behavioral approach to help children tolerate aversive medical procedures more effectively, but empirical longitudinal research evaluating the outcome of such interventions has been limited. In the present study, 36 children with acute lymphoblastic leukemia between the ages of 6 and 12 years of age undergoing repeated bone marrow aspirations (BMAs) were randomized to hypnosis or play comparison groups. Subjects were selected on their behavioral performance on baseline procedures and received interventions prior to their next three BMA procedures. Major results indicated an improvement in self-reported distress over baseline with both interventions, with no differences between them. Girls exhibited more distress behavior than boys on three of four dependent measures used. Suggestions of an interaction effect between sex and treatment group were noted. The role of rapport between patient and therapist in therapeutic outcome was also evaluated. Results are discussed in terms of potential individual differences in responding to stress and intervention that warrant further research.

Minichiello, William E. (1987). Treatment of hyperhidrosis of amputation site with hypnosis and suggestions involving classical conditioning. International Journal of Psychosomatics, 7-8.

Hyperhidrosis of an amputation site utilizing hypnosis and/or behavioral strategies has not been reported in the literature. This case report is on the successful use of hypnosis utilizing principles of classical conditioning in the treatment of a patient with hyperhidrosis of an amputated limb with two previous unsuccessful sympathectomies. The patient possessing moderate hypnotic ability as measured by the Stanford Hypnotic Clinical Scale (SHCS), reported a pre-treatment score of 10 on a 0-10 severity and intensity of sweating scale, and a post-treatment score of 0. All gains were maintained at the two-year follow-up.

#### NOTES

The patient was hypnotized while an electric fan was blowing on his stump and prosthesis. Direct suggestions were given according to procedures of thermal biofeedback. The suggestions were: 1. You will notice in days ahead that your stump feels increasingly cooler and drier. 2. You will feel throughout the day as if a cool breeze from a fan is blowing on your stump. 3. Whenever you pay attention to your leg during the day, particularly after the first few hours of the morning, you will associate that leg with a cool dry breeze from a fan blowing on it. 4. You will increasingly develop the power to cool and dry your stump.

The results were that 2 1/2 weeks later patient reported reduced frequency and intensity of sweating and significant healing of the stump ulcers; rating = 2. One month later, patient reported continued progress with almost normal skin color and stump condition; the patient discontinued disability, and

returned to work. Patient returned one month later reporting, "It's cured and my physician can't believe it." Rating = 0.

Author concludes that hypnosis should be tried prior to more invasive traditional procedures. In this case two previous sympathectomies failed to correct the condition and a third sympathectomy was being contemplated.

1986

DeBenedittis, Giuseppe; Sironi, Vittorio A. (1986). Depth cerebral electrical activity in man during hypnosis: A brief communication. International Journal of Clinical and Experimental Hypnosis, 34, 63-70.

To the authors' knowledge, hypnosis has never been induced in epileptic patients during a depth EEG study. This neurosurgical diagnostic procedure has been routinely used in medically resistant epileptic patients for the preoperative exact delimitation of the epileptogenic lesion. It offers a unique opportunity to obtain fundamental information on the possible neurophysiological mechanisms implicated in hypnosis. Observations were carried out on 1 patient affected by medically resistant partial seizures with complex symptomatology. A chronic deep electrode study explored rhinencephalic structures as well as specific target areas of the cerebral cortex. Background electrical activity during hypnosis showed a significant decrease of slow waves and an increase of alpha and beta rhythms, with constant increase of amplitude, when compared to activity in the pre- and posthypnosis states. Focal interictal abnormalities were dramatically reduced during hypnosis.

#### NOTES

Hypnotizability was assessed with the Barber Suggestibility Scale in order to test for suggestibility without a prior induction of hypnosis. The patient's score was 7 out of 8 possible. Patient was hypnotized with a standard induction procedure (Barber & Calverley, 1963).

Experimental Protocol: 15 minutes resting baseline; 15 minute test of mental imagery (waking suggestions with imagination instructions); hypnosis with progressive relaxation; suggestions for dissociation; suggestions for amnesia; arousal from hypnosis (the patient was successful with positive hallucinations, catalepsy, total amnesia, and spontaneous analgesia); and posthypnosis awake and alert (5 minutes eyes open, 5 minutes eyes closed, then 15-minute recording of post-treatment waking baseline).

EEG background activity was scored for the number of sec/minute of delta (0-4), theta (4-7), alpha (8-12), and beta (13-30) rhythms, for each 5-min period. Score = percent as related to the 1-minute epoch. Number, amplitude, and diffusion of interictal spikes also were measured but ictal activity was not recorded during the periods considered. Experimenters also measured heart rate, respiratory rate, and mean blood pressure.

ANOVA for 4 conditions (resting, waking suggestion, hypnosis, and posthypnosis) was computed for background and for focal interictal activities, and the t-test used to evaluate significant differences. ANOVA indicated a significant effect across the four experimental conditions for theta and alpha in the temporal anterior cortex, temporal posterior cortex, and frontal convexity cortex. The effect was attributable only to changes in theta and alpha between baseline and hypnosis (theta decreasing, alpha increasing as the patient went into hypnosis). No other significant difference was found. Following arousal from hypnosis, EEG activity was similar to the EEG activity before the induction.

Interictal focal abnormalities were reduced during hypnosis, compared with before hypnosis. The effect was due to changes in the area of Ammon's horn, the amygdala, the posterior temporal cortex, the mesial temporal cortex, and the inferior temporal cortex.

In their Discussion, the authors note that their data supports earlier work indicating that the limbic system is implicated in hypnosis. They cite the publications of Arnold (1959, *International Journal of*

Clinical and Experimental Hypnosis) and Crasilneck, McCranie, and Jenkins (1956). The latter authors observed EEG records taken during brain surgery on one patient. Hypnosis terminated every time the hippocampus was stimulated, leading them to suggest that the hippocampus is part of the neural circuit involved in hypnosis.

"If it is assumed that a convulsion can be considered a result of both pathophysiological and emotional events operating in the individual, emotions being the most common precipitating factor in epilepsy, then any amelioration of one will raise the convulsive threshold or lower the seizure level (Goldie, 1979; MacCabe & Habovick, 1963). Although 'voluntary control of the alpha rhythm' was achieved over 40 years ago (Jasper & Shagass, 1941), only since 1969 has such control been used for clinical purposes (Kamiya, 1969). One striking characteristic of the EEG pattern of many epileptics is the absence of a 12 to 14 c/s rhythm normally recorded from the anterior portions of the brain (sensorimotor rhythm) and the presence of a 4 to 7 c/s rhythm at the same location (Olton & Noonberg, 1980). Biofeedback may enable the individual to increase the amount of sensorimotor rhythm and to decrease the amount of 4 to 7 c/s activity. As a consequence, clinically significant decreases in seizure activity have been found after biofeedback training (Serman, 1973, 1977).

"The present data demonstrate that in this female patient hypnosis induced a highly significant reduction of the interictal activity, concomitant with an increase of alpha and sensorimotor rhythm and a decrease of slow activity, similar to biofeedback but without prior training.

" In conclusion, a depth EEG study in one epileptic patient comparing EEG activity during hypnosis and pre- and posthypnosis suggests the following conclusions: (a) hypnosis may be associated with significant decrease of slow activity and an increase of alpha and relatively high frequency, beta activity; (b) electrophysiological correlates of hypnotic behavior support the possible role of the limbic system in mediating the trance experience; and (c) hypnosis is effective in reducing focal interictal abnormalities in this patient and so it can be considered a promising technique to prevent and/or reduce emotional precipitating factors and the tendency to develop seizure activity" (p. 69).

Birk (Ed.), *Biofeedback: Behavioral medicine.* New York: Grune & Stratton, Pp. 147-165.

Serman, M. B. (1977). Effects of sensorimotor EEG feedback training on sleep and clinical manifestations of epilepsy. In J. Beatty & H. Legewie (Eds.), *Biofeedback: Behavioral medicine.* New York: Plenum, 1977, Pp. 167-200.

Omer, Haim; Friedlander, Dov; Palti, Zvi (1986). Hypnotic relaxation in the treatment of premature labor. *Psychosomatic Medicine*, 48, 351-361.

Hypnotic relaxation was used as an adjunct to pharmacologic treatment with 39 women hospitalized for premature contractions in pregnancy. The control group received medication alone and consisted of 70 women. Treatment was started at the time of hospitalization and lasted for 3 hr on the average. Patients were also given cassettes with a hypnotic - relaxation exercise for daily practice. The rate of pregnancy prolongation was significantly higher for the hypnotic - relaxation than for the medication-alone group. Infant weight also showed the advantage of the hypnotic - relaxation treatment. Background variables of the two groups were compared and it was shown that they could not have explained the treatment effect obtained.

Bennett, Henry L.; Davis, H. S.; Giannini, Jeffrey A. (1985). Non-verbal response to intraoperative conversation. *British Journal of Anesthesiology*, 57, 174-179.

In a double-blind study, 33 patients (herniorrhaphy, cholecystectomy and orthopedic) were randomly assigned to either suggestion or control groups. Under known clinical levels of nitrous oxide and

enflurane or halothane anesthesia, suggestion patients were exposed to statements of the importance of touching their ear during a postoperative interview. Compared with controls, suggestion patients did touch their ear (tetrachoric correlation 0.61,  $P < 0.02$ ). test, U (Mann-Whitney frequently more so did they and

LaRiccia, P. J.; Katz, R. H.; Peters, J. W.; Atkinson, G. W.; Weiss, T. (1985). Biofeedback and hypnosis in weaning from mechanical ventilators. Chest, 87, 267-269.

Weaning patients from mechanical ventilation can be hindered by both physical and psychologic factors. Biofeedback has been used successfully as an adjunct in difficult weaning problems. We have used a combination of hypnosis and biofeedback to wean a patient with neurologic disease who previously failed weaning by standard procedures. A 30-year-old woman with respiratory failure secondary to multiple sclerosis with transverse myelitis was given eight sessions of biofeedback over 12 days in which the movements of her chest wall, as monitored by magnetometers, were displayed on an oscilloscope. The patient was praised for targeted respiratory rate, amplitude, and rhythm. These sessions included hypnosis in which the patient was given suggestions of well-being and that she could breathe as she had five years earlier. In this manner the patient was successfully weaned. Respiratory biofeedback and hypnosis appear to be useful adjuncts in weaning patients from ventilators.

Morris, Don M.; Nathan, Ronald G.; Goebel, Ronald A.; Blass, Norman H. (1985). Hypnoanesthesia in the morbidly obese. Journal of the American Medical Association, 253 (22), 3292-3294.

The advent of chemical anesthesia relegated hypnosis to an adjunctive role in patients requiring major operations. Anesthesia can be utilized with acceptable risk in the great majority of patients encountered in modern practice. But an occasional patient will present--such as one with morbid obesity--who needs a surgical procedure and who cannot be safely managed by conventional anesthetic techniques. This report describes our experience with such a patient and illustrates some of the advantages and disadvantages of hypnoanesthesia. The greatest disadvantage is that it is unpredictable. Close cooperation between the patient, hypnotist, anesthesiologist, and surgeon is critical. However, the technique may be utilized to remove very large lesions in selected patients. Hypnoanesthesia is an important alternative for some patients who cannot and should not be managed with conventional anesthetic techniques.

1984

Bishay, Emil; Stevens, Grant; Lee, Chingmuh (1984). Hypnotic control of upper gastrointestinal hemorrhage: A case report. American Journal of Clinical Hypnosis, 27, 22-25.

The use of hypnosis for control of bleeding during and after surgical procedures is common practice. It has also been a useful tool for control of bleeding in hemophiliac children, especially during dental procedures, and in traffic accidents. This paper presents the successful treatment with hypnosis of a patient with upper gastrointestinal tract bleeding. After treatment, the patient was discharged from the hospital without the need for surgical intervention. NOTES 1:

NOTES

The physician explained to the patient that nothing would hurt her and that nobody would do anything against her will, that if she could "relax," then her unconscious mind would help her control her bleeding. [Gives script used in the hypnosis.] Trance terminated after 20 minutes. "One hour later, endoscopy performed under local anesthesia revealed 'non-bleeding gastritis, no ulcers seen.' She had no bleeding following the hypnotherapy" (p. 23).

Katcher, Aaron; Segal, Herman; Beck, Alan (1984). Comparison of contemplation and hypnosis for the reduction of anxiety and discomfort during dental surgery. American Journal of Clinical Hypnosis, 27, 14-21.

Complex moving visual stimuli are used to induce states of relaxation, hypnosis and revery. To test the efficacy of using aquarium contemplation to induce relaxation, 42 patients were randomly assigned to one of five treatments prior to elective oral surgery: 1) contemplation of an aquarium, 2) contemplation of a poster, 3) poster contemplation with hypnotic induction, 4) aquarium contemplation with hypnosis, and 5) a non intervention control. Blood pressure, heart rate, and subjective and objective measures of anxiety were used as dependent measures. Pretreatment with aquarium contemplation and hypnosis, either alone or in combination, produced significantly greater degrees of relaxation during surgery than poster contemplation or the control procedure. Two-way ANOVA demonstrated that a formal hypnotic induction did not augment the relaxation produced by aquarium contemplation.

#### NOTES

The consent form was designed to reduce anxiety about hypnosis by stating that if hypnosis was used, it would be used only to induce relaxation. Patients were then randomly assigned to one of the 5 pretreatment groups, with 8 in each of the four contemplation groups and 10 in the nonintervention control.

1. Aquarium contemplation. Ss contemplated it for 40 minutes; during the 1st 25 min, 5 tests of suggestibility were administered (from the Stanford) which eliminated all tests the authors considered anxiety-provoking such as suggested hallucination. Also, the terms hypnotically relaxed or hypnotic relaxation replaced the term hypnosis throughout the protocol.

2. Poster contemplation was the same, using a color photo of a mountain waterfall.

3. Poster contemplation with hypnosis used a protocol derived from Stanford, with visual fixation on poster, then the 5 tests, then Ss contemplated the poster for 10 minutes under hypnosis and were given post hypnotic suggestion that they could reenter hypnosis during the dental procedure by closing their eyes and visualizing the poster

4. Aquarium contemplation with hypnosis was like #3 except that Ss were asked to look at "either one fish or a portion of the aquarium" during induction and were told to reenter hypnosis during treatment by closing their eyes and visualizing the aquarium

5. Nonintervention control Ss were given no tests of suggestibility; they were seated in a chair and told to "relax."

During surgery, an observer recorded overt signs of anxiety or agitation on a check list, making entries at five-minute intervals.

The surgeries took variable lengths of time (5-90 minutes) and variable kinds of procedures (multiple injections, removal of bone, etc.) Surgeons varied in management-- gentleness, etc.

Blood pressure fell significantly during all 5 pretreatments without any significant differences between groups. Analysis of interaction effects, significant at the 0.1 level for all 3 dependent variables, indicated that hypnosis had a major effect on relaxation only when the S was contemplating a poster. Hypnosis had no significant influence on the levels of relaxation obtained by contemplation of the aquarium.

There were no significant differences between groups in the number of suggestions accepted.

Hilgard, Josephine R.; LeBaron, Samuel (1982). Relief of anxiety and pain in children and adolescents with cancer: Quantitative measures and clinical observations. International Journal of Clinical and Experimental Hypnosis, 30, 417-442.

Children and adolescents with cancer, chiefly forms of leukemia, aged 6 to 19 years, underwent medical treatments which required repeated bone marrow aspirations, normally a painful and anxiety-provoking experience. Data were obtained in baseline bone marrow observations on 63 patients, who were then offered the opportunity to volunteer for hypnotic help in pain control. Of the 24 patients who accepted hypnosis, 9 were highly hypnotizable. 10 of the 19 reduced self-reported pain substantially by the first hypnotic treatment (the prompt pain reducers) and 5 more reduced self-reported pain by the second treatment (the delayed pain reducers) while none of the 5 less hypnotizable patients accomplished this. The latter benefitted by reducing anxiety. Short case reports illustrate the variety of experiences.

Analysis of baseline observations before any therapeutic intervention revealed age and sex differences. The difference between self-reported and observed pain was not statistically significant for patients under age 10 but was significant for the patients age 10 and older ( $p < .001$ ). There were minor but significant sex differences both in observed pain ( $p < .01$ ) and in self-reported pain ( $p < .05$ ), with the females reporting more pain.

1980

Hart, R. (1980). The influence of a taped hypnotic induction treatment procedure on the recovery of surgery patients. International Journal of Clinical and Experimental Hypnosis, 28, 324-331.

A study of 40 open heart surgery patients assigned to 1 of 2 equal size treatment groups sought to evaluate the efficacy and utility of a tape-recorded hypnotic induction procedure that preoperatively prepared patients for surgery. The dependent variables included daily blood pressure measurements and postsurgical outcome data pertaining to postoperative units of blood required, state/trait anxiety, and locus of control dimensions. Results of the study tended to provide some support for the tape-recorded hypnotic induction procedure in lessening state anxiety and in promoting a more self-directed attitude toward surgical recovery.

1977

Chertok, Leon; Michaux, D.; Droin, M. C. (1977). Dynamics of hypnotic analgesia: Some new data. Journal of Nervous and Mental Disease, 164, 88-96.

Following two surgical operations under hypnotic anesthesia, it was possible, during subsequent recall under hypnosis, to elicit a representation of the past operative experience. It would seem that under hypnosis there is a persistence of the perception of nociceptive information and of its recognition as such by the subject. From an analysis of these two experiments in recall, it is possible to formulate several hypotheses concerning the psychological processes involved in hypnotic analgesia. In consequence of an affective relationship, in which the hypnotist's word assumes a special importance for the subject, the latter has recourse to two kinds of mechanism: a) internal (assimilation to an analogous sensation, not, however, registered as dangerous-- rationalization); and b) external (total compliance with the interpretations proposed by the hypnotist), which lead to a qualitative transformation of nociceptive information, as also the inhibition of the behavioral manifestations normally associated with a painful stimulus.

Ashton RC Jr. Whitworth GC. Seldomridge JA. Shapiro PA. Michler RE. Smith CR. Rose EA. Fisher S. Oz MC. The effects of self-hypnosis on quality of life following coronary artery bypass surgery: preliminary results of a prospective, randomized trial. *Journal of Alternative & Complementary Medicine* 1995;1(3):285-90 The effects of complementary techniques and alternative medicine on allopathic therapies is generating much interest and research. To properly evaluate these techniques, well controlled studies are needed to corroborate the findings espoused by individuals practicing complementary medicine therapies. To this end, we evaluated the role of one of these therapies, self-hypnosis relaxation techniques, in a prospective, randomized trial to study its effects on quality of life after coronary artery bypass surgery. Subjects were randomized to a control group or a study group. Study group patients were taught self-hypnosis relaxation techniques the night prior to surgery. The control group received no such treatment. Patients then underwent routine cardiac management and care. The main endpoint of our study was quality of life, assessed by the Profile of Moods Scale. Results demonstrated that patients undergoing self-hypnosis the night prior to coronary artery bypass surgery were significantly more relaxed than the control group ( $p = 0.0317$ ). Trends toward improvement were also noted in depression, anger, and fatigue. This study demonstrates the beneficial effects of self-hypnosis relaxation techniques on coronary surgery. This study also identifies endpoints and a study design that can be used to assess complementary medicine therapies. Results of this preliminary investigation are encouraging and demonstrate a need for further well-controlled studies.

1997

Cruise CJ. Chung F. Yogendran S. Little D. Music increases satisfaction in elderly outpatients undergoing cataract surgery. *Canadian Journal of Anaesthesia* 1997;44(1):43-8 **PURPOSE:** Music has long been known to reduce anxiety, minimize the need for sedatives, and make patients feel more at ease. The purpose of the study was to evaluate the effect of music in elderly outpatients undergoing elective cataract surgery with retrobulbar block and monitored anaesthetic care using fentanyl or alfentanil and midazolam. **METHODS:** One hundred and twenty one patients were prospectively and randomly assigned to hear: relaxing suggestions, white noise, operating room noise or relaxing music via audio-cassette headphones. Vital signs were documented before and after retrobulbar block and every 15 min thereafter. Anxiety was assessed using the State-Trait Anxiety Inventory (STAI) before and after surgery. Visual analogue scales (VAS) were used to assess anxiety and patient satisfaction postoperatively with a standardized questionnaire. Between group comparisons were made using Chi-Square, or ANOVA, where appropriate. **RESULTS:** There were no differences between groups in STAI or anxiety VAS scores at any time. Differences were noted in systolic blood pressure, but not in other vital signs. Patients' ratings of the whole operative experience, satisfaction with the tape played, general level of relaxation and preference for the chosen tape for subsequent surgery were different (music > relaxing suggestions > white noise and OR noise,  $P < 0.05$ ). **CONCLUSIONS:** Elderly patients undergoing cataract surgery under retrobulbar block were more satisfied with their experience if they heard relaxing music, rather than relaxing suggestions or white noise or OR noise. The type of auditory stimuli to which the patients were exposed did not influence the level of anxiety.

1993

Disbrow EA. Bennett HL. Owings JT. Effect of preoperative suggestion on postoperative gastrointestinal motility *Western Journal of Medicine*. 1993;158(5):488-92 Autonomic behavior is subject to direct suggestion. We found that patients undergoing major operations benefit more from instruction than from information and reassurance. We compared the return of intestinal function after intra-abdominal operations in 2 groups of patients: the suggestion group received specific instructions for the early return of gastrointestinal motility, and the control group received an equal-length interview offering reassurance and nonspecific instructions. The suggestion group had a significantly shorter average time to the return of intestinal motility, 2.6 versus 4.1 days. Time to

discharge was 6.5 versus 8.1 days. Covariates including duration of operation, amount of intraoperative bowel manipulation, and amount of postoperative narcotics were also examined using the statistical model analysis of covariance. An average savings of \$1,200 per patient resulted from this simple 5-minute intervention. In summary, the use of specific physiologically active suggestions given preoperatively in a believable manner can reduce the morbidity associated with an intra-abdominal operation by reducing the duration of ileus.

Enqvist B, Fischer K. Preoperative hypnotic techniques reduce consumption of analgesics after surgical removal of third mandibular molars: a brief communication. *International Journal of Clinical & Experimental Hypnosis* 1997;45(2):102-8 The effects of hypnosis in connection with surgery have been described in many clinical publications, but few controlled studies have been published. The aim of the present study was to evaluate the effects of preoperative hypnotic techniques used by patients planned for surgical removal of third mandibular molars. The patients were randomly assigned to an experimental (hypnotic techniques) or a control (no hypnotic techniques) group. During the week before the surgery, the experimental group listened to an audiotope containing a hypnotic relaxation induction. Posthypnotic suggestions of healing and recovery were given on the tape together with advice regarding ways to achieve control over stress and pain. The control group received no hypnotic intervention. Only one surgeon who was not aware of patient group assignments performed all the operations. Thirty-six patients in the control group were compared to 33 patients in the experimental group. Anxiety before the operation increased significantly in the control group but remained at baseline level in the experimental group. Postoperative consumption of analgesics was significantly reduced in the experimental group compared to the control group.

Evans C, Richardson PH Therapeutic suggestions during general anesthesia *Advances* 1988;5(4):6-11 Tested the hypothesis that the quality and duration of recovery from surgery would be improved by therapeutic suggestions made while patients were under general anesthesia, in a double-blind randomized controlled study of 39 adult hospital patients who were admitted for an abdominal hysterectomy. Results support the hypothesis.

Greenleaf M, Fisher S, Miaskowski C, DuHamel K. Hypnotizability and recovery from cardiac surgery. *American Journal of Clinical Hypnosis* 1992;35(2):119-28 We studied 32 coronary bypass patients to examine the effect of hypnosis on recovery from surgery. The patients were assessed for hypnotizability with the Hypnotic Induction Profile (HIP) and assigned to experimental groups with a random stratification procedure to equate for differences in hypnotizability, age, and severity of illness. We taught patients in groups one and two formal hypnosis with different treatment strategies; patients in group three were not taught formal hypnosis or a treatment strategy. Scores on the HIP were significant predictors of recovery, independent of experimental treatment with formal hypnosis. Patients who scored "Midrange" stabilized more quickly in the intensive care unit (ICU) than those who scored "High" or "Low" ( $p < .05$ ). Patients who scored "High" had more labile blood pressure in the ICU compared to the "Midrange" and "Lows" ( $p < .05$ ). Measured hypnotizability was associated with the recovery sequence from surgery.

Johnston M, Vogele C Benefits of psychological preparation for surgery: A meta analysis *Ann Behav Med.* 1993;15(4):245-256 There is now substantial agreement that psychological preparation for surgery is beneficial to patients. It is important, however, to establish which benefits can be achieved by psychological preparation and if all forms of preparation are equally effective. The results of randomized controlled trials of psychological methods of preparing adult patients for surgery were analyzed in terms of eight outputs (negative affect, pain, pain medication, length of stay, behavioral and clinical indices of recovery, physiological indices, and satisfaction). In order to reduce publication bias, published as well as unpublished studies were included in the meta analysis. It was concluded that significant benefits can be obtained on all of the major outcome variables that have been explored. Procedural information and behavioral instructions show the most ubiquitous effects in improving

measures of post-operative recovery. The results have implications for the improvement of patient care in surgical units.

Lambert SA. The effects of hypnosis/guided imagery on the postoperative course of children. *Journal of Developmental & Behavioral Pediatrics*. 1996;17(5):307-10 Hypnosis, guided imagery, and relaxation have been shown to improve the postoperative course of adult surgical patients. Children have successfully used hypnosis/guided imagery to significantly reduce the pain associated with invasive procedures and to improve selected medical conditions. The purpose of this study was to examine the effect of hypnosis/guided imagery on the postoperative course of pediatric surgical patients. Fifty-two children (matched for sex, age, and diagnosis) were randomly assigned to an experimental or control group. The experimental group was taught guided imagery by the investigator. Practice of the imagery technique included suggestions for a favorable postoperative course. Significantly lower postoperative pain ratings and shorter hospital stays occurred for children in the experimental group. State anxiety was decreased for the guided imagery group and increased postoperatively for the control group. This study demonstrates the positive effects of hypnosis/guided imagery for the pediatric surgical patient.

McLintock TT. Aitken H. Downie CF. Kenny GN. Postoperative analgesic requirements in patients exposed to positive intraoperative suggestions. *BMJ* 1990;301(6755):788-90 **OBJECTIVE--**To establish whether positive suggestions given to a patient under general anaesthesia reduce postoperative pain and analgesic requirements. **DESIGN--**Prospective double blind randomised study. **SETTING--**Operating theatre and gynaecology ward of a teaching hospital. **PATIENTS--**63 Woman undergoing elective abdominal hysterectomy were randomised to be played either a tape of positive suggestions or a blank tape during the operation through a personal stereo system. **INTERVENTIONS--**Three women were withdrawn from the study. Anaesthesia was standardised for all of the women. Postoperative analgesia was provided through a patient controlled analgesia system for the first 24 hours. Pain scores were recorded every six hours. **MAIN OUTCOME MEASURES--**Morphine consumption over the first 24 hours after the operation; pain scores. **RESULTS--**Mean morphine requirements were 51.0 mg (95% confidence interval 42.1 to 60.0 mg in the women played positive suggestions; and 65.7 mg (55.6 to 75.7 mg) in those played a blank tape. The point estimate (95% confidence interval) for the difference of means was 14.6 mg (22.4%) (1.9 (2.9%) to 27.3 mg (41.6%)] ( $p = 0.028$ ). Pain scores were similar in the two groups. **CONCLUSION--**Positive intraoperative suggestions seem to have a significant effect in reducing patients' morphine requirements in the early postoperative period.

## T RESE3ARCH

### TASK MOTIVATION.

1999

Comey, Gail; Kirsch, Irving (1999). Intentional and spontaneous imagery in hypnosis: The phenomenology of hypnotic responding. *International Journal of Clinical and Experimental Hypnosis*, 47 (1), 65-85.

Students were given 1 of 2 versions of the Carleton University Responsiveness to Suggestion Scale (CURSS): (a) the original version, which contains instructions to intentionally imagine goal-directed fantasies, and (b) a modified version, in which instructions for suggestion-related imagery were deleted. Participants were asked to report their goal-directed fantasies and to indicate whether these occurred spontaneously or were generated intentionally. They were also asked whether they had tried intentionally to generate the suggested experience and to indicate whether they had believed that the suggested states of affairs were real (e.g., whether they thought a hallucinated cat really existed). The

deletion of instructions for goal-related imagery significantly increased responsiveness to CURSS suggestions. Spontaneous goal-directed imagery was significantly correlated with behavioral response, but intentional imagery was not. Most successful responders tried to generate suggested experiences intentionally, indicated that they could have resisted challenge suggestions if they really wanted to, and reported believing in the reality of suggested ideomotor and challenge experiences but not of cognitive suggestions. Voluntary attempts to generate suggested experiences were correlated with subjective responding.

1992

Bowers, Kenneth S. (1992). Imagination and dissociation in hypnotic responding. International Journal of Clinical and Experimental Hypnosis, 40 (4), 253-275.

A neodissociative model of mind is better equipped than a social-psychological model to deal with the complexities of hypnosis, and of human behavior generally. It recognizes, as Coe's (1992) model does not, that behavior can be more automatically activated than strategically enacted. In particular, Coe's emphasis on human behavior as purposeful and goal directed does not distinguish between goal-directed behavior that serves a purpose, and goal-directed behavior that is performed on purpose. It is this distinction that permits goal-directed behavior to be dissociated from a person's conscious plans and intentions. In addition to offering a critique of Coe's "limited process" view of hypnosis, 4 main points are made in the interest of developing a slightly modified, neodissociation view of hypnosis. First, it is argued that goal-directed fantasies are more limited in their ability to mediate hypnotic responding than is commonly appreciated; as well, they do not seem to account for the nonvolitional quality of hypnotic responding. Second, it is argued that hypnotic ability is not unidimensional, with compliance and social influence more apt to account for the low than for the high hypnotizable's responsiveness to suggestion. Third, compared to low hypnotizables, the hypnotic responsiveness of high hypnotizables seems more likely to result from dissociated control. In other words, for high hypnotizables, hypnotic suggestions may often directly activate subsystems of cognitive control. Consequently, the need for executive initiative and effort to produce hypnotically suggested behavior is minimized, and such responses are therefore experienced as nonvolitional. Fourth and finally, while goal-directed fantasies typically accompany hypnotically suggested responses, they are in many cases more a marker of dissociated control than a mediator of suggested effects.

1988

Spanos, Nicholas P.; Gwynn, Maxwell I.; Della Malva, C. Lori; Bertrand Lorne D. (1988). Social psychological factors in the genesis of posthypnotic source amnesia. Journal of Abnormal Psychology, 97 (3), 322-329.

Three experiments assessed the role of social psychological variables in source amnesia. Experiment 1 found that low-hypnotizable subjects instructed to simulate partial amnesia were more likely to exhibit source amnesia than high-hypnotizable hypnotic or task-motivated subjects. Experiment 2 found equivalent rates of source amnesia in low-hypnotizable simulators and high-hypnotizable hypnotic subjects. In addition, the findings of Experiment 2 failed to support the idea that the instructions for partial amnesia given to simulators cued for the occurrence of source of amnesia as well as for the occurrence of partial amnesia. In Experiment 3, preliminary instructions that legitimated source amnesia as a role-appropriate response produced significantly more posthypnotic source amnesia than did neutral or no instructions. Together, the findings of the 3 experiments support the relation of source amnesia to experimental demands and subjects' expectations.

1986

Sweeney, Carol A.; Lynn, Steven Jay; Bellezza, Francis S. (1986). Hypnosis, hypnotizability, and imagery-mediated learning. International Journal of Clinical and Experimental Hypnosis, 34, 29-40.

The relationship between hypnotizability, imagery utilization ability, and hypnosis was examined in a study described to Ss (N = 157) as an 'imagery experiment.' In Session 1, the Tellegen Absorption Scale (Tellegen, 1976) was completed and the imagery-mediated paired-associate learning task was administered as a baseline measure. In Session 2, either hypnosis, task motivation, or no treatment instructions were administered and the learning task was repeated with a different word list (each 15 high, 15 low imagery pairs). In Session 3, the Harvard Group Scale of Hypnotic Susceptibility, Form A (Shor & E. C. Orne, 1962) was administered. Overall, recall was superior for high imagery words. Hypnotizability was not associated with imagery-mediated recall. Recall performance, however, was correlated with Tellegen Absorption Scale scores. Interestingly, learning and recall performance decreased between Sessions 1 and 2 for hypnotized Ss but remained the same for task motivated and control Ss. The decrease in performance was mediated by less concern for performance and diminished anxiety. Self-reports of imagery utilization did not differ among groups of Ss.

## NOTES

The authors review literature on the relationship between hypnotizability, hypnosis, and imagery abilities, noting that results are conflicting. One reason for differing results may be that imagery scales are self-report measures, subject to reporting bias of varying types. The imagery-mediated paired-associate learning paradigm, using high and low imagery paired associates, may address that reporting bias issue.

This investigation used 157 Ss grouped into high (9-12), medium (5-8), and low (0-4) hypnotizability levels on the basis of the Harvard Scale. Given the fact that high imagery words are usually recalled more easily than low imagery words (Paivio, 1971), a relationship observed between hypnotizability and imagery-mediated recall would elucidate the role of imagery utilization for memory functions.

The experimental conditions included hypnosis, task motivation, and a no treatment control condition, in order to evaluate the possible enhancement effects of hypnosis on imagery utilization for memory functions. The task motivation group was included to control for motivational factors, and the no treatment control condition to control for the practice effects of repeated testing.

The word pair stimuli were from Paivio et al (1968): 30 pairs consisting of 15 high and 15 low imagery noun pairs. Each Subject participated in three experimental sessions.

Session 1. Ss were told that they were in an experiment on imagery to remember pairs of words. They completed the Tellegen Absorption Scale, then were given instructions for using imagery for recalling words, and for rating vividness and clarity of each image immediately after it was formed. Finally they performed the learning task.

Session 2. Ss received either hypnosis, task motivation instructions ("try to form good interacting images of the word pairs" with exhortation to score as high as possible), or control (Like Session 1). No one in hypnosis group refused the induction (despite the fact that they were not forewarned in Session 1 that the experiment might involve hypnosis). Ss completed a questionnaire on the percentage of word pairs they used images to remember, how easy it was to block out or ignore distractions, how vivid and clear were images of words during recall, how concerned they were about their performance, and how much anxiety, if any, they experienced during the experiment.

Session 3. The Harvard Scale was administered. Three Ss declined to participate in the Harvard Scale administration.

The results were analyzed with a 3 x 2 x 2 x 2 repeated-measures ANOVA: hypnotizability, instruction (hypnotic induction, task motivation, no treatment), session (1 and 2), and pair imagery (high and low). The expected enhanced memory performance of high hypnotizables with high imagery words in the hypnosis condition did not emerge in the results. However, the expected stimulus-imagery effect was

observed (a higher proportion of high imagery words than low imagery words recalled). The expected higher imagery ratings for hypnotized high hypnotizable Ss also was not found. Furthermore, there was a significant interaction effect for recall session by hypnotizability: low hypnotizable Ss rated imagery less vivid in Session 2 than in Session 1, while highs rated it more vivid in Session 2 than in Session 1. Thus, low hypnotizable Ss' imagery ratings actually decreased between Recall Session 1 and 2, while high hypnotizable Ss' imagery ratings increased between Recall Session 1 and 2.

While the Absorption Scale correlated with the Harvard (.28,  $p < .001$ ) and with various measures of recall, hypnotizability did not correlate with any of the recall measures. The questionnaires administered during Session 2 suggested that hypnotized Ss were less concerned and anxious than the no treatment control Ss, and less concerned than the Ss receiving task motivation instructions.

In their Discussion, the authors speculate that the strong stimulus-imagery effects might have made it unlikely for them to find differences between high, medium, and low hypnotizable Ss in imagery-based paired associate learning. They suggest including word pairs that range across the continuum of imagery ratings in future research. They also speculate that differences between hypnotizability levels might be found (as 'T Hoen reported in 1978 publication) if Ss were required to respond in a shorter time interval, or if hypnotizability were measured by a scale with more cognitive items than the Harvard Scale--both conditions in 'T Hoen's research protocol.

"The most striking finding of the present research is that instead of facilitating performance in an imagery-mediated recall task, hypnosis resulted in a decrement in recall relative to control conditions. In the hypnotic condition, the amount of learning actually decreased from one session to the next (waking-hypnosis) but remained equivalent in the task motivation (waking-task motivation) and no treatment groups (waking-waking)" (p. 37). The authors note that it is not possible to determine from their research design whether hypnosis interfered with the learning task, the retrieval task, or both.

"The findings suggest that hypnotizability may be related to reported vividness and clarity of imagery but unrelated to the actual ability to utilize imagery in an imagery-mediated paired-associate learning task. ... Although high hypnotizables' self-report ratings of imagery and vividness increased, their recall performance was not accordingly enhanced. The disparity between subjective and objective measures underscores the importance of including both types of measures in studies of imagery abilities" (pp. 37- 38).

To a considerable degree, this study controlled for Ss' expectancies regarding hypnosis better than some earlier studies. This study differs from earlier research in that (1) Experimenters didn't test hypnotizability prior to the imagery-mediation task; and (2) the study was defined as an experiment on imagery, and hypnosis was not mentioned until just before the induction in Session 2.

"In conclusion, the present results indicate that, under certain conditions, hypnosis may decrease Ss' motivation and performance. No support was provided for the ability of hypnosis to facilitate imagery utilization and performance on an imagery-mediated task. The results are compatible with the views proffered [sic] by theoreticians who have emphasized the importance of expectancies and the experimental context (e.g., Barber, 1979; Coe & Sarbin, 1977; M. T. Orne, 1951, 1959; Spanos, 1982)" (p. 38).

1985

Ashton, M.A.; McDonald, R.D. (1985). Effects of hypnosis on verbal and non-verbal creativity. International Journal of Clinical and Experimental Hypnosis, 33 (1), 15-26.

60 female volunteers, 30 hypnotizable and 30 un hypnotizable, screened on 2 measures of hypnotizability, were assigned to a hypnosis, simulation, or waking motivated treatment condition to assess whether hypnosis has a differentially enhancing effect upon verbal and non-verbal creativity test performance. Verbal and figural components of the Torrance Tests of Creative Thinking (Torrance, 1974) and the Sounds and Images Test (Cunnington & Torrance, 1965) were the principal

dependent variables. Postexperimental measures of absorption and effortless experiencing were also obtained. A 2 x 3 independent groups ANOVA did not sustain the prediction of an interaction effect between S hypnotizability and the presence of hypnosis on 3 composite measures of verbal and nonverbal creativity. Although there was an absence of treatment effects, hypnotizable Ss consistently achieved higher scores on the Torrance scoring categories, and their performance was statistically superior on a composite index of overall creativity. Absorption and effortless experiencing measures were also significantly higher for hypnotizable Ss than for un hypnotizable Ss.

Salzberg, H. C.; DePiano, F. A. (1980). Hypnotizability and task motivating suggestions: A further look at how they affect performance. International Journal of Clinical and Experimental Hypnosis, 28 (3), 261-271.

An attempt was made to ferret out the separate effects on cognitive performance of hypnotic susceptibility, task motivating suggestions, and the hypnotic trance state. An equal number of susceptible and unsusceptible Ss were given 3 cognitive tasks, first to ascertain their baseline performances, and then again following either a traditional hypnotic induction, an alert trance induction or a short interview. All Ss were given task motivating suggestions prior to administering the alternate form of the 3 tasks. An additional control group of Ss was used to assess practice effects. Results indicated that task motivating suggestions were effective in enhancing performance for all groups on the digit symbol and abstract reasoning tasks but not on the memory task. Waking suggestion Ss performed as well as hypnotized SWs when both groups of Ss were given task motivating suggestions. It was concluded that when the experimental design of a study incorporates necessary controls, hypnosis does not facilitate performance.

Spanos, Nicholas P.; Radtke-Bodorik, H. Lorraine; Shabinsky, Michael A. (1980). Amnesia, subjective organization, and learning of a list of unrelated words in hypnotic and task-motivated subjects. International Journal of Clinical and Experimental Hypnosis, 28 (2), 126-139.

Hypnotic and task-motivated Ss learned a list of unrelated nouns and were then administered an amnesia suggestion for the list. Hypnotic Ss showed slower learning but more amnesia than task-motivated Ss. Hypnotic and task-motivated Ss showed an equivalent degree of "breakdown" in the subjective organization of their recall following the amnesia suggestion. However, the extent of this breakdown in subjective organization, was unrelated either to Ss' degree of amnesia or to their level of hypnotic susceptibility. A substantial proportion of Ss who failed to recall any words following the suggestion (total nonrecallers) later reported that they remembered but did not say at least some of the words. The theoretical implications of these findings are discussed.

1976

Connors, J.; Sheehan, P. W. (1976). Analysis of the cue characteristics of task motivational instructions. International Journal of Clinical and Experimental Hypnosis, 24, 287-299.

This study investigated the assumption of Barber's model of hypnosis that its set of task motivational instructions is thoroughly "nonhypnotic" in character. If this assumption is correct, then the cues associated naturally with task motivational instructions should be more compatible with a suggestibility test situation explicitly defined as nonhypnotic than with one defined as hypnotic, and this affinity should be reflected in both Ss' objective and subjective suggestibility test scores. Barber's (1965) Suggestibility Scale data collected from 90 Ss did not confirm the main prediction under test, but results failed to provide unequivocal support for the model; subjective evidence, in particular, supported least well the assumptions of the paradigm.

Spanos, Nicholas P.; Spillane, Jeanne; McPeake, John (1976). Cognitive strategies and response to suggestion in hypnotic and task-motivated subjects. American Journal of Clinical Hypnosis, 18, 254-262.

Thirty-two male and 32 female subjects, exposed to an hypnotic induction or task-motivational instruction, were administered either three suggestions which provided a cognitive strategy (i.e., a goal-directed fantasy, GDF) for experiencing suggested effects, or three suggestions that did not provide such a strategy. Subjects provided with GDF strategies were more responsive overtly and subjectively to two out of the three suggestions. Subjects in the No GDF Strategy treatment who spontaneously devised their own goal-directed fantasies were more responsive to suggestions than subjects who failed to devise such a strategy. These results support the contention that goal-directed fantasy helps both hypnotic and non-hypnotic subjects experience suggested effects.

1970

Swiercinsky, Dennis; Coe, William C. (1970). Hypnosis, hypnotic responsiveness, and learning meaningful material. International Journal of Clinical and Experimental Hypnosis, 18 (3), 217-222.

RESPONSES TO TEST SUGGESTIONS (E.G., HALLUCINATION AND AMNESIA) WERE ASSESSED UNDER THE FOLLOWING TREATMENTS: MOTIVATIONAL INSTRUCTIONS ALONE, HYPNOTIC PROCEDURE WITH MOTIVATIONAL INSTRUCTIONS, AND IMAGINATION-CONTROL. COMPARISONS WERE MADE ACROSS INDEPENDENT GROUPS, EACH TESTED UNDER 1 TREATMENT, AND ALSO WITHIN THE SAME SS TESTED TWICE UNDER VARIOUS COMBINATIONS OF THE TREATMENTS. ALTHOUGH SS WERE SUGGESTIBLE UNDER THE IMAGINATION-CONTROL TREATMENT, BOTH THE MOTIVATIONAL INSTRUCTIONS ALONE AND THE HYPNOTIC PROCEDURE GIVEN TOGETHER WITH THE MOTIVATIONAL INSTRUCTIONS RAISED SUGGESTIBILITY ABOVE THE CONTROL LEVEL. THE HYPNOTIC-MOTIVATIONAL TREATMENT TENDED TO PRODUCE AN INCREMENT IN SUGGESTIBILITY WHICH WENT SLIGHTLY BEYOND THAT ATTRIBUTABLE TO THE MOTIVATIONAL INSTRUCTIONS. THE LATTER INCREMENT IS INTERPRETED AS DUE TO THE SLIGHTLY GREATER EFFECTIVENESS OF THE HYPNOTIC PROCEDURE IN DEFINING THE SITUATION AS ONE IN WHICH UNUSUAL MANIFESTATIONS, SUCH AS HALLUCINATION AND AMNESIA, ARE WITHIN SS' CAPABILITIES AND DEFINITELY EXPECTED BY E. Bowers, Kenneth S. (1968). Hypnosis and creativity: A preliminary investigation. International Journal of Clinical and Experimental Hypnosis, 16, 38-52.

24 HIGHLY SELECTED, HYPNOTICALLY TRAINED COLLEGE STUDENTS WERE CAST INTO HYPNOTIC AND HYPNOSIS SIMULATING GROUPS AND GIVEN SUGGESTIONS TO BEHAVE CREATIVELY ON THE CONSEQUENCES TEST OF ORIGINALITY. NO DIFFERENCES BETWEEN THE 2 GROUPS APPEARED. THEY DID APPEAR, HOWEVER, ON A CONCEPT FORMATION TASK AS A FUNCTION OF TASK-INVOLVEMENT INSTRUCTIONS, IRRESPECTIVE OF WHETHER SS WERE HYPNOTIZED OR SIMULATING HYPNOSIS. MOREOVER, AWARENESS OF RESPONSE REINFORCEMENT CONTINGENCIES WAS STRONGLY INFLUENCED BY THE INVOLVING SUGGESTIONS. THE NEGATIVE FINDINGS ON THE CREATIVITY TEST WERE ATTRIBUTED TO THE EXCELLENT PERFORMANCE OF THE SIMULATOR SS. IT IS SUGGESTED THAT PERHAPS

SUSCEPTIBILITY PER SE INTERACTS WITH ROLE PLAYING INSTRUCTIONS IN GENERATING MORE REGRESSIVE MODES OF THINKING. (SPANISH + GERMAN ABSTRACTS) (2 P. REF.) (PsycINFO Database Record (c) 2002 APA, all rights reserved)

1967

Hartman, B. J. (1967). Hypnotizability as affected by attitudinal and motivational variables. International Journal of Clinical and Experimental Hypnosis, 86-90.

ATTEMPTED TO DISCOVER WHETHER TASK-MOTIVATED SS WOULD BE MORE HYPNOTIZABLE THAN THOSE NOT GIVEN TASK-MOTIVATION INSTRUCTIONS, AND WHETHER THE ATTITUDE OF THE E WOULD AFFECT SS' HYPNOTIZABILITY. THE BARBER SUGGESTIBILITY SCALE WAS EMPLOYED FOR MEASURING SUSCEPTIBILITY TO HYPNOSIS. SS WERE DIVIDED RANDOMLY INTO 6 GROUPS OF 10: TASK-MOTIVATED, E NEUTRAL; NON-TASK-MOTIVATED, E NEUTRAL; TASK-MOTIVATED, E FRIENDLY; TASK-MOTIVATED, E HARSH; NON-TASK-MOTIVATED, E FRIENDLY; AND NON-TASK-MOTIVATED, E HARSH. ANALYSES OF VARIANCE, BOTH FOR OBJECTIVE AND SUBJECTIVE SCORES, DID NOT YIELD SIGNIFICANT RESULTS FOR THE TASK-MOTIVATION VARIABLE BUT DID YIELD SIGNIFICANT RESULTS ( $P = .01$ ) FOR THE VARIABLE DEALING WITH E ATTITUDE. (GERMAN + SPANISH SUMMARIES) (PsycINFO Database Record (c) 2002 APA, all rights reserved)

1961

Glass, Louis B.; Barber, Theodore X. (1961). A note on hypnotic behavior, the definition of the situation and the placebo effect. Journal of Nervous and Mental Disease, 132, 539-541.

Subjects were tested for responses to hypnotizability tests under three conditions: after 20 minute induction, after being told they would not be hypnotized but would take tests of imagination (with motivating instructions to do well), after taking a placebo pill that "would make them deeply hypnotized." Of 12 Ss who dropped in score between Session 1 and Session 2, 11 attained higher scores following placebo than during the control session; mean scores under placebo and control (5.8 and 3.7) differed significantly,  $p < .01$ . Scores were as high in the third as the first session (5.8 and 6.3 respectively).

## TECHNIQUE

1993

Lynn, Steven Jay; Neufeld, Victor; Mare, Cornelia (1993). Direct versus indirect suggestions: A conceptual and methodological review. International Journal of Clinical and Experimental Hypnosis, 31, 124-152.

The article reviews the literature on the effects of direct versus indirect hypnotic suggestions. A conceptual and methodological analysis of direct versus indirect suggestions is also provided. Three conclusions follow from the review: (a) Contrary to views of Ericksonian hypnotists, suggestion style has little effect on objective responding to hypnotic test items; (b) studies of clinical- and laboratory-induced pain and other measures of subjective experience have yielded contradictory results--however, the best controlled studies have not indicated that indirect suggestions are superior to direct suggestions; and (c) there is insufficient evidence to conclude that hypnotizability level and suggestion wording interact, such that low hypnotizable subjects are particularly responsive to indirect suggestions. Methodological and conceptual problems in defining and studying hypnotic

communications, the lack of rigorous experimental controls, and research issues and directions are highlighted.

#### NOTES

Although this article is primarily concerned with the nature of suggestion, the review also mentions several studies comparing hypnosis with other interventions for pain, in passing:

Crowley (1980)

Snow (1979)

Omer, Darnel, Silberman, Shuval, & Palti (1988)

Stern (1982)

Bassman (1983)

"Like the clinical studies using the RIA [Rapid Induction Analgesia], pain studies that did not use the RIA lack appropriate control groups: Neither Bassman's (1983) nor Stern's (1982) research explicitly compared direct and indirect suggestions. What our review does suggest is that studies (e.g., Crowley, 1980; Snow, 1979; Van Gorp et al., 1985) that imposed the greatest degree of methodological control yielded the outcomes least favorable to the hypothesis that indirect suggestions are effective and account for the pain relief achieved, above and beyond factors common to placebo treatments" (p. 132).

"Lynn and his colleagues' studies indicate that whereas indirect suggestions enhance archaic representations of the hypnotist, direct suggestions facilitate involvement in the events of hypnosis, as measured by subjective involvement and involuntariness" (p. 136).

Schoen, Marc (1993). Resistance to health: When the mind interferes with the desire to become well. American Journal of Clinical Hypnosis, 36, 47-54.

Secondary gain has long been viewed as a variable that can significantly affect a patient's recovery from such conditions as chronic pain disorders, factitious and somataform disorders, and other psychological disorders. Secondary gain has not been evaluated in terms of its impact on major illnesses such as cancer or autoimmune disorders. In this paper I discuss how secondary gain can be present in such illnesses and how it results in a resistance to health. This resistance to health can lead not only to medical noncompliance, but can also ultimately affect the progression and recovery from the illness. I describe how hypnosis can be used to ferret out this resistance to health and how patients in a hypnotic state will indicate or express their resistance to becoming healthy. The advantage of this approach is that it enables the clinician to deal directly with the patient's unconscious resistance to health.

Szabo, Csaba (1993). The phenomenology of the experiences and the depth of hypnosis: Comparison of direct and indirect induction techniques. International Journal of Clinical and Experimental Hypnosis, 41, 225-233.

The effect of two hypnotic induction styles on subjective experience was measured in an experiment in which 44 subjects participated in both traditional direct hypnosis, induced by the Stanford Hypnotic Susceptibility Scale, Form A, and indirect hypnosis (presented in counterbalanced order), followed by 4 minutes of rest before dehypnosis. The depth of hypnosis was measured retrospectively by a subjective scale, and the structure of experiences was measured by the Phenomenology of Consciousness Inventory. Subjects were subsequently administered the Stanford Hypnotic Susceptibility Scale, Form B, so that awareness of their hypnotizability would not affect their subjective depth reports. No differences were found in a comparison of subjects' structure of experiences in direct and indirect hypnosis. In addition, low and medium hypnotizable subjects reported indirect hypnosis as deeper. This may reflect the possibility that while hypnotized different mechanisms come into play for subjects high in hypnotizability compared to those who are less hypnotizable.

1992

Blankfield, Robert; Scheurman, Kathleen; Bittel, Sue; Alemagno, Sonia; Flocke, Sue; Zyzanski, Stephen (1992, October). Taped therapeutic suggestions and taped music as adjuncts in the care of coronary artery bypass graft patients. [Paper] Presented at the annual meeting of the Society for Clinical and Experimental Hypnosis, Arlington, VA.

#### NOTES

18 studies have explored the issue with an experimental design; half used tapes, half didn't; majority of studies found benefits; 2 were of heart surgery patients.

This study used taped suggestions with coronary bypass patients. Used tape recorder rather than person delivering suggestions because it was more convenient; used tape intra-surgery and post-operatively for more impact.

We hypothesized: shorter length of stay, less narcotic analgesia, less anxiety, faster recovery, more positive mental outlook, resume activities sooner, have less symptoms postoperatively, etc.

Used a prospective, randomized, single-blind trial in 2 community hospitals in Cleveland with coronary artery bypass graft surgery patients. Study was done between Dec 1989 - Feb 1992.

3 groups were involved: (1) Suggestion, (2) music, and (3) tape. Control subjects had a blank tape. Tapes were played continuously and repeatedly with headphones. Postoperatively, a different tape was played.

Excluded: Patients with emergent surgery, hearing impairment, poor comprehension of English, patients who died in hospital, patients whose hospital stay lasted longer than 14 days (3 of them). 5% of sample were eliminated for last 2 reasons.

Music: Herb Ernst, Dreamflight II. Suggestions: Music background, permissive, based on Evans & Richardson's study.

Outcome Measures: Nurse assessment of anxiety and progress post operatively, Symptom scale, Depression scale.

Mean age 62, 3/4 men, 92% white, 75% married. The groups were same on a variety of preoperative variables (status of heart and arteries). Length of stay was 6.5 in all 3 groups. No difference in narcotics use, in nurse assessment of anxiety or of progress; of depression scale, or activities of daily living.

Recategorized data into patients who said the tapes were helpful (both music and suggestion) N = 33 vs the other patients N = 62. No difference in the variables evaluated.

Herbert, James D.; Mueser, Kim T. (1992). Eye movement desensitization: A critique of the evidence. Journal of Behavior Therapy and Experimental Psychiatry.

The scientific evidence supporting the efficacy of eye movement desensitization (EMD), a novel intervention for traumatic memories and related conditions, is reviewed. The sparse research conducted in this area has serious methodological flaws, precluding definite conclusions regarding the effectiveness of the procedure. Clinicians are cautioned against uncritically accepting the clinical efficacy of EMD.

Lohr, Jeffrey M.; Kleinknecht, Ronald A.; Conley, Althea T.; Dal Cerro, Steven; Schmidt, Joel; Sonntag, Michael E. (1992). A methodological critique of the current status of eye movement desensitization (EMD). Journal of Behavior Therapy and Experimental Psychiatry.

Eye Movement Desensitization (EMD) has been recently advocated as a rapid treatment for the elimination of traumatic memories responsible for the maintenance of a number of anxiety disorders

and their clinical correlates. Despite a limited conceptual framework, EMD has attracted considerable interest among clinicians and researchers. The popularity and interest generated by EMD will likely result in wide usage. We present a methodological critique of it with reference to assessment, treatment outcome, and treatment process. We also provide guidelines for judging the methodological adequacy of research on EMD and suggest intensive research to assess effectiveness, treatment components, and comparisons with other procedures.

Page, Roger A.; Handley, George W. (1992). Effects of 'deepening' techniques on hypnotic depth and responding. International Journal of Clinical and Experimental Hypnosis, 40, 157-168.

The present study attempted to assess the effectiveness of commonly used deepening techniques and of surreptitiously provided stimulation on hypnotizability scores, in-hypnosis depth reports, retrospective realness ratings, and the Field Inventory of Hypnotic Depth (Field, 1965). High, medium, and low hypnotizables were assigned in equal numbers to 1 of 3 groups, each containing 54 Subjects. Controls were compared to Subjects receiving 2 deepening techniques or 2 suggestions for positive and negative hallucinations that were surreptitiously enhanced. Of the 4 dependent measures employed, the only significant difference between groups related to a change in depth reports for the manipulation items themselves, leading to the conclusion that the effect of the techniques was at best minimal and transient. Some methodological and conceptual issues are also discussed.

Sheehan, Peter W. (1992). The phenomenology of hypnosis and the Experiential Analysis Technique. In Fromm, Erika; Nash, Michael R. (Ed.), Contemporary hypnosis research (pp. 364-389). New York: Guilford Press.

## NOTES

The problem with behavioral assessment methods such as hypnotizability scales is that similar behavioral responses to hypnotic suggestions may occur for very different reasons. It is important to assess the phenomenological experience of hypnotic Ss. The Experience Analysis Technique (EAT) is a method for assessing the phenomenology of hypnosis. The EAT "consists of gathering the comments of hypnotic subjects about their hypnotic behavior and experience, as they view the video playback of their hypnotic sessions" (p. 372). The EAT draws its origins from Kagan's method of Interpersonal Process Recall [IPR], in which "counselors in training could review and react to, their contact with clients immediately after therapy sessions. An independent person, present at the review of the session, would inquire into the interaction between the counselor and client by stopping the tape and questioning the client about his or her underlying feelings and thoughts, so facilitating and clarifying the information being recalled" (p. 371). It is important that the interviewer be a different person than the hypnotist.

Hammer, Walker & Diment (1978) applied the IPR to hypnosis, using audiotape. Using the videotape EAT with hypnosis, Sheehan & McConkey (1982; Sheehan, McConkey & Cross, 1978) noted that hypnotic Ss might exhibit any of three different response styles, sometimes related to hypnotic task complexity: 1. Concentrative/cooperative style - S focuses on hypnotist's words, imagining a literal interpretation 2. Independent style - S interprets hypnotist's words in a way that is meaningful to them 3. Constructive style - S considers the communications "from a position of preparedness to process incoming stimuli in a schematic way, so as to structure or re-organize events according to the hypnotist's suggestions"

Some Ss who are high in susceptibility show greater flexibility in the use of cognitive styles than low susceptibility Ss.

Examples of the use of the EAT to evaluate several phenomena observed in experimental and clinical settings are provided: 'duality' during age regression, trance logic, posthypnotic amnesia, pseudomemories, and rapport.

The author reviews the concept of 'countering.' "Countering occurs when a S responds in accord with the wishes of the hypnotist when social influences to respond otherwise are also present in the situation. ... Counterers display a constructive (i.e. active and idiosyncratic) style of cognizing which enables them to make personal sense of the conflicting demands by preserving the integrity of each. ... Counterers, even though they demonstrate a higher degree of involvement with the hypnotist, fail reliably to score as highly on standard tests of susceptibility (e.g. the Stanford Hypnotic Susceptibility Scale, Form C) as subjects who do not counter (Sheehan, 1980). This second finding points to differential effects of rapport on Ss which are not explicable in terms of level of hypnotic susceptibility or simple willingness to comply with anticipated, obvious suggestions. Techniques like the EAT, which are sensitively attuned to detect the personal commitment of subjects to the hypnotist, are needed to detect subtle processes of this kind" (pp. 385- 386).

The author evaluates different reporting techniques used to examine the phenomenological experience of hypnosis (the Chicago Paradigm of Fromm & Kahn, 1990; Shor's phenomenological method; the Field's Inventory Scale of Hypnotic Depth) and evaluates the effects of rapport with the E on the measurement of subjective response. He suggests various experimental controls (e.g. disguising the true aims of the experiment). A measure of rapport or psychodynamic transference to the hypnotist, the Archaic Involvement Measure (AIM) has been developed by Nash and Spinler (1989).

"Experience cannot simply be observed objectively; it may not be reported spontaneously by the experienter; and it may not even be elicited through ordinary forms of interaction" (p. 388).

"What phenomenological research has shown over the last decade is that hypnotic experience is both multifaceted and complex. It has given us a view of the hypnotic subject as a person who participates actively in the hypnotic process, who is susceptible to the influence of motivations and expectations, and who employs a variety of cognitive strategies so as to manage and respond to multiple levels of communication received in the hypnotic setting. Standard techniques of assessment, especially those emphasizing the primacy of behavioral data and those offering structured choices, are not equipped to reveal the full meaning of hypnotic responsiveness" (p. 388).

"If an instrument of assessment assumes a unidimensional underlying process when there are multiple dimensions operating, then that instrument will be deficient in measuring experience by producing equivalent ratings for very different experiences, and thus will be deficient in measuring overall experience. Measurement of trance-depth poses just such a problem, and measurement of hypnotic experience in its full complexity even more so" (pp. 388-389).

Spira, James L.; Spiegel, David (1992). Hypnosis and related techniques in pain management. Hospice Journal, 8, 89-119.

Hypnosis has been used successfully in treating cancer patients at all stages of disease and for degrees of pain. The experience of pain is influenced not only by physiological factors stemming from disease progression and oncological treatment, but also from psychosocial factors including social support and mood. Each of these influences must be considered in the successful treatment of pain. The successful use of hypnosis also depends upon the hypnotizability of patients, their particular cognitive style, their specific motivation, and level of cognitive functioning. While most patients can benefit from the use of hypnosis, less hypnotizable patients or patients with low cognitive functioning need to receive special consideration. The exercises described in this chapter can be successfully used in groups, individual sessions, and for hospice patients confined to bed. Both self-hypnosis and therapist guided hypnosis exercises are offered.

1991Mauer, D. R. (1991, October). A comparison of cognitive-behavioral and hypnotic techniques in the management of electromyography pain (Dissertation, University of Iowa). Dissertation Abstracts International, 53 (4), 1070-B. (Order No. DA 9217180)

"Compared a cognitive behavioral technique that included providing specific sensory and procedural information combined with relaxation with a hypnotic technique (relaxation with guided imagery) and a control group for management of acute EMG pain and anxiety. Pain and anxiety ratings were gathered from 45 EMG patients and observers for both nerve conduction and needle electrode components of the EMG exam. It was found that only the hypnosis group significantly reduced pain and anxiety during the needle electrode portion of the procedure. Patients with unexplained or functional symptoms reported more EMG pain and anxiety than patients who had an organically based disease. Because having had a prior EMG seemed to have an effect on the efficacy of treatment, the data were reexamined. Results determined that inexperienced EMG patients who were treated had less pain and anxiety than patients who experienced EMG before, but inexperienced control patients had an increase in pain and anxiety over experienced patients" (p. 1070).

Strauss, Billie S. (1991). The use of a multimodal image, the apple technique, to facilitate clinical hypnosis: A brief communication. International Journal of Clinical and Experimental Hypnosis, 39, 1-5.

A 1- to 3-minute exercise involving imagination (of an apple) and ideomotor ideation (hand levitation) is a simple, benign technique that is useful for illustrating to patients the nature of imagery and hypnosis. It avoids power struggles and allows a reasonable approximation of the patient's capacity for imagery and hypnotic responsiveness, without emphasizing the use of a hypnotic procedure. When administered to 35 college students, the hand levitation component of this exercise correlated with the Stanford Hypnotic Susceptibility Scale, Form C (Weitzenhoffer & E. R. Hilgard, 1963) ( $r = .66$ ,  $p < .001$ ) and with the Stanford Hypnotic Clinical Scale: Adult (Morgan & J. R. Hilgard, 1975, 1978/79) ( $r = .60$ ,  $p < .001$ ).

NOTES: Hypnosis is explained as involving imagination and concentration. Then the patient is asked to participate as the clinician checks their imagination. The patient is asked to close their eyes and hold out their hand, after which the clinician says "I'm going to put an apple in your hand; describe the apple to me." The patient is prompted to report multiple sensory modalities with questions Like, "Does the apple have weight? Does it have a smell? Would you Like to take a bite out of the apple? How does it sound as you chew it?" The clinician can obtain useful information about the patient's preferred sensory modalities, the amount of structure required to engage in imaginal activities, etc.

If the patient becomes very involved with the image and would Like to continue the experience on into hypnosis, the clinician can ask them to concentrate on the apple's weight, then tell the patient that s/he will take the apple from the patient's hand and the patient will notice that the hand feels light. As this imagery progresses, the clinician can move into suggesting a sense of lightness, and ultimately an arm levitation procedure Like that of Chiasson, i.e. that "when the hand reaches the patient's face, the patient will find himself or herself in a comfortable state of hypnosis" (p. 2).

"At any point where the patient does not appear to respond to suggestions or remain involved with the imagery, techniques are shifted. For example, if the patient indicates that the apple does not appear to have weight or the hand does not feel light, I suggest simply that the patient continue to listen to my voice, to breath deeply, and to continue to enjoy this comfortable state, perhaps using imagery commensurate with the skills shown by the patient when he or she first imagined the apple. Finally, patients are roused, with posthypnotic suggestions for alertness, comfort, and control" (p. 2).

The author administered this Apple Technique to 12 patients, following the administration with an interview to learn about their subjective responses. Of the 12, 6 showed at least some hand levitation and scored 3-5 on SHCS:A; 6 had no levitation and scored 0-1 on SHCS:A. When administered to 35 college students, only 3 did not experience a sensation of weight when imagining an apple in their hand. A three-point rating (1 = no hand movement; 2 = some hand movement, but not to the face; 3 = hand movement to the face) correlated .66 with SHSS:C and .60 with SHCS:A.

The author has found that good Ss can go into hypnosis within 2-3 minutes using the Apple Technique, while poor Ss conversely may reveal limited imaginative involvement or ideomotor skill within the same amount of time.

1990Avants, S. Kelly; Margolin, Arthur; Salovey, Peter (1990-91). Stress management techniques: Anxiety reduction, appeal, and individual differences. Imagination, Cognition and Personality, 10, 3-23.

## NOTES

Four stress management techniques were evaluated for their general appeal, their immediate benefits, and the subjective experiences they evoke. One hundred undergraduates were randomly assigned to one of five treatment groups: (1) progressive muscle relaxation (PMR); (2) distraction imagery; (3) focused imagery; (4) listening to music; (5) sitting quietly (control). Distraction imagery and listening to music were the only techniques found to reduce anxiety to a greater extent than simply sitting quietly. The techniques differed in the way they made subjects feel, but not in their general appeal. Individuals with a 'blunting' coping style were more likely to find all five techniques appealing.

Tests used included the Miller Behavioral Style Scale, Cognitive-Somatic Anxiety Questionnaire of Schwartz, Davidson & Golman, Life Orientation Test of Scheier & Carver, Somatic Perception Questionnaire of Landy and Stern, Body Consciousness Questionnaire of L. C. Miller, Murphy, & Buss, Betts' Questionnaire Upon Mental Imagery, Shortened Form, State-Trait Anxiety Inventory, and Technique Evaluation Questionnaire of the authors.

Progressive muscle relaxation was according to Bernstein & Borkovec. Distraction imagery involved successively imagining a walk along a beach, a stroll across a flower filled meadow, sitting by a stream, a walk into the woods, sitting in a cabin in the woods listening to the rain against the windowpane, all including images in a variety of sense modalities. Focused imagery involved creating an image of a stressor, then through symbolic imagery experiences Ss were guided through a typical day's events that might lead up to the stressor, reinterpreting cues associated with the stressor as signals that they are in control, visualizing encountering the stressor feeling strong and determined, and any physical sensations reinterpreted as 'energy' that would help them to cope, visualizing enjoying their success (from Crits-Cristoph & Singer. Music was a 20-min tape (10 min of music used in the distraction imagery tape--Natural Light by Steve Halpern & David Smith) and 10 min of music used in background of the focused imagery tape (Structures of Silence by Michael Lanz). A 5th group, Control, was instructed to sit quietly with eyes closed.

This data can be used in support of imagery-suggestion types of hypnosis (as in surgery study) reducing anxiety. It shows particularly strong effects for people high in cognitive anxiety or low in optimism, pre-treatment.

Discussion: "... we feel confident that our distraction techniques were more effective for the immediate relief of anxiety than was PMR. This conclusion is consistent with the Suls and Fletcher meta-analysis (29) that suggested that 'avoidance' is an effective short-term coping strategy. That distraction (positive) imagery may be a more useful clinical technique than focused (active involvement) imagery was concluded in a study comparing these two techniques in the treatment of phobias (24)" (p. 19. [Ref #24 is Crits-Cristoph & Singer (1983) in *Imagination, Cognition, and Personality*.])

"Pessimism and cognitive anxiety emerged as the only individual difference variables to influence anxiety reduction. Pessimism as measured by the LOT is cognitive in nature, with most of the items relating to expectations of negative outcomes; similarly, cognitive anxiety is characterized by worry and an inability to control negative thoughts and images. That individuals who perceive their world somewhat negatively should have entered the study more anxious than individuals who do not is hardly surprising. What is surprising is that despite an inverse relation between cognitive anxiety and the ability to relax, these individuals were able to benefit from whatever technique they performed to a

greater extent than were individuals with a more positive outlook. In fact, after performing the technique, pessimists had reduced their anxiety to the level of optimists" (p. 19).

"The stress management techniques used in the current study did not differ in their appeal" (p. 20).

"Our finding that PMR produced more somatic effects than did focused imagery and less cognitive effects than did distraction imagery, listening to music, or sitting quietly is consistent with the model of anxiety proposed by Davidson and Schwartz (17). Our findings are also generally consistent with a conclusion reached by Woolfolk and Lehrer (4): that although various techniques are generally stress reducing, they seem to have highly specific effects. However, we found no support for the hypothesis that individuals who express anxiety cognitively (or somatically) prefer and benefit most from techniques that produce cognitive (or somatic) effects. In fact, the extremely high correlation found between the cognitive and somatic anxiety subscales of the Schwartz et al. measure (5) casts some doubt on the usefulness of a cognitive-somatic distinction, as does the corr between the experience of physical symptoms under stress (the Somatic Perception Questionnaire) with the cognitive, as well as the somatic, anxiety subscale.

"The finding that blunters experiences more 'somatic effects' regardless of the technique they were assigned may have been the result of a single response--'how much did mind-wandering interfere with performing the technique'--which was the only Factor 2 item that was highly inversely related to blunting. Since blunters are more likely to perceive mind wandering as the essence of stress management rather than as 'interference,' we do not view this main effect as particularly illuminating" (p. 20). "However, our finding that blunters experienced all techniques as appealing is consistent with the results of Martelli et al. (1) who found that individuals with low information-preference benefitted from what the authors labeled an 'emotion-focused' intervention, but which, in fact, included many of the quite diverse stress management techniques that we compared in the current study. That 'avoiders' failed to benefit from any intervention in the Scott and Clum study (11) may be due to the nature of the stressor [postsurgical pain]. Our undergraduates may have been more like the Martelli dental patients in terms of their level of distress than were the Scott and Clum subjects who were patients undergoing major surgery (hysterectomy or cholecystectomy). Future research needs to examine possible three-way, technique by patient by stressor-type, interactions (cf. 19)" pp 20-21.

Evans, Frederick J.; Stanley, R. O. (1990). Psychological interventions for coping with surgery: A review of hypnotic techniques. Australian Journal of Clinical and Experimental Hypnosis, 18, 97-105. Illness, hospitalization, and surgery pose many severe stresses for many patients, to the extent that their ability to understand and cope with what is happening may be significantly reduced. Many of these stresses result from the nature and significance of patients' surgical procedures and post-operative treatment. This paper reviews the range of psychological interventions aimed at helping patients cope with pre- and post-operative treatment regimens. The range and content of hypnotic interventions are examined in detail. It is concluded that more rigorous research studies are required to determine the relative effectiveness of different types of interventions and to evaluate the effects of patients' psychological characteristics on the effectiveness of these interventions.

1989

Bryant, Richard A.; McConkey, Kevin M. (1989). Hypnotic blindness: A behavioral and experiential analysis. Journal of Abnormal Psychology, 98, 71-77.

NOTES

"This research examined the influence of visual information on a decision task that subjects were administered during hypnotically suggested blindness. Real, hypnotizable subjects and simulating, un hypnotizable subjects were tested in two experiments. Experiment 1 focused on behavioral responses, and Exper. 2 focused on experiential reactions. In both experiments, the findings indicated

that the behavioral responses of reals were influenced by visual info. despite their reported blindness. The behavioral responses of reals and simulators were essentially similar. The experiential data in Experiment 2 provided information about the phenomenal nature of subjects' reported blindness. The experiential reactions of reals and simulators were essentially different. The research is discussed in terms of the issues that need to be considered in the development of a model of hypnotic blindness" (p. 71).

Eppley, Kenneth R.; Abrams, Allan I.; Shear, Jonathan (1989). Differential effects of relaxation techniques on trait anxiety: A meta-analysis. Journal of Clinical Psychology, 45, 957-974.

Conducted a meta-analysis of studies on the effects of relaxation techniques on trait anxiety. Effect sizes for the different treatments (e.g., progressive relaxation, biofeedback, meditation) were calculated. Most treatments produced similar effect sizes, although transcendental meditation (TM) produced a significantly larger effect size than other forms of meditation and relaxation. A comparison of the content of the treatments and their differential effects suggests that this may be due to the lesser amount of effort involved in TM. Meditation that involved concentration had a significantly smaller effect than progressive relaxation.

1988

Dougherty, John E.; Payne, Paul A. (1988). The use of breathing rhythm to enhance the vividness of mental imagery. Imagination, Cognition and Personality, 8 (2), 175-179.

The study assessed Jencks' claim that responses to certain suggestions are enhanced by being paced with different phases of the breathing cycle. Following hypnotic induction, twenty-four subjects were given four treatments in counterbalanced order: 1) exhalation-enhanced suggestions paced to exhalation, 2) inhalation-enhanced suggestions paced to inhalation, 3) inhalation-enhanced suggestions counterpaced to exhalation, and 4) exhalation-enhanced suggestions counterpaced to inhalation. Subjects' reports of imagery vividness provided marginal support ( $p < .06$ ) for Jencks' hypothesis. Post-experimental inquiry indicated subjects were unaware of the breathing contingency. Results suggest that appropriate pacing may make a greater difference for the energy-confidence group of suggestions (inhalation-paced) than for the calm-relaxation group (exhalation-paced).

Kuttner, Leora (1988). Favorite stories: A hypnotic pain-reduction technique for children in acute pain. American Journal of Clinical Hypnosis, 30, 289-295.

For young children (aged 3 to 6-11) with leukemia, a hypnotic trance consisting of a child's favorite story was found to be statistically more effective than behavioral distraction and standard medical practice in alleviating distress, pain, and anxiety during painful bone marrow aspirations. Measured by a behavioral checklist and judgment ratings by physician, parent, nurse, and observers, the favorite-story hypnotic technique had immediate therapeutic impact on these young patients, and the reduction in distress, pain, and anxiety was sustained on subsequent medical procedures. Self-report measures, however, were nonsignificant.

1985

Matthews, William J.; Kirsch, Irving; Mosher, Donald (1985). Double hypnotic induction: An initial empirical test. Journal of Abnormal Psychology, 94 (1), 92-95.

## NOTES

In separate experimental sessions, 34 undergraduate students experienced audiotapes of a standard hypnotic induction and a double induction similar to that described by Bandler and Grinder (1975). In the double induction, subjects heard a hand-levitation induction through the ear that is contralateral

to the dominant cerebral hemisphere and, simultaneously, heard grammatically childlike messages through the other ear. Half of the subjects experienced the double induction first. There were no significant within-subject differences between the two inductions. However, subjects who experienced the double induction prior to the standard induction were significantly less responsive to suggestions following both inductions, which suggests that the double induction as a first experience of hypnosis may have a negative impact on subsequent experiences of hypnosis.

**1984**

Gillett, Penny L.; Coe, William C. (1984). The effects of rapid induction analgesia (RIA), hypnotic susceptibility and the severity of discomfort on reducing dental pain. American Journal of Clinical Hypnosis, 27, 81-90.

The study was designed to address three issues involved in hypnotic analgesia for dental pain: 1) The effectiveness of J. Barber's (1977) hypnotic procedure for producing analgesia in its usual form and a shortened form, 2) the relationship of hypnotic susceptibility to analgesic responsiveness, and 3) the effect of dental procedure discomfort level on hypnotic analgesia. Sixty unselected dental patients were administered either J. Barber's (1977) RIA or a shortened version of it (SI) before their dental treatment. Measures of hypnotic susceptibility were obtained as were dentists' ratings of the discomfort levels involved in the various dental procedures administered. The 52% success rate of the present study failed to replicate Barber's very high (99%) success rate, although procedural differences might explain the lower rate. RIA and SI were equally effective. Hypnotic susceptibility level did not relate significantly to success with hypnotic analgesia. The level of dental procedure discomfort was the clearest predictor of success with hypnotic analgesia. The greater the discomfort rating of a procedure the less likely that hypnotic analgesia would be successful.

**1983**

Diamond, Michael Jay (1983). Therapeutic indications in applying an innovative hypnotherapeutic technique: The client-as-hypnotist. American Journal of Clinical Hypnosis, 25 (4), 242-247.

A novel hypnotic induction technique is described wherein the client reverses roles and serves as hypnotist for the therapist willing to enter trance. Indications and contraindications in employing innovative hypnotherapeutic interventions are considered in terms of the therapeutic goals and context, patient-therapist interaction, and patient as well as therapist characteristics. Benefits provided by the technique to the client, client-therapist interaction, and therapist respectively are briefly discussed. The specific methodology of this technique is described according to seven steps: (1) permission request: (2) client observation: (3) session structure: (4) client confidence: (5) therapist trance: (6) feedback: and (7) subsequent utilization. Relevant clinical examples are provided.

**1982**

Stern, T. E. (1982). The effects of Ericksonian hypnosis and biofeedback on self-reported measures of pain (Dissertation). Dissertation Abstracts International, 43, 3744-B.

**NOTES**

Conducted a 6-subject case study comparing the effectiveness of so-called Ericksonian hypnosis and biofeedback on chronic pain. Two subjects improved more on subjective and behavioral pain measures using biofeedback, three improved more using hypnosis, and one did not improve in either condition.

**1981**

McConkey, Kevin M.; Sheehan, Peter W. (1981). The impact of videotape playback of hypnotic events on posthypnotic amnesia. Journal of Abnormal Psychology, 90 (1), 46-54.

Examined the breakdown of amnesia by showing 48 hypnotic and nonhypnotic undergraduates (Harvard Group Scale of Hypnotic Susceptibility) a videotape of the hypnotic events they had experienced. The extent of the amnesia for these events was defined precisely, and simulating procedures were employed to analyze the cues in the overall test situation. Videotape display of the hypnotic events was presented via the Experiential Analysis Technique and served to optimize conditions for breakdown. Some hypnotic Ss' amnesia could not be broken down even though they were exposed via videotape playback to the events to be recalled and when suggestions for the period of amnesia were quite explicit. Simulators showed breaching of amnesia but attributed their recall to the videotape rather than to the hypnotic session. Hypnotic Ss were distinctive in their inability to recall experiential aspects of their performance even though they could recall behavioral aspects. The data are discussed in relation to the hypothesis that dissociative cognitive mechanisms underlie posthypnotic amnesia. (22 ref).

1980

Crowley, R. (1980). Effects of indirect hypnosis (Rapid Induction Analgesia) for relief of acute pain associated with minor podiatric surgery (Dissertation). Dissertation Abstracts International, 40, 45-49.

#### NOTES

Lynn et al. (1993) cited this dissertation. They noted that all 30 volunteer subjects responded painfully when stimulated by a needle administered by a podiatrist and that the Rapid Induction Analgesia of Joseph Barber (RIA) was not as effective as local chemical analgesia. Furthermore, according to Lynn et al., RIA patients did not report a reduction in their anxiety following podiatric surgery comparable to that reported by patients who received chemical analgesia. The author also found that hypnotizability was related to multiple chronic pain indices.

Diamond, Michael Jay (1980). The client-as-hypnotist: Furthering hypnotherapeutic change. International Journal of Clinical and Experimental Hypnosis, 28, 197-207.

A novel hypnotic induction technique is described wherein the client reverses roles and serves as hypnotist for the therapist. Relevant theoretical processes are discussed as are mutual hypnosis, modeling, and the uncommon techniques of Erickson (1964). 3 case illustrations are presented and implications discussed. It is hypothesized that the 'client-as-hypnotist' may in certain special situations further hypnotherapy by: (a) increasing client motivation; (b) enhancing therapeutic rapport; (c) increasing both client trust and skills in utilizing unconscious processes; (d) overcoming resistance and increasing hypnotizability; (e) providing a useful psychodiagnostic and behavior assessment index; (f) presenting a role 'model' for dealing with feelings, alterations in consciousness, and self-control; (g) providing a client-centered framework for subsequent therapeutic interventions; (h) increasing client self-esteem, mastery, and ego strength; and (i) increasing client self-control skills. Potential risks and contraindications for use of the technique are also discussed.

Edwards, William Henry (1980). Direct versus indirect hypnosis for the relief of chronic pain in spinal cord injured patients (Dissertation, United States International University). Dissertation Abstracts International, 40 (10-B), 4996.

#### NOTES

This study compared effectiveness of direct hypnosis and indirect hypnosis (Rapid Induction Analgesia, developed by Joseph Barber) in reducing experimental and clinical pain in spinal cord injured patients. The 30 male paraplegic patients who had chronic benign pain volunteered for the study. They were administered three tests: the Pain Estimate Scale (Sternbach, 1974), Ischemic Muscle Pain Test (IMPT), and the Stanford Profile Hypnotic Susceptibility Scale, Form II -- SPHSS -- (Weitzenhoffer and Hilgard, 1967). Each patient experienced three sessions: (1) Baseline Control, (2) Direct Hypnosis, and (3) Indirect Hypnosis. Patients were randomly assigned to Sessions (2) and (3). The results indicated no significant statistical difference in the effectiveness of direct versus indirect hypnotic analgesia in these chronic pain patients. Direct and indirect hypnosis were equally effective; hypnotizability was not associated with outcome. Furthermore, there was no interaction between treatment effects and pretreatment pain level. The results were similar for both clinical and experimental pain.

1979

Araoz, Daniel L. (1979). Hypnosis in group-therapy. International Journal of Clinical and Experimental Hypnosis, 27 (1), 1-13.

Therapeutic groups are defined to include both therapy groups and enrichment or extensional groups, either goal-specific or goal-individualized. After reviewing the literature, 3 modalities for the use of 6 hypnotherapeutic techniques are presented. These modalities are: (a) simultaneous group hypnosis, (b) working with one member and then fostering group interaction, and (c) cooperative group self-hypnosis. The 6 group hypnotherapy techniques are: (a) relaxation, (b) positive revivification, (c) dream production, (d) age regression and recovery of early recollections, (e) age progression and mental rehearsal, and (f) ego strengthening. The need for research in group hypnotherapy is stressed, especially in the areas of transference, countertransference, and 'co-transference.'

Benson, Herbert; Frankel, Fred H.; Apfel, Roberta; Daniels, Michael D.; Schniewind, Henry E.; Nemiah, John C.; Sifneos, Peter E.; Crassweller, Karen D.; Greenwood, Martha M.; Kotch, Jamie B.; Arns, Patricia A.; Rosner, Bernard (1978). Treatment of anxiety: A

We have investigated prospectively the efficacy of two nonpharmacologic relaxation techniques in the therapy of anxiety. A simple, meditational relaxation technique (MT) that elicits the changes of decreased sympathetic nervous system activity was compared to a self-hypnosis technique (HT) in which relaxation, with or without altered perceptions, was suggested. 32 patients with anxiety neurosis were divided into 2 groups on the basis of their responsivity to hypnosis: moderate-high and low responsivity. The NIT or HT was then randomly assigned separately to each member of the two responsivity groups. Thus, 4 treatment groups were studied: moderate-high responsivity MT; low responsivity MT; moderate-high responsivity HT; and low responsivity HT. The low responsivity HT group, by definition largely incapable of achieving the altered perceptions essential to hypnosis, was designed as the control group. Patients were instructed to practice the assigned technique daily for 8 weeks. Change in anxiety was determined by three types of evaluation: psychiatric assessment; physiologic testing; and self-assessment. There was essentially no difference between the two techniques in therapeutic efficacy according to these evaluations. Psychiatric assessment revealed overall improvement in 34% of the patients and the self-rating assessment indicated improvement in 63% of the population. Patients who had moderate- high hypnotic responsivity, independent of the technique used, significantly improved on psychiatric assessment ( $p = 0.05$ ) and decreased average systolic blood pressure from 126.1 to 122.5 mm Hg over the 8-week period ( $p = 0.048$ ). The responsivity scores at the higher end of the hypnotic responsivity spectrum were proportionately correlated to greater decreases in systolic blood pressure ( $p = 0.075$ ) and to improvement by psychiatric assessment ( $p = 0.003$ ). There was, however, no consistent relation between hypnotic responsivity and the other assessments made, such as diastolic blood pressure, oxygen consumption,

heart rate and the self-rating questionnaires. The meditational and self-hypnosis techniques employed in this investigation are simple to use and effective in the therapy of anxiety.

Parker, Jerry C.; Gilbert, Gary S.; Thoreson, Richard W. (1978). Reduction of autonomic arousal in alcoholics: A comparison of relaxation and meditation techniques. Journal of Consulting and Clinical Psychology, 46 (5), 879-886.

To investigate and compare the effects of progressive relaxation training and meditation training on autonomic arousal in alcoholics, 30 subjects were selected from a population of alcoholics in a Veterans Administration hospital substance-abuse program. The subjects were randomly assigned to one of the following three experimental conditions: (a) progressive relaxation training group, (b) meditation training group, or (c) quiet rest control group. All groups met for 3 weeks during which state anxiety, blood pressure, heart rate, and spontaneous galvanic skin responses were measured. The measures were designed to assess the treatment effects following the first training session and at the end of the total training period. The results indicate that both progressive relaxation training and meditation training are useful for reducing blood pressure in alcoholics. In addition, significant differences between the groups in the effectiveness of the relaxation procedures were found. Meditation training induced blood pressure decreases at an earlier point in the 3-week training period and affected decreases in systolic blood pressure that progressive relaxation training did not. These results support the idea of considerable specificity of response to relaxation techniques.

Porter, J. W. (1978). Suggestions and success imagery for study problems. International Journal of Clinical and Experimental Hypnosis, 26, 63-75.

A procedure is presented for dealing with study problems in cases where patients come with an expectancy of help through hypnosis. Specific suggestions directly related to the study difficulty are given. "Success imagery" is outlined for use under hypnosis and by the student himself in his daily life. Two self-management techniques associated with the relaxation induced by exhalation are given further strength by being made posthypnotic suggestions. A direct posthypnotic suggestion for "concentration and recall" is combined with contingency management to effect more efficient performance when the decision is made to study. Four sessions are shown by clinical experience to be generally adequate to allow a transition from therapy to self-management of the problem aided by the student's own use of self-hypnosis. A general outline of how this is achieved for the first three sessions incorporates both Wolberg's (1965) suggestions to remove barriers preventing progress and Stanton's (1977) Rational-Emotive Therapy suggestions to strengthen the person's belief in himself.

Sanders, Shirley (1978). Creative problem-solving and psychotherapy. International Journal of Clinical and Experimental Hypnosis, 26, 15-21.

The techniques described comprise a creative problem-solving approach to short-term individual psychotherapy which appears effective in conjunction with hypnosis. The techniques include describing and visualizing the client's problem, imagining alternative reactions, dreaming about new solutions, and trying the solutions in real life. The method is illustrated by 2 clinical examples. The discussion focuses on a comparison of the techniques used with individuals versus with small groups, the fostering of regression in the service of the ego, and the redirection of attention from the physically out of control to the recognition of the possibility of obtaining control. This shift of attention fosters active coping on the part of the client.

Stanton, Harry E. (1978). A one-session hypnotic approach to modifying smoking behavior. International Journal of Clinical and Experimental Hypnosis, 26, 22-29.

Recent literature reviewing attempts to modify smoking behavior through the use of hypnosis is outlined, and an approach utilizing only 1 treatment is described. This single session includes: (a) the establishment of a favorable "mental set" on the part of the patient, (b) a hypnotic induction, (c) ego-enhancing suggestions, (d) specific suggestions directed toward the cessation of smoking, (e) an adaption of the "red balloon" visualization, and (f) success visualization. Of 75 patients treated by this technique, 45 ceased smoking. 6 months after the treatment session, 34, or 45%, were still nonsmokers, attesting to the efficacy of the method.

1977

Anderson, J. W. (1977). Defensive maneuvers in two incidents involving the Chevreul pendulum: A clinical note. International Journal of Clinical and Experimental Hypnosis, 25, 4-6.

#### NOTES

"Hypnosis frequently facilitates increased access to the unconscious. In both of these cases, the hypnotized subject gained contact with a thought which otherwise would likely have remained out of awareness. Then the ego quickly resorted to defensive maneuvers in order to deny the thought" (p. 6). Ansel, Edward Leslie (1977). A simple exercise to enhance response to hypnotherapy for migraine headache. International Journal of Clinical and Experimental Hypnosis, 25 (2), 68-71.

A common method of hypnotherapy for migraine headache utilizes suggestions of warmth for the hands and coldness for the head. This procedure reverses the abnormal pattern of vasodilation and excess supply of blood in the head and decreased supply in the extremities associated with this type of headache, thereby relieving the pain. A simple exercise, utilizing centrifugal force to dramatically increase blood flow to the hands, is described. It promotes relief in itself and provides a vivid background experience to enhance productino of this effect in hypnosis. It appears to be especially useful in patients exhibiting lesser degrees of trance capacity.

Barber, Joseph (1977). Rapid induction analgesia: A clinical report. American Journal of Clinical Hypnosis, 19, 138-149.

This is a report of clinical dental experience using a newly developed, hypnotic pain control procedure. Characteristics of the procedure are outlined, an explanation for its success is suggested, and the broader implications of this success are discussed. The unusually high incidence of clinical analgesia rapidly obtained with this procedure leads the author to question the meaning and relevance of the concept of 'hypnotic susceptibility' for the practical clinical application of hypnosis.

Dillbeck, Michael C. (1977). The effect of the transcendental meditation technique on anxiety level. Journal of Clinical Psychology, 33 (4), 1076-1078.

Two weeks of twice-daily practice of the Transcendental Meditation (Transcendental meditation) technique was compared with 2 weeks of twice-daily practice of passive relaxation as a means of reduction of anxiety, as measured by the Trait scale of the State-Trait Anxiety Inventory. Thirty-three graduate and undergraduate students were assigned randomly to a relaxation group and a Transcendental meditation group. After a 2-week experimental interval, the relaxation Ss began Transcendental meditation. As hypothesized, in the comparison between the relaxation and meditation Ss, as well as between conditions of the relaxation-meditation group, Transcendental meditation was

significantly more effective in reducing anxiety level. Thus, the anxiety-reducing effect of the practice of Transcendental meditation cannot be attributed merely to sitting quietly twice daily, although additional research must determine the extent to which S expectations for change contributed to this effect.

1975

Alexander, A. Barney (1975). An experimental test of assumptions relating to the use of electromyographic biofeedback as a general relaxation technique. Psychophysiology, 656-662.

Twenty-eight normal adults participated in an experimental test of two assumptions underlying the use of electromyographic (EMG) biofeedback as a general relaxation training technique: 1) that trained EMG reduction in one muscle generalizes to untrained muscles; and 2) that subjective feelings of relaxation are related to EMG reduction. An experimental group received 5 sessions, during the middle 3 of which EMG biofeedback training was offered on the frontalis muscle. Throughout all sessions, EMG recordings were also taken from the forearm and lower leg, and rating of subjective relaxation feelings were obtained at regular intervals. A control group, matched with the experimental group on baseline frontalis EMG, received 5 similar sessions without feedback. Employing a maximum  $p$  of .05, the results revealed no evidence of generalization of EMG reduction from the frontalis to the untrained sites, nor any tendency for successful frontalis EMG reduction to result in increased feelings of relaxation beyond what was obtainable from relaxing without the benefit of training. The results were interpreted as suggesting the EMG biofeedback cannot yet be accepted as a viable general relaxation training technique.

Mullen, G.; Perry, C. (1975). The effects of hypnotic susceptibility on reducing smoking behavior treated by a hypnotic technique. Journal of Clinical Psychology, 31, 498-505.

In order to examine the relationship between hypnotizability and treatment outcome in which hypnosis is used, 54 people ages 19-47 who undertook to stop smoking were studied. Although it is logical that there should be a relationship, clinical anecdotal material published by people who used hypnosis (Freud, Weitzenhoffer, Lazarus, Sheehan, Orne) suggests that may not be the case. Hypnotic susceptibility was evaluated with a clinical procedure developed by Orne and O'Connell (the DRP). Patients were taught self hypnosis using a brief procedure developed by Herbert Spiegel. Baseline smoking rate and three-month follow-up with postcards mailed every week were employed as measures. Success in the treatment program was defined as a 50% reduction in smoking behavior. After 3 months, 7 people were abstinent, 10 had reduced smoking to criterion level (50%), 16 people had discontinued the investigation, and 21 did not change. Considering only the 15 most and 15 least hypnotizable, 12 of the 15 high susceptibles had reduced smoking by at least 50%, as compared to 5 of the 15 of the low susceptibles. ( $\chi^2 = 4.88$ ,  $df = 1$ ,  $p < .05$ ).

1971

Aiken, Linda H.; Henrichs, Theodore F. (1971). Systematic relaxation as a nursing intervention technique with open heart surgery patients. Nursing Research, 20, 212-217.

## NOTES

Psychiatric problems frequently occur after open heart surgery, usually from day 2 to day 7 postoperatively. Symptoms include impairment of consciousness, disorientation, sensory disturbances like visual and auditory hallucination, and sometimes delusions and paranoid behavior. Authors defined a postoperative adverse reaction as "when the patient experienced impairment of consciousness with motor restlessness, disordered thinking, sensory disturbances, visual and/or

auditory illusions or hallucinations, and paranoid ideation. All of these symptoms do not usually occur together and an additional definition was given for a minor reaction which occurred if only one of the above symptoms was present for 12 hours or less" (p. 214).

The population from which samples were drawn consisted of adult male patients admitted to a university medical center for open heart surgery. The experimental group (N = 15) consisted of all patients admitted from September 1969 through June 1970 (omitting two who were not willing to participate). Controls were 15 adult males admitted for open heart surgery in the prior year.

A relaxation and systematic desensitization technique was used for the experimental group, each patient being given a tape recorder with a 15-minute tape of the exercise "to use whenever he wanted to relax" (p. 214) but at the least four times a day.

On basis of previous research one would expect postoperative adverse reactions of 40% but the Relaxation group had only 8%. (The control group had 27%, but the difference between groups was not significant with Fisher's exact probability test-- $p < .10$ .) Mortality rate was same in both groups.

The results must be interpreted in the context of differences between groups during surgery, which may or may not relate to the intervention. The Relaxation Group was significantly lower than Control Group on 4 of 5 surgical risk factors: anesthesia time, cardiopulmonary bypass time, total units of blood, and degree of hypothermia. They were (nonsignificantly) better on duration of hypothermia; and there was no difference on multivalve replacement. This suggests the Relaxation Group were less exposed to these factors to a significant degree.

**Discussion:** The groups were matched on age, sex, preoperative diagnosis, type of surgical procedure, incidence of severe economic problems, family adjustment problems, and history of psychiatric problems (i.e. the groups did not differ). "The major difference between the two groups was in relation to the surgical stress factors studied: degree of hypothermia, amount of time on cardiopulmonary bypass, anesthesia time, and total units of blood received. The experimental group was significantly lower on mean values for all of these stress factors. Without further research it is impossible to conclude that these factors did or did not influence the lower incidence of postoperative reactions found in the experimental group. It should be noted, however, that the decreased surgical stress factors had no apparent effect on reducing mortality in this sample. Also as previously stated, prior research has not been able to demonstrate a direct relationship between these surgical stress factors and the incidence of postoperative reactions" (p. 215).

"The population used in this research ranged from patients with mild symptoms of heart disease to those with severe decompensation and congestive heart failure. It was anticipated prior to beginning the research that some patients would be physically incapable of cooperating due to fatigue and dyspnea; this prove not to be the case" (p. 216).

This intervention is usable by nurses, and "provides an alternative which the professional nurse may prescribe after systematically assessing a patient's needs" (p. 216). "It is a new skill to be learned that is comparable to the skill of giving an injection or learning to recognize arrhythmias. The amount of time required to teach a patient the technique of systematic relaxation is realistically within the scope of any staff nurse's role" (p. 216).

## 1970

Hall, J. A.; Crasilneck, H. B. (1970). Development of a hypnotic technique for treating chronic cigarette smoking. International Journal of Clinical and Experimental Hypnosis, 18, 283-289.

4 hypnotic sessions were found successful, in the majority of cases, in eliminating cigarette smoking without undesirable substitution symptoms. Patients were strongly motivated by the referring physicians and by various nonhypnotic techniques incorporated into the treatment program. Examples are given of the specific nature of both the hypnotic and the nonhypnotic suggestions employed. (German & Spanish summaries) (PsycINFO Database Record (c) 2002 APA, all rights reserved)

**Maher-Loughnan, G. P. (1970). Hypnosis and auto-hypnosis for the treatment of asthma. International Journal of Clinical and Experimental Hypnosis, 18 (1), 1-14.**

Conducted 2 controlled studies into the use of hypnosis in 252 asthma patients. Several different control procedures were used. Methods and results were summarized, and the same conclusion was reached: That hypnosis supplemented by autohypnosis was significantly more effective than control procedures. An outline is given of details of treatment methods. A current analysis of Ss involving up to 6 yr. of follow-up, is presented to provide a working guide to the regime in regular practice. To be fully effective hypnosis should be employed before steroids are started. Steroid-dependent asthma is rarely totally relieved by hypnotherapy. (Spanish & German summaries) (PsycINFO Database Record (c) 2003 APA, all rights reserved)

**1969**

**Raginsky, Bernard B. (1969). Hypnotic recall of aircrash cause. International Journal of Clinical and Experimental Hypnosis, 17, 1-19.**

Discusses the use of hypnotic techniques to help a 33-yr-old male recall suppressed material which implicated him in an aircrash. The cause was found after 2 short hypnotic sessions, where other methods used over 2 years had failed. The method can be used in all cases of amnesia. The S was made to hallucinate a threatening situation, and his hallucination gave a clue to the basic problem. He was then made to hallucinate a pleasant scene, which gave an indication of the method he used to escape from the problem. This was repeated at the 2nd session for confirmation. If the patient did not bring up the required material by free association under hypnosis, a dissociation of the personality induced in which the observing ego watched what the experiencing ego was doing to cause the accident. The results demonstrated that hypnotic techniques were more successful than sodium amytal interviews, free association, psychiatric interviews, physical and emotional isolation, pressure by authorities, and kindness of friends. Reference was made to the problems involved when the interests of the S were in conflict with public safety. (Spanish & German summaries) (PsycINFO Database Record (c) 2002 APA, all rights reserved)

**1967**

**Evans, Frederick J. (1967). An experimental indirect technique for the induction of hypnosis without awareness. International Journal of Clinical and Experimental Hypnosis, 15, 72-85.**

A procedure is described which has been used in an experimental setting as a method of indirectly inducing hypnosis without S's awareness. Ss are not told that hypnosis is involved in the procedure, but are told they will be taught how to relax. The aim of the indirect procedure is to create different expectations and preconceptions from those normally occurring in the special hypnotic relationship. Evidence from 3 studies (samples of 63, 63, 120) indicates that the procedure successfully induces hypnosis comparable in depth to other standard hypnotic procedures. About half of the Ss tested apparently do not recognize the procedure involves hypnosis. Approximately 30% of the Ss who receive the procedure, as well as 30% of the Ss in the control group who did not receive the procedure, but were tested with the same test suggestions, recognized that an attempt had been made to induce hypnosis. The perceptions about whether hypnosis was involved were unrelated to scores on typical hypnotic phenomena. It was concluded that the indirect induction technique successfully induces hypnosis and is a useful technique for manipulating S-expectations in an experimental context.

**NOTES**

"[The Subject] is told, 'A series of experiments are being conducted investigating the effects of relaxation on behavior. Because of confusing results in the literature, this study is designed to examine the relationship between relaxation and several other psychological phenomena, some of which might remind you of a variety of other phenomena which you may have heard or read about.' The S was told that a technique had been devised that would assist him to relax completely. His main task was to relax as completely as possible. This would be facilitated by lying comfortably on a couch, and by allowing his mind to become completely blank. To prevent himself from falling asleep, he should concentrate his attention on some object or idea. To help exclude other thoughts from his mind, E would continue to talk in a monotonous voice saying little of importance, while the S stared at a spot on the wall. This shaping of the situation was continued with a considerable degree of apparent permissiveness.

"The S's attention was slowly directed to the rhythm of his own breathing as suggestions were given of eye fatigue. If S closed his eyes, he might find it convenient to concentrate on the rhythm of his own breathing. Perhaps this would be easy to think about if he visualized a pendulum swinging in time with his breathing. The E continued to talk and count in rhythm with S's breathing. Special words, such as 'breathing in and out; the pendulum swings back and forward,' were always spoken as S inhaled or exhaled. Counting was also timed to coincide with exhalation. Deeper relaxation was suggested as E counted slowly from 1 to 21, and later, from 1 to 31.

"Throughout the procedure, phrases and words (such as 'hypnosis,' 'trance,' 'drowsy') traditionally employed with hypnotic induction techniques were avoided. After approximately 30 minutes, a natural transition was made to the testing procedure. Suggestions of continued deep relaxation were intermingled between various tests administered. Termination was effected by suggesting that the relaxation would end as E counted from 'A' to 'H'" (p. 75).

1965

Halpern, Seymore (1965). Body-image symbols of repression. International Journal of Clinical and Experimental Hypnosis, 13 (2), 83-91.

Hypnointrospection, a method of hypnoanalysis which emphasizes self-perception during voluntary immobilization, is of demonstrable value in the elucidation of the problem of body-image. Hypnointrospective fragments of a case history showing the reorganization of the body-image during therapy are presented. The sequence of body-image phenomena is interpreted as an expression of attitudinal compromises among conflicting wishes implemented through neuromuscular channels. The continuous reorganization of the physical self as perceived by the patient during hypnointrospective analysis appears to be of significance for a general theory of body-image. Jackson, Bill (1965). The autoblink: A technique to explore nonveridical visual perception. International Journal of Clinical and Experimental Hypnosis, 13 (4), 250-260.

The Autoblink technique was developed to allow objective, quantitative investigation of perceptual abnormalities found in psychiatric and normal populations under various experimental conditions. A pilot study demonstrated that spontaneous visual percepts could be elicited by this technique in a group of psychiatric patients and that wide individual differences were present. A 2nd study found significant differences in Autoblink rate between normal and hallucinating psychotic male Ss and also suggested that sensory deprivation and prestige suggestion are variables related to Autoblink rate. A 3rd study further explored differences between psychiatric patients and normal Ss as well as examining sex differences. The latter 2 studies are reported in detail. 1964

Ludwig, Arnold M.; Lyle, William H., Jr.; Miller, Jerome S. (1964). Group hypnotherapy techniques with drug addicts. International Journal of Clinical and Experimental Hypnosis, 12 (2), 53-66.

This study was designed to investigate the appropriateness of a number of group hypnotherapeutic techniques which might be used in the treatment of addict patients. It is the belief of the investigators that the more "magical," "authoritative," and practical-oriented techniques seem more appropriate and useful than techniques designed to elicit deep, insightful understanding of the emotional problems underlying drug addiction. Many of the specific hypnotherapeutic techniques used are described, and some of the difficulties and advantages of group hypnosis as a treatment method are discussed. Rose, J. T. (1962). The use of relevant life experiences as the basis for suggestive therapy. International Journal of Clinical and Experimental Hypnosis, 10, 221-229. (Abstracted in *Imagery* 63: Mar., S-543)

A brief, directive method of hypnotherapy is described which combines limited insight therapy with hypnotic suggestions based on relevant life experiences of the patient. By integrating suggestions and experiences familiar to the patient, the former are more likely to have greater meaning to the patient and are therefore more effective. (PsycINFO Database Record (c) 2002 APA, all rights reserved)

1961

Cheek, David B. (1961). Value of ideomotor sex-determination technique of LeCron for uncovering subconscious fear in obstetric patients. International Journal of Clinical and Experimental Hypnosis, 9, 249-259.

(Author's Summary) "Unrecognized subconscious fears can be uncovered while using ideomotor questioning with a Chevreul pendulum or with finger signals. The technique described by LeCron for evaluating knowledge regarding the sex of an unborn child is a most helpful way of approaching subconscious fears. The frightened patient refuses to indicate knowledge of the sex of her unborn child. Uncovered fears can be resolved by appealing to conscious-level understanding with adroit questioning" (p. 258).

McCartney, James L. (1961). A half century of personal experience with hypnosis. International Journal of Clinical and Experimental Hypnosis, 9, 23-33.

NOTES

(Author's Summary and Conclusions). "After fifty years of experience with hypnosis, it is evident that it is not a superficial and careless technic but should be utilized only by capable, trained physicians, as are the other complex and difficult medical technics. ... In order to induce hypnosis, the patient must be perfectly willing to be hypnotized, he must have confidence in the practitioner, and he must concentrate on doing exactly as he is told. In selected cases, drugs or electrical impulses may be used

for the initial induction of hypnotic sleep, but if hypnotherapy is to be continued, the physician must keep in contact with the patient by repeated suggestions. The technic used should fit the individual patient, but in most cases, verbal suggestions are all that is necessary to bring about dissociation. Hypnosis may be used to facilitate the beginning of mental catharsis, the establishment of transference, and may be easily instituted following narcosynthesis, electroshock therapy, minimum stimulus, or Sedac. Suggested activity under hypnosis may be carried out at a designated time, place, and manner after awakening. This is a result of autosuggestion and may be mistaken for psychopathic behavior. Such suggestions may be instituted by television, movies, radio, telephone, or recorded or written instruction. Hypnosis may be used to plant suggestions; if misused, it may create an obsessive-compulsive neurosis, while when properly used, it may overcome many functional symptoms and may be used to supplement other forms of psychotherapy" (p. 32).

Skemp, Richard R. (1961). Note on an hypnotic induction device. International Journal of Clinical and Experimental Hypnosis, 9 (4), 303-304.

## NOTES

Author describes a technique for increasing suggestibility by causing the person to experience effects that he believes are caused by the hypnotist. "If one fixates the edge of a coloured strip on a white background, a narrow line of deeper colour will be seen close to the edge. This is because small movements of the fixation point bring this strip, for part of the time, on to an area of the retina which has been fatigued by the white. (The effect is best obtained if the colour is unsaturated). At the same time a narrow strip of brighter white will appear along the other side of the edge. If fixation is continued, this band of brighter white gradually takes on the colour complementary to that of the coloured band. These effects are unexpected to a naive subject, and therefore satisfy the requirements for a feed-back process" (p. 303). Thus, if the color is red, then the hypnotist suggests that a green line will appear, that the green band will continue to become greener, the red part redder; then suggests that the eyes will blink faster and faster, eventually closing, etc. After the eyes are closed, the suggestion that one will continue to see the green line is given.

## 1960

Conn, Jacob H. (1960). The psychodynamics of recovery under hypnosis. International Journal of Clinical and Experimental Hypnosis, 8, 3-16.

Defines hypnosis as primarily a change in reality testing, and considers it as both an altered state of consciousness and a multilevel dynamic relationship in which the S is always aware of the operator. Hypnosynthesis emphasizes the patient's values and expectations and his freedom to choose what to say and how he should be treated. Preference is given to terms of "more or less" consciousness. The patient does not receive any training in hypnosis and there is no encouragement of acting out in hypnosynthesis. Attention is directed to repetitive patterns, and the hypnotic experience is utilized as a present dynamic experience. Hypnosynthesis demonstrates that symptom removal is possible without symptom substitution when there is an effective working relationship. The common factor in every psychogenic cure, including hypnotherapy, is the fostering of self-esteem and active participation, both of which are achieved by effective collaboration in the therapeutic situation. ## 1959

Kroger, William S.; Schneider, Sidney A. (1959). An electronic aid for hypnotic induction: A preliminary report. International Journal of Clinical and Experimental Hypnosis, 7, 93-98.

## NOTES

The BWS or brain wave synchronizer is "an instrument specifically designed to induce various levels of hypnosis by subliminal and photic stimulation of the brain waves" (p. 93). It was developed after noticing that radar operators on ships sometimes fell into deep hypnotic states while watching signals on a radar screen. It has been used with 2500 subjects, 200 of whom were receiving pre-natal training for childbirth under hypnosis.

"For the first five minutes there is a gradual increase in the number of subjects who enter deep hypnosis. At this level, a figure of 50% reach the deep state" (p. 95).

The instructions given were, "Concentrate on the center of the instrument. When your eyes become tired and heavy, as they will, just let them close and feel yourself going deeper and deeper into a relaxed state." It is acknowledged that this procedure worked when Ss expected to experience hypnosis; the rate of deep hypnosis increased as the expectancy of hypnosis increased. "Deep hypnosis in individual inductions reached 80% under the following conditions:

A. Synchronizer on 5 minutes

B. Expectation Level of 50 [on a scale in which 100 represented having seen demonstrations of conventional hypnosis and an explanation of what the instrument would do]" (p. 97).

Pascal, G. R.; Salzberg, H. C. (1959). A systematic approach to inducing hypnotic behavior. International Journal of Clinical and Experimental Hypnosis, 7 (3), 161-167.

## NOTES

"Summary

The paper reports an experiment in inducing hypnotic behavior. Hypnotic behavior is considered as operant behavior subject to the principles of such behavior. Using a procedure based on this systematic position 52 per cent of 56 subjects were brought to the deep trance state in one session, a considerable gain over results reported in the literature. It is felt that the approach presented suggests that hypnosis may be brought into the realm of behavioral science" (p. 166).

A detailed description of the procedure is provided. It begins with providing information, establishing rapport, using demonstrations of hypnotic-like behavior (the Kohnstamm phenomenon and body sway suggestions), followed by relaxation in a stimulus-attenuated room with verbal suggestions and operant (verbal) reinforcement. It proceeds with a series of frankly hypnotic suggestions for arm analgesia and lightness/floating, amnesia, etc.

Moss, C. Scott (1957). A forced hypnoprojective fantasy used in the resolution of pseudo-epileptic seizures. Journal of Clinical and Experimental Hypnosis, 5 (2), 59-66. (Abstracted in Psychological Abstracts, 58: 5812)

## NOTES

A dream that occurred in natural sleep was used as the starting point for exploration in hypnosis, e.g. suggesting that the patient was seated in a movie theater and would see an element that had been in the dream, projected on the movie screen; then would see substitute pictures which had for him the same meaning as that element. "... as in the dream, commitments to reality [in hypnosis] are minimized and there are evidences of the archaic drive-oriented primary process and a loss of distance from the fantasy so that it becomes a transitory hallucinatory experience. In addition, the censorship function is reduced but not eliminated so that this case study is highlighted by the defensive symbolic substitutions provoked by the persistent demands of the therapist" (pp. 64-65).

Solovey, Galina; Milechnin, Anatol (1956). Concerning some points about the nature of hypnosis. Journal of Clinical and Experimental Hypnosis, 4 (2), 83-88.

Two experiments with young children explored the similarity between mothers' sleep inducing speech and hypnotic induction. The first group were six normal children ranging in age from 25 to 37 months. Author interviewed their mothers for details on their sleep inducing behavior. Then "we followed a procedure that as a rule consisted in leaning over the little one, dedicating all our attention to him, repeating the mother's own series of soothing diminutives in a softly-modulated voice, and stroking gently the child's hair, forehead, or arm. In four to thirty-five minutes, the children relaxed, stopped moving, let their eyelids droop, and showed a particularly placid facial expression. Their appearance was completely similar to that of a hypnotized person" (p. 83). Signs of catalepsy (e.g. following suggestions of holding a teddy bear more and more tightly) and concentration of attention to the exclusion of outside stimuli were taken to indicate the hypnotic state.

The second experiment involved infants 3 to 24 months old, lulling them into a state of quiet relaxation. "The difficulty does not consist in producing this special state, but in demonstrating that it is really hypnosis. However, if we consider the identity of the means employed in bringing it about, and the similarity of the results to those occurring at a slightly later age, it would be unreasonable to think that there is a certain reaction up to a certain age and a fundamentally different one from that age on" (p. 85).

The author relates her findings to those of investigators who studied populations of infants and children who, lacking "psychological mothering" failed to thrive or even died. She concludes that the "psychological mothering" in normal families "produces hypnotic states in the infant daily, from the moment of birth" (p. 88).

1955

Ambrose, Gordon (1955). Multiple sclerosis and treatment by hypnotherapy. Follow-up and further cases. Journal of Clinical and Experimental Hypnosis, 3 (4), 203-209.

NOTES

"Summary. Present day treatment of multiple sclerosis appears inadequate from the psychological view point and patients are too often forced to show a negative response to their illness.

"Six patients have been treated by hypnotherapy with marked subjective improvement. Three of these cases are described.

"The aim in these cases is to put the patient more in control of his organism. Patients should be told that their symptoms must never control them, they must control their symptoms.

"The very nature of the illness prevents the medical attendant from feeling scientific in his approach to these cases. Long follow-up is a necessity but much subjective improvement is possible using hypnotherapy.

"In the hypnoanalytical approach the usual exaggeration of the emotions allied with the psychosomatic reaction will often be found. Hypnosis appears to produce a rapid lessening of tension and anxiety in these cases.

"A deep state of hypnosis should be aimed at and auto-hypnosis must always be taught. It is sometimes useful to place a trusted person en rapport with the patient to carry on with positive and direct suggestions.

Hart, Hornell (1955). Measuring some results of autohypnosis. Journal of Clinical and Experimental Hypnosis, 3 (4), 229-242.

NOTES

The author developed self ratings for mood (euphoria-dysphoria) and alertness-fatigue, which were administered to college students in neutral conditions and after self-hypnosis conditions. The self hypnosis, or "auto-conditioning" usually involved deep relaxation self suggestions followed by other

suggestions. The suggestions involved using the word 'you' to be able to re-instate the autoconditioning more and more effectively; suggestions for attitude change (e.g. that 'No matter what comes, we will grapple with it courageously'); and euphoria auto-suggestions (e.g. that 'you will come out of this deep relaxation, feeling rested, alert, cheerful and courageous').

In both single session experiments, as with a class of nurses who experienced an 8 minute auto-conditioning procedure, and in experiments extending over time, depression decreased. He noted that "for various reasons, the students who participated in autoconditioning experiments between February and May, 1955, were in many respects less successful than some of the previous experimental groups had been" (p. 235).

Increased alertness and diminished fatigue was also observed.

Many students chose to give themselves suggestions to correct the habit of procrastination. Two-thirds of the participants reported complete success, up to the level specified, and only one of 43 experiments on correcting procrastination was a "flat failure."

Schneck, Jerome M. (1955). Hypnosis-death and hypnosis-rebirth concepts in relation to hypnosis theory. Journal of Clinical and Experimental Hypnosis, 3 (1), 40-43.

#### NOTES

The author presents a few case notes in support of his proposition that hypnosis is symbolically connected with ideas of death and rebirth in some patients. The final sentence of this article reads, "The unconscious identification of the hypnotic state with processes relating to death and rebirth may be involved far more frequently than realized with widespread belief regarding alleged remarkable beneficial effects of the hypnotic state and procedure which incorporates simple, authoritative suggestion" (pp. 42-43).

Schneck, Jerome M. (1955). Hypnotic interviews with the therapist in fantasy. Journal of Clinical and Experimental Hypnosis, 3 (2), 109-116. (Abstracted in Psychological Abstracts, 56: 1126)

" Summary. This report furnishes illustrations from two patients of the technique consisting of hypnosis interviews conducted by the patients with the therapist in fantasy. This method emerged from previous work with visual imagery in the form of scene visualization and some of its derivatives. The writer believes that further work with the technique presented now may prove to be beneficial in psychotherapy. At the same time it offers an opportunity for further study of personality functioning in general and certain aspects of psychodynamics. The patients manipulate the session in a way which furthers a duality in their functioning as a result of which they attempt to probe and contend with contradictory tensions in their unconscious. The image of the therapist undergoes certain distortions demonstrating dynamisms such as projection and identification as utilized by the patient. The therapist is in a position to view all of this and to discern elements in his relationship with the patient which may otherwise have escaped him. Countertransference issues may be clarified in this way. The technique may assist at points where the therapist seems to be functioning too blindly and where the patient may more pointedly show the way by guiding the therapist while relating to a mental image of him. There is a possibility that some aspects of this approach in treatment may prove of value in psychotherapy which does not incorporate hypnosis. This may be of assistance to workers who have not been trained in hypnotherapy" (pp. 115-116).

Erickson, Milton H. (1954). Pseudo-orientation in time as an hypnotherapeutic procedure. Journal of Clinical and Experimental Hypnosis, 2 (4), 261-283. (Abstracted in Psychological Abstracts 55: 5753)

#### NOTES

The author reports employing an experimental therapy technique, projection into future time while in

hypnosis, with five patients. "This technique was formulated by a utilization of those common experiences and understandings embraced in the general appreciation that practice leads to perfection, that action once initiated tends to continue and that deeds are the offspring of hope and expectancy. These ideas are utilized to create a therapy situation in which the patient could respond effectively psychologically to desired therapeutic goals as actualities already achieved. ... 'time projection'" (p. 261).

Erickson, Milton H. (1954). Special techniques of brief hypnotherapy. Journal of Clinical and Experimental Hypnosis, 2, 109-129. (Abstracted in Psychological Abstracts 55: 2508)

#### NOTES

Author describes techniques used with patients who aren't able, for internal or environmental reasons, to undertake comprehensive therapy, "Intentionally utilizing neurotic symptomatology to meet the unique needs of the patient" (p. 109). He provides 8 case reports.

Patient 1 was reassured, in hypnosis, that his arm paralysis was due to "inertia syndrome" which he would continue to have, but it wouldn't interfere with his work.

Patient 2, also with arm paralysis had another comparable, non-incapacitating, symptom substituted.

Patients 3 and 4, for whom restrictions on therapy were the limits of time and situational realities, had their symptoms transformed (e.g. by introducing in hypnosis the obsessional thought or worry that he would NOT have the symptom for which he sought help).

Patients 5 and 6 were helped, through hypnosis, to symptom amelioration. (Patient 5 had an IQ of 65.)

Patient 7 "Therapy was achieved ... by a deliberate correction of immediate emotional responses without rejecting them and the utilization of time to palliate and to force a correction of the problem by the intensity of the emotional reaction to its definition" (p. 121)

Patient 8 "the procedure was the deliberate development, at a near conscious level, of an immediately stronger emotion in a situation compelling an emotional response corrective, in turn, upon the actual problem" (p. 121).

Erickson, Milton H. (1954). The development of an acute limited obsessional hysterical state in a normal hypnotic subject. Journal of Clinical and Experimental Hypnosis, 2, 27-41.

#### NOTES

The 25 year old female graduate student in psychology had often been used in hypnosis experiments and as a demonstration subject, and had witnessed induction of hypnotic deafness, blindness, and color-blindness though she had not been given those suggestions herself. Scientific curiosity appeared to be the motivation for volunteering to experience hypnotic blindness, but she was skeptical about her ability to experience it. The author gave a series of "exceedingly tedious" suggestions to develop somnambulism (passively responsive and receptive) followed by suggestions leading gradually to development of "blindness" with the intention of concealing it from the hypnotist, with attendant strong and mixed emotions.

The initial attempts failed because the subject ostensibly was deceiving herself into thinking she had developed hypnotic blindness, but the author also was of the opinion that she was seeking to meet unconscious personality needs. The author then covertly changed the goal of the experiment "to develop in the subject an acute hysterical obsessional compulsive mental state which would be accompanied by hypnotic blindness and which would parallel or resemble the obsessive compulsive hysterical mental disturbances encountered in psychiatric practice" (p. 32). The author developed a monologue of suggestions based in part on the utterances of hospitalized obsessive patients and in part on trauma relating to traumatic blindness in a kitten and a friend of the subject. In a slow but directed manner the author built up a double-bind situation which eventually led to the experience of hypnotic blindness as well as heightened emotional reactivity, crying etc.

Kline, Milton V.; Guze, Henry (1954). The alteration of oral temperature through hypnotic techniques: I. Pilot experimentation. Journal of Clinical and Experimental Hypnosis, 2 (3), 233-237.

#### NOTES

The authors used a variety of hypnotic techniques to attempt to modify the oral temperature of a normal 30 year old male who was capable of both positive and negative hypnotic hallucinations and of reaching a somnambulistic level with spontaneous, complete, post-hypnotic amnesia. Techniques included direct suggestions (general for temperature rising as when ill, and specific, i.e. his oral area was getting hot), time regression to when he had experienced a fever, age regression to age 10 when he had a high fever, direct suggestion of temperature drop, and positive hallucination of extreme elevation in a plane. A waking simulation control was run for each condition.

Although the subject appeared uncomfortable and showed behavioral changes, the mean oral temperatures did not differ from the baseline mean significantly for either hypnosis or simulation conditions, except for the hallucinated experience of flying in a plane at an altitude of 100,000 feet. That condition lowered the temperature an average of 3 degrees Fahrenheit. In that experimental condition there was no mention of temperature alteration per se, "thus indirect mechanism rather than direct mechanism appears to be more effective in the hypnotic control of temperature" (p. 237).

LeCron, Leslie M. (1954). A hypnotic technique for uncovering unconscious material. Journal of Clinical and Experimental Hypnosis, 2, 76-79. (Abstracted in Psychological Abstracts, 54: 7497)

"Summary. A technique is given whereby unconscious material and information may be learned under hypnosis through automatic movements of the fingers, or of Chevreul's pendulum. The movements are controlled by the unconscious mind of the patient. Questions are asked which can be answered either 'yes' or 'no.' With most people the movements of the pendulum can even be elicited in the waking state. Essentially, the method is a variation of automatic writing with movements substituted for writing. A brief case history is given wherein knowledge was gained in this way as to the causes for severe menstrual pains" (p. 79).

Rosen, Harold; Erickson, Milton H. (1954). The hypnotic and hypnotherapeutic investigation and determination of symptom-function. Journal of Clinical and Experimental Hypnosis, 2 (3), 201-219. (Abstracted in Psychological Abstracts, 55: 7017)

#### NOTES

"Summary.

1. Symptoms and even syndromes may subserve the repetitive enactment of traumatic events; may reproduce, instead, specific life situations; may satisfy repressed erotic and aggressive impulses; or may at one and the same time constitute defenses against, and punishment for, underlying instinctual drives. They may mask underlying schizophrenic reactions, or hold suicidal depressions in check. They may serve these and other functions concurrently, or none, or any specific one or combination of them.

2. With selected patients under hypnosis, symptom-function may be determined rapidly and in a therapeutic setting. Various techniques can be utilized. Attacks may be precipitated and then blocked, either by direct hypnotic suggestion or by regressing the patient to a period pre-dating the onset of his disease, so that substitutive motor or other activity will be precipitated in a form accessible to therapeutic investigation; attacks may be precipitated in slow motion, so that individual components can be therapeutically investigated in detail; dissociated states may be induced; dream acting-out may be suggested; or symptoms may be suggested away while emotions back of symptoms are concurrently

intensified, so that, again, underlying dynamic material will immediately become accessible for therapy. Still other techniques may be utilized.

3. If treatment, as well as evaluation, be through these techniques, and if treatment be successful, it may be that the analogy of a log jam will be of value. The jam can usually be broken by pulling out one or two key logs. The rest then start falling into place -- and the whole log jam disappears. This may be what happens, although to a limited extent, during therapy of this type.

4. Various of these techniques have been illustrated throughout this paper. Case histories however, have at times been distorted in order to maintain the anonymity of the patients involved" (pp. 218-219).

Schneck, Jerome M. (1954). A hypnoanalytic investigation of psychogenic dyspnea with the use of induced auditory hallucinations and special additional hypnotic techniques. Journal of Clinical and Experimental Hypnosis, 2, 80-90.

"Summary. This paper describes in detail and with discussion the hypnoanalytic session which was instrumental in relieving a patient of severe dyspnea and fatigue based on intense, long standing psychological conflict. The conflict entailed the intermingling of past concerns and current pressing problems. These had to do with the patient's long repressed feelings about having been told that her birth had been unplanned. They related to current indecision about becoming pregnant. Attitudes toward her parents were significant and these involved mixed feelings with the significance of her conscious and unconscious images of them. Into this picture there were projected the patient's attitudes toward herself and her methods of functioning somatically as well as psychologically. The symbolic connotation of her symptoms as deterioration and dying in relation to needs for self-destruction were clarified. The symptoms of one and a half to two years duration were dissipated within a few hours and improvement had been maintained for more than a year at the time of writing.

"The use of induced music associations in order to make inroads into the core of the conflict is described. The dynamic significance of spontaneous choice of such theme [sic] is discussed. Other hypnotic techniques involve visual imagery with dream-like qualities and in the form of scene visualizations (8, 9). Attention is centered on induced auditory hallucinations and interesting facets of such experiences are discussed in relation to subjective and objective qualities of such hallucinations and the issue of dynamic validity" (p. 90).

Schneck, Jerome M. (1954). Hypnotherapy in a case of claustrophobia and its implications for psychotherapy in general. Journal of Clinical and Experimental Hypnosis, 2 (4), 251-260. (Abstracted in Psychological Abstracts, 55: 6064)

## NOTES

"Summary. This report presents the hypnotherapy of a patient with claustrophobia. The crucial event responsible for symptom formation occurred in military service when the patient was trapped in a trench by a tank which stopped over the patient before proceeding, and at which time the sides of the trench began to cave in. Subsequent traumatic events served as reenforcement. It is likely that a low threshold for the development of anxiety predisposed this patient to the development of the claustrophobia, although the major trauma sustained was undoubtedly of tremendous impact and a distinct threat to life. Emotional experiences were sealed and free expression was permitted through hypnotic revivification. The dynamics, further elaborated in the report, suggest that similar occurrences not necessarily in military settings may be approached therapeutically in this way. Aside from the reliving technique, recall stimulation through a dream induction approach was employed. Other hypnotic methods were described and further implications for psychotherapy in general were

elaborated. Hypnotherapeutic and hypnoanalytic approaches to phobic reactions have been described at length elsewhere" (p. 260).

**Kline, Milton V. (1953). Delimited hypnotherapy: The acceptance of resistance in the treatment of a long standing neurodermatitis with a sensory imagery technique. Journal of Clinical and Experimental Hypnosis, 1 (4), 18-22.**

**Author's Summary - A case of experimental hypnotherapy of a chronic neurodermatitis has been presented within which the resistance of the patient was accepted as reasonable. Therapy was structured by the patient's limitations and the results, at least in this one case, justified the procedure. It is suggested that a more global perception of resistance be recognized apart from its unconscious meaning and that cognitive aspects of resistance be evaluated and utilized in treatment planning. The problem of an artifact neurotic reaction in resistance oriented therapy is discussed.**

**Kline, Milton V. (1953). Hypnotic retrogression: A neuropsychological theory of age regression and progression. Journal of Clinical and Experimental Hypnosis, 1, 21-28.**

**Author's Summary - In a review of the salient aspects of research in hypnotic age regression an evaluation of the data tended to indicate that under certain conditions valid age regression is discussed in the light of a neuropsychological theory of age regression. This theory based upon a concept of hypnotic retrogression views regression and progression phenomena in hypnosis as a form of psychological activity involving disorientation for the subject and a reorganization of his perceptual equilibrium and control mechanisms with particular reference to time-space perception. The term hypnotic retrogression is used to describe the centrally induced state which alters time-space perception and renders hypnotic regression and progression possible.**

**Rosen, Harold (1953). Hypnodiagnostic and hypnotherapeutic fantasy---evocation and acting-out techniques. Journal of Clinical and Experimental Hypnosis, 1 (1), 54-66.**

## **NOTES**

**Developed techniques to reach patients who have little motivation for psychotherapy, sometimes hypnotizing them without their knowledge or conscious consent. "By still other techniques, symptom-formation was then blocked and the inevitable, resultant anxiety reaction repressed, so that underlying fantasies could erupt into conscious awareness even to the point of being acted out" (p. 65). By these means he determined the neurotic of psychotic functions being served by the patient's physical symptoms. The hypnotic interpersonal relationship is "a fantasy-evoking one in which the patient, on the basis of his own experiential background and with more ready access to his pre-conscious, thinks, feels, experiences, reacts and even acts-out exactly as he believes the hypnotist wishes him to, projecting his own impulses, desires and fantasies to the therapist" (p. 66).**

**1993**

**Hall, Howard; Minnes, Luke; Olness, Karen (1993). The psychophysiology of voluntary immunomodulation. International Journal of Neuroscience, 69, 221-234.**

**In twenty-two studies of intentional efforts of humans to change immune measures, only four monitored psychophysiologic parameters. One study reported physiologic alterations associated with**

immune changes. In this current study we examined changes in pulse rate and peripheral temperature associated with intentional changes in neutrophil adherence. Subjects had blood, pulse and temperature recordings collected before and after either a rest condition (Group A), or a self-regulation exercise (Groups B and C) for two sessions. Group C had four prior training sessions before participating in the experimental sessions. This study found no association between psychophysiological alterations and neutrophil changes. The control group (A) demonstrated no significant neutrophil changes but showed physiologic alterations, whereas, the experimental group (C) that showed increases in neutrophil adherence demonstrated no significant physiologic changes. It was speculated that intentional changes on neutrophil adherence and the pattern of the psychophysiological measures were associated with and reflective of cognitive activity.

1992

Hajek, P.; Jakoubek, B.; Kyhos, K.; Radio, T. (1992). Increase in cutaneous temperature induced by hypnotic suggestion of pain. Perceptual and Motor Skills, 74, 737-738.

Eight patients with atopic eczema and six healthy subjects were given hypnotic suggestion to feel pain in the upper part of the back and in one case on the palm. An average local increase in skin temperature of 0.6 degrees centigrade (detected by thermovision) occurred under this condition. For some patients cutaneous pain threshold was increased before the experiment by means of repetitive hypnotic suggestion of analgesia. These subjects reported feeling no pain subjectively, but the local change in skin temperature was equal in both cases. The results suggest a central mechanism induced by measuring changes in pain threshold in the skin, which changes are independent of local changes in blood flow. Local pain in the middle of the upper part of the back, and in one subject for comparative purposes in the region of the right palm, was induced during a single hypnotic session by specific suggestion which emphasized a subjective feeling of local pain lasting for 6 minutes. In four of the eczema patients long-lasting cutaneous analgesia was induced before this experiment by a different suggestion which stressed the impossibility of conducting pain from the skin to the brain and which was repeated in ten consecutive hypnotic sessions. The spatial thermal reaction of the skin surface was monitored, with consecutive recordings taken at 20-sec. intervals before and after finishing the hypnotic suggestion of pain. There was a gradual increase in temperature (1.08 degrees Fahrenheit). In the four eczema patients with long-lasting cutaneous analgesia treated equally, the thermal reaction of the skin was similar to that described above although no subjective feeling of pain was reported. These subjects reported feeling only that their skin was getting warmer at the specified place.

Miller, Scott D.; Triggiano, Patrick J. (1992). The psychophysiological investigation of multiple personality disorder: Review and update. American Journal of Clinical Hypnosis, 35, 47-61.

## NOTES

A review and methodological critique. Updates Putnam, 1984. Currently, psychophysiological differences reported in the literature include changes in cerebral electrical activity, cerebral blood flow, galvanic skin response, skin temperature, event-related potentials, neuroendocrine profiles, thyroid function, response to medication, perception, visual functioning, visual evoked potentials, and in voice, posture, and motor behavior. Reviews the new research on the psychophysiological investigation of MPD from published, unpublished, and ongoing studies, and attempts to place current findings into a conceptual framework. Authors note results from unpublished and ongoing studies and include a critical analysis of current research methodology as well as suggestions for future research.

Mittleman, K. D.; Doubt, T. J.; Gravitz, Melvin A. (1992). Influence of self-induced hypnosis on thermal responses during immersion in 25 degrees C water. Aviation, Space & Environmental Medicine, 63, 689-695.

The efficacy of self-induced posthypnotic suggestion to improve thermogenic responses to head-out immersion in 25 degrees C water was evaluated in 12 males. An online computerized system permitted the change in body heat storage to be used as the independent variable and immersion time as the dependent variable. Two one- hour hypnotic training sessions were used. There were no differences in rates of heat production, heat loss, mean skin temperature, or rectal temperature between control and hypnotic immersions. Individual hypnotic susceptibility scores did not correlation with changes in thermal status. Ratings of perceived exertion during exercise were similar for both immersions, but perceived sensation of cold was lower during the second rest period of the hypnotic immersion. Three subjects used images of warm environments during their hypnotic immersion and lost heat at a faster rate than during control immersions. These results indicate that brief hypnotic training did not enhance the thermogenic response to cool water immersion.

Wallace, Benjamin; Kokoszka, Andrzej (1992). Experience of peripheral temperature change during hypnotic analgesia. International Journal of Clinical and Experimental Hypnosis, 40, 180-193.

Many Subjects who experience hypnotic analgesia in a portion of their body often report that it is accompanied by sensations of coldness in the affected area. Experiments were conducted to determine if such reports are the result of a physical change in peripheral temperature or are due to psychological factors. When analgesia was induced in a limb or in the back of the neck, a concomitant physical change in temperature was not observed. Subjects did report experiencing coldness, however, in the affected body part. Such experiences were attributed to associations that Subjects developed between numbness or analgesia and a drop in peripheral temperature. As a result, coldness as an associate of hypnotic analgesia is suggested as a manipulation check for the presence of such sensation reduction.

## NOTES

When a limb feels numb, there also appears to be degradation of proprioceptive abilities (Wallace & Garrett, 1973, 1975; Wallace & Hoyenga, 1980). When Ss are asked to touch their nose with finger, either subjects miss the nose or they take longer to do the task. This kind of proprioceptive decrement has also been reported by Spanos, Gorassini, and Petrusic (1981) and Welch (1978, p. 27).

This study used highly hypnotizable Ss (10-12 on Harvard Group Scale of Hypnotic Susceptibility, Form A (HGSHS:A) and low hypnotizables (0-2) in Experiment 1 which established temperature variability in an arm and sites for measuring temperature during hypnotic analgesia.

In Experiment 2, 40 subjects (20 highs and 20 lows by above standards, with group assignment confirmed by Stanford Hypnotic Susceptibility Scale, Form C, on which highs  $M = 10.4$ , lows  $M = 1.2$ ) were given relaxation imagery (e.g. to imagine a white, fluffy cloud gently moving across a deep, blue sky during a count of 20, while at the same time, listening only to the voice of E describing the scene to them.

The analgesia suggestion was that "their right arm had been injected with massive doses of Novocain, that Novocain had been injected in their shoulder, in their elbow, in their forearm, in their hand, and in their fingers ... their arm would become progressively more and more numb as E counted backward from 20 to 1" (p. 185; for more details see Wallace & Hoyenga, 1981). They were asked to perform the nose touch test as confirmation of the analgesia suggestion response.

Highs and lows who served as control subjects had the same treatment except instead of analgesia instructions they were told their arm would become progressively more and more relaxed as E counted backwards from 20 to 1.

The peripheral skin temperature was monitored during the procedures, and following the experimental manipulation Ss completed a questionnaire on their experience of numbness, heaviness, changes in limb temperature (very warm to very cold), and changes in mobility.

Analyses of variance were used to analyze the results. Although there were no objective skin temperature changes, there was a significant interaction effect for pointing error. Highs who received analgesia suggestions were off 4.35 cm; the other 3 groups had mean error of .45 cm or less. There was also an interaction effect for latency of response: highs with analgesia instructions took 3.05 seconds longer than in relaxation condition, while other three groups only took .27 sec longer, on average. Additionally, there was a correlation between receiving analgesia instructions and feeling limb heaviness for the high hypnotizables ( $r = .68$ ) but not for lows or for any Ss asked to relax their arm during the procedures.

The sensation of coldness was reported by the majority of highs receiving analgesia suggestions (7 of 10), but 2 Ss scoring 12 on the SHSS:C did not report coldness. Cold sensation was not reported by any S in any of the three other groups. The correlations between cold sensation and heaviness ( $r = .65$ ,  $p < .05$ ) and cold sensation and immobility ( $r = .79$ ,  $p < .05$ ) were found only in the High hypnotizable, analgesia suggestion group.

The authors performed a third experiment to determine whether temperature change could be used to confirm analgesia. This would be useful when one cannot confirm with inability to move the body part, e.g. when the analgesia is being developed in a part of the body that usually doesn't move. The design for Experiment 3 was the same as for Experiment 2.

Analgesia rated on a 7-point scale was reported as 6.1 by high hypnotizables and 1.2 by low hypnotizables. "Reports of a temperature change during the induction were also related to hypnotic analgesia and being classified as high in hypnotizability. Such a relationship was only significant, however, for a feeling of coldness ( $r = .63$ ,  $p < .05$ ), and 7 of the 10 high hypnotizable Subjects assigned to the analgesia group reported the aforementioned sensation. A significant experiencing of a temperature change (cold or warm) was not reported by the other three groups of Subjects" (p. 189).

In their Discussion, the authors suggest that expectancy might account for the results, since during post-experiment interviews many Ss said that they expected their arm would become cold when it was numb. That was based on their previous experience, e.g. in placing ice on the skin. Notable, people did not exhibit this association if they were not able to develop the analgesia in response to suggestion.

The authors also take note of the fact that none of the Subjects reported associating cold with pain, though cold and pain often are concurrently experienced. This might be because only extreme cold is painful, and coolness might actually be perceived as pleasant.

## 1988

Wakeman, R. J. (1988). Hypnotic desensitization of job-related heat intolerance in recovered burn victims. American Journal of Clinical Hypnosis, 31, 28-32.

The thermally injured patient who suffers extensive third-degree burns usually finds the adaptation to high temperature environments quite difficult. A 7-year study of 50 thermally injured patients with greater than 45% total body surface second- and third-degree burns was conducted to assess the usefulness of hypnosis for improved heat adaptation at the work site. There were 25 subjects in the experimental group who received hypnotic training and 25 in a matched control group. The experimental group achieved a mean of 6.25 hours worked over 16 weeks and 63.5 days worked out of 80. They worked 4.5 to 6.5 hours per day for an average of 221 days per year for up to 3 years from

baseline. The control group achieved a mean of 4.5 hours worked over 16 weeks and 54.33 days worked out of 80. The efficacy of hypnosis in heat desensitization is discussed.

## NOTES

Mean age was 38 for the hypnosis group, 33 for the control group; both groups had mean educational level of 8 grades. Mean percentage of total body surface burn was 50% for hypnosis and 54% for control groups.

Each patient was seen for 16 weeks, for 2 hours/week. The hypnosis group received hypnosis, were taught self hypnosis, and were given cassette tapes for use at home. The hypnosis training included a variety of techniques (e.g. progressive deep muscle relaxation, eye-fixation, eye-roll, and visual imagery techniques). They were given suggestions for lower skin temperature, lower 'inner body' temperature, less itching, gradual improvement of time spent on the job, as well as ego strengthening suggestions. The control patients received supportive psychotherapy, family consultation, and cognitive behavior therapy for the same amount of contact time with the same therapist.

The hypnosis group was to do self hypnosis every two hours at the worksite, in addition to home practice. Visual imagery suggestions were things like imagery of a cool waterfall flowing over the skin, having a tall cold glass of beer or soft drink, etc. They also had biofeedback of skin temperature during office visits, to reinforce decreases in skin temperature near the burned sites. They had exposure to heat (in a 95 degree sauna) for in gradually increased periods of time (15 to 120 minutes) before returning to the worksite.

Three years after treatment 20 of 25 control patients had quit their jobs or transferred to a cooler worksite, and all 25 had resigned from their original jobs or applied for further disability benefits. In contrast, only 2 of 25 experimental Ss were working in controlled-temperature settings, and none had applied for permanent disability benefits.

The authors note that family support was essential for the hypnosis patients to carry out their treatment program, and family consultations were essential for every patient. They also found the 'fade-in' technique using the sauna in the hospital occupational therapy area very useful for bridging the gap between practice in the office and going back to the work setting. "This procedure enabled the subject to practice self- hypnosis under controlled physical conditions while performing a work task that was more realistic than 'imagined heat' in the office setting" (p. 31).

## 1987

Price, Donald D.; Barber, Joseph (1987). An analysis of factors that contribute to the efficacy of hypnotic analgesia. Journal of Abnormal Psychology, 96, 46-51.

An analysis was made of factors that contribute to the magnitude of hypnotic analgesia produced by indirect hypnotic suggestions. Two groups of human volunteers made sensory and  affective  visual analogue scale (VAS) responses to nociceptive temperatures (44.5-51.5C) before and after hypnotic suggestions were given for analgesia. Group 1 was given suggestions for developing a hypnotic state only once just before analgesic testing and did not have significantly reduced VAS responses to experimental pain after hypnosis. Group 2 was continuously given cues for maintaining a hypnotic state during their analgesia testing session and had large reductions in both VAS- sensory and, especially, VAS-affective responses to pain. A small but statistically reliable correlation was found between hypnotic susceptibility and overall magnitude of reduction in VAS-sensory responses ( $R = .4$ ). The correlations were much larger for intense stimuli compared to those near threshold. Reductions in VAS-affective pain responses were not correlated with hypnotic susceptibility.

## 1986

Pereira, Robert Peter (1986, July). The role of organismic involvement in hypnotic emotional behavior (Dissertation, Wayne State University). Dissertation Abstracts International, 47 (1), 385-B. (Order No. DA8605027)

"Two hundred college undergraduates were pretested via the Harvard Group Scale of Hypnotic Susceptibility: Form A. Fifty subjects scoring in the range 7-12 were designated as Reals, while 25 subjects scoring in the range 0-4 were designated as Simulators. Reals and Simulators were given differential instructions before the administration of a second hypnotic induction procedure, which was accompanied by a task in which subjects were asked to relive each of three emotional experiences, i.e., fear, anger, and happiness. Reals were given instructions encouraging cooperation, while Simulators were instructed to try to convince a group of experienced hypnotists that they were deeply hypnotized, when, in fact, they would not be. "Physiological, overt-behavioral, and cognitive measures taken either during or following the relived-emotions task served as indices of Sarbin's organismic involvement construct. A post-experimental measure of the realness of subjects' relived emotional experience was regressed on these organismic indices in order to test Sarbin's assumption of a positive linear relationship between organismic involvement and belief-in imaginings, using data from the Real group only. Results indicated that, across all three emotions, the linear composite of organismic indices shared statistically significant amounts of variance with the criterion of experiential realness. Obtained amounts of shared variance ranged from 22% (during anger) to 55% (during happiness). These findings were interpreted as offering clear and robust support for Sarbin's theory of hypnosis. Suggestions for further research were offered. "The question of Real-Simulator differences was explored through several multivariate analyses of variance and covariance, using the organismic indices as dependent variables. These analyses were performed on the original sample of Reals and Simulators, and on two subsamples of Reals/Highs and Simulators/Lows which were created through the use of pre- and/or post-experimental exclusion criteria. Reals/Highs showed statistically higher levels of effort than did Simulators/Lows during all three emotions, as well as higher levels of skin conductance and finger temperature during anger. These findings were interpreted as being of theoretical and practical significance. Multiple replications of the physiological findings were recommended in order to assess the extent to which the skin conductance and finger temperature variables might be used in practical, i.e., forensic contexts" (p. 385-B).

Sargent, Joseph; Solbach, Patricia; Coyne, Lolafaye; Spohn, Herbert; Segerson, John (1986). Results of a controlled, experimental, outcome study of nondrug treatments for the control of migraine headaches. Journal of Behavioral Medicine, 9, 291-323.

Headache variables were examined for 136 subjects who participated for 36 weeks in one of four groups: No Treatment, Autogenic Phrases, EMG Biofeedback, Thermal Biofeedback. All subjects kept daily records of headache activity and medication usage and participated in 22 laboratory sessions during which frontalis EMG and hand temperature measurements were taken; those in the 3 treatment groups practiced at home. There was a substantial reduction in headache variables in all groups. The No- Treatment Group differed significantly from the treatment groups combined, with the least reduction in headache variables. The thermal biofeedback group vs EMG biofeedback and autogenic phrases groups showed a suggestive trend toward improvement in the frequency and intensity of total headache.

Williams, David A.; Thorn, Beverly E. (1986). Can research methodology affect treatment outcome? A comparison of two cold pressor test paradigms. Cognitive Therapy and Research, 10 (5), 539-545.

Examined the effect of fixed or open latency instructions on subjective pain report for the cold pressor test using a single cognitive training strategy with 80 undergraduates. The fixed latency paradigm instructed Ss to leave their hand in the cold water for a fixed amount of time (e.g., 3 min), whereas the tolerance paradigm asked Ss to endure pain for as long as possible. Results suggest that the fixed latency paradigm is associated with lower subjective pain ratings especially when a cognitive strategy is used. The tolerance groups failed to decrease their subjective perception of pain but evidenced longer latencies when a cognitive strategy was used. It is concluded that while other research has used these paradigms interchangeably to assess efficacy, these 2 paradigms apparently pose different challenges to Ss. (15 ref).

1985

Schlesinger, Jay Lawrence (1985). Hypnotizability in relation to success in learning biofeedback training: Attentional involvement (Dissertation, Adelphi University). Dissertation Abstracts International, 45 (n8-B), 2701. (Order No. DA 8424937)

#### NOTES

"This study investigated the role of attentional focus in the relationship between hypnotizability and success in learning two types of biofeedback training. 40 female college students, aged 18-25, were measured for hypnotic responsiveness, and given one session of EMG biofeedback and one session of temperature biofeedback. For the biofeedback training, 20 Ss received written instructions designed to establish a passive, non-volitional attentional focus on the feedback signal, and 20 received written instructions intended to establish an active, volitional attentional focus on the feedback signal.

"It was hypothesized that level of hypnotizability would be positively related to success in learning EMG and temperature biofeedback training for the Ss given passive, non-volitional attentional instructions, while level of hypnotizability would be negatively related to success in learning biofeedback training for the Ss given active, volitional attentional instructions. It was also hypothesized that higher hypnotizables would perform better with temperature biofeedback than with EMG biofeedback, and that lower hypnotizables would perform better with EMG biofeedback than with temperature biofeedback.

"The hypotheses were not supported, nor was any overall relationship between level of hypnotizability and success in learning biofeedback demonstrated. There was support to suggest that an active, volitional attentional focus on the biofeedback signal was most adequately maintained by the 20 Ss given the active volitional instructions. Clinical implications of these findings and directions for future research were discussed" (p. 2701).

1984

Holmes, David S. (1984). Meditation and somatic arousal evidence. American Psychologist, 39 (1), 1-10.

The conceptual and methodological issues associated with research on the effects of meditation are reviewed. A summary of the research in which the somatic arousal of meditating subjects was compared to the somatic arousal of resting subjects did not reveal any consistent differences between meditating and resting subjects on measures of heart rate, electrodermal activity, respiration rate, systolic blood pressure, diastolic blood pressure, skin temperature, oxygen consumption, EMG activity, blood flow, or various biochemical factors. Similarly, a review of the research on the effects of meditation in controlling arousal in threatening situations did not reveal any consistent differences between meditating and nonmeditating (no-treatment, antimeditation, or relaxation) subjects. The implications of these findings for research and practice are discussed.

Raynaud, Jeanne; Michaux, Didier; Bleirad, Guilhem; Capderou, Andre; Bordachar, Janine; Durand, Jacques (1984). Changes in rectal and mean skin temperature in response to suggested heat during hypnosis in man. Physiology and Behavior, 33, 221-226.

Rectal temperature, mean skin temperature and heart rate were recorded in 7 subjects during hypnosis, induced either alone or while sensations of heat were suggested. During hypnosis alone, a fall in the heart rate of about 10 beat-min<sup>-1</sup> was the only autonomic response observed; body temperatures were unaltered. In contrast, during hypnosis with suggestion of heat, the following changes occurred: (1) Mean rectal temperature decreased 0-.20 degrees C. (p<.05) within 50 min. Its mean time course differed significantly from that for hypnosis alone (p<0.001). (2) Comparison of individual rectal temperature time sequences showed that in fact this temperature only declined in 4 subjects out of 7, and tended to form a plateau located 0.35 degrees C below the value of the preceding waking state. Despite reinforcement of heat suggestion, the plateau continued until the end of the hypnotic trance. (3) Mean skin temperature tended to rise. (4) When hypnosis with suggestion ceased, both rectal and skin temperatures very slowly returned to their levels during the preceding waking state.

1983

Borgeat, Francois; Goulet, Jean (1983). Psychophysiological changes following auditory subliminal suggestions for activation and deactivation. Perceptual and Motor Skills, 56, 759-766.

This study was to measure eventual psychophysiological changes resulting from auditory subliminal activation or deactivation suggestions. 18 subjects were alternately exposed to a control situation and to 25-dB activating and deactivating suggestions masked by a 40-dB white noise. Physiological measures (EMG, heart rate, skin-conductance levels and responses, and skin temperature) were recorded while subjects listened passively to the suggestions, during a stressing task that followed and after that task. Multi-variate analysis of variance showed a significant effect of the activation subliminal suggestions during and following the stressing task. This result is discussed as indicating effects of consciously unrecognized perceptions on psycho- physiological responses.

1982

Barabasz, Arreed F. (1982). Restricted environmental stimulation and the enhancement of hypnotizability: Pain, EEG alpha, skin conductance and temperature responses. International Journal of Clinical and Experimental Hypnosis, 30, 147-166.

Restricted environmental stimulation procedures were used with 10 Ss. The Stanford Hypnotic Clinical Scale: Adult, modified to include a posthypnotic suggestion for an analgesic reaction, and pain threshold and tolerance tests were administered prior to restricted environmental stimulation technique (REST), immediately after REST, and 10-14 days later. Occipital EEG alpha, skin conductance, and peripheral, core, and chamber temperature data were collected prior to, during, and after REST. A control group of 10 Ss was used to assess the effects of repeated hypnosis upon susceptibility scores and demand characteristics of the experiment. Multivariate analysis of variance results showed SHCS and pain tolerance scores to be significantly enhanced for Ss exposed to REST immediately after and 10-14 days later. Orne's (1959) postexperimental inquiry technique did not reveal experimental demand characteristics which might account for the results. EEG alpha density increased significantly in REST, but the increase was not progressive during the REST period. The maintenance of hypnotizability and pain tolerance at follow-up failed to support Reyher's (1965) theory of brain function and behavioral regulation. E. R. Hilgard's (1977) neodissociation interpretation combined with J. R. Hilgard's (1974, 1979) imaginative involvement findings is viewed as a possible explanation.

**Credidio, Steven G. (1982). Comparative effectiveness of patterned biofeedback vs meditation training on EMG and skin temperature changes. Behaviour Research and Therapy, 20, 233-241.**

Examined whether a low arousal, relaxation pattern of frontalis EMG decreases and peripheral skin temperature increases could be attained more effectively through biofeedback or meditation training. 30 21-59 yr old females were randomly assigned to 1 of 3 groups: patterned biofeedback, clinically standardized meditation, or control. Prior to training, Ss were administered the Eysenck Personality Inventory. Each S was seen weekly for 7 sessions. Subjective experiences and time spent practicing at home were also recorded. Results indicate that the meditation group showed significantly lower EMG levels at the end of treatment than did the control group. The biofeedback group had difficulty in patterning the 2 feedback signals simultaneously. Extraverts in the control group had the highest EMG levels. The most positive subjective reports came from Ss in the meditation group. It is suggested that meditation offers a viable alternative as a relaxation procedure, requiring little time to learn and devoid of any performance criteria levels.

**Spanos, Nicholas P.; McNeil, Conrad; Stam, Henderikus J. (1982). Hypnotically 'reliving' a prior burn: Effects on blister formation and localized skin temperature. Journal of Abnormal Psychology, 91 (4), 303-305.**

60 Ss who had previously been burned were "hypnotically age regressed" and given both suggestions to "relive" the burn experience and suggestions that a blister was forming. Although 17 Ss reported vividly imagining the burn events, none showed localized skin-coloration changes or evidence of blister formation. Moreover, skin temperature measured before, during, and after age regression indicated no overall suggestion effects. Nevertheless, 1 S did show differential skin-temperature response to the suggestion. This S had showed only moderate hypnotic susceptibility on the Harvard Group Scale of Hypnotic Susceptibility. (10 ref)

#### NOTES

The male subject who appeared to show changes in response to the suggestion increased temperature differences between the burn site and the contralateral site from .3 degrees C before the imagining period to a maximum of 2.7 degrees C during the imagining period and decreased to 0 degrees C after the imagining period. However, temperature differences between the adjacent sites remained very small (never more than .1 degree C) throughout the session. This subject answered "no" to all seven items on the skin-sensitivity questionnaire. He testified postexperimentally to being only "slightly hypnotized" (score 1), "not at all age regressed" (score 0), and to have experienced imagery that was only 50% as vivid as the real experience. (His HGS:AS score was 8.)

**Claghorn, James L.; Mathew, Roy J.; Largen, John W.; Meyer, John S. (1981). Directional effects of skin temperature self-regulation on regional cerebral blood flow in normal subjects and migraine patients. American Journal of Psychiatry, 138, 1182-1187.**

Vascular headache of the migraine type is associated with vasomotor changes in cerebral arteries. The authors studied whether skin temperature training (biofeedback) reduced the frequency, severity, and duration of these headaches by measuring the regional cerebral blood flow (CBF) in 11 female migraine patients (27-52 years) and 9 female volunteers (22-37 years), using the noninvasive <sup>133</sup>Xe inhalation technique. Half of each group was randomly assigned to a hand-warming or a hand-cooling group. CBF increased in several regions of the left hemisphere to a significant degree only for the

migraineurs who were in the hand-warming group. The pattern of vasomotor regulation apparently differed between migraine and normal Ss. The migraineurs' headache symptoms were affected by both warming and cooling, but warming produced more salutary effects.

Piedmont, Ralph L. (1981). Effects of hypnosis and biofeedback upon the regulation of peripheral skin treatment. Perceptual and Motor Skills, 53, 855-862.

The purpose of this study was to examine the influence of hypnosis on the regulation of peripheral skin temperature. The independent variables were the presence of a hypnotic trance during the session on thermal regulation and the number of trials received. A two-factor mixed-design analysis of variance with repeated measures on one factor showed a significant main effect for trials and a significant interaction between hypnosis and trials. It may be concluded that hypnosis, in conjunction with thermal regulation techniques, exerts a significant influence over performance. The cognitive characteristics influenced by hypnosis may account for this finding.

1980

Crosson, B. (1980). Control of skin temperature through biofeedback and suggestion with hypnotized college women. International Journal of Clinical and Experimental Hypnosis, 28 (1), 75-87.

4 groups of 9 college women attempted to raise finger temperature relative to forehead temperature during hypnosis. After a hypnotic induction, each group of Ss received 1 of the following treatments for temperature control: (a) biofeedback, (b) suggestion and imagery, (c) biofeedback plus suggestion and imagery, and (d) a relaxation, false-feedback control. Groups were initially balanced for hypnotic susceptibility. Between-subject differences in baseline temperatures were statistically controlled. After 4 training sessions, only Ss in the groups receiving biofeedback and biofeedback plus suggestion and imagery demonstrated evidence of learned temperature control, and only Ss in the biofeedback group demonstrated a significantly greater ability to control skin temperature than Ss in the control group. Changes in temperature during hypnotic induction did not appear to affect changes during the subsequent treatment. There was no significant correlation between hypnotic susceptibility and temperature control for Ss in any group, contrary to popular assumption. Future research should attempt to ascertain if combined use of biofeedback and hypnosis offers any advantages to the use of biofeedback alone.

1978

Parwatarikar, Sadashiv D.; Brown, Marjorie S.; Stern, John A.; Ulett, George A.; Sletten, Ivan S. (1978). Acupuncture, hypnosis and experimental pain - I. Study with volunteers. Acupuncture and Electro-Therapeutic Research: International Journal, 3, 161-190.

An experiment was designed to evaluate the protective effects of different agents - acupuncture, hypnosis, Morphine, aspirin, Diazepam and placebo - upon experimentally-induced pain in humans. Twenty normal, healthy volunteers were subjected to cold water and tourniquet-induced pain and the protective effects of 35 minutes of hypnotic suggestion, electro-stimulation of both acupuncture points and non-acupuncture points, 10 mg/kg of Morphine, 5 grains of aspirin, 10 mg of Diazepam and a mild sugar placebo were evaluated. Data was collected on subjective evaluation of pain, EKG, EEG, respiration, skin temperature, peripheral vascular activity and EMG. A special study was also done to evaluate the effects of all the above agents on the somatosensory evoked potentials and EEG. The data were further analyzed on the basis of hypnotic susceptibility of the volunteers. The results indicated: 1) Hypnosis, acupuncture at specific sites with electrical stimulation and Morphine Sulphate had about the same reduction in experimental pain. 2) Hypnosis produced different effects from those resulting

from acupuncture stimulation on EEG. 3) Acupuncture stimulation in specific loci resulted in a latency increase in the early secondary response on somatosensory evoked potential. 4) Cold water pain was remarkably reduced after true acupuncture point stimulation. 5) Tourniquet (ischemic) pain was reduced by both hypnosis and true acupuncture site stimulation. 6) Skin temperature was significantly reduced on the side of acupuncture points (true) stimulation.

**1977**

Ansel, Edward Leslie (1977). A simple exercise to enhance response to hypnotherapy for migraine headache. International Journal of Clinical and Experimental Hypnosis, 25 (2), 68-71.

A common method of hypnotherapy for migraine headache utilizes suggestions of warmth for the hands and coldness for the head. This procedure reverses the abnormal pattern of vasodilation and excess supply of blood in the head and decreased supply in the extremities associated with this type of headache, thereby relieving the pain. A simple exercise, utilizing centrifugal force to dramatically increase blood flow to the hands, is described. It promotes relief in itself and provides a vivid background experience to enhance productivity of this effect in hypnosis. It appears to be especially useful in patients exhibiting lesser degrees of trance capacity.

**1976**

Dugan, Michelle; Sheridan, Charles (1976). Effects of instructed imagery on temperature of hands. Perceptual and Motor Skills, 42, 14.

#### NOTES

Sixteen college student volunteers were involved in the research. Subjects were randomly assigned to two groups, either to warm or to cool their hands. All 10 subjects attempting to cool their hands were able to cool at least one hand, and six people cooled both hands. For those trying to warm their hands, five warmed at least one hand and one was able to warm both hands. Four people were able to cool their hands without hypnosis, conditioning, or feedback.

Jackson, T. L.; Barkley, R. A.; Pashko, S. M. (1976). The effects of hypnotic induction versus high motivation on oral temperature. International Journal of Clinical and Experimental Hypnosis, 24, 22-28.

The hypothesis that changes in oral temperature are associated with neutral hypnotic induction was investigated using neutral hypnosis and a high motivation condition as controls. 33 Ss were assigned to 3 experimental conditions: (1) neutral hypnotic induction, (2) high motivation control, and (3) no treatment control. Ss in all 3 conditions received pre- and post-treatment oral temperature measurements after a 20-minute temperature stabilization showed a significantly greater increase in oral temperature as compared to Ss in both the high motivation and no treatment control conditions. Ss in the latter 2 conditions did not differ from each other in this regard. The methodological considerations of future research in this area are also discussed.

**1973**

Roberts, Alan H.; Kewman, Donald G.; Macdonald, Hugh (1973). Voluntary control of skin temperature: Unilateral changes using hypnosis and feedback. Journal of Abnormal Psychology, 82 (1), 163-168.

To demonstrate the ability of human Ss to achieve control over specific autonomic functions, hypnosis and auditory feedback were used to train a select group of hypnotically talented subjects to produce a

difference in skin temperature in one hand relative to the other in a direction specified by the experimenter. Large and reliable effects were shown demonstrating that some individuals are capable of achieving a high degree of voluntary control over the autonomic processes involved in peripheral skin temperature regulation. Individual differences between subjects were noted, and variables that might account for these are discussed.

**1969**

Timney, Brian N.; Barber, Theodore X. (1969). Hypnotic induction and oral temperature. International Journal of Clinical and Experimental Hypnosis, 17, 121-132.

Measured oral temperature in 19 Ss under hypnotic and control conditions. Confirming a study by A. F. Reid and G. Curtsinger (see 42:10), the hypnotic induction procedure gave rise to a significant increase in oral temperature ( $p < .01$ ). This significant rise was due to the data of 10 of the 19 Ss, 6 did no change and 3 dropped in temperature. The temperature change was not related to Ss' responsiveness to suggestions or to their testimony that they were or were not hypnotized. Although good and poor hypnotic Ss manifested the same degree of temperature rise, there was a tendency for those who had the least previous hypnotic experience to show the greatest rise. Data suggest a hypothesis for further research: oral temperature rises during hypnotic induction to the extent that Ss perceive the hypnotic situation apprehensively, i.e., as mysterious or foreboding. **1968**

Reid, Allen F.; Curtsinger, George (1968). Physiological changes associated with hypnosis: The effect of hypnosis on temperature. International Journal of Clinical and Experimental Hypnosis, 16, 111-119.

STUDIED THE PHYSIOLOGICAL EFFECT ON TEMPERATURE OF HYPNOSIS. UNDER NEUTRAL HYPNOSIS, 20 SS EXPERIENCED AN INCREASE OF ORAL TEMPERATURE AVERAGING .6DEGREES F, WHICH SUBSIDED AFTER TERMINATION OF THE TRANCE. WHEN SKIN TEMPERATURE ON THE FOREHEAD, CHEST, AND HAND WERE MEASURED ON 4 SS, THERE WAS AN EVEN MORE PRONOUNCED INCREASE; MEASUREMENTS ON THE VOLAR SURFACE OF THE FOOT WERE EQUIVOCAL. CONTROL ORAL TEMPERATURE MEASUREMENTS USING RELAXATION WITHOUT HYPNOSIS SHOWED NO SIGNIFICANT INCREASE. IT IS CONCLUDED THAT NEUTRAL HYPNOSIS IS GENERALLY ACCOMPANIED BY AN INCREASE IN ORAL AND SKIN TEMPERATURE. (GERMAN + SPANISH SUMMARIES) (PsycINFO Database Record (c) 2002 APA, all rights reserved)

**1954**

Kline, Milton V.; Guze, Henry (1954). The alteration of oral temperature through hypnotic techniques: I. Pilot experimentation. Journal of Clinical and Experimental Hypnosis, 2 (3), 233-237.

**NOTES**

1:  
The authors used a variety of hypnotic techniques to attempt to modify the oral temperature of a normal 30 year old male who was capable of both positive and negative hypnotic hallucinations and of reaching a somnambulistic level with spontaneous, complete, post-hypnotic amnesia. Techniques included direct suggestions (general for temperature rising as when ill, and specific, i.e. his oral area was getting hot), time regression to when he had experienced a fever, age regression to age 10 when he had a high fever, direct suggestion of temperature drop, and positive hallucination of extreme elevation in a plane. A waking simulation control was run for each condition.

Although the subject appeared uncomfortable and showed behavioral changes, the mean oral temperatures did not differ from the baseline mean significantly for either hypnosis or simulation conditions, except for the hallucinated experience of flying in a plane at an altitude of 100,000 feet. That condition lowered the temperature an average of 3 degrees Fahrenheit. In that experimental condition there was no mention of temperature alteration per se, "thus indirect mechanism rather than direct mechanism appears to be more effective in the hypnotic control of temperature" (p. 237).

## **TERMINAL ILLNESS-DEATH**

**1999**

**Harper, Gary W. (1999). A developmentally sensitive approach to clinical hypnosis for chronically and terminally ill adolescents. American Journal of Clinical Hypnosis, 42 (1), 50-60**

Adolescents who suffer from terminal and/or chronic medical illnesses must face difficult developmental issues coupled with increased burdens of physical discomfort and uncertainty about survival. Clinical hypnosis is one technique that can be used to help these individuals gain a sense of comfort and control over their lives. I describe the use of a developmentally sensitive hypnotherapeutic intervention for chronically and terminally ill adolescents. I have used the technique for the reduction of various types of physical and psychological discomfort secondary to a range of medical problems such as cancer, end-stage renal disease, organ transplant, and HIV disease. The treatment focuses on the use of personalized procedures that attempt to increase perceptions of control through interactive formats. Movement through a personally intriguing journey is used as a metaphor for controlling and moving away from discomfort. I also present three case examples as well as general treatment recommendations for clinical use.

**1994**

**Alden, P. A. (1994, October). Hypnotic approaches in pain control with terminally-ill patients. [Paper] Presented at the annual meeting of the Society for Clinical and Experimental Hypnosis, San Francisco.**

## **NOTES**

( These notes do not cover the entire presentation, which was based on clinical practice experience.) One conclusion reached was that J. Barber's Rapid Induction Analgesia (RIA) is more immediately effective than a direct approach to induction, but that a direct approach improves with time. RIA seems to work better for low hypnotizables. Next she plans to study whether patients would benefit from being given a tape of RIA routinely as an adjunct to pain control.

**1992**

**Morse, Donald R.; Martin, John; Moshonov, Joshua (1992). Stress induced sudden cardiac death: Can it be prevented?. Stress Medicine, 8, 35-46.**

Previously, psychosomatically induced death relative to stress, hypnosis, mind control, and voodoo was discussed. In this article, emphasis is on one aspect of that - stress induced sudden cardiac death (SCD). A brief review is presented of the sympathetic aspects of the acute stress response and stress induced SCD. Findings from previous studies are presented to highlight sympathetic aspects of the acute stress response. This is followed by a presentation of various strategies to prevent or decrease the possibilities for stress induced SCD. These include long-term measures (e.g. diet control, smoking control, hypertension control, stress management strategies) and immediate measures (e.g. calm, controlled approach, elicitation of the relaxation response, selected use of drugs, and heart rate

variability monitoring). Relative to prevention strategies, findings are presented both from previous studies and new investigations.

Spira, James L.; Spiegel, David (1992). Hypnosis and related techniques in pain management. Hospice Journal, 8, 89-119.

Hypnosis has been used successfully in treating cancer patients at all stages of disease and for degrees of pain. The experience of pain is influenced not only by physiological factors stemming from disease progression and oncological treatment, but also from psychosocial factors including social support and mood. Each of these influences must be considered in the successful treatment of pain. The successful use of hypnosis also depends upon the hypnotizability of patients, their particular cognitive style, their specific motivation, and level of cognitive functioning. While most patients can benefit from the use of hypnosis, less hypnotizable patients or patients with low cognitive functioning need to receive special consideration. The exercises described in this chapter can be successfully used in groups, individual sessions, and for hospice patients confined to bed. Both self-hypnosis and therapist guided hypnosis exercises are offered.

Vijselaar Joost; Van der Hart, Onno (1992). The first report of hypnotic treatment of traumatic grief: A brief communication. International Journal of Clinical and Experimental Hypnosis, 40 (1), 1-6.

In 1813 the Dutch physicians Wolthers, Hendriksz, De Waal, and Bakker reported the hypnotic treatment of a woman suffering from traumatic grief, in which the therapist had to deal directly with the patient's spontaneous reenactments of the circumstances surrounding the death. This report, summarized in the present article, has historical value, as it is probably the first known precursor of the uncovering hypnotic approach. The original authors' views on the case are discussed, and a modern view for understanding the patient's traumatic grief and its treatment is presented.

Morse, Donald R.; Martin, John; Moshonov, Joshua (1991). Psychosomatically induced death: Relative to stress, hypnosis, mind control, and voodoo: Review and possible mechanisms. Stress Medicine, 7, 213-232.

A common denominator in psychosomatically induced death is stress. Death can occur slowly, as from the preponderance of chronic stressor, or it can come on suddenly, as from an acute stressor. Sudden death is more likely in an individual with preexistent serious medical conditions, which were outlined. Seven types of individuals more prone to sudden death were outlined. Most cases of sudden death are related to the presence of a severely stressful situation in which there appears to be no means of control or escape. With mind control, hypnosis, and voodoo curses, circumstances can be manipulated to achieve severe stress and uncontrollability.

1988

Van Der Hart, O. (1988). An imaginary leave-taking ritual in mourning therapy. International Journal of Clinical and Experimental Hypnosis, 36 (2), 63-69.

One form of mourning therapy is the therapeutic leave-taking ritual, the essence of which is that by parting with symbols connected with the deceased, patients take their leave of the deceased and can start a new life of their own. In the case described in the present paper, the patient performed such a ritual in her imagination while under hypnosis. Her extreme grief response is explained in terms of Janet's theory of emotions. It is emphasized that successfully performing the ritual necessarily

involved a change in attitude towards the deceased, and it is argued that the specific characteristics of hypnosis--involuntariness and effortlessness--add an extra dimension to guided imagery approaches to unresolved mourning.

Levitan, Alexander A. (1985). Hypnotic death rehearsal. American Journal of Clinical Hypnosis, 27 (4), 211-215.

Death rehearsal is a technique developed to help terminally ill patients and their families deal with anxieties about death. It has proven useful in demystifying the dying process by answering the question "What is it like to die?" Patients, who are able to hypnotically experience the death process, learn to deal with both grief and anxiety with the help of the hypnotherapist. - Author's abstract

Stumpfe, Von Klaus-Dietrich (1985). Psychosomatic reactions of near-death experiences. A state of affective dissociation. Zeitschrift fur Psychosomatische Medizin, 31, 215-225.

The feelings of persons who had encountered life-threatening danger were analyzed and compared with the feelings of persons, who are in hypnosos or trained in autogenic training. The symptoms are widely alike. The result of the comparison is, that there exists a state of affective dissociation, which can be caused by conscious or unconscious actions.

**1984**

Handelman, Mitchell M. (1984). Self-hypnosis as a facilitator of self-efficacy: A case example. Psychotherapy, 21 (4), 550-553.

This article presents the four-session treatment of Elaine, using self- hypnosis to facilitate the mourning process. It is argued that self-hypnosis-- rather than enhancing imagery-- increases self-efficacy, a person's feeling that he/she can perform behaviors that lead to desired outcomes. Elaine's sense of self-efficacy was increased by allowing her to choose scenes from her life to be explored in the context of the use of imagery. Elaine imagined events surrounding her father's death, and "rewrote history" in an attempt to permit herself the direct expression of emotions.

**1977**

Mystical states by-pass usual sensory perception and logical thinking. They often represent the ultimate goal of long apprenticeships in Eastern or Western monastic practices which stress self-discipline and meditation; or they correlate with sudden religious conversions. While interest has also been revived in mystical experiences stimulated by hallucinogens within the appropriate physical, intellectual, and emotional environment, less attention has been paid to those mystical experiences which appear spontaneously during hypnosis and Transcendental Meditation. The present author facilitates the unleashing of mystical experiences by using hypnotic approaches specifically aimed at altering space and time perceptions. Case presentations illustrate the methodologies for guiding receptive subjects to mystical states with the aim of relieving or correcting organic and functional painful syndromes unresponsive to other interventions. The probable biopsychological processes are discussed.

The original authors' views on the case are discussed, and a modern view for understanding the patient's traumatic grief and its treatment is presented.

Morse, Donald R.; Martin, John; Moshonov, Joshua (1991). Psychosomatically induced death: Relative to stress, hypnosis, mind control, and voodoo: Review and possible mechanisms. Stress Medicine, 7, 213-232.

A common denominator in psychosomatically induced death is stress. Death can occur slowly, as from the preponderance of chronic stressor, or it can come on suddenly, as from an acute stressor. Sudden death is more likely in an individual with preexistent serious medical conditions, which were outlined. Seven types of individuals more prone to sudden death were outlined. Most cases of sudden death are related to the presence of a severely stressful situation in which there appears to be no means of control or escape. With mind control, hypnosis, and voodoo curses, circumstances can be manipulated to achieve severe stress and uncontrollability.

**1988**

Van Der Hart, O. (1988). An imaginary leave-taking ritual in mourning therapy. International Journal of Clinical and Experimental Hypnosis, 36 (2), 63-69.

One form of mourning therapy is the therapeutic leave-taking ritual, the essence of which is that by parting with symbols connected with the deceased, patients take their leave of the deceased and can start a new life of their own. In the case described in the present paper, the patient performed such a ritual in her imagination while under hypnosis. Her extreme grief response is explained in terms of Janet's theory of emotions. It is emphasized that successfully performing the ritual necessarily involved a change in attitude towards the deceased, and it is argued that the specific characteristics of hypnosis--involuntariness and effortlessness--add an extra dimension to guided imagery approaches to unresolved mourning.

Levitan, Alexander A. (1985). Hypnotic death rehearsal. American Journal of Clinical Hypnosis, 27 (4), 211-215.

Death rehearsal is a technique developed to help terminally ill patients and their families deal with anxieties about death. It has proven useful in demystifying the dying process by answering the question "What is it like to die?" Patients, who are able to hypnotically experience the death process, learn to deal with both grief and anxiety with the help of the hypnotherapist. - Author's abstract

Stumpfe, Von Klaus-Dietrich (1985). Psychosomatic reactions of near-death experiences. A state of affective dissociation. Zeitschrift fur Psychosomatische Medizin, 31, 215-225.

The feelings of persons who had encountered life-threatening danger were analyzed and compared with the feelings of persons, who are in hypnoses or trained in autogenic training. The symptoms are widely alike. The result of the comparison is, that there exists a state of affective dissociation, which can be caused by conscious or unconscious actions.

1984

Handelsman, Mitchell M. (1984). Self-hypnosis as a facilitator of self-efficacy: A case example. Psychotherapy, 21 (4), 550-553.

This article presents the four-session treatment of Elaine, using self-hypnosis to facilitate the mourning process. It is argued that self-hypnosis-- rather than enhancing imagery-- increases self-efficacy, a person's feeling that he/she can perform behaviors that lead to desired outcomes. Elaine's sense of self-efficacy was increased by allowing her to choose scenes from her life to be explored in the context of the use of imagery. Elaine imagined events surrounding her father's death, and "rewrote history" in an attempt to permit herself the direct expression of emotions.

1977

Mystical states by-pass usual sensory perception and logical thinking. They often represent the ultimate goal of long apprenticeships in Eastern or Western monastic practices which stress self-discipline and meditation; or they correlate with sudden religious conversions. While interest has also been revived in mystical experiences stimulated by hallucinogens within the appropriate physical, intellectual, and emotional environment, less attention has been paid to those mystical experiences which appear spontaneously during hypnosis and Transcendental Meditation. The present author facilitates the unleashing of mystical experiences by using hypnotic approaches specifically aimed at altering space and time perceptions. Case presentations illustrate the methodologies for guiding receptive subjects to mystical states with the aim of relieving or correcting organic and functional painful syndromes unresponsive to other interventions. The probable biopsychological processes are discussed.

1976

Gardner, G. G. (1976). Childhood, death, and human dignity: Hypnotherapy for David. International Journal of Clinical and Experimental Hypnosis, 24, 122-139.

Hypnotherapy can be a significant part of the treatment of a dying child. A detailed clinical report illustrates how hypnotherapy was integrated with other treatment modalities to help a terminally ill child and his family cope effectively with problems and enhance their ability to use their own resources for personal growth and mastery throughout the dying process.

Crasilneck, Harold B.; Hall, James A. (1962). The use of hypnosis with unconscious patients. International Journal of Clinical and Experimental Hypnosis, 10 (3), 141-144.

8 of 10 patients dying of cancer were found to continue a simple motor response to a hypnotic command, even though they revealed no other evidence of interaction with the environment and were considered unconscious by their physicians. Certain theoretical considerations are mentioned. (PsycINFO Database Record (c) 2002 APA, all rights reserved)

1956

Stokvis, B. (1956). The application of hypnosis in organic diseases. Journal of Clinical and Experimental Hypnosis, 4 (2), 79-82.

NOTES

"SUMMARY. Hypnotherapy, applied as a symptomatic treatment, is especially indicated in those cases

1:

of organic diseases in which the patient has neurotically elaborated his physical suffering. In cases presenting neither etiological nor secondary psychic factors one may try to improve the patient's condition by hypnotic treatment. Description of a case (hypnotherapy in a woman with carcinoma mammae)[sic]. The writer's lack of appreciation of hypnotherapy in organic diseases does not include the treatment of diseases which are definitely psychosomatically determined" (pp. 81-82).

1955

Schneck, Jerome M. (1955). Hypnosis-death and hypnosis-rebirth concepts in relation to hypnosis theory. Journal of Clinical and Experimental Hypnosis, 3 (1), 40-43.

The author presents a few case notes in support of his proposition that hypnosis is symbolically connected with ideas of death and rebirth in some patients. The final sentence of this article reads, "The unconscious identification of the hypnotic state with processes relating to death and rebirth may be involved far more frequently than realized with widespread belief regarding alleged remarkable beneficial effects of the hypnotic state and procedure which incorporates simple, authoritative suggestion" (pp. 42-43).

#### TEST- SCALE

1994

Grant, Carolyn (1994). The Computer-Assisted Hypnosis Scale: Standardization and norming of a computer-administered measure of hypnotic ability (Dissertation). Dissertation Abstracts International, 54 (10/B), 5387.

"In a counterbalanced, within-subjects, repeated measures design, 130 subjects were administered both the Computerized Assisted Hypnosis Scale (CAHS) and the Stanford Hypnotic Susceptibility Scale, Form C (Stanford Hypnotic Susceptibility Scale: C). For each hypnotic procedure responsiveness was assessed along three dimensions: behavioral (CAHS, Stanford Hypnotic Susceptibility Scale: C), subjective depth (Field Depth Inventory), and relational involvement (Archaic Involvement Measure). Subjects also completed a Stanford Hypnotic Susceptibility Scale: C self scoring measure and the Tellegen Absorption Scale. The CAHS was shown to be a psychometrically sound instrument for measuring hypnotic ability. The various dimensions of CAHS hypnotic responsiveness were highly positively related, and the CAHS compared favorably with the Stanford Hypnotic Susceptibility Scale: C across the three dimensions assessed. Results are discussed in terms of the theory and practice of clinical assessment, noting directions for future research" (p. 5387).

1993

Balthazard, Claude G. (1993). The hypnosis scales at their centenary: Some fundamental issues still unresolved. International Journal of Clinical and Experimental Hypnosis, 41, 47-73.

Current approaches to the measurement of hypnotic performance can be traced back to the 19th century. In part because of these early origins and in part because of the nature of hypnotic phenomena, the hypnosis scales are unique psychometric instruments. The classic hypnosis scales are based on the notion of a "performance ladder"; items are scored on a pass/fail basis and can be arranged in increasing order of difficulty. Some of the implications on [sic]this "performance ladder" approach are reviewed. The evidence for two-mechanism models of hypnotic performance is reviewed. It is argued that this kind of formulation is at least as plausible as one that argues that the hypnosis scales measure "one thing" or "mostly one thing." If it were the case that the hypnosis scales were tapping two different and distinct processes, the label "hypnotic susceptibility" could not be

unambiguously applied to scores on the hypnosis scales. The hypnosis scales would appear well-suited to the investigation of underlying mechanisms, yet no consistent picture of the mechanisms underlying hypnotic performance on the scales has emerged thus far. No resolution is presented, but some of the reasons why such a resolution is so elusive are discussed. The future of hypnosis scales is discussed with respect to multidimensional assessment and alternatives to the "work sample" approach.

## NOTES

Author discusses the hypnotizability scales' history and psychometric properties, suggesting that they cannot have construct validity if more than one construct is involved. He states that many of the alternative formulations "posit structurally similar two- mechanisms models, where the relative contributions of one and the other mechanism changes gradually with the difficulty of the hypnotic performance--that is, one mechanism is more important for easy items and the other more important in the difficult range. This kind of formulation has been advanced by a number of authors .... Although these formulations are structurally similar, the nature of the mechanisms has been variously conceptualized: nonability and ability components (Shor, Orne & O'Connell, 1962), primary suggestibility and somnambulism (Weitzenhoffer, 1962), minor and major dissociations (Hilgard, 1977), compliance and true hypnosis (Tellegen, 1978-1979), and cooperativeness and expectation at one end and absorption at the other (Spanos, Mah, Pawlak, D'Eon, & Ritchie, 1980). ... In a formulation such as Hilgard's (1977), where both mechanisms are dissociative, it may be that it makes some sense to understand both mechanisms as aspects of the same complex construct. In other formulations... it would appear more cogent to speak of two constructs. Spanos et al. (1980) found that 'cooperativeness and expectation may be particularly important in responding to ideomotor and challenge suggestions, while the ability to convincingly treat imaginings as real (i.e., absorption) becomes increasingly important for more difficult 'cognitive' items" (p. 21). Balthazard & Woody (1992) presented evidence that the more difficult items on hypnotizability scales are related to absorption more than the easier items.

Balthazard & Woody (1989) investigated the proposition that hypnotizability scores are distributed bimodally, and concluded that statistical problems clouded the issue. Furthermore, most analyses previously have been of surface structure, which does not relate directly to the underlying mechanisms of hypnosis, and current psychometric methods cannot address the mechanisms that underlie surface relations. "There are two aspects of hypnotic processes ... that obscure underlying mechanism: synergisms and overdetermination. Synergisms occur when mechanisms potentiate each other in such a way that a combination of processes becomes more than the sum of its parts. Overdetermination occurs when co-occurring mechanisms do not potentiate each other, such that any one of the mechanisms would have been sufficient to produce the observed effect" (p. 63-64).

The author suggests there are two options at present: Corrective Scoring (like the Curss.OI, an objective-involuntary score which, although unreliable on test-retest, appears it could be more a measure of "pure" hypnotizability) and not using the typical "work sample" approach. Balthazard and Woody (1992) suggested the Absorption Scale may provide a better measure of "hypnotizability" than the standard hypnosis scales because absorption scores are more strongly related to difficult hypnotic performances.

Bertrand, Lorne D.; Stam, Henderikus J.; Radtke, Lorraine (1993). The Carleton Skills Training Package for modifying hypnotic susceptibility--a replication and extension: A brief communication. International Journal of Clinical and Experimental Hypnosis, 41, 6-14.

This study employed the Carleton Skills Training Package (CSTP) to attempt to enhance both objective and subjective components of hypnotic susceptibility. In addition, changes in susceptibility were compared for subjects administered a standard hypnotic induction procedure and for subjects

given brief "place yourself in hypnosis" instructions. Results indicated that subjects who were administered the CSTP exhibited significant gains in both objective and subjective susceptibility scores that were maintained at two separate posttests with different scales. No differences were observed between the groups administered the standard induction and those administered the self-induction instructions.

The authors do not make much of the latter finding, but I find it to be the more interesting outcome. "Two experiments (Barber & Calverley, 1969; Stam & Fraser, 1986) found that subjects who sat quietly for 5 minutes following an instruction to "place yourself in hypnosis" attained similar scores when responding to test suggestions as did subjects who were administered a 5-minute hypnotic induction procedure. The CSTP informs subjects that hypnotic induction procedures do not achieve their effects by inducing a trance state and that such procedures function to produce relaxation rather than to enhance responsiveness to suggestion. In addition, the CSTP emphasizes to subjects that responses to suggestions do not 'just happen' but must be actively generated. To the extent that subjects attend to these aspects of the CSTP procedure, they should exhibit equivalent increments on behavioral and subjective indexes of susceptibility regardless of whether they are administered a formal hypnotic induction procedure or simply told to 'place themselves into hypnosis.'" (p. 7).

"That naive subjects can produce equivalent objective, subjective, and involuntariness scores following such instructions highlights the degree to which hypnotic responses are not dependent on formal induction procedures. The fact that so-called active-alert induction procedures are also equivalent in producing hypnotic responses supports this notion (Banyai & Hilgard, 1976)" (p. 13).

Bruehl, Stephen; Carlson, Charles R.; McCubbin, James A. (1993). Two brief interventions for acute pain. Pain, 54, 29-36.

This study evaluated two brief (3-5 min) interventions for controlling responses to acute pain. Eighty male subjects were randomly assigned to 1 of 2 intervention groups (Positive Emotion Induction (PEI) or Brief Relaxation (BR)) or to 1 of 2 control groups (No-instruction or Social Demand). The PEI focused on re-creating a pleasant memory, while the BR procedure involved decreasing respiration rate and positioning the body in a relaxed posture. All subjects underwent a 60-sec finger pressure pain trial. Analyses indicated that the PEI subjects reported lower ratings of pain, fear, and anxiety, and experienced greater finger temperature recovery than controls. The BR procedure resulted in greater blood pressure recovery, but did not alter ratings of pain or emotion relative to controls. Further research is needed to explore the clinical use of the PEI for acute pain management.

Cardena, Etzel (1993, October). Hypnotizability and mental boundaries: A correlational study. [Paper] Presented at the annual meeting of the Society for Clinical and Experimental Hypnosis, Arlington Heights, IL.

#### NOTES

Author is developing Ernest Hartman's Mental Boundaries Questionnaire. Hartman does research on chronic nightmare sufferers. He says they have thin mental boundaries, defined in various ways. Art students have thin boundaries, Navy officers thick boundaries. The questionnaire has 145 items, less 7 that are scored zero.

Item Groups: Sleep/wake/dream Unusual experiences (e.g., deja vu) Thoughts, feelings, moods Child, Adolescent, Adulthood feelings Sensitivity Neat, exact, precise Edges, lines, clothing (flexible space) = Personal score

Opinions about children about organizations about people, nations, groups, about beauty, truth = World total

**Sumbound (personal + world total) Hypnotizability should relate to Personal score more than World total.**

**Also used: 2. Field's Inventory 3. Kirsch's Inner subjective experiences (of the Harvard Scale) 4. Tellegen's Absorption Scale 5. Harvard Hypnotizability Scale**

**Gave the measures in different contexts from the hypnotizability measures. The Absorption scale (different subscales) correlated best with the Hartman's scale, but subjective scales also correlated with "Personal Score."**

**The lack of significant correlation between Harvard and Thinness of Boundaries questionnaires may be due to differences in voluntariness experience on the Harvard. Or Woody and others suggest hypnotic response may be due to compliance in some samples. Barrett had found a correlation of .19 with hypnotizability; and Robert Kunzendorf found a similar correlation.**

**Council, James R.; Grant, Debora L. (1993, October). Context effects: They're not just for hypnosis anymore. [Paper] Presented at the annual meeting of the Society for Clinical and Experimental Hypnosis, Arlington Heights, IL.**

## **NOTES**

**Context effects in Absorption research are found in correlations, not in mean differences. Original paper has been replicated and yet results are not always significant. Now we are trying to generalize the effect to other areas: an individually administered measure will influence other measures made in the same session.**

**Other tests that correlate with hypnosis are studied with 2 x 2 design, enabling order effects and same vs separate contexts to be studied. Or two tests are administered at two points in time, with "bridges" between the two sessions (e.g. same experimenter, same consent forms, etc.) As one adds more and more bridging cues, the correlation of Absorption with other Tellegen MPQ subscales increases.**

**Same context assessment increases correlation between hypnotizability and 6-8 other scales; with childhood trauma scale when trauma scale is administered first; with beliefs in paranormal phenomena when the measure is related to an adjustment scale. The same inflation of correlations was found in Beck Depression scale research.**

**These results are of concern because we may have to re-do a lot of personality research that suggested correlation between personality test variables, as the correlations may be inflated by the effects of testing in the same context.**

**Kronenberger, William G.; La Clave, Linda; Morrow, Catherine (1993, October). Assessment of the hypnotic state in the clinical setting: Development of the hypnotic state assessment questionnaire. [Paper] Presented at the annual meeting of the Society for Clinical and Experimental Hypnosis, Arlington Heights, IL.**

## **NOTES**

**We do research, clinical work and teaching. In this setting students ask, how do I know when somebody is hypnotized? We wanted to give them a normative sense of what to expect. Supervisory issues arise--e.g. when student reports that a patient "looked very hypnotized." We also wanted a measure that could track changes from one hypnotherapy session to another. We wanted quantification of hypnotic response (e.g. to use in medical charts).**

**We looked at self report measures, reviewed by Tart (number ratings) and hypnotizability scales; we reviewed articles, looked at what we teach, etc.. Criteria for the scale we developed were: 1. brief 2. unobtrusive (not introducing something different into the hypnosis process) 3. easy to use 4. have both behavioral and subjective components 5. clinically useful 6. apply to wide age range (we have patients**

ages 7-60) 7. apply to many different types of inductions (though there is no clinical scale that will apply to all types of inductions). We use a more permissive, relaxation induction ourselves.

We assessed observed behavior during hypnosis as well as immediately following hypnosis, and then asked patients questions about what the experience was like for them. From their responses we developed the Hypnotic State Assessment Questionnaire. The scale has 18 items, as follows: 1.

**Hypnotic State Observation (HSO) Items**

Noise Factor (e.g. drumming fingers)

Noise

Spontaneous Verbalizations

Behavior Factor

Motoric behavior (spontaneous)

Focused attention (not moving eyes)

Rhythmical Breathing

Relaxed state/Lack of tension Each are coded 1-5 with behavioral anchors at 1, 3, and 5 2. Post Hypnotic Observations

Positive Experience Factor (rated Yes-No)

Smile

Spontaneously Verbalize Positive Experiences 3. Post Hypnotic Inquiry

Automaticity Factor

Thoughts/feelings happen by selves

Thoughts happen without trying to think

PHI Uniqueness/Relaxation Factor

Felt this way before (not hypnosis)

Interrater Reliabilities of Subscales are higher than .9 except for Waking (rubbing eyes and stretching). We studied the HSAQ in 50 patients with a variety of problems (anxiety, depression, eating problems, smoking, somataform problems).

Scores have a floor effect; HSAQ can't determine very high depth from moderate depth, but we don't know if that is clinically meaningful. The HSO behavior factor was significantly correlated with after-hypnosis observations and inquiry. The HSO behavior factors also significantly correlated with the patient's ability to resist unexpected distractions, to comply with therapist requests, and to respond to post-hypnotic suggestions

1992

**Balthazard, Claude G.; Woody, Erik Z. (1992). The spectral analysis of hypnotic performance with respect to 'Absorption'. International Journal of Clinical and Experimental Hypnosis, 40, 21-43.**

In factor analyses of the hypnosis scales, the essential result is that the items form a continuous, 2-dimensional fan-shaped pattern. This continuum is referred to as the "spectrum of hypnotic performance." "Spectral analysis" is introduced as an exploratory procedure which makes use of this notion of continuum or spectrum. Spectral analysis consists of a graphical display of the level of latent correlation between a variable and individual hypnotic performances when the latter are arranged according to their position in the spectrum. The spectral analysis of hypnotic performance with respect to absorption is illustrated using data from a sample of 160 Ss. The results indicate that absorption is more strongly related to difficult hypnotic performances than to easy ones. In particular, illustrative item characteristic curves are presented to show that although easy hypnotic performances do not require the processes tapped by individual differences in absorption, a certain level of absorption is necessary to pass difficult hypnotic items. In addition, a high level of absorption may be sufficient in and of itself for difficult hypnotic performances. These results are discussed in light of some speculations by Shor, M. T. Orne, and O'Connell (1962) and Tellegen (1978/1979) concerning the

differential contribution of ability components to performance on difficult hypnotic suggestions. The results are also related to a variety of work in social psychological models of hypnotic performance.

## NOTES

Spectral analysis "consists of a graphical display of the level of latent correlation between a variable and individual hypnotic performances when these hypnotic performances are arranged according to their position in the spectrum--which is indexed by item difficulty" (p. 25). Difficulty (the proportion of Ss that pass a given item) is on the X-axis; the degree of latent correlation is on the Y-axis. "It is necessary to differentiate between the manifest and the latent relationship of a variable to a dichotomously scored hypnotic performance. The manifest relationship is given by the point biserial correlation and the latent relationship is given by the biserial correlation. ... By inspecting the overall pattern of these biserial correlations as a function of item difficulty, it is possible to overcome the difficulty-content confound, because the biserial correlations are not affected by item difficulty" (p. 25).

"Throughout the easy and middle ranges [of item difficulty], the biserial correlation of hypnotic performance with absorption remains slightly above .2, then it rises sharply in the difficult range--beginning roughly where only one in four Ss can pass the item--to a value slightly above .5" (p. 27). "In essence, the proportion of Ss that pass a particular hypnosis suggestion given a particular score on the absorption scale is being plotted" (p. 30).

In their discussion, the authors relate their position to that of other theorists. Shor, Orne, & O'Connell (1962) proposed that both ability and nonability components contributed to hypnosis, with ability being the primary determinant of hypnotic performance at deeper levels. Shor et al. found a correlation between depth ratings and a questionnaire that tapped 'hypnotic-like experiences' to be .45; the correlation was .84 when computed for only the Ss who became deeply hypnotized, but only .17 for Ss who were only lightly or medium-level hypnotized. They concluded that their questionnaire predicted hypnotizability only for the "deeper region" of hypnosis.

Tellegen (1978/1979) proposed a two-factor model, one factor being genuine responsiveness and the other being compliance. He suggested that various hypnosis test items draw on the two factors in differing degrees. Tellegen's genuine responsiveness factor would be similar to Shor et al.'s ability components, and Tellegen's compliance factor would be similar to Shor et al.'s non-ability components. (The Shor model goes farther than Tellegen in positing a gradual shift in the relative contributions of the two components as one moves from easy to difficult items, and this gradualness is part of the authors' spectrum model.)

The two-factor model is different from the general factor (plus special factors) model suggested by E. R. Hilgard (1965); Hilgard's general factor would probably correspond better to the Tellegen genuine responsiveness factor and the Shor et al. ability component than to the compliance factor or nonability component, which probably would correspond more to the easier items on hypnotizability scales.

Spanos et al. (1980) suggested that cooperativeness and expectation might be more important with ideomotor and challenge suggestions, and ability to treat imaginings as real (i.e. absorption) more important for more difficult cognitive items. Sarbin (1984) developed a typology with two types of individuals--those who respond to the hypnosis context by "joining the game" and knowingly create an illusion that their response is involuntary (the compliance kind of response), and those who convince themselves and others that their response is involuntary (the genuine responsiveness factor kind of response).

[Speaking of the context effects observed but not replicated 100% of the time, on the correlation between absorption and hypnotizability.] "It is possible that context effects may depend on the difficulty of the hypnotic suggestions and the latent abilities of the sample used. For relatively good hypnotic Ss performing relatively difficult suggestions, the correlation of absorption with hypnotizability may be stable across different contexts; however, for less able Ss performing relatively

easy suggestions, the correlation, depending more on the 'non-ability' component, may be quite responsive to context manipulations. It might also be mentioned parenthetically that details of the instructions used to introduce the particular hypnosis scale employed may differentially pull for one kind of component or the other" (p. 39).

Frischholz, Edward J. (1992, October). Dissociation. [Paper] Presented at the annual meeting of the Society for Clinical and Experimental Hypnosis, Arlington, VA.

## NOTES

There are two approaches for studying dissociation 1. phenomenological: describe difference types of dissociative phenomena, e.g., forgetting, multiple personality disorder or MPD 2.theoretical: explain the physiological/ psychological processes by which things become associated/disassociated, e.g., Freud (repression) vs. Janet (dissociation).

Two types of dissociation: 1. dissociation of awareness (amnesia, unconscious cognitions) 2. dissociation of volition (loss of executive control over behavior, psychological automatisms)

Normal Dissociation is characterized as: 1. content is narrow and specific 2. duration is brief 3. awareness of loss of material exists 4. control can be re-established

Abnormal Dissociation is characterized as: 1. content is broad (self-identity) 2. duration is extended 3. no awareness of loss of material exists 4. no re-establishment of control

The most widely used measure is Dissociative Experience Scale (Bernstein & Putnam) which has .84 to .96 test-retest correlation (Bernstein & Putnam, 1986; Frischholz et al.)

Mean Scores for DES MPDs 55. DD NOS 40.8 Students 23.8

He advocates a cutoff score above 40 as indicating abnormal dissociative experiences (that would yield 6% false negatives). Above 65, suspect faking or over-reporting of dissociative experiences.

Factor Analysis of the DES would associate the following items: 1. Absorption Factor: 2, 14, 15, 17, 18, 20 (normal dissociation) 2. Amnesia Factor: 3, 4, 5, 8, 25, 26 (pathological dissociation) 3. Depersonalization/Derealization Factor: 7, 12, 13, 14, 27, 28

Correlations of DES with other tests:

Tellegen Ambiguity Jenkins

Absorption Tolerance Activity DES Total .39 .24 .04 DES Amnesia .24 .22

See Table from AJCH in July 1992, which replicates a study by Nadon Table 2  $r = .12$  with hypnotizability (Nadon reported .18).

One could use both the DES and hypnotizability scores to distinguish between different clinical groups. For example, dissociative patients reverse amnesia while schizophrenics don't.

One could distinguish real MPDs vs Simulators based on Special Hypnotic Phenomena: with Real MPDs half show the hidden observer phenomenon, therefore they hide their MPD; simulators show the hidden observer phenomenon 100% of the time. Another item that discriminates is the Orne Double Person Hallucination item. MPDs 50- 62% show it, but 92-80% [incorrect percentage in these notes?] of simulators do experience the hallucination. Of these 70-75% of the MPDs are able to distinguish the hallucination; only 45-40% of simulators are able to distinguish the hallucination. Real MPDs know, can tell difference between a hallucinated person and the real person whereas simulators maintain they can't tell who is the real person.

It's not true that MPDs are extremely high in hypnotizability. They score in 8-10 range. The MPDs score 1 SD above normals but they are not off the end of the scale.

These are good ways of testing whether someone is faking MPD. We have replicated this many times, getting better replication of MPD simulators than high hypnotizable simulators.

Another method for distinguishing true MPDs from simulators involves demonstration of the Einstellung (learning set) effect.

Looking at Water Jar Problems, patients learn to solve the problems the long way. They teach personality A how to solve problem by long solution method (four trials of B - A - 2C); on the fifth trial, 95% of Ss solve the problem by the long method, the Einstellung (learning set) effect. Switch to personality B and give the same test. If there were no transfer, people immediately see A-C, which is a short method for solving the problem. It has been observed that 50-60% of MPDs do not show Einstellung effect; they immediately see the short solution.

Have done this also with retroactive interference word learning model.

Effect of context. Kohlenberg (Behavior Therapy Journal) selectively reinforced one personality of an MPD, which then 'came out' more often; during extinction the frequency of seeing that personality went back to baseline.

I used Greenspan's and Erickson's learning without awareness paradigm. When a low baseline frequency personality emerged, I'd reinforce the person; when a dominant personality came out I'd start yawning, look out the window, etc. During extinction the frequency went back toward normal baseline level, but not all the way. These indicate you can shape the appearance of one personality, but not that it's iatrogenic.

Can also do this with schizophrenics, normal highly hypnotizable subjects.

Frischholz, Edward J. (1992, October). Myths about hypnosis that never were true: And always will be. [Paper] Presented at the annual meeting of the Society for Clinical and Experimental Hypnosis, Arlington, VA.

#### NOTES

Hypnotizability is not normally distributed on either the Stanford Scales (Hilgard's published graphs) or the HIP. However the eye roll sign is normally distributed.

In a meta-analysis, the average correlation between the eyeroll sign and the Stanford hypnotizability score is .33 (not, as most think, a zero).

New data relate the eyeroll sign to the HIP Induction score (.25 - .52), SHSS:C (.44 - .60), and SRSC (.43 - .31) for normal and clinical populations, respectively.

Many investigators have correlated Absorption with hypnotizability, but Nadon's summary, with 5079 Ss the correlation is only .23.

Why has the eye roll been so neglected in hypnosis research, when it correlates .33 and the Absorption scale correlates .23?

Lastly, for a rapprochement, the handout provides data on a correlation between Absorption and the HIP. With 226 smokers, 95 phobics, 65 chronic pain patients treated by Spiegel, who 20 minutes later administered the Absorption scale, the HIP Induction score correlated .41 with Absorption. The Eyeroll alone correlated .43 with Absorption. The Eyeroll correlated only .24 [?] with Induction score.

This means a combination of eyeroll sign plus Absorption raises the correlation of predictors with hypnotizability up to .48 for the entire sample. Using just smokers as Sample 1 and others as a Validation Sample, for a double cross validation: Eyeroll plus Induction Score to predict Absorption, the correlation is  $r = .46$ .

I want to advocate wider use of the eyeroll test, which requires an extra 5 minutes. We can dispel the myth that the HIP is not a valid measure.

Frischholz, Edward (1992, October). The dimensionality of hypnotic performance. [Paper] Presented at the annual meeting of the Society for Clinical and Experimental Hypnosis, Arlington, VA.

#### NOTES

A 1985 article by Balthazar & Woody in Psychological Bulletin is the best I have read on this topic, and on how factor analysis can be used fruitfully.

Many people using the same data sets have arrived at different conclusions. My results are based on two data sets: Balthazar & Woody's, in which they created a unidimensional scale. (If you factor analyze a simplex matrix you obtain a 3 factor matrix; yet you knew it was unidimensional. They pointed out the 2nd factor correlated with item difficulty, and the 3rd factor had a U-shaped correlation with item difficulty.)

Factor analysis may not be best way to demonstrate unidimensionality.

I decided to use non metric multidimensional analysis to confirm unidimension. By this, Form A appears to be multidimensional. The same holds true for Stanford Form C scale.

Interpretability of the different dimensions? I agree with Dr. Stone: unidimensions are better for interpreting tests. But you should start out by constructing one in the first place.

I argue that Form C is unidimensional, because the items were selected by using item/full score correlations, hence a first component was built into it. But what does the scale measure? The only way to know is to correlate it with external measures, like Woody does. There are no studies using factor analysis showing that different factors on hypnotizability tests have different correlations with external measures (e.g. Factor 1 doesn't correlate differently with Absorption than Factor 3).

We might better start with a theory if we are going to construct new hypnotizability scales. Don't just use item total correlations. It would be better to find items representing different dimensions, scale the items, then correlate them with different external referents.

Then when we do collect data, make sure the items are unidimensional representations.

Third, we should appropriately validate these dimensions.

Giolas, M. H.; Saners, B. (1992). Pain and suffering as a function of dissociation level and instructional set. Dissociation, 5, 205-209.

48 female student Ss who scored above 20 on the Dissociative Experiences Scale and 48 subjects scoring below 20 on the DES were compared for response to ischemic pain. Experimental conditions included (1) a group imagining their arm becoming numb and insensitive, (2) a distraction group focusing on their breathing, and (3) a control group with no instructions. Subjects rated pain at one-minute intervals for the sensory experience of pain and for suffering (the emotional experience). The procedure was ended at subject's request or after 20 minutes. Across all conditions, the high dissociative group tolerated pain significantly longer than low dissociatives. Analysis revealed lower suffering ratings for high dissociators in the condition where, like in hypnosis, they imagined their arm numb. This is consistent with beliefs that during abuse in childhood the child learns to use imagination to reduce suffering.

Frischholz, Edward J.; Braun, Bennett (1991, August). Diagnosing dissociative disorders: New methods. [Paper] Presented at the annual meeting of the American Psychological Association, San Francisco.

Five new methods which have proven useful in the differential diagnosis of dissociative disorders from other psychiatric syndromes are identified. The first method involves the use of the Dissociative Experiences Scale, a self-report questionnaire which significantly discriminates dissociative psychopathology from normal dissociative experiences. The second method involves the use of various measures of hypnotizability (e.g., Hypnotic Induction Profile; Stanford Hypnotic Susceptibility Scale, Form C; self-ratings of hypnotizability) in discriminating between various psychiatric groups. The third method involves the use of qualitative responses to individual test items (e.g., instructed posthypnotic amnesia) to discriminate between different psychiatric syndromes. The fourth method involves the use of an implicit memory test to measure the amount of between-personality state amnesia in patients suffering from Multiple Personality Disorder. The fifth method involves the use of

special hypnotic phenomena (e.g., the Orne double person hallucination and the Hilgard hidden observer item) to discriminate between dissociative disorder patients and subjects simulating dissociative psychopathology. (ABSTRACT from Bulletin of Division 30, Psychological Hypnosis, Provided by former Editor, James Council.)

#### NOTES

Five new methods have proven useful in the differential diagnosis of dissociative disorders. The first method involves the use of the Dissociative Experiences Scale, a self-report questionnaire which significantly discriminates dissociative psychopathology from normal dissociative experiences.

The second method involves the use of various measures of hypnotizability in discriminating between various psychiatric groups.

The third method involves the use of qualitative responses to individual test items (e.g., instructed posthypnotic amnesia) to discriminate between different psychiatric syndromes.

The fourth method involves the use of an implicit memory test to measure the amount of between-personality state amnesia in patients suffering from Multiple Personality Disorder.

The fifth method involves the use of special hypnotic phenomena (e.g., the Orne double person hallucination and the Hilgard hidden observer item) to discriminate between dissociative disorder patients and subjects simulating dissociative psychopathology.

Avants, S. Kelly; Margolin, Arthur; Salovey, Peter (1990-91). Stress management techniques: Anxiety reduction, appeal, and individual differences. Imagination, Cognition and Personality, 10, 3-23.

#### NOTES

Four stress management techniques were evaluated for their general appeal, their immediate benefits, and the subjective experiences they evoke. One hundred undergraduates were randomly assigned to one of five treatment groups: (1) progressive muscle relaxation (PMR); (2) distraction imagery; (3) focused imagery; (4) listening to music; (5) sitting quietly (control). Distraction imagery and listening to music were the only techniques found to reduce anxiety to a greater extent than simply sitting quietly. The techniques differed in the way they made subjects feel, but not in their general appeal. Individuals with a 'blunting' coping style were more likely to find all five techniques appealing.

Tests used included the Miller Behavioral Style Scale, Cognitive-Somatic Anxiety Questionnaire of Schwartz, Davidson & Golman, Life Orientation Test of Scheier & Carver, Somatic Perception Questionnaire of Landy and Stern, Body Consciousness Questionnaire of L. C. Miller, Murphy, & Buss, Betts' Questionnaire Upon Mental Imagery, Shortened Form, State-Trait Anxiety Inventory, and Technique Evaluation Questionnaire of the authors.

Progressive muscle relaxation was according to Bernstein & Borkovec. Distraction imagery involved successively imagining a walk along a beach, a stroll across a flower filled meadow, sitting by a stream, a walk into the woods, sitting in a cabin in the woods listening to the rain against the windowpane, all including images in a variety of sense modalities. Focused imagery involved creating an image of a stressor, then through symbolic imagery experiences Ss were guided through a typical day's events that might lead up to the stressor, reinterpreting cues associated with the stressor as signals that they are in control, visualizing encountering the stressor feeling strong and determined, and any physical sensations reinterpreted as 'energy' that would help them to cope, visualizing enjoying their success (from Crits-Cristoph & Singer. Music was a 20-min tape (10 min of music used in the distraction imagery tape--Natural Light by Steve Halpern & David Smith) and 10 min of music used in background of the focused imagery tape (Structures of Silence by Michael Lanz). A 5th group, Control, was instructed to sit quietly with eyes closed.

This data can be used in support of imagery-suggestion types of hypnosis (as in surgery study) reducing anxiety. It shows particularly strong effects for people high in cognitive anxiety or low in optimism, pre-treatment.

Discussion: "... we feel confident that our distraction techniques were more effective for the immediate relief of anxiety than was PMR. This conclusion is consistent with the Suls and Fletcher meta-analysis (29) that suggested that 'avoidance' is an effective short-term coping strategy. That distraction (positive) imagery may be a more useful clinical technique than focused (active involvement) imagery was concluded in a study comparing these two techniques in the treatment of phobias (24)" (p. 19. [Ref #24 is Crits-Cristoph & Singer (1983) in *Imagination, Cognition, and Personality*.]

"Pessimism and cognitive anxiety emerged as the only individual difference variables to influence anxiety reduction. Pessimism as measured by the LOT is cognitive in nature, with most of the items relating to expectations of negative outcomes; similarly, cognitive anxiety is characterized by worry and an inability to control negative thoughts and images. That individuals who perceive their world somewhat negatively should have entered the study more anxious than individuals who do not is hardly surprising. What is surprising is that despite an inverse relation between cognitive anxiety and the ability to relax, these individuals were able to benefit from whatever technique they performed to a greater extent than were individuals with a more positive outlook. In fact, after performing the technique, pessimists had reduced their anxiety to the level of optimists" (p. 19).

"The stress management techniques used in the current study did not differ in their appeal" (p. 20). "Our finding that PMR produced more somatic effects than did focused imagery and less cognitive effects than did distraction imagery, listening to music, or sitting quietly is consistent with the model of anxiety proposed by Davidson and Schwartz (17). Our findings are also generally consistent with a conclusion reached by Woolfolk and Lehrer (4): that although various techniques are generally stress reducing, they seem to have highly specific effects. However, we found no support for the hypothesis that individuals who express anxiety cognitively (or somatically) prefer and benefit most from techniques that produce cognitive (or somatic) effects. In fact, the extremely high correlation found between the cognitive and somatic anxiety subscales of the Schwartz et al. measure (5) casts some doubt on the usefulness of a cognitive-somatic distinction, as does the corr between the experience of physical symptoms under stress (the Somatic Perception Questionnaire) with the cognitive, as well as the somatic, anxiety subscale.

"The finding that blunterners experiences more 'somatic effects' regardless of the technique they were assigned may have been the result of a single response--'how much did mind-wandering interfere with performing the technique'--which was the only Factor 2 item that was highly inversely related to blunting. Since blunterners are more likely to perceive mind wandering as the essence of stress management rather than as 'interference,' we do not view this main effect as particularly illuminating" (p. 20). "However, our finding that blunterners experienced all techniques as appealing is consistent with the results of Martelli et al. (1) who found that individuals with low information-preference benefitted from what the authors labeled an 'emotion-focused' intervention, but which, in fact, included many of the quite diverse stress management techniques that we compared in the current study. That 'avoiders' failed to benefit from any intervention in the Scott and Clum study (11) may be due to the nature of the stressor [postsurgical pain]. Our undergraduates may have been more like the Martelli dental patients in terms of their level of distress than were the Scott and Clum subjects who were patients undergoing major surgery (hysterectomy or cholecystectomy). Future research needs to examine possible three-way, technique by patient by stressor-type, interactions (cf. 19)" pp 20-21.

Biasutti, M. (1990). Music ability and altered states of consciousness: An experimental study. *International Journal of Psychosomatics*, 37, 82-85.

The relationship between music and altered states of consciousness was studied with 30 subjects divided into hypnosis and control groups. The "Test di abilità musicale" was applied. The hypnosis group did the retest after posthypnotic suggestions and the second in waking conditions. The hypnosis group had better results than the control group, especially in the rhythm test ( $p < 0.0001$ ).

Briere, John; Runtz, Marsha (1990). Augmenting Hopkins SCL scales to measure dissociative symptoms: Data from two nonclinical samples. Journal of Personality Assessment, 55, 376-379.

Describes a 13-item dissociation scale (DS) that uses numerical ratings and presents preliminary data regarding its reliability. The DS was administered to 2 samples of undergraduate women ( $N=569$ ). Ss also completed the SCL-90 or the Hopkins Symptom Checklist (HSCL). The DS was found to be reliable, and there was a correlation of the DS with self-reported child abuse history. Designed to complement the SCL-90 and the HSCL, the DS may be useful in research on the effects of psychological trauma.

Fischer, Donald G.; Elnitsky, Sherry (1990). A factor analytic study of two scales measuring dissociation. American Journal of Clinical Hypnosis, 32, 201-207.

The present study was designed to investigate the construct validity of dissociation. We administered the PAS and the DES to 507 male (48%) and female (52%) undergraduate students. Factor analysis on each scale separately showed that neither the PAS nor the DES adequately measures the three dimensions hypothesized to underlie dissociative experience. For both scales, a single factor emerged as replicable and reliable. Use of the scales, in their present form, therefore, should be limited to a single dimension representing disturbances in affect-control in the case of the PAS and disturbances in cognition-control if the DES is used at least with normal populations. Analysis of the combined items showed that the scales are measuring conceptually different but statistically correlated dimensions of dissociation. Further development of both scales is desirable, and further research should investigate the effect of different response formats on the internal structure of the scales.

## NOTES

The stated purpose of this study was to investigate the internal structure of the Perceptual Alterations Scale (PAS) and the Dissociative Experiences Scale (DES) using a large sample from a normal population.

"Sanders (1986) conceived of dissociation as a personality trait that is characterized by modification of connections between affect, cognition, and perception of voluntary control over behavior, as well as modifications in the subjective experience of affect, voluntary control, and perception. She chose items from the MMPI to represent this trait. Bernstein and Putnam (1986), utilizing the DSM-III definition of dissociation, constructed items from information derived from interviews with patients and clinicians to represent a number of different types of dissociative experiences" (0. 202).

"The PAS (Sanders, 1986) is a 27-item scale; subjects respond by checking one of the following categories using a 4-point Likert format: never, sometimes, frequently, almost always. The items related to modifications of regulatory control, changes in self-monitoring, concealment from self and others, and modifications of sensory, perceptual, and affective experiences.

"The DES (Bernstein & Putnam, 1986) contains 28 items. Subjects indicate the percentage of time they experience the feelings or behavior described by the items on a 10-point scale. The items related to the experience of disturbances in identity, memory, awareness and cognition, and feelings of derealization or depersonalization" (pp. 202- 203).

Results were as follows. The one-factor solution for the PAS accounted for 18.5% of the total variance.; 11 of the 28 items did not load significantly on the factor. The one-factor solution for the

DES accounted for 26.3% of the total variance; 7 of the 28 items did not load significantly on the factor.

"The 3-factor solution obtained by Sanders (1986) for the PAS was not replicated. An obvious reason for the different is that principal factor extraction was used in the present study, whereas principal components extraction was utilized by Sanders. ... Even when principal components analysis is performed on the present data, however, there are difficulties with the 3-factor solution" (pp. 204-205). "All of the criteria suggest that a single factor best represents the latent structure of dissociative experience as measured by the PAS and DES. Although the total amount of variance accounted for is low, the one-factor solutions for both scales are interpretable, replicable, and have high internal consistency. The items for the PAS appear to represent primarily the affect and control dimensions, whereas those for the DES represent the cognitive dimension" (pp. 205-206).

"Overall, both scales contain similar items, although the DES has more items relating to disturbances in memory and altered perception of time (i.e., cognition), whereas the PAS has more items reflecting specific disturbances in identity and control. It appears, therefore, that the scales are measuring conceptually separate but statistically correlated dimensions of dissociation" (p. 206).

Frischholz, Edward J.; Braun, B. G.; Sachs, R. G.; Hopkines, L.; Schaeffer, D. M.; Lewis, J.; Leavitt, F.; Pasquotto, J. N.; Schwartz, D. R. (1990). The dissociative experiences scale: Further replication and validation. Dissociation, 3, 151-153.

Interrater reliability for the DES was .96-.99, test-retest reliability was .93-.96, and internal consistency of DES scores was very high .93-.95. Both MPD and dissociative disorder NOS (DDNOS) patients scored significantly higher than students, and MPD patients scored significantly higher than DDNOS patients. A cutoff score of 45 to 55 maximizes the probability of distinguishing students from dissociative disorders (87%) while minimizing false positives (2%-6%) and false negatives (7%-11%). Suggestions for further research are made.

Gil, Karen M.; Williams, David A.; Keefe, Francis J.; Beckham, Jean C. (1990). The relationship of negative thoughts to pain and psychological distress. Behavior Therapy, 21 (3), 349-362.

Examined the degree to which negative thoughts during flare-ups of pain are related to pain and psychological distress in 3 pain populations: sickle cell disease, rheumatoid arthritis, and chronic pain. 185 adults completed the Inventory of Negative Thoughts in Response to Pain (INTRP), a pain rating scale, the SCL-90 (revised), and a coping strategies questionnaire. Factor analysis of the INTRP revealed 3 factors: Negative Self-Statements, Negative Social Cognitions, and Self-Blame. High scorers on Negative Self-Statement and Negative Social Cognitions reported more severe pain and psychological distress. Ss with chronic daily pain had more frequent negative thoughts during flare-ups than those having intermittent pain secondary to sickle cell disease or rheumatoid arthritis. The INTRP appears to have adequate internal consistency and construct validity.

1989

Grant, Guy (1989, June). An investigation of hypnotic susceptibility in self-hypnosis and imagery (Dissertation, University of Utah). Dissertation Abstracts International, 49 (12), 5517-5518-B.

NOTES

"There were two phases in the study. In Phase One hypnotic susceptibility scores were assessed for 43 graduate student subjects by the Harvard Group Scale of Hypnotic Susceptibility: Form A (HGSHS:A). In addition, the Self-Hypnosis Research Questionnaire (an experimental scale) provided performance scores for subjects under three hypnosis conditions: heterohypnosis, self-directed self-

hypnosis, and tape-assisted self-hypnosis. The first purpose in Phase One was to calculate correlations between hypnotic susceptibility and each of the hypnosis conditions. The second purpose was to determine if there were significant differences across the three types of hypnosis. The third purpose was to discover if any existing differences were dependent on level (e.g., low, medium, or high) of hypnotic susceptibility. Analysis of the data yielded significant correlations between hypnotic susceptibility and (a) heterohypnosis, (b) self-directed self-hypnosis, and (c) tape-assisted self-hypnosis. There were significant performance differences across the three hypnosis conditions with heterohypnosis being somewhat superior to tape-assisted self-hypnosis, and tape-assisted self-hypnosis being slightly superior to self-directed self-hypnosis. This relationship held true regardless of level of hypnotic susceptibility (e.g., low, medium, and high).

"In Phase Two, 49 graduate student subjects were administered the shortened form of the Betts' Questionnaire Upon Mental Imagery (QMI) as well as the HGSHS:A, and to determine if mental imagery is an important component of hypnotic susceptibility. Analysis yielded a significant correlation between the two measures.

"Based on the current data, it was concluded that the HGSHS:A had some utility for predicting performance in hypnosis. It was noted that, as compared with self-hypnosis, heterohypnosis provided the greatest chance of eliciting a positive hypnotic response from subjects not trained or experienced in hypnosis. It was also concluded that the QMI was correlated with and had some utility for predicting performance on the HGSHS:A. It had difficulty, however, differentiating between low and medium hypnotizability" (pp. 5517- 5518).

Hoyt, Irene P.; Nadon, Robert; Register, Patricia A.; Chorny, Joseph; Fleeson, William; Grigorian, Ellen M.; Otto, Laura; Kihlstrom, John F. (1989). Daydreaming, absorption and hypnotizability. International Journal of Clinical and Experimental Hypnosis, 37, 332-342.

## NOTES

It appears that the consistent correlation between hypnotizability and positive-constructive daydreaming is carried largely by three subscales--Acceptance of Daydreaming, Positive Reactions to Daydreaming, and Problem-Solving. Number other subscales consistently correlated with hypnotizability.

When absorption was taken into account, daydreaming activity made no independent contribution to the prediction of hypnotizability. "The present results differ from Crawford's (1982) somewhat, however, in terms of the specific aspects of daydreaming activity that are associated with hypnosis. Crawford found that hypnotizability correlated consistently (i.e., in both men and women) with three subscales tapping imagery variables: the presence of visual and auditory imagery in daydreams and the hallucinatory vividness of daydream imagery. In the present study, the imagery subscale, including both visual and auditory items, did not correlate significantly with hypnotizability; unfortunately, the hallucinatory vividness subscale is not represented on the short form (SIPI) of the daydreaming questionnaire used in this study. Crawford (1982) did not find consistent correlations between hypnotizability and scales measuring acceptance, positive reactions, and problem solving--the subscales that consistently yielded significant correlations in the present study. Not too much interpretive weight should be given to any of the correlations between hypnotizability and daydreaming subscales, until a full replication with reliable subscale measurements (such as those provided by the long, original IPI) has been completed. The important point made by Crawford (1982), and confirmed in the present study, is that hypnotizability is related to positive-constructive rather than guilty-dysphoric daydreaming" (p. 338). The two studies agree that absorption and hypnosis are not correlated with daydreaming scales reflecting poor attentional control. Given the theoretical emphasis in both domains on the narrowing of attention and exclusion of potentially distracting input, negative correlations with this aspect of daydreaming might have been expected.

Kihlstrom, John F.; Register, Patricia A.; Hoyt, Irene P.; Albright, Jeanne Sumi; Grigorian, Ellen M.; Heindel, William C.; Morrison, Charles R. (1989). Dispositional correlates of hypnosis: A phenomenological approach. International Journal of Clinical and Experimental Hypnosis, 37, 249-263.

Attempted to construct and validate a questionnaire measure of hypnotic- like experiences based on Shor's (1979) 8-dimension phenomenological analysis of hypnosis. Separate item pools were developed to measure each disposition: Trance, Nonconscious Involvement, Archaic Involvement, Drowsiness, Relaxation, Vividness of Imagery, Absorption, and Access to the Unconscious. Based on preliminary testing (total Number - 856), a final questionnaire was produced containing 5 items measuring normal, everyday experiences in each domain. Results from a standardization sample (Number - 468) showed that each of the subscales, except for Archaic Involvement, possessed satisfactory levels of internal consistency and test-retest reliability. Factor analysis indicated that 6 subscales loaded highly on a common factor similar to the absorption construct (Tellegen & Atkinson, 1974), while items pertaining to Relaxation and Archaic Involvement formed separate factors. Validation testing on 4 samples receiving the Harvard Group Scale of Hypnotic Susceptibility, Form A (HGSHS:A) of Shor and E. Orne (1962) (total Number = 1855) showed that the Absorption and Trance dimensions correlated most strongly with HGSHS:A; the correlations with Drowsiness, Relaxation, and Nonconscious Involvement approached 0. The scales derived from Shor's analysis, however, did not improve the prediction of hypnotizability over that obtained with the absorption scale (Tellegen & Atkinson, 1974).

1988

Bogenberger, Robert; Allen, Steven (1988, November). Relationship between Rorschach responses and hypnotic responsiveness. [Lecture] Presented at the annual meeting of the Society for Clinical and Experimental Hypnosis, Asheville, NC.

#### NOTES

The Rorschach is stable in adults, in terms of introversive vs. extroversive direction. Investigated four dependent variables: (1) distortions (e.g. "I felt the walls closing in."), (2) Loss of Distance (e.g. "I thought of abortions and infanticide."), (3) abstract/conceptual, (4) irrelevant imagery (e.g. "I thought of the book Watership Down.")

Highs gave responses more often in these groups. The combination of these four and some others discriminated Highs hypnotized from Highs not hypnotized and from Lows in both hypnotized and not hypnotized conditions.

Bowers, Patricia G.; Laurence, Jean-Roch; Hart, David (1988). The experience of hypnotic suggestions. International Journal of Clinical and Experimental Hypnosis, 36, 336-349.

The experience of nonvolition in response to hypnotic suggestions was investigated for 126 Ss. 2 different scales, a new scale providing discrete options for response and a previously used volition rating scale, gave Ss an opportunity to describe some of their subjective experiences after completion of a 12-item adaptation for group administration of the Stanford Hypnotic Susceptibility Scale, Form C (Weitzenhoffer & Hilgard, 1962). Ratings of depth of hypnosis were also obtained. Ss had been previously administered the Harvard Group Scale of Hypnotic Susceptibility, Form A (Shor & E. Orne, 1962). Distribution of descriptions of experience for passed and failed items were obtained. Total scores on subjective indices were found to be highly correlated with the behavioral score on the Waterloo-Stanford Scale of Hypnotic Susceptibility: Group C. Items differed, however, in the degree to which responses seem to occur effortlessly. Some suggestions have a substantial number of passed responses lacking the "classic suggestion effect," but only 7% of Ss have more than 2 such responses.

## NOTES

Earlier research on the subjective perception of voluntary enactment of suggestions found from 20% (K. Bowers, 1981; P. Bowers, 1982) to 55% (Spanos, Radtke, Hodgins, Stam, & Bertrand, 1983) of hypnotic responses were described as voluntary in nature. Methodological differences could account for the range in probability levels, and rating scales used did not provide for absence of behavioral response to a particular suggestion.

This research investigated three issues: "1. Using a choice format to describe experiences during hypnosis, what is the distribution of the different descriptions used to index the construct of nonvolition? When S gives a mid-point rating on a volition rating scale, to what experiences does he/she refer? 2. How do two aspects of subjective experience: nonvolitional experience descriptions and hypnotic depth reports, covary with behavioral passing and failing of items and with levels of hypnotizability? 3. How frequently does S pass an item behaviorally but indicate either that he/she did not experience the response or that he/she purposefully enacted it? On what items is this a more or less frequent occurrence? Are there just a few people who pass items in this fashion or is it a common observation?" (p. 339).

The Ss were seen in small groups. Immediately after hypnosis they scored their own hypnotizability scales. Then they were asked to rate their subjective response to each suggestion: - how much they had experienced the suggestion (1-5) - how involuntary their response had been (1-5) (These two items comprised the Voluntary Rating Scale (VRS) used by K. Bowers, 1981, and P. Bowers, 1982.) - how deeply hypnotized they had felt (1-10, Perry & Laurence format, 1980) - Choice Scale (example from the hand magnetism item below) "Choice Scale of Nonvolitional Experience:

Listed below are various ways people experience the hands together item. Please check the description(s) that most closely describe your experiences: (1) My hands did not move together at all. (2) I purposefully directed the movement of my hands most of the time. (3) I found I directed the movement of my hands and then later they continued to move together with no effort on my part. (4) I found my hands moving together without my helping them. (5) During this experience, the feelings of purposefully moving my hands were completely mixed with feelings that they were moving on their own. None of the above" (p. 340).

Considering both the passed and failed items, and after excluding the 'None of the above' category, "37% of items [on the W-SGSHS:C] were not experienced, 12% were enacted purposefully, 14% were experienced as intertwined volition and nonvolition, 17% were experienced as beginning purposefully but becoming nonvolitional, and 20% 'happen by themselves'" (p. 341). See Table 2, taken from the article.

Table 2 Average Percent of Ss per Item Choosing Each of the Options

Begins

No Purposeful Completely Purposefully; Happened Itself

Exper. Enactment Mixed Continues On NoTryng

Own Passed 7.5 12.2 21.8 26.2 32.2 Failed 60.4 13.9 10.4 9.3 5.9

Passed Items 3.0 10.7 30.0 47.2 9.1 Rated 3 on Volition Rating Scale

Thus of those failing an item, 60% reported that they did not experience the suggestion, while almost 26% reported some level of subjectively experienced nonvolition.

This research demonstrated that the Choice Scale is an improvement over the Voluntary Rating Scale, which has an ambiguous midpoint of '3' between voluntary and nonvoluntary extremes (on a 5-point scale). Almost half of the ambiguous '3' responses on the VRS were associated with a more meaningful response on the Choice Scale, indicating that the response started off voluntarily but then continued 'on its own.' Another third of the Ss indicated that there was an intertwining of volition and nonvolition.

The Choice Scale (transformed into an ordinal scale) was correlated with the VRS and hypnotizability and depth estimate scales. The correlations were "consistently high, suggesting that typically one reports feeling more deeply hypnotized when many suggestions are performed and passed, and more deeply hypnotized Ss report feeling that suggestions occur more 'by themselves' than do less hypnotizable Ss" (p. 342).

The authors note the complex relationship between behavioral and subjective experience. High hypnotizables report experience of nonvolition even with some failed items, and rate themselves as deeply hypnotized even when failing items. This is not true for low hypnotizables, whose self-rated depth varies directly with passing or failing items.

Mismatches were defined as passing an item behaviorally but reporting either that it was not experienced (Choice 1) or purposefully enacted (Choice 2). 93% of Ss had less than 3 mismatches; of the 8 Ss exhibiting 3 or more mismatches, 3 were medium-low hypnotizables, 4 were medium-highs, and 1 was highly hypnotizable. When one corrects their total hypnotizability score for the mismatch, people remain close to their original score however.

Some items had many more mismatches than others (See Table 6). The 'classic suggestion effect' reflected in a low percentage of mismatches (3-9%) was found for five items; three items had a moderate level of mismatches (16-22%); but four suggestions had mismatches on 34-41% of the passed responses. Item difficulty could not account for whether the classic suggestion effect occurred: two very difficult items were at opposite ends of the spectrum--positive music hallucination had the fewest and negative visual hallucination the most frequent mismatches. "One might speculate that the nature of one's ordinary imaging during the day makes some hallucinations well practiced and easier to produce, while others are rarely practiced and seem to require cognitive effort to reconstruct. ... Thus, instead of a mismatch representing 'faked' responses, it may at times represent S's report of a hallucination's seeming real while simultaneously requiring effort. Ideomotor suggestions have few mismatches. If they feel 'real,' it is by virtue of their seeming to occur without effort or volition" (pp. 346-347).

Table 6 Item % Mismatch Hand Lowering 2.9 Hands Together 4.8 Arm Rigidity 5.6 Music Hallucination 7.7 Dream 8.7 Arm Immobilization 15.5 Amnesia 21.6 Age Regression 21.8 Taste Hallucination 33.8 Negative Hallucination 34.6 Mosquito 38.1 Post-hypnotic Suggestion 40.8

Since highly hypnotizable people experience nonvoluntariness even when they fail items, tested hypnotizability must reflect more than simply passing test items on suggestion. "Research focusing exclusively on the nonvolitional aspect of hypnotic experience may be somewhat 'off the mark,' at least for some types of suggestions. Reports of nonvolition may be tracking the experience of effortless responding which may be just one aspect of a complex hypnotic response to cognitive suggestions. ... It may be that studies using free reports from Ss responsive to hallucination suggestions would be necessary prior to devising an appropriate 'choice' scale for these items. The work of Sheehan and McConkey (1982) provides a solid basis for such a task. The Choice Scale in the present study was derived from an understanding of the 'classic suggestion effect,' the concept of which is closely tied to ideomotor suggestions. This concept may or may not prove to be of central relevance to hypnotic hallucinations or more generally to cognitively demanding suggestions" (p. 347).

Hines, Larry; Handler, Leonard (1988, November). Hypnotizability and ego functions. [Paper] Presented at the annual meeting of the Society for Clinical and Experimental Hypnosis, Asheville, NC.

## NOTES

Researchers employed Bellak's Ego Functions Test (based on the clinical interview). Ss were 47 students and 1 non-student, some of whom had previously experienced hypnosis. They were all volunteers. Studied 12 ego functions. Used plateau hypnotizability which was defined as no improvement in Stanford Hypnotic Susceptibility Scale Form C after two hypnotic inductions; if they

did not reach a plateau by Session 4, the highest score was used. Stanford Hypnotic Susceptibility Scale scores ranged 4-12. High 10-12, Medium 6-9, Low 4-5.  $\bar{x}=9.04$ ,  $SD=2.21$ .

On the Bellak Test, High 12-13, Medium 10-11 (average functioning.), Low 1-9. Range 5-13; widest range was in Adaptive Regression in Service of Ego

Highest Mean = reality testing Lowest Mean = ARISE Majority fell into the medium range on all 12 ego functions measured.

A significant difference was found between High and Low hypnotizables on the following ego functions. [N.B. There may be transcription errors in the figures that follow.] 1. ARISE  $p<.02$   $r = .31$  Highs have greater ability to experience pleasure in regression. 2. Stimulus Barrier  $p<.003$  Highs are more flexible in their ability to separate from stimuli in their environment, Lows experienced stimulus overload. 3. Autonomous Functioning  $p<.01$  Primary acct./ in attention, learning, memory, motor function. 4. Objective Relativity  $p<.07$  5. Regulating control of drive  $p<.06$

Multiple regression accounted for 33% of variance in 12 ego functions. Stimulus Barrier alone accounted for 14% ( $p<.005$ ); ARISE accounted for 5% ( $p<.01$ ).

47% of Ss were High hypnotizables, 42% were in the Medium range.

1987

Crist, Dwayne Anderson (1987). The effect of suggestibility on the efficacy of relaxation training instruction: A multisession evaluation (Dissertation, University of Alabama). Dissertation Abstracts International, 47 (n9-B), 3950.

"Progressive relaxation is a well established procedure used in the treatment of anxiety related disorders. Research has suggested that the muscle tension-release component of progressive relaxation is the critical variable in producing relaxation effects. However, other techniques which do not employ muscle-tension release have proven effective. It has been suggested that treatment type may interact with personality characteristics to produce greater effects. Suggestibility was selected as a personality characteristic that may facilitate or inhibit relaxation effects. Fifty high and 50 low suggestible individuals were selected to participate based on scores from the Creative Imagination Scale. Half of each group as randomly assigned to either a progressive relaxation or imagery relaxation treatment. Subjects received four weekly sessions of relaxation training. The Relaxation Scale was administered before and after each session to assess effects of training. The results indicated that high suggestible individuals had significantly greater increases in relaxation within session on each of the three scales of the Relaxation Scale, but this appeared to be a result of lower pre-test scores. Only the Physical Assessment scale also demonstrated higher post-test scores for the high suggestible participants. A ceiling effect appeared to be operating for both the Physiological Tension and Cognitive Tension scales. There were no significant differences between the progressive relaxation and imagery relaxation treatments. It appears that muscle tension release may not be a critical variable in relaxation effects" (p. ).

De Sano, Christine F.; Persinger, M. A. (1987). Geophysical variables and behavior: XXXIX. Alterations in imaginings and suggestibility during brief magnetic field exposures. Perceptual and Motor Skills, 64, 968-970.

12 male and 12 female volunteers were evaluated for their suggestibility before and after an approximately 15-min. exposure to either sham, 1-Hz or 4-Hz magnetic fields that were applied across their mid-superior temporal lobes. During the field application subjects were instructed to view a green light that was pulsating at the same frequency as the field and to imagine countering an alien situation. Results were commensurate with the hypothesis that weak brain-frequency fields may influence certain aspects of imaginings and alter suggestibility.

## NOTES

"Subjects who had been exposed to the 4-Hz fields showed a significant decrease ... in heart rate compared to those who had been exposed to either the 1 Hz or sham-field conditions. A significant ... interaction of sex by field ... was noted for the change in HIP [Hypnotic Induction Profile] scales. Whereas both men and women in the sham-field condition tended to show less induction (~ 1 unit) on the second occasion ... women showed much greater (8.4 + 1.1) induction (= 3 units) if they had been exposed to the 1-Hz field while men showed much greater (8.0 + 1.5) induction (= 3 units) if they had been exposed to the 4-Hz fields. On the protocols, women reported significantly more fear responses than men. In addition, subjects who were exposed during the imaginings to the 4-Hz field showed more imaginings ... and more references to vestibular experiences (e.g., self or entity rising or floating) ... than those exposed to the other conditions" (p. 969).

"Dissociation scores on the HIP were correlated significantly ... with vestibular (0.44), imagery (0.43), and fear (-0.45) scores from the transcripts. Floating responses on the HIP were correlated with the amount of imagery. (0.46). There was a significant positive Pearson correlation between the compliance measure and the amount of arm levitation during the second induction only. These results suggest that hypnotic susceptibility may be increased following magnetic-field exposure but that the effective frequency is not the same for each sex. In addition, the amount of the imagery (particular vestibular experiences) increased if the person observed a light that was flashing at the same frequency as a 4-Hz applied magnetic field" (p. 969).

Hilgard, Ernest R. (1987). Research advances in hypnosis: Issues and methods. International Journal of Clinical and Experimental Hypnosis, 35, 248-264.

There are substantial areas of agreement upon the classical phenomena of hypnosis, illustrated by what we now have learned about hypnotic talent, amnesia, hallucinations, analgesia, and dissociative processes. While genuine advances in knowledge about hypnosis have been made in recent decades, differing orienting attitudes have kept some controversy alive, particularly in the interpretation of empirical findings. Differences of interpretation of the phenomenal and behavioral facts are to be expected in the present stage of developmental, cognitive, and social psychology.

## NOTES

The author writes of the "domain of hypnosis" as within the larger domain of social psychology (because it is usually interpersonal); cognitive psychology (because of alterations in perception, imagination, memory, and thought); developmental and personality psychology (because of individual differences); and physiological psychology (because of neurophysiological aspects).

In terms of what we know about hypnotic talent, he notes that high hypnotizability is not generally associated with psychopathology; that it may however be associated with a personality measure called absorption; and that there may be some inherited ability (Morgan, 1973). In the author's view, hypnosis is no longer considered simply a response to suggestion, since imagination and/or fantasy are very important.

In reviewing evidence of posthypnotic amnesia the author writes, "Subtleties in language require making careful distinctions among concepts such as compliance, suggestion, compulsivity, belief, self-deception, automaticity, the voluntary, the involuntary, and a happening. If these distinctions are glossed over, the choice of words (e.g., substituting compliance for response to suggestion) may give the impression that a finding departs more widely from conventional views than it does. We, too, have found that Ss used varied strategies or skills during amnesia, but this need not deny augmentation by suggestion.

"It takes genuinely high Ss to illustrate truly high posthypnotic amnesia... Many of the truly high hypnotizable individuals cannot break amnesia, no matter how hard they try" (p. 253).

Regarding the evidence for hypnotic hallucinations and trance logic, the author suggests that trance logic is not a clear concept because the Subject is capable of good logic while tolerating some inconsistencies. "It is ordinary logic to assume that if your hallucination is your own construction, it is you who can influence it by your own wishes. In the rare cases of transparent or diaphanous hallucinations there is still an 'out there' quality. People who report that they see wispy ghosts also see them as 'out there,' so that they qualify as hallucinations. The distinction appears to be one of perception and perception-like experiences within hypnosis rather than of logic" (p. 256).

In reviewing the evidence for hypnotic analgesia, the author acknowledges that pain relief is available with other kinds of interventions, or by using other kinds of psychological processes, but that does not diminish the contribution of hypnosis (which has a long and impressive clinical history). Following laboratory studies, it is noted that "the amount of alleviation of pain through hypnosis is positively correlated with the hypnotizability of the candidate for pain reduction. This result is not universally accepted, because some clinicians are convinced that those unsuccessful in hypnotic pain reduction are resisting hypnosis" (p. 256-257). In the present paper he acknowledges but does not review physiological literature on hypnoanalgesia.

Regarding the concept of dissociation, the author indicates that he considers it a more useful concept than the concept of trance or hypnotic state "when a person is only slightly or moderately involved in hypnosis ... . The advantage is that dissociations, as compared with altered states, can be described according to limited or more pervasive changes in the cognitive or motor systems that are being activated or distorted through suggestion in the context of hypnosis. Perhaps when all-inclusive enough, such changes can justify the use of the term trance or altered state, but I believe that these terms should be used, if at all, only for those for whom the immersion in the hypnotic experience is demonstrably pervasive" (pp. 258-259).

The author goes on to describe his initial discovery of the 'hidden observer' in an experimental context, and to relate the 'hidden observer' to others' earlier observations of a secondary report of an experience previously concealed from S's consciousness (Binet, 1889-1890/1896; Estabrooks, 1957; James, 1899; Kaplan, 1960). "The issues are still being worked on, but as in the case of trance logic the heart of the problem is not whether to speak of a hidden observer, but to recognize that there may be cognitive distortions in hypnosis even while some more realistic information is being processed in parallel, so that everything is not reportable by S" (p. 260).

1986

Bernstein, Eve; Putnam, Frank W. (1986). Development, reliability, and validity of a dissociation scale. Journal of Nervous and Mental Disease, 174, 727-734.

"Dissociation is a lack of the normal integration of thoughts, feelings, and experiences into the stream of consciousness and memory. Dissociation occurs to some degree in normal individuals and is thought to be more prevalent in persons with major mental illnesses. The Dissociative Experiences Scale (DES) has been developed to offer a means of reliably measuring dissociation in normal and clinical populations. Scale items were developed using clinical data and interviews, scales involving memory loss, and consultations with experts in dissociation. Pilot testing was performed to refine the wording and format of the scale. The scale is a 28-item self-report questionnaire. Subjects were asked to make slashes on 100-mm lines to indicate where they fall on a continuum for each question. In addition, demographic information (age, sex, occupation, and level of education) was collected so that the connection between these variables and scale scores could be examined. The mean of all item scores ranges from 0 to 100 and is called the DES score. The scale was administered to between 10 and 39 subjects in each of the following populations: normal adults, late adolescent college students, and

persons suffering from alcoholism, agoraphobia, phobic-anxious disorders, posttraumatic stress disorder, schizophrenia, and multiple personality disorder. Reliability testing of the scale showed that the scale had good test-retest and good split-half reliability. Item-scale score correlations were all significant, indicating good internal consistency and construct validity. A Kruskal-Wallis test and post hoc comparisons of the scores of the eight populations provided evidence of the scale's criterion-referenced validity. The scale was able to distinguish between subjects with a dissociative disorder (multiple personality) and all other subjects."

1985

Balthazard, Claude G.; Woody, Erik Z. (1985). The 'stuff' of hypnotic performance: A review of psychometric approaches. Psychological Bulletin, 98, 283-296.

Reviews psychometric investigations into the nature of the processes that underlie hypnotic performance and examines issues that underlie psychometric investigations of hypnosis scales, such as the Stanford Hypnotic Susceptibility Scale. The issues addressed are dimensionality and the problem of difficulty factors, the interpretation of factorial dimensions, and componential alternatives to the factor analytic approach. It is argued that hypnotic performances are most likely overdetermined in that they reflect the combined influence of a plurality of processes. The relevance of various componential models, each reflecting a different contemporary theoretical perspective toward hypnosis, and some of the implications of such models for future research are discussed. (77 ref).

Kelly, Paul James (1985, November). The relationship between hypnotic ability and hypnotic experience (Dissertation). Dissertation Abstracts International, 46 (5), 1690-B.

"This study investigated the relationship between four types of hypnotic experience and hypnotic ability. The types of experiences were: dissociation, the experience of involuntariness, altered state effects, such as perceptual alterations and diminished reality sense rapport, transference-like involvement with the hypnotist, and relaxation. A 47-item scale, the Hypnotic Experience Questionnaire was developed to measure types of hypnotic experience. It was given to 484 subjects and then to a subsample of 272 students. When the scale was factored, four stable factors emerged: Nonconscious/Trance, Rapport, Relaxation, and Cognitive Rumination. A Group Profile Scale was also developed to measure students and when it was factor analyzed four factors were extracted: Hallucinations and Fantasies, Amnesias and Post-Hypnotic Compulsions, Motor Inhibition, and Direct Motor Suggestion. "Two statistical approaches were used to investigate the connections between hypnotic ability and hypnotic experience . Canonical analysis was used to identify the main relationships between hypnotic ability and hypnotic experience and factor analysis was used to explore the relationship among measures of hypnotizability and hypnotic experience. Two canonical variates from the canonical analysis were significant. The first variate was characterized by a dissociative-imaginative involvement process, and the second variate tapped a rapport-social compliance process. "When 25 variables, representing components of hypnotic ability and hypnotic experience, were factored, five factors were extracted. Imaginative Involvement, Ideomotor Response, Rapport, Cognitive Inhibition, and Relaxation. The results of the factor analysis suggested that dissociative experience and altered state experience are related to hypnotic ability but rapport and relaxation are not. "The results of study, taken as a whole, suggest that relaxation and rapport may happen in the hypnotic situation, but neither experience is related to the condition of being hypnotized in any essential way. The results suggest that the hypnotic condition is characterized by dissociative experience, altered state experience, and by successful performance on hypnotic ability tasks. From a theoretical point of view, the results strongly supported Hilgard's theory, partially supported Shor's theory, and failed to support Edmonston's theory" (p. 1690).

1984

The mainstream of neuropsychological research and practice has been devoted to the impact of the brain as an independent variable on behavior as a dependent variable. Evidence is currently available to make clear that the order of causation may be reversed: Behavioral changes can have a durable impact on the brain. The results of extensive research indicate that a large number of neuroanatomical, neurophysiological, neurochemical, and neuropsychological parameters of the animal brain can be modified through environmental manipulation, sensory experience, and systematic training. Some evidence is available to show that psychological stimulation has certain effects on the physiology of the human brain. For instance, hemisphere-specific stimulation through the presentation of words flashed in a visual hemifield appears to modify the electrophysiological activity of the contralateral hemisphere in dyslexic children and to affect their subsequent reading performance. Neuropsychology may profit from paying more attention to the ecology of the human brain.

#### NOTES

An 18th Century anatomist in Italy, Malacarne, demonstrated increased cerebellar folds in the brains of trained (vs. untrained) dogs and birds. His approach to neuroanatomy was not continued because psychology has been more concerned with innate traits of the individual, and because of philosophical rationalism (citing Walsh, 1981). Until very recently, scientists have viewed the brain as "structurally insensitive to environmental experience" (p. 3).

Now we have evidence that animal brains are modifiable by experience, in gross morphology, fine (synapse) morphology, and neurochemicals. "Rich environments [for rats] ... produce heavier and thicker cerebral cortices and callosal connections (Walsh, 1981), larger cortex/subcortex weight ratios, larger cell bodies and nuclei (Walsh, 1981), and higher metabolic activity as suggested by increased RNA/DNA ratios (Rosenzweig, Bennett, & Diamond, 1972)" (p. 4). Enrichment leads to more extensive dendritic fields (occipital and temporal cortex, some hippocampal regions); this implies that each neuron has more synapses. Researchers have found large Purkinje-cell bodies and many dendrites in richly educated monkeys.

"Some evidence is available to show that 'preventive' and 'therapeutic' environments positively affect behavioral performances of brain-lesioned animals. However, knowledge about the brain mechanisms which underly these effects is, as yet, lacking" (p. 6). Rats that were handled during the first 21 days of life exhibited different brain lateralization from rats that were not (Denenberg, cited by Marx, 1983). Those stimulated early stored memories mainly in the right hemisphere.

The author also reviews evidence that human brains are psychologically modifiable. Children with astigmatism generate weakened cortical response to visual stimulation (Freeman & Thibos, 1973), because they experience difficulty in processing some visual-spatial patterns. People who have visual-field defects due to brain damage can improve in vision when forced to make eye movements toward lighted targets flashed in the blind areas (Zihl, 1981).

Bakker theorizes that hemispheric control of reading shifts from right to left during the learning-to-read process of normal readers; at least some aspects of reading are successively mediated by the right hemisphere at age 6 and by the left hemisphere at age 8, according to electrophysiological data in a longitudinal study (Licht, Bakker, Kok, & Bouma, 1983). He thinks P-type dyslexia results from continuing to rely on right- hemispheric strategies, leading to slow reading with fragmentation errors and repetitions. L-type dyslexia results from prematurely adopting a left-hemispheric strategy, i.e. at the very beginning of the learning process, making child insensitive to the perceptual features of script with consequent substantive errors such as omissions and additions. Thus, P- type dyslexics presumably show functional overdevelopment of the right hemisphere and L-types of the left hemisphere. Treatment would involve specific stimulation of the hemisphere that they are ignoring.

He presents data suggesting that "some electrophysiological parameters of the cerebral hemispheres can be modified in dyslexic children through hemisphere-specific stimulation and loading, and that these modifications may induce better reading" (p. 12)

Kelly, Paul James (1984, December). The relationship between hypnotic ability and hypnotic experience. Newsletter of Division 30, Psychological Hypnosis, of the American Psychological Association, 5.

This study investigated the relationship between four types of hypnotic experience and hypnotic ability. The types of experience were: dissociation, the experience of involuntariness; altered state effects, such as perceptual alterations and diminished reality sense; rapport, transference-like involvement with the hypnotist; and relaxation. A sample of 230 students was given the HGSHS:A, a group version of the SHSS:C, and the Hypnotic Experience Questionnaire (Kelly, 1984), a 47-item multidimensional scale of hypnotic experience. Items were taken from these tests to form 11 hypnotic ability variables (Positive Hallucinations, Dreams and Regressions, Post-Hypnotic Compulsions, Amnesia (HGSHS:A), Amnesia (SHSS:C), Arm Rigidity, Arm Immobilization, Other Motor Inhibitions, Head Falling, Moving Hands Together, and Hand Lowering). Fourteen hypnotic experience variables were also formed (Generalized Dissociative Effects, Dissociative Inhibition, Trance, Unawareness, Transference-like Involvement, Trust, Friendliness, Physical Relaxation, Mental Relaxation, Imagery Presence, Imagery Vividness, Imagery Detail, Self Consciousness, and Analytic Thoughts). The 25 variables were intercorrelated and factored with principal axis factoring. Five factors with eigenvalues greater than 1 were extracted and rotated to varimax criteria. These factors, which accounted for 54.4 percent of the variance, were called: Imaginative Involvement, Ideomotor Response, Rapport, Cognitive Inhibition, and Relaxation. Hypnotic ability variables loaded significantly on three of the factors (Imaginative Involvement, Ideomotor Response, and Cognitive Inhibition) and these three factors also tapped some aspect of altered state experience and/or dissociative experience. It was concluded therefore that dissociative experience and altered state experience are related to hypnotic ability. The remaining two factors, Rapport and Relaxation, showed significant loadings only for rapport variables and relaxation variables, respectively. Neither of these two factors were related to any of the traditional measures of hypnotic ability or to the experience of dissociative effects or altered state effects. The results of this study suggest that rapport and relaxation may happen in the hypnotic situation but neither experience is related to the condition of being hypnotized in any essential way. The hypnotic condition is characterized by dissociative experience, altered state experience, and by successful performance on hypnotic ability tasks. The results also raise questions about Edmonston's (1981) theory that relaxation is the essence of hypnotic responsiveness. The finding that the experience of relaxation is unrelated to hypnotic ability is more congruent with Hilgard's (1977) view that relaxation is a nonhypnotic process.

1983

Farthing, G. William; Venturino, Michael; Brown, Scott W. (1983). Relationship between two different types of imagery vividness questionnaire items and three hypnotic susceptibility scale factors: A brief communication. International Journal of Clinical and Experimental Hypnosis, 31, 8-13.

122 Ss were administered the Harvard Group Scale of Hypnotic Susceptibility, Form A (HGSHS:A) of Shor and E. Orne (1962), the Tellegen Absorption Scale (Tellegen & Atkinson, 1974), and 2 tape-recorded questionnaires on vividness of mental imagery. On 1 imagery questionnaire the items were impersonal, objective visual scenes (MIQ:VS), whereas on the other questionnaire the items involved discrete personal actions which elicited a combination of visual and kinesthetic imagery (MIQ:PA). Imagery vividness scores from both questionnaires correlated significantly with hypnotizability scores. MIQ:VS vividness scores were better than MIQ:PA vividness scores at predicting cognitive factor item

scores of HGSHS:A, but not ideomotor or challenge factor items scores. Multiple correlations involving MIQ:VS vividness and the Tellegen predicted cognitive factor scores better than ideomotor or challenge factor scores.

Harris, Gina M.; Johnson, Suzanne Bennett (1983). Coping imagery and relaxation instructions in a covert modeling treatment for test anxiety. Behavior Therapy, 14, 144-157.

The present study compared the efficacy of instructing test anxious subjects to use personalized coping imagery based on nonacademic experiences of competence with coping imagery based on academic experiences of competence. The effect of relaxation was also examined and the relationship of imagery elaborateness and content to treatment effectiveness was assessed. Sixty-three subjects were randomly assigned to one of four treatments or a waiting list control group. Test anxiety as measured by a self-report instrument significantly decreased in all treatment groups. Improvement in grade point average occurred for all treatment groups except for academic coping imagery without relaxation which was also the least efficient treatment. The waiting list control group significantly deteriorated in academic performance. Relaxation training did not appear to enhance treatment effectiveness or influence the elaborateness or content of the imagery used. Test anxiety scenes elicited highly response-oriented images by all subjects. However, the stimulus/response content of the subjects' images was not influenced by treatment outcome. In contrast, successful treatment was primarily associated with reduction in negative coping imagery descriptions, although an increase in positive coping statements cured as well.

John, Rodney; Hollander, Barbara; Perry, Campbell (1983). Hypnotizability and phobic behavior: Further supporting data. Journal of Abnormal Psychology, 92 (3), 390-392.

Twenty women who were phobic to snakes, spiders, or rats were individually evaluated for hypnotic susceptibility using the standard audiotaped version of the Harvard Group Scale of Hypnotic Susceptibility, Form A. Consistent with the findings of three earlier studies using the Hypnotic Induction Profile (HIP), 55% of the present sample was found to be highly responsive to hypnosis. An item analysis comparing item pass percentages for the phobic subjects with item difficulties obtained from a normative sample of 357 female college students indicated that the two samples were significantly correlated. The discrepancy between the findings of studies using standard measures of hypnotizability and studies using HIP is discussed.

1982

Crawford, Helen J.; Hilgard, Josephine R.; MacDonald, Hugh (1982). Transient experiences following hypnotic testing and special termination procedures. International Journal of Clinical and Experimental Hypnosis, 30, 117-126.

For those who are responsive to hypnosis, the experiences can be unusual and involving. It is not surprising, therefore, that such experiences in response to tests of susceptibility may not be fully terminated when the hypnotic sessions end. In order to study the initial persistence of the effects, following administration of the Harvard Group Scale of Hypnotic Susceptibility, Form A (HGSHS:A) of Shor and E. Orne (1962) and the Stanford Hypnotic Susceptibility Scale, Form C (SHSS:C) of Weitzenhoffer and E. R. Hilgard (1962), 107 college Ss were interviewed about their hypnotic experiences and subsequent experiences related to hypnosis. 72% of Ss reported feelings of relaxation and being rested following SHSS:C. Only 5% reported minor transient posthypnotic experiences following HGSHS:A, while 29% of Ss reported these feelings following SHSS:C. Except in 1 case, cognitive distortions or confusion were reported only following the more cognitively oriented SHSS:C

by Ss who scored significantly higher on cognitive items than those Ss who reported feeling drowsy. A special termination procedure involving exercise and conversation had no significant effect on the number of transient experiences. Such minor transient experiences are not a risk to Ss and any slight discomfort or uneasiness they cause can easily be dealt with by a well-trained hypnotist.

Frankel, Fred H. (1982). Hypnosis and hypnotizability scales: A reply. International Journal of Clinical and Experimental Hypnosis, 30, 377-392.

The use of the hypnotizability scales in the experimental setting is briefly reviewed, as is the need to separate the effect of hypnosis from the influence of factors such as relaxation and placebo which accompany the use of hypnosis clinically. The clinical relevance of the scales, most of which were developed primarily for experimental work, is affirmed by several studies conducted in the clinical context, in which the scales were used. Levels of hypnotizability have correlated well with patterns of clinical behavior. Although the scales are useful in many instances in helping to plan treatment strategy, their value in investigative studies is emphasized. Sacerdote's (1982) criticisms of the scales are considered. While it is true that the scales are blind to some of the qualitative aspects of the hypnotic experience, the great majority of clinically hypnotizable patients are able to respond to the items on the scales. Sacerdote's reluctance to learn about the value of the scales is evident in his preference for conjecture when he could readily have gathered irrefutable data through the administration of the scales, without the least risk to the treatment of his patients, once the course of treatment was underway or complete.

Howarth, Edgar; Schokman-Gates, Kar-La (1981). Self-report multiple mood instruments. British Journal of Psychology, 72, 421-441.

## NOTES

### Mood and hypnotizability

Zuckerman, Persky, & Lind (1967; *Journal of Consulting Psychology*) used the Zuckerman-Lubin MAACL to test the hypothesis that affect states just prior to hypnosis induction are related to subsequent hypnotizability, while affect traits are not so related (P. 464). The mood states of subjects in two treatment conditions (either small and highly motivated groups or large and less motivated groups) were measured just before trance induction, while the MMPI affect-trait measures were administered afterwards. The MAACL hostility scale was found to have a significant negative correlation with hypnotizability, but the affect-trait measures were unrelated.

In an attempt to determine the 'real relationships between personality traits and hypnotizability, Silver (1973) tested 40 male students on the Byrne (1964) Repression- Sensitization Scale, and in a following session the Wessman-Ricks PFS and a short form of the Nowlis MACL. Hypnotizability was also assessed using the Stanford Hypnotic Susceptibility Scale, Form C (Weitzenhoffer & Hilgard, 1962). While repression was not found to be related to hypnotizability, mood was, both on the PFS and the MACL, with bright affective states being positively related and dark states showing the opposite relationship. (Factor analysis revealed that the Nowlis measured emotional energy or buoyancy overall, whereas the Wessman-Ricks measured life satisfaction). Silver (1974) found that the surgency scale of the Nowlis MACL predicted hypnotizability as well or better than the MACL's overall mood index. This suggest (sic) that, although the overall mood may determine one's susceptibility to hypnotic induction, those who are in a surgent mood will be the ones most readily hypnotized.

1979

Hilgard, Ernest B.; Crawford, Helen Joan; Bowers, Patricia; Kihlstrom, John F. (1979). A tailored SHSS:C, permitting user modification for special purposes. International Journal of Clinical and Experimental Hypnosis, 27 (2), 125-133.

In the selection of Ss for the study of specific topics within hypnosis it is often desirable to include a few Ss known to have the specialized ability under investigation. To that end a modification of the SHSS:C of Weitzenhoffer and Hilgard (1962) has been tested in which one of the original items is replaced at the option of the investigator with an item selected for the purposes of any intended investigation. An empirical test of substituting 4 such items in each of 4 subgroups compared with a standard SHSS:C demonstrated that such a replacement of 1 item by another can be done without violating the usefulness of the established norms on the standardized test. The new form is described as a "tailored" SHSS:C.

1978

Counts, D. Kenneth; Hollandsworth, James G., Jr.; Alcorn, John D. (1978). Use of electromyographic biofeedback and cue-controlled relaxation in the treatment of test anxiety. Journal of Consulting and Clinical Psychology, 46 (5), 990-996.

The effect of using electromyographic (EMG) biofeedback to increase the efficacy of cue-controlled relaxation training in the treatment of test anxiety was studied. Forty college undergraduates scoring in the upper third on a self-report measure of test anxiety were randomly assigned to one of four treatment conditions - EMG-assisted cue-controlled relaxation, cue-controlled relaxation alone, attention-placebo relaxation, and no-treatment control. Pre-post self-report measures of test anxiety, state anxiety, and trait anxiety were obtained. In addition, a performance measure in the form of a mental abilities test was administered. Subjects from the three relaxation groups received six 45-minute individual sessions over a period of 2 weeks. All treatments were conducted using audiotape recordings. The results indicate that cue-controlled relaxation is effective in increasing test performance for test anxious subjects, that EMG biofeedback does not contribute to the effectiveness of this procedure, and that self-report measures of anxiety are susceptible to a placebo effect.

Hiscock, Merrill (1978). Imagery assessment through self-report: What do imagery questionnaires measure?. Journal of Consulting and Clinical Psychology, 46, 223-229.

Four studies examined imagery questionnaires and addressed issues of reliability, agreement among different questionnaires, social desirability, and construct validity. The Betts, Paivio, and Gordon scales were examined. In two studies the Betts and Paivio correlated .45-.50, but correlations involving the Gordon were inconsistent from one study to the next. Imagery measures generally were not influenced by social desirability. Factor analysis indicated that subjective and objective measures of visualization are independent. Concludes that imagery is not a unitary construct and that criteria other than visuospatial tests may be appropriate for validating imagery questionnaires.

1977

Botto, R. W.; Fisher, S.; Soucy, G. P. (1977). The effect of a good and a poor model on hypnotic susceptibility in a low demand situation. International Journal of Clinical and Experimental Hypnosis, 25, 175-183.

A review of recent studies reveals that there has yet to be a clear demonstration of a behavioral model affecting hypnotic levels. Two studies were conducted to test whether a peer model who portrayed deep or light hypnosis could affect S hypnotizability under minimal demand conditions. Using a low

demand version of the Harvard Group Scale of Hypnotic Susceptibility, Form A (Shor & E. Orne, 1962), the first study showed a difference (Good Model scoring higher than Poor Model) that only approached significance. A replication on a larger sample, however, showed significantly higher scores for those Ss observing a good model rather than a poor model. Although base scores were not obtained on these Ss, norms from comparable populations suggest that the poor model seems more effective than the good model; but this difference does not appear attributable to differential attitudes created by the models.

**1976**

Coe, William C. (1976). Effects of hypnotist susceptibility and sex on the administration of standard hypnotic susceptibility scales. International Journal of Clinical and Experimental Hypnosis, 24, 281-286.

Hypnotists' susceptibility and sex were examined for their effects on the administration of the Stanford Hypnotic Susceptibility Scale, Form C (Weitzenhoffer & Hilgard, 1962). Neither resulted in different hypnotic responsiveness from Ss. Comparatively inexperienced hypnotists obtained data similar to the normative sample for the Stanford scale. The results suggest that inexperienced hypnotists are capable of administering standardized scales validly, and that characteristics of the hypnotist are relatively ineffective in distorting Ss' responses to these scales.

**1970**

Bakan, Paul (1970). Handedness and hypnotizability. International Journal of Clinical and Experimental Hypnosis, 18, 99-104.

Carried out 2 studies with 251 and 228 undergraduates to determine the relationship between self-reports of handedness and scores on a shortened version of the Harvard Group Scale of Hypnotic Susceptibility, Form A. It was found that left-handed Ss were more likely than right-handed Ss to score at the extremes of the hypnotizability scale, either low or high, and less likely to score in the middle of the scale. Results of 2 independent studies were in agreement. (Spanish & German summaries) (15 ref.) (PsycINFO Database Record (c) 2003 APA, all rights reserved)

**1969**

Field, Peter B.; Palmer, R. (1969). Factor analysis: Hypnosis inventory. International Journal of Clinical and Experimental Hypnosis, 17, 50-61.

An inventory scale of hypnotic depth and the Stanford Hypnotic Susceptibility Scale, Form A were factor analyzed, based on a sample of 223 college students. Both measures yielded a general factor of hypnotic depth. Rotation yielded inventory factors of unawareness, drowsiness, enthusiasm, subjective conviction, and Stanford factors of challenge and ideomotor-posthypnotic suggestibility. Results of an earlier study describing development of the hypnosis inventory were successfully cross-validated. (Spanish & German summaries) (19 ref.) (PsycINFO Database Record (c) 2002 APA, all rights reserved)

Dittborn, Julio M. (1968). A brief nonthreatening procedure for the evaluation of hypnotizability. International Journal of Clinical and Experimental Hypnosis, 16, 53-60.

**DESCRIBES A TECHNIQUE FOR THE SELECTION OF SS POTENTIALLY HIGH IN HYPNOTIZABILITY WITHOUT INFORMING THEM THAT HYPNOSIS IS BEING INDUCED.**

**IT INVOLVES AN OBJECTIVE BEHAVIORAL OUTPUT (SLEEP WRITING) AS WELL AS CLINICAL SIGNS THAT CAN BE USED TO EVALUATE HYPNOTIZABILITY. IT HAS THE ADVANTAGE OF BEING ABLE TO BE ADMINISTERED BY INDIVIDUALS OTHERWISE UNTRAINED IN HYPNOTIC TECHNIQUES. (SPANISH + GERMAN ABSTRACTS) (PsycINFO Database Record (c) 2002 APA, all rights reserved)**

**Faw, Volney; Sellers, David J.; Wilcox, Warren W. (1968). Psychopathological effects of hypnosis. International Journal of Clinical and Experimental Hypnosis, 16, 26-37.**

The probability that hypnotic induction produces psychopathological effects has not been experimentally determined. The present study hypothesizes various negative effects following hypnosis such as increased signs of personality disturbances, increased need for medical attention, greater tendencies toward suicide, and negative effects among the more maladjusted persons of the population sample. 107 college students were assigned at random to experimental and control groups. The experimental group was hypnotized 3 times in successive weeks. A comparison between control and experimental groups in respect to pre- and post-MMPI score differences plus a follow-up with the college counseling center and infirmary for a 90-day period following induction led to the rejection of the hypotheses. A comparison of measures yielded some significant differences in favor of the experimental group. It is concluded that there are nondetrimental effects when hypnosis is used with a normal college population.

**1966**

**Cooper, Leslie M.; London, Perry (1966). Sex and hypnotic susceptibility in children. International Journal of Clinical and Experimental Hypnosis, 14, 55-60.**

Sex differences in hypnotic susceptibility were investigated in a sample of 240 children. The Children's Hypnotic Susceptibility Scale was administered to 10 boys and 10 girls at each age level for 5-16 yr. There were no differences between the means of the boys and girls at any age for the 3 scores yielded by the measure. The percentage passing each item at each age for each sex was also computed. Of the resulting 264 comparisons only 1 (Item 10, Eye Catalepsy) was found to be significantly different at 1 age level (7 yr. of age) and was attributed to chance. It was concluded that there were no sex differences for the various items at the ages tested. (PsycINFO Database Record (c) 2002 APA, all rights reserved)

**Evans, Frederick J.; Schmeidler, D. (1966). Relationship between the Harvard Group Scale of Hypnotic Susceptibility and the Stanford Hypnotic Susceptibility Scale: Form C. International Journal of Clinical and Experimental Hypnosis, 14, 333-343.**

**3 SUBGROUPS OF 20 SS WITH HIGH, MEDIUM, OR LOW SCORES ON A SLIGHTLY MODIFIED, TAPE-RECORDED VERSION OF THE HARVARD GROUP SCALE OF HYPNOTIC SUSCEPTIBILITY, FORM A (HGSHS:A) WERE LATER ADMINISTERED THE STANFORD HYPNOTIC SUSCEPTIBILITY SCALE, FORM C (SHSS:C). THE 2 SCALES CORRELATED .59, WHICH IS LOWER THAN WOULD BE PREDICTED BY SCALE RELIABILITIES. THIS, TOGETHER WITH OTHER DATA BASED ON ITEM CHARACTERISTICS, INDICATES THAT THE 2 SCALES ARE NOT EQUIVALENT, BUT IN PART MEASURE DIFFERENT ASPECTS OF HYPNOTIC PERFORMANCE. SCORES ON HGSHS:A FOR LOW SS ARE PREDICTIVE OF SHSS:C SCORES, BUT THE STABILITY OF PERFORMANCE BETWEEN HGSHS:A AND SHSS:C IS NOT AS MARKED FOR MEDIUM AND HIGH SS ON HGSHS:A. THIS IS PARTLY A RESULT OF THE FAILURE OF PASSIVE MOTOR (PRIMARY) SUGGESTIBILITY TO**

**DISCRIMINATE BETWEEN LEVELS OF SUSCEPTIBILITY, ALTHOUGH CHALLENGE ITEMS DO. THE 2 CLUSTERS OF ITEMS CORRELATE .23 AND .43 IN HGSHS:A AND SHSS:C, RESPECTIVELY. THE PASSIVE SUGGESTIBILITY ITEMS DETRACT FROM THE VALIDITY OF THE 2 SCALES. (SPANISH + FRENCH SUMMARIES) (20 REF.) (PsycINFO Database Record (c) 2002 APA, all rights reserved)**

**Cooper, Leslie M.; Pedersen, Darhl M. (1965). A note on the failure to find personality differences between volunteers and nonvolunteers for hypnotic research. International Journal of Clinical and Experimental Hypnosis, 13 (4), 274-278.**

**Personality measures were administered to 136 students in an introductory psychology class at Brigham Young University. 30 Ss subsequently volunteered to have their hypnotic susceptibility assessed. There were no significant differences found between the means of the resulting 23 variables for the 30 volunteers and 106 nonvolunteers. 2 variables (age and ego strength) showed significantly different variances for the 2 groups, but these may be attributed to chance because of the number of significance tests made. (PsycINFO Database Record (c) 2002 APA, all rights reserved)**

**Das, J. P. (1965). Relationship between body-sway, hand-levitation, and a questionnaire measure of hypnotic susceptibility. International Journal of Clinical and Experimental Hypnosis, 13 (1), 26-33.**

**67 randomly selected college students were administered the body-sway test, a questionnaire measure of tranceability, and an induction procedure utilizing hand-levitation to determine hypnotic susceptibility. The 6 Es varied in age, sex; 5 of them had little experience as hypnotists. All reference to "hypnosis" was omitted from the induction procedure. Significant phi-coefficients between body-sway and levitation (.52), levitation and tranceability frequency (.28) and intensity (.25), and body-sway and tranceability intensity (.33) were obtained. (16 ref.) (PsycINFO Database Record (c) 2002 APA, all rights reserved)**

**Field, Peter B. (1965). An inventory scale of hypnotic depth. International Journal of Clinical and Experimental Hypnosis, 13, 238-249. (Abstracted in American Journal of Clinical Hypnosis, 1966, 1, 86)**

**An inventory of 300 items describing subjective experiences during hypnosis was administered to 102 students after they had wakened from hypnosis. The 38 items that correlated best with a standard measure of hypnotic susceptibility are proposed as an inventory measure of hypnotic depth. Items dealing with absorption and unawareness, automaticity and compulsion, and discontinuity from normal experience correlated best with the criterion, while items dealing with conscious motivation to enter hypnosis, feelings of surface compliance with suggestions, and unusual bodily sensations showed generally weaker relationships to the hypnotizability criterion. (PsycINFO Database Record (c) 2002 APA, all rights reserved)**

**Field, Peter B.; Evans, Frederick J.; Orne, Martin T. (1965). Order of difficulty of suggestions during hypnosis. International Journal of Clinical and Experimental Hypnosis, 13, 183-192.**

**This study tests the hypothesis that successful response to suggestion during hypnosis predisposes to further successful response, but failure leads to subsequent failure. The Harvard Group Scale of Hypnotic Susceptibility was administered to 2 groups of 51 volunteer students. For 1 group, 8 of the 12 items were administered in the order easy-to-difficult; for the 2nd group, in the order difficult-to-easy. Total and 8-item mean scores, and frequency distributions, did not differ significantly between groups.**

Except for the item measuring posthypnotic amnesia, item difficulties for the 2 groups did not differ significantly. Although the difficult-to-easy group was more amnesic, the 2 groups recalled a similar number of additional items when amnesia was "lifted." The block of 4 easier items was relatively easier when preceded by a block of 4 harder items and, similarly, the harder items were relatively less difficult if preceded by a block of easier items. The magnitude of this effect was small, and the order effect hypothesis was basically not supported. Future research should consider the S's subjective impression of success and failure. (16 ref.) Coe, William C. (1964). Further norms on the Harvard Group Scale of Hypnotic Susceptibility, Form A. International Journal of Clinical and Experimental Hypnosis, 12 (3), 184-190.

The Harvard Group Scale of Hypnotic Susceptibility, Form A was administered to 168 upper level college students. Findings are congruent with the original normative data reported by Shor and E. C. Orne. Differences between the 2 samples' mean scores and distributions are discussed in terms of sample composition. Further support for the group scale as an accurate predictor of hypnotic susceptibility was indicated by a significant relationship between the group scale and the individually-administered Stanford Hypnotic Susceptibility Scale, Form C. (PsycINFO Database Record (c) 2002 APA, all rights reserved)

Cooper, G. W.; Dana, R. H. (1964). Hypnotizability and the Maudsley Personality Inventory. International Journal of Clinical and Experimental Hypnosis, 12, 28-33.

The Maudsley Personality Inventory was administered to 349 male college students. 9 male Ss were chosen to represent each of the 4 possible combinations (total N = 36) of extreme high and low extraversion and introversion scores. An attempt was made to hypnotize each S by means of the Stanford Hypnotic Susceptibility Scale, Form C. Analysis of variance indicated no significant relationship between either extraversion or neuroticism and hypnotizability, although the relationship between extraversion and hypnotizability approached significance. (PsycINFO Database Record (c) 2002 APA, all rights reserved)

Evans, Frederick J.; Schmeidler, D. (1964). Reliability of two observers scoring the Stanford Hypnotic Susceptibility Scale, Form C. International Journal of Clinical and Experimental Hypnosis, 12 (4), 239-251.

2 Os scored the responses of 60 Ss on a 12-item objective test, Stanford Scale of Hypnotic Susceptibility, Form C (Weitzenhoffer & Hilgard, 1962). Mean total scores reported by the 2 Es did not differ significantly. The correlation between the total scores of the 2 Es was .947. Nevertheless, differences in total scores assigned occurred with 40% of Ss, which is a significant departure from

perfect agreement. The 2 Es disagreed about correct scoring of 54 items (7.5% of all items scored). The extent of disagreement was significantly greater than 0. Disagreement was not related to the level of susceptibility of Ss, nor to the relative experience of Es with hypnosis. More than 1/2 of the disagreements involved systematic differences in the interpretation and application of the scoring criteria for 2 items; item 6: Dream, and item 9: Anosmia to Ammonia. These systematic differences affecting scoring reliability happened to counterbalance to produce similar total scores in this study. Several sources of potential scoring unreliability of SHSS:C are discussed. (PsycINFO Database Record (c) 2002 APA, all rights reserved)

**Furieux, W. D. (1964). The heat-illusion test and the structure of suggestibility. International Journal of Clinical and Experimental Hypnosis, 12 (3), 169-180.**

2 similar forms of the heat-illusion test are shown to correlate to a smaller degree than would be expected if they measure the same attribute. The 2 versions also differ in the way in which they correlate with other suggestibility tests. It is shown that linear regression techniques are not appropriate for analyzing the data concerned. The interaction of various nonlinear relationships with a difference in "difficulty," as between the 2 forms of the illusion, seems to provide an adequate explanation for the results. It is suggested that these nonlinear relationships may indicate the existence of an attribute which prevents some Ss from responding to any suggestibility test, irrespective of what the specific mechanisms of response may be. **Bentler, P. M.; Hilgard, Ernest R. (1963). A comparison of group and individual induction of hypnosis with self-scoring and observer-scoring. International Journal of Clinical and Experimental Hypnosis, 11, 49-54. (Abstracted in Index Medicus, 63, June, S-1599)**

45 volunteer Ss were hypnotized in small groups and were subsequently hypnotized in individual sessions. In both sessions observer- and self-scores were recorded for all suggestions of the Harvard Group Scale adaptation of the Stanford Hypnotic Susceptibility Scale. The correlation between observer- and self-scores indicated that hypnotic susceptibility in the 2 sessions was very similar. Group self-scores were also found to predict quite accurately objective hypnotist scores of the subsequent individual session. A 2nd sample of 34 nonvolunteer male Ss were hypnotized individually following Form A of the Stanford scale. Self-scoring was found to be remarkably similar to observer ratings, and the results of group administration very comparable to those of individual administration of hypnotic susceptibility tests. **Dittborn, Julio M.; Munoz, L.; Aristeguita, A. (1963). Facilitation of suggested sleep after repeated performances of the sleep suggestibility test. International Journal of Clinical and Experimental Hypnosis, 11, 236-240.**

The sleep suggestibility test (SST) was individually administered to a group of young volunteer soldiers. There was increased susceptibility with each successive SST administration. It was possible to transform suggested sleep into somnambulistic hypnosis in a majority of Ss. (PsycINFO Database Record (c) 2002 APA, all rights reserved)

**Evans, Frederick J. (1963). The Maudsley Personality Inventory, suggestibility and hypnosis. International Journal of Clinical and Experimental Hypnosis, 11, 187-200.**

An attempt to replicate the claim of Furneaux and Gibson (1961) that stable extraverts and neurotic introverts were more susceptible to hypnotic suggestion than neurotic extraverts and stable introverts, using the MPI dimensions, was unsuccessful. Some "trends" are discussed. (PsycINFO Database Record (c) 2002 APA, all rights reserved)

## **TEXTBOOK**

**1995**

Holroyd, Jean (1995). Handbook of clinical hypnosis, by Judith W. Rhue, Steven Jay Lynn, & Irving Kirsch (Eds.) [Review]. International Journal of Clinical and Experimental Hypnosis, 43 (4), 401-403.

## **NOTES**

"This is a book for the thinking clinician" (p. 401). "The editors are to be congratulated for making this volume much more coherent than most edited books" (p. 402). "My impression is that the book is best suited for an intermediate or advanced course on hypnotherapy, or for people who are already using hypnosis in treatment. Although there is some material on the basics of hypnotic inductions and a few introductory sample scripts for inductions, a beginners' course should probably use a different book, or this book could be accompanied by an inductions manual. ... I recommend it very highly" (p. 403).

**1986**

Zilbergeld, Bernie; Edelstien, M. Gerald; Araoz, Daniel L. (1986). Hypnosis - Questions & Answers. New York NY: Penguin Books.

## **NOTES**

The editors requested experts in hypnosis to answer common questions that resulted from questionnaires given to over 600 health professionals who had taken a course in hypnosis during the previous three years, as well as a few questions suggested by colleagues. "We do not view this book as providing right answers, but instead as something clinicians can turn to when they have questions or want to learn how a recognized authority handles a particular issue. There are, in fact, no right answers, no one-and-only best way" (p. xviii).

Freeman, Robert; Barabasz, Arreed; Barabasz, Marianne (2000). Hypnosis and distraction differ in their effects on cold pressor pain. American Journal of Clinical Hypnosis, 43 (2), 137-148.

This study sought to determine whether highly hypnotizable Ss differ from low hypnotizables in perceived pain and neocortical electrical activity in 3 conditions. On the bases of E. R. Hilgard's neo-dissociation theory (1977) and N. P. Spano's (1982) sociocognitive theory, Ss selected for high and low hypnotizability (10 in each group) were exposed to a cold pressor pain test during counterbalanced conditions of waking relaxation, distraction, and hypnosis. To better discriminate between hypnosis and distraction conditions, a new distraction procedure was developed involving the memorization of a sequence of colored lights. High hypnotizables showed significantly greater pain relief for hypnosis vs distraction or waking relaxation conditions. They also demonstrated significantly greater pain relief than low hypnotizables in response to hypnosis. Electroencephalographic findings showed significantly greater high theta (5.5-7.5 Hz) activity for highs as compared to lows at parietal (P3) and occipital (O1)

sites during both hypnosis and waking relaxation conditions. The findings fail to support the sociocognitive conceptualization of hypnotic behavior but provide evidence supporting the neo-dissociation theory and state based theories of hypnosis. (PsycINFO Database Record (c) 2002 APA, all rights reserved)

Montgomery, Doil D.; Dwyer, Kimberly V.; Kelly, Shannon M. (2000). Relationship between QEEG relative power and hypnotic susceptibility. American Journal of Clinical Hypnosis, 43 (1), 71-75.

Investigated the relationship between quantitative electroencephalograph relative amplitude, relative power and hypnotic susceptibility. Ss were 41 adults (aged 22-40 yrs). Hypnotic susceptibility, measured by the Wickramasekera Experience Inventory, was found to be positively correlated with QEEG theta relative amplitude. In addition, hypnotic susceptibility was found to be negatively correlated with QEEG alpha relative amplitude and alpha relative power. These findings suggest that QEEG relative amplitude and QEEG relative power, as correlates of hypnotic susceptibility, may be a promising avenue for future research. 1999

Anderson, Kathryn (1999, November). A test of Barabasz' alert hypnosis on EEG Beta and Theta production for children with ADHD. [Paper] Presented at Annual Meeting of the Society for Clinical and Experimental Hypnosis, New Orleans, LA.

This study tested the effects of Barabasz's Instant Alert Hypnosis (IAH), also known as Instantaneous Neuronal Activation Procedure (INAP, Barabasz and Barabasz, 1995) used as an adjunct to neurotherapy. The sixteen children who participated in this study met DSM - IV criteria for attention deficit hyperactivity disorder (AD/HD). Trials of neurotherapy alone were compared to neurotherapy combined with alert hypnosis on beta-theta ratios at five electrode sites (Fp1, Fp2, Fz, Cz and Pz). The results showed that EEG beta-theta ratio means were significantly higher (more than twice as large) in the trials of neurotherapy combined with alert hypnosis in contrast to neurotherapy alone. Beta was significantly enhanced while theta was inhibited. The clinical implications of these findings with regard to improved treatment efficacy and reduced time in treatment are discussed. [Abstract taken from SCEH "FOCUS", Winter 2001..]`

Nishith, Pallavi; Barabasz, Arreed; Barabasz, Marianne; Warner, Dennis (1999). Brief hypnosis substitutes for alprazolam use in college students: Transient experiences and quantitative EEG responses. American Journal of Clinical Hypnosis, 41 (3), 262-268.

We sought to determine: 1) whether a simple hypnotic induction with an alprazolam experience derived suggestion could recreate the subjective effects of alprazolam (Xanax), 2) whether the effects of alprazolam are greater than the effects of hypnosis plus this suggestion, and 3) whether the effects of hypnosis plus this suggestion were greater than the relaxation effects produced by hypnosis alone. High and low hypnotizable student volunteer subjects (Ss) ingested 1 mg of alprazolam. A hypnotic suggestion was developed on the basis of their reported reactions to alprazolam. Four days later the same Ss were exposed to hypnosis only and hypnosis plus the alprazolam experience based suggestion conditions in counterbalanced order. Ss exposed to the hypnosis plus suggestion condition demonstrated greater levels of relaxation as measured by the tension-anxiety scale of the Profile of Mood States (POMS) (Eichman & Umstead, 1971) than in the alprazolam condition or the hypnosis only condition. High hypnotizables showed significantly greater levels of relaxation than the low hypnotizables in each of the three conditions (hypnosis plus suggestion, hypnosis only, alprazolam only). EEG data showed frontal and occipital sites were specifically involved in both the alprazolam

and the hypnotic suggestion conditions. The findings indicate a basis for the use of hypnosis as a substitute for sedative drug use. Limitations and implications for clinicians are discussed.

1997

Ray, William J. (1997). EEG concomitants of hypnotic susceptibility. International Journal of Clinical and Experimental Hypnosis, 45 (3), 301-313.

Numerous historical attempts have been directed at understanding electrocortical concomitants of hypnosis. Today, with the availability of more sophisticated multichannel recording technologies and signal-processing approaches, it is possible to reconsider and update previous attempts. The most solid relationship between electrocortical activity and hypnotizability exists in the EEG theta frequency range. Given the stable electrocortical differences found in high and low susceptible individuals, the question arises whether we can use additional EEG measures to help understand the nature of these individual differences. One possible alternative is the pointwise or fractal dimension, which we examined during baseline conditions with high and low hypnotic susceptible individuals. The dimensionality measures suggest that high susceptible individuals display underlying brain patterns associated with imagery, whereas low susceptible individuals show patterns consistent with cognitive activity (i.e., mental math). This type of speculation is similar to that of Tellegen, who makes a distinction between imaginative versus realistic responding. Future research should address the exact nature of the underlying process (imagination, effortlessness, suggestibility, etc.) seen in high and low susceptible individuals. Journal Abstract.

1995

Graffin, Nancy F.; Ray, William J.; Lundy, Richard (1995). EEG concomitants of hypnosis and hypnotic susceptibility. Journal of Abnormal Psychology, 104, 123-131.

Electroencephalograph (EEG) measures described high- and low-hypnotizable participants in terms of 3 conditions: an initial baseline period; baselines preceding and following a standard hypnotic induction; and during the induction. The following results were obtained. 1. High and low-hypnotic susceptible participants displayed a differential pattern of EEG activity during the baseline period, characterized by greater theta power in the more frontal areas of the cortex for the high-susceptible participants. 2. In the period preceding and following a standardized hypnotic induction, low-susceptible participant displayed an increase in theta activity, whereas high-susceptible participants displayed a decrease. 3. During the actual hypnotic induction itself, theta power significantly increased for both groups in the more posterior areas of the cortex, whereas alpha activity increased across all sites. Implications of these data include the possibility of psychophysiological measures offering a stable marker for hypnotizability, and anterior/posterior cortical differences being more important than hemispheric foci for understanding hypnotic processes.

#### NOTES

7970, Lynn & Nash, 1994 ABSTRACT: In this article we address a number of issues relevant to the practice of psychotherapy and hypnotherapy: How reliable is memory? How are therapists' and clients' beliefs and expectancies related to pseudomemory formation? Are certain clients particularly vulnerable to pseudomemory creation? Does hypnosis pose special hazards for pseudomemory reports? What are the variables or factors that mediate hypnotic pseudomemories? In addition to reviewing the literature on these topics, we intend to sensitize the clinician to the potential pitfalls of critical reliance on the patient's memories, as well as uncritically accepted clinical beliefs and practices.

Ray, William J. (1995, November). EEG signatures of hypnotic susceptibility and hypnosis: It's what's up front that matters. [Paper] Presented at the annual meeting of the Society for Clinical and Experimental Hypnosis, San Antonio, TX.

## NOTES

We have done three studies: a psychometric study, one in which we used traditional ways of looking at EEG, and more recent research.

Study I found that hypnotizability related to absorption, but not to tests of absent mindedness/cognitive failures, abuse/neglect, attachment, depression and anxiety, NEO Five Factor Test scales (Neuroticism, Extroversion, Openness to Experience, Agreeableness, and Conscientiousness) or the Marlow Crown Social Desirability Scale. Also there was no relationship to Bernstein and Putnam's measure of dissociation, the DES. There is a hint of a relationship to the Openness Scale, actually.

Study II included a literature review on 3 questions: 1. Are there differential electrocortical differences between high and low susceptible individuals? 2. Are there electrocortical markers for the hypnotic state itself? 3. Are electrocortical differences found in the trance state mediated by hypnotic procedures?

Results of Study II are published in Graffin, Ray, & Lundy, 1995.

Study III investigated three questions: 1. Are there initial baseline psychophysiological differences between High and Low susceptible Ss? 2. Are there psychophysiological differences in baseline? 3. Are there behavioral differences on the challenge tasks during the Stanford-C?

The Pre-induction baseline followed by post-induction baseline are reported today. (They also administered tasks, not discussed here.)

Literature indicates that EEG theta is much higher for highs than lows, especially in frontal and temporal areas. This is a stable finding in a number of studies. There are also posterior differences, but they are not as significant. The differences in theta between highs and lows remains across different tasks (like imaging, spatial rotations, math). Whatever differences in theta exist when high and low hypnotizable subjects walk into the room, continue across tasks. The difference also is observable in alpha.

In the whole study we found no alpha differences and no hemisphere differences, but we did find theta differences.

We thought there would be less dimensionality as someone enters hypnosis. Dimensionality reflects EEG wave form (e.g. a sine wave is simple; more complex wave is multidimensional) and is analyzed with "chaos measures" [these notes may be poor regarding this issue]. But we didn't find less dimensionality as people entered hypnosis. So if dimensionality reflects brain state maybe people don't change state as they enter hypnosis.

Highs do show higher dimensionality vs lows, across all brain areas. What does this mean? It's as if Highs walk into the experiment in a more imagery mode than lows, and they continue that way throughout the whole experiment.

The differences found in baseline were all in theta. We compared the Standard Induction vs Self Induction on the EEG Theta variable: highs show more theta across the whole brain than lows, and it doesn't matter what type of induction is used.

De Pascalis gets me thinking about the role of attention in hypnosis. Following an induction, on 35-45 Hz band of EEG there is greater frontal activity for Lows whereas for Highs you see more activity posteriorly. The difference is on the rostral-caudal dimension rather than the lateral

1994

Crawford, Helen J. (1994). Brain dynamics and hypnosis: Attentional and disattentional processes. International Journal of Clinical and Experimental Hypnosis, 42 (3), 204-232.

This article reviews recent research findings, expanding an evolving neuropsychophysiological model of hypnosis (Crawford, 1989; Crawford & Gruzelier, 1992), that support the view that highly hypnotizable persons (highs) possess stronger attentional filtering abilities than do low hypnotizable persons, and that these differences are reflected in underlying brain dynamics. Behavioral, cognitive, and neurophysiological evidence is reviewed that suggests that highs can both better focus and sustain their attention as well as better ignore irrelevant stimuli in the environment. It is proposed that hypnosis is a state of enhanced attention that activates an interplay between cortical and subcortical brain dynamics during hypnotic phenomena, such as hypnotic analgesia. A body of research is reviewed that suggests that both attentional and disattentional processes, among others, are important in the experiencing of hypnosis and hypnotic phenomena. Findings from studies of electrocortical activity, event-related potentials, and regional cerebral blood flow during waking and hypnosis are presented to suggest that these attentional differences are reflected in underlying neurophysiological differences in the far fronto-limbic attentional system.

Freeman, R.; Barabasz, A.; Barabasz, M. (1994, October). EEG topographic differences between dissociation and distraction during cold pressor pain in high and low hypnotizables. [Paper] Presented at the annual meeting of the Society for Clinical and Experimental Hypnosis, San Francisco.

## NOTES

Hilgard once said we should study what is going on inside the skull when we study hypnotic behavior. Theta EEG was studied, in 3.5 and 5.5-7.5 band widths, based on Crawford's research (no differences between high and low hypnotizables in low range but significant differences in waking state, eyes closed condition).

Also employed new type of distraction procedure. Previously used as comparison conditions things like imagine a pleasant scene, do whatever you can do to reduce pain, or imagine an instructor giving a lecture. Barabasz theorized that highs, given the opportunity, may spontaneously get involved in imagery; so distraction used in some experiments may actually become hypnosis. Here, distraction involved using a storage box, with plexiglass covering front, and 3 lights--subjects were to recall sequence of light changes that occurred during 60 sec when arm was in the cold water.

Cold pressor pain. 3 immersions with simultaneous pain reporting and EEG monitoring. --Waking State --Light array distraction --Hypnotic induction and suggested analgesia (Distraction and hypnosis with analgesia were presented in a balanced design)

Pain Ratings ranged from 0 = no pain, 10 = level would very much like to remove arm from water (rating could exceed 10 however). After removing arm, subjects were to report the maximum amount of pain that they had felt. Pain Scores were obtained at 30 seconds and 60 seconds after immersion in the cold water.

Also got qualitative data. During recovery period after each arm immersion, Subjects were asked what if anything they had done to reduce the pain felt.

30 second pain scores: Waking 7.60 vs 7.50 Distraction 8.60 vs 6.80 Hypnotic analgesia 7.80 vs 4.10 (Significantly different).

60 second pain scores: Showed same trend

There was no difference whatsoever for the lows.

Results for the 2 EEG sites: P3 left hemisphere parietal in waking and hypnotic analgesia, high theta, had significantly different activity O1 left hemisphere in waking and hypnotic analgesia, was significantly different between highs and lows (same as above).

Results for two theta ranges: Low theta range, T4 temporal right hemisphere, for lows in waking and [missed words] condition--hard to interpret this finding.

**RESULTS.** Highs demonstrated pain reduction in hypnotic analgesia compared to waking and distraction conditions and compared to lows. Lows had no differences in any condition.

Enhanced EEG theta in left parietal area differentiated highs and lows. This suggests that highs generate enhanced disattention that may be controlled by these areas.

P3 area regulates the integration and association of somatic perceptions. The O1 area controls processing of visual imagery. Perhaps high hypnotizables have more ability to alter afferent sensory information through focused attentional processes. Also, the ability to alter the suffering portion of pain experience may involve visual imagery activity.

State and trait differences are apparent.

The low theta range may be more closely related to slower delta range 0-3.5 that is associated with sleep and drowsiness. High theta = low arousal and attention capacity. That's why theta seems associated with wide range of behaviors that appear contradictory

The qualitative data shows highs reported they spontaneously preferred strategies that were more than distraction (associating colors with warmth, thinking of warm water) and the most frequent responses of lows were "nothing" or "told myself it would be over soon."

Highs in analgesia condition used no specific strategy: 8/10 reported the arm simply felt more numb.

Ray, William J.; Moraga, R.; Faith, M. (1994, October). Psychometric and psychophysiological studies of hypnotizability and dissociation. [Paper] Presented at the annual meeting of the Society for Clinical and Experimental Hypnosis, San Francisco.

## NOTES

In the last 5-6 years we see a beginning of a consistency in this type of research on EEG and hypnosis. Baseline EEG theta for high and low hypnotizable Ss was higher significantly in frontal and temporal areas; less significantly in parietal and occipital areas. It begins to look like a signature of hypnotizability. Our research will be published in the Journal of Abnormal Psychology next year.

In Japan they see theta as sustained attention; some aspects of theta relate to MAO and also to dopamine. Betsy Faith did the same research, replicating almost exactly.

There are no differences between Highs and Lows in alpha or beta; but we find differences in theta (especially frontal, and in 40 Hz more posteriorly). It may not be L-R hemisphere difference as previously thought, but more a rostral-caudal dimension.

The signature to hypnotizability is more frontal theta at baseline. This may also relate to a drop in theta after induction, but those results are not so clear. Highs have a larger drop in theta from pre to post induction than is observed in the Lows.

We did a "chaos analysis" of EEG. There are three main measures, including dimensionality. Dimensionality is a measure of complexity. People demonstrate high dimensionality when asked to do tasks, low dimensionality in anesthesia.

High hypnotizable Ss start an induction with higher dimensionality than the Low hypnotizable Ss, and as we go through the induction they remain the same. So this measure shows individual differences but does not give evidence of a state (because it doesn't change).

Chaos dimensions for 2 mental math problems show lower dimensions in frontal compared to posterior areas; but for imagery [labeled on slide as positive and negative emotional tasks] the dimension is the same across areas.

For the dimension measures, lows look like they are doing mental math and highs look like they are doing imagery, in baseline.

**SECOND PART OF RESEARCH--DISSOCIATION.** For 100 years dissociation and hypnosis have been viewed as similar. Two dissociation scales were used - Putnam's DES and Reilly's scale. A factor analysis found four factors: 1. absorption or derealization 2. depersonalization 3. segment amnesia 4. in situ amnesia

(Segment amnesia differs from in situ amnesia because you wake up to it at that moment in the in situ vs the segment case.)

We have 20-30 people who score very high on hypnotizability.

Colin Ross finds the same factors as our factors 1 and 2, but he finds only one amnesia factor where we find two.

The correlation between DES and Harvard ranges .05 to .18. Are the high hypnotizables related to high dissociatives, with others not related? A scatter plot did not reveal that.

FFT EEG bands during baseline for high and low dissociation Ss find no differences for high and low dissociative subjects. We conclude that dissociation and hypnosis are two orthogonal processes.

Now we are beginning to look at the pathways that lead one to become highly hypnotizable or dissociative.

#### COMMENTS FROM THE AUDIENCE:

**Ian Wickramasekera:** Have you introduced threat to high or low DES people? **Answer:** High and Low DES people with happy and unhappy imagery tasks do the opposite, with the dimensionality measure. With emotionality you don't see stable baseline differences, you see reactivity differences.

**A. Barabasz:** I think the DES isn't a good measure of dissociation in hypnosis which is voluntary and not pathological.

**D. Spiegel:** Sabourin's study found more theta in left frontal during hypnosis, whereas you found less. **Answer:** That's why I don't know what to do about the state effects.

**J. Crawford:** Sabourin had Ss doing tasks, so they may have been more active than yours.

#### 1992

Atkinson, Richard P.; Crawford, Helen J. (1992). Individual differences in afterimage persistence: Relationships to hypnotic susceptibility and visuospatial skills. *American Journal of Psychology*, 105 (4), 527-539.

To investigate the moderating role of individual differences in hypnotic susceptibility and visuospatial skills on afterimage persistence, we presented a codable (cross) flash of light to 40 men and 46 women who had been dark adapted for 20 minutes. In an unrelated classroom setting, subjects had previously been given two standardized scales of hypnotic susceptibility (Harvard Group Scale of Hypnotic Susceptibility, Shor & Orne, 1962; Group Stanford Hypnotic Susceptibility Scale, Form C, Crawford & Allen, 1982) and the Mental Rotations Test (Vandenberg & Kuse, 1978). The first afterimage interval and the afterimage duration correlated significantly with hypnotic responsiveness, supporting Wallace (1979), but did not show the anticipated relationships with mental rotation visuospatial skills. Individuals in the high hypnotizable group had (a) significantly longer afterimage intervals between its first appearance and first disappearance than did those in low groups, but those in medium groups did not differ significantly from the other groups. Discriminant analysis using the afterimage persistence measures classified correctly 65.2% of high hypnotizables, 37.5% of medium hypnotizables, and 54.8% of low hypnotizables. Hypothesized cognitive skills that assist in the maintenance of afterimages and underlie hypnotic susceptibility include abilities to maintain focused attention and resist distractions over time and to maintain vivid visual images.

#### NOTES

**DISCUSSION** "Because there is no apparent evidence for physiological differences of the visual system between low and high hypnotizables (e.g., Wallace, 1979), cognitive factors are suggested as possible moderators of afterimage persistence.

"Hypnotic susceptibility per se is not the moderator of afterimage duration. Rather, we argue that hypnotic susceptibility represents a constellation of underlying cognitive skills (e.g., for reviews, see Crawford, 1989; Kihlstrom, 1985) that assist an individual to respond to hypnotic suggestions as well

as assist in the persistence of afterimages by interacting with more primary casual mechanisms that are physiological in origin. These cognitive skills are thought to include the abilities to focus attention selectively upon both external stimuli and internally generated images, to maintain vivid visual images, to sustain attention over time and remain absorbed in the experience at hand, and to resist distractions. The relationships between these cognitive skills and hypnotic susceptibility are reported in a large body of literature (e.g., Crawford, 1982, 1989; Crawford et al., 1991; Crawford & Grumbles, 1988; Finke & Macdonald, 1978; Grumbles & Crawford, 1981; Mitchell, 1970; Tellegen & Atkinson, 1974)....

"Sustained and selective attention without interference from extraneous stimuli plays an important role in hypnosis. Individuals who are responsive to hypnosis demonstrate greater skills in extremely focused and sustained attention (e.g., Crawford et al., 1991; Tellegen & Atkinson, 1974). Electrophysiological research had found that high hypnotizables often generate substantially more theta electroencephalogram (EEG) power than do low hypnotizables (e.g., Crawford 1990, 1991; Crawford & Gruzelier, 1992; Sabourin, Cutcomb, Crawford, & Pribam, 1990). Such a relationship may be interpreted as further evidence of greater attentional skills in highs, because certain theta waves have been correlated with enhanced problem solving and attentional task performance (e.g., Crawford & Gruzelier, 1992; Schacter, 1977)....

"Hypnosis is seen often as a condition of amplified attention, where attention can be either more focused or diffuse dependent upon set (e.g., Krippner & Binder, 1974). Increases in vigilant performance during hypnosis have been reported, albeit inconsistently (e.g., Barabasz, 1980; Fehr & Stern, 1967; Kissen, Reifler, & Thaler, 1964; Smyth & Lowy, 1983). Fehr and Stern's results suggest that hypnotized subjects devote more attention to a primary task with less available attentional resources for a secondary task. Hypnosis has been found to have an enhancing effect on the imaginal processing of information-to-be-remembered that consists of literal or untransformed representations of pictorial or nonverbal information for high but not low hypnotizables (Crawford & Allen, 1983; Crawford, Nomura, & Slater, 1983; Crawford, Wallace, Nomura, & Slater, 1986). This may possibly be the result of increased attention and/or shifts in cognitive strategies. Supportive of the hypothesis that sustained attention can be enhanced during hypnosis, Atkinson (1991) recently found that high but not low hypnotizables report significantly more persistent afterimages in hypnosis than in waking.

"Although we have argued for a cognitive explanation for individual differences in afterimage persistence and their possible relationship to hypnotic susceptibility and sustained attentional abilities, as has Wallace (1979, 1990), we must point out the possibility that high hypnotizables may be more suggestible to imagery instructions or more willing to discuss or experience imagery than low hypnotizables, particularly in the context of hypnosis and hypnotic susceptibility testing (e.g., Zamansky, Scharf, & Brightbill, 1964). A contextual account of the longstanding relationship between hypnotic susceptibility and absorption was raised by Council, Kirsch, and Hafner (1986), but was not supported by two independent, and more methodologically sound, studies reported by Nadon, Hoyt, Register, and Kihlstrom (1991). The context of hypnosis was not an issue in the present study, because none of the subjects was aware of the investigated relationship between afterimage persistence and hypnotic susceptibility at the time of recruitment or participation" (pp. 533-535).

## 1991

Graffin, N. W. (1991, October). EEG concomitants of hypnotic susceptibility and hypnosis (Dissertation, Pennsylvania State University). Dissertation Abstracts International, 52 (4), 2296.

"Many previous studies of EEG and hypnosis were completed prior to development of spectral analysis and typically included data from a limited number of electrode sites. The categorization of subjects as high and low hypnotizables was often done inappropriately, and disparate findings were obtained. In this study, subjects scoring 10 or more and 3 or less on the Stanford Hypnotic

Susceptibility Scale, Form C were defined as high and low respectively. EEG was monitored during resting baseline, mental arithmetic, and mental spatial rotation, and before, during, and after hypnotic induction. EEG was recorded monopolarly at frontal (F3,F4), parietal (P3,P4), temporal (T3,T4), and occipital (O1,O2) derivations, and data were fast Fourier analyzed. Mental arithmetic and mental spatial rotation did not produce differential hemispheric activation. High hypnotizables had greater frontal and temporal theta at baseline than lows. All subjects showed increases in parietal and occipital theta during hypnotic induction. During prehypnotic induction baseline, highs had greater parietal and occipital theta than lows, but this difference was smaller after induction. Baseline temporal alpha was greater for highs than lows, but after hypnotic induction, all subjects had less alpha at all sites than before induction. Increases in alpha at all sites for all subjects occurred during hypnotic induction. Beta activity was unrelated to susceptibility but was greater in waking than in hypnotic states for all subjects at all sites. Increases in alpha at all sites for all subjects occurred during hypnotic induction. The theta activity observed suggests that high hypnotizables have a greater capacity for selective attention and imagery and that during hypnosis all subjects experience enhancement of these abilities. The alpha results may suggest an increase in the focusing of subjects on internal processes during hypnosis and greater scanning of the environment after induction" (p. 2296).

1990

Sabourin, M. E.; Cutcomb, S. D.; Crawford, H. J.; Pribram, K. (1990). EEG correlates of hypnotic susceptibility and hypnotic trance: Spectral analysis and coherence. International Journal of Psychophysiology, 10, 125-142.

EEG was recorded during waking rest, hypnosis (rest, arm immobilization, mosquito hallucination, hypnotic dream), and waking rest. Twelve very low and 12 very highly hypnotizability subjects participated. Evaluations were fast-Fourier spectral analysis, EEG coherence between selected derivations, and maximum spectral power within EEG bands. In eyes-open and eyes-closed conditions in waking and hypnosis, highly hypnotizability subjects generated substantially more mean theta power than did low-hypnotizable subjects at all occipital, central, and frontal locations in almost all conditions of waking and hypnosis, with a larger difference in frontal locations. Both low and high hypnotizables showed increased mean theta power in hypnosis, suggesting an intensification of attentional processes and imagery enhancement. Mean alpha power was never a predictor of hypnotic susceptibility. Interactions with hypnotic susceptibility showed that highly susceptible subjects had more beta activity in the left than in the right hemisphere, whereas low-susceptible subjects showed only weak asymmetry. No main effects for or interactions between waking/hypnosis and hypnotic level were found for coherence between derivations or maximum spectral power within theta, alpha, and beta EEG bands.

1975

Tebecis, A. K.; Provins, K. A.; Farnbach, R. W.; Pentony, P. (1975). Hypnosis and the EEG: A quantitative investigation. Journal of Nervous and Mental Disease, 161, 1-17.

A quantitative investigation of the EEG during hypnosis was made by analyzing the analogue power frequency spectrum of one group of subjects in the awake and hypnotized conditions, and another group (random sample) in the awake condition. Individuals of the first group were thoroughly experienced in self-hypnosis and highly hypnotizable, whereas those of the second group had never been hypnotized and were low in waking suggestibility. There were no statistically significant differences in mean power of the whole EEG spectrum between the awake and hypnotized conditions of the experimental group, although a trend toward increased theta (4 to 8 Hz) density during hypnosis was apparent. This group, however, exhibited significantly more theta activity during both the

hypnotized and the awake conditions than the random sample of controls in the awake condition, irrespective of whether the eyes were closed or open. We suggest that this increased theta density in the EEG is related to frequent experience of self- hypnosis, high hypnotizability, or both.

## THEORY

1995

Jasiukaitis, Paul; Spiegel, David (1995, November). Relateralizing hypnosis, or have we been barking up the wrong hemisphere?. [Paper] Presented at the annual meeting of the Society for Clinical and Experimental Hypnosis, San Antonio, TX.

## NOTES

The association between the right hemisphere and hypnotizability dates to the Gurs and Bakan; and to Hilgard and Morgan who developed a measure based on EEG power spectrum. Results from the body of research using alpha are conflicting. De Pascalis, 1988, also couldn't show a large alpha difference between hemispheres.

Research on hypnotic hallucination with Pribram found Highs in a visual obstruction condition reduced P200 and P300; there was a slightly greater response at O2 than O1 EEG leads, leading us to think it was maybe a Right hemisphere task. But it was a foveal stimulus.

We tested with hemifield stimuli, blocking perception of 1/2 of the visual monitor; had them do the obstruction hallucination. P200 had the greatest reduction, with stimuli presented on the left. With obstruction of left visual field, we got little response. So ERP results were greater in right visual field (left hemisphere). This suggests the earlier observation was predominantly due to left, not right, hemisphere influence.

Martha Farah's work on imagery is instructive. Also Steve Kosslyn. The Right hemisphere answers "Where" do you see something. The Left answers "What is it you see?" The left hemisphere generates image patterns that match what you see. When you ask people to generate an image, the activity is in O1 area. Also, patients with left hemisphere damage can't generate images; callosotomy patient also gave evidence. Many inductions use generation of images (left occipital and temporal regions). So when asking subjects to generate a hallucinated image blocking the screen, they are using that area.

The cortex can serve as an amplifier or a suppressor of response. In earlier study of somatosensory potential we observed bigger response when asking person to be more aware of pain. The cortex has an arousal system. There are two relevant systems in the brain (see Posner)--posterior and anterior. Hypnotizability is correlated with a metabolite of dopamine, which is associated with the anterior system which is dopaminergic.

Tucker & Williamson, in article in Psychological Review, 1984, write that activation is "the determination of information control by previous, stored internal representations" as opposed to arousal which is the "determination by novel [missed words....]"

Kinsbourne, in Consciousness and Contemporary Science, 1988. wrote that if at any time a hemisphere works like an automaton, it is the left hemisphere. With R. Davidson, he has shown the left hemisphere elevates affect, the right depresses it. Many people report that hypnosis is a pleasurable thing to do, maybe because it elevates mood.

One obstacle to this formulation is the idea that the left hemisphere governs logical thought.

We may disturb the relationship between words and images in hypnosis; you start to manipulate images and passively receive words, so that language is now a passive, receptive experience and images are active (instead of the usual pattern of actively using words and passively using images).

1994

Freyd, Jennifer J. (1994). Betrayal-trauma: Traumatic amnesia as an adaptive response to childhood abuse. Ethics and Behavior, 4.

Betrayal-trauma theory suggests that psychogenic amnesia is an adaptive response to childhood abuse. When a parent or other powerful figure violates a fundamental ethic of human relationships, victims may need to remain unaware of the trauma not to reduce suffering but rather to promote survival. Amnesia enables the child to maintain an attachment with a figure vital to survival, development, and thriving. Analysis of evolutionary pressures, mental modules, social cognitions, and developmental needs suggests that the degree to which the most fundamental human ethics are violated can influence the nature, form, processes, and responses to trauma.

#### NOTES

"A logical extension of this research direction, based on a strategy that has been very effective in cognitive neuroscience, would be to look for neuroanatomical underpinnings of the cognitive mechanisms implicated in dissociation. ... For instance, the ability to dissociate current experience may depend partly on representational structures that support spontaneous perceptual transformations of incoming events. One possible perceptual transformation that is amenable to scientific investigation, would be the creation of spatial representations in which the mental 'observer' is spatially distinct from the real body of that observer. Such a representation would fit patient descriptions of 'leaving their body' during a traumatic episode and viewing the scene as if from afar. Additionally one could investigate the role of mental recoding and restructuring during memory 'recovery' and psychotherapy" (pp. 19-20).

1993

Balthazard, Claude G. (1993). The hypnosis scales at their centenary: Some fundamental issues still unresolved. International Journal of Clinical and Experimental Hypnosis, 41, 47-73.

Current approaches to the measurement of hypnotic performance can be traced back to the 19th century. In part because of these early origins and in part because of the nature of hypnotic phenomena, the hypnosis scales are unique psychometric instruments. The classic hypnosis scales are based on the notion of a "performance ladder"; items are scored on a pass/fail basis and can be arranged in increasing order of difficulty. Some of the implications on [sic]this "performance ladder" approach are reviewed. The evidence for two-mechanism models of hypnotic performance is reviewed. It is argued that this kind of formulation is at least as plausible as one that argues that the hypnosis scales measure "one thing" or "mostly one thing." If it were the case that the hypnosis scales were tapping two different and distinct processes, the label "hypnotic susceptibility" could not be unambiguously applied to scores on the hypnosis scales. The hypnosis scales would appear well-suited to the investigation of underlying mechanisms, yet no consistent picture of the mechanisms underlying hypnotic performance on the scales has emerged thus far. No resolution is presented, but some of the reasons why such a resolution is so elusive are discussed. The future of hypnosis scales is discussed with respect to multidimensional assessment and alternatives to the "work sample" approach.

#### NOTES

Author discusses the hypnotizability scales' history and psychometric properties, suggesting that they cannot have construct validity if more than one construct is involved. He states that many of the alternative formulations "posit structurally similar two- mechanisms models, where the relative contributions of one and the other mechanism changes gradually with the difficulty of the hypnotic performance--that is, one mechanism is more important for easy items and the other more important in the difficult range. This kind of formulation has been advanced by a number of authors .....

Although these formulations are structurally similar, the nature of the mechanisms has been variously conceptualized: nonability and ability components (Shor, Orne & O'Connell, 1962), primary suggestibility and somnambulism (Weitzenhoffer, 1962), minor and major dissociations (Hilgard, 1977), compliance and true hypnosis (Tellegen, 1978-1979), and cooperativeness and expectation at one end and absorption at the other (Spanos, Mah, Pawlak, D'Eon, & Ritchie, 1980). ... In a formulation such as Hilgard's (1977), where both mechanisms are dissociative, it may be that it makes some sense to understand both mechanisms as aspects of the same complex construct. In other formulations... it would appear more cogent to speak of two constructs. Spanos et al. (1980) found that 'cooperativeness and expectation may be particularly important in responding to ideomotor and challenge suggestions, while the ability to convincingly treat imaginings as real (i.e., absorption) becomes increasingly important for more difficult 'cognitive' items" (p. 21). Balthazard & Woody (1992) presented evidence that the more difficult items on hypnotizability scales are related to absorption more than the easier items.

Balthazard & Woody (1989) investigated the proposition that hypnotizability scores are distributed bimodally, and concluded that statistical problems clouded the issue. Furthermore, most analyses previously have been of surface structure, which does not relate directly to the underlying mechanisms of hypnosis, and current psychometric methods cannot address the mechanisms that underlie surface relations. "There are two aspects of hypnotic processes ... that obscure underlying mechanism: synergisms and overdetermination. Synergisms occur when mechanisms potentiate each other in such a way that a combination of processes becomes more than the sum of its parts. Overdetermination occurs when co-occurring mechanisms do not potentiate each other, such that any one of the mechanisms would have been sufficient to produce the observed effect" (p. 63-64).

The author suggests there are two options at present: Corrective Scoring (like the Curss.OI, an objective-involuntary score which, although unreliable on test-retest, appears it could be more a measure of "pure" hypnotizability) and not using the typical "work sample" approach. Balthazard and Woody (1992) suggested the Absorption Scale may provide a better measure of "hypnotizability" than the standard hypnosis scales because absorption scores are more strongly related to difficult hypnotic performances.

1992

Balthazard, Claude G.; Woody, Erik Z. (1992). The spectral analysis of hypnotic performance with respect to 'Absorption'. International Journal of Clinical and Experimental Hypnosis, 40, 21-43.

In factor analyses of the hypnosis scales, the essential result is that the items form a continuous, 2-dimensional fan-shaped pattern. This continuum is referred to as the "spectrum of hypnotic performance." "Spectral analysis" is introduced as an exploratory procedure which makes use of this notion of continuum or spectrum. Spectral analysis consists of a graphical display of the level of latent correlation between a variable and individual hypnotic performances when the latter are arranged according to their position in the spectrum. The spectral analysis of hypnotic performance with respect to absorption is illustrated using data from a sample of 160 Ss. The results indicate that absorption is more strongly related to difficult hypnotic performances than to easy ones. In particular, illustrative item characteristic curves are presented to show that although easy hypnotic performances do not require the processes tapped by individual differences in absorption, a certain level of absorption is necessary to pass difficult hypnotic items. In addition, a high level of absorption may be sufficient in and of itself for difficult hypnotic performances. These results are discussed in light of some speculations by Shor, M. T. Orne, and O'Connell (1962) and Tellegen (1978/1979) concerning the differential contribution of ability components to performance on difficult hypnotic suggestions. The results are also related to a variety of work in social psychological models of hypnotic performance.

## NOTES

Spectral analysis "consists of a graphical display of the level of latent correlation between a variable and individual hypnotic performances when these hypnotic performances are arranged according to their position in the spectrum--which is indexed by item difficulty" (p. 25). Difficulty (the proportion of Ss that pass a given item) is on the X-axis; the degree of latent correlation is on the Y-axis. "It is necessary to differentiate between the manifest and the latent relationship of a variable to a dichotomously scored hypnotic performance. The manifest relationship is given by the point biserial correlation and the latent relationship is given by the biserial correlation. ... By inspecting the overall pattern of these biserial correlations as a function of item difficulty, it is possible to overcome the difficulty-content confound, because the biserial correlations are not affected by item difficulty" (p. 25).

"Throughout the easy and middle ranges [of item difficulty], the biserial correlation of hypnotic performance with absorption remains slightly above .2, then it rises sharply in the difficult range--beginning roughly where only one in four Ss can pass the item--to a value slightly above .5 " (p. 27). "In essence, the proportion of Ss that pass a particular hypnosis suggestion given a particular score on the absorption scale is being plotted" (p. 30).

In their discussion, the authors relate their position to that of other theorists. Shor, Orne, & O'Connell (1962) proposed that both ability and nonability components contributed to hypnosis, with ability being the primary determinant of hypnotic performance at deeper levels. Shor et al. found a correlation between depth ratings and a questionnaire that tapped 'hypnotic-like experiences' to be .45; the correlation was .84 when computed for only the Ss who became deeply hypnotized, but only .17 for Ss who were only lightly or medium-level hypnotized. They concluded that their questionnaire predicted hypnotizability only for the "deeper region" of hypnosis.

Tellegen (1978/1979) proposed a two-factor model, one factor being genuine responsiveness and the other being compliance . He suggested that various hypnosis test items draw on the two factors in differing degrees. Tellegen's genuine responsiveness factor would be similar to Shor et al.'s ability components, and Tellegen's compliance factor would be similar to Shor et al.'s non-ability components. (The Shor model goes farther than Tellegen in positing a gradual shift in the relative contributions of the two components as one moves from easy to difficult items, and this gradualness is part of the authors' spectrum model.)

The two-factor model is different from the general factor (plus special factors) model suggested by E. R. Hilgard (1965)); Hilgard's general factor would probably correspond better to the Tellegen genuine responsiveness factor and the Shor et al. ability component than to the compliance factor or nonability component, which probably would correspond more to the easier items on hypnotizability scales.

Spanos et al. (1980) suggested that cooperativeness and expectation might be more important with ideomotor and challenge suggestions, and ability to treat imaginings as real (i.e. absorption) more important for more difficult cognitive items. Sarbin (1984) developed a typology with two types of individuals--those who respond to the hypnosis context by "joining the game" and knowingly create an illusion that their response is involuntary (the compliance kind of response), and those who convince themselves and others that their response is involuntary (the genuine responsiveness factor kind of response).

[Speaking of the context effects observed but not replicated 100% of the time, on the correlation between absorption and hypnotizability.] "It is possible that context effects may depend on the difficulty of the hypnotic suggestions and the latent abilities of the sample used. For relatively good hypnotic Ss performing relatively difficult suggestions, the correlation of absorption with hypnotizability may be stable across different contexts; however, for less able Ss performing relatively easy suggestions, the correlation, depending more on the 'non-ability' component, may be quite responsive to context manipulations. It might also be mentioned parenthetically that details of the

instructions used to introduce the particular hypnosis scale employed may differentially pull for one kind of component or the other" (p. 39).

Bindler, Paul R. (1992, October). Biofeedback-assisted hypnosis: Theoretical and clinical perspectives. [Paper] Presented at the annual meeting of the Society for Clinical and Experimental Hypnosis, Arlington, VA.

## NOTES

Relates personality trait of absorption to biofeedback literature. Surprisingly, low absorption ability Ss do better than high absorption Ss on biofeedback (Qualls & Sheehan). All but one study that compared biofeedback and hypnosis found no difference in effectiveness. However recently Miller & Cross found high hypnotizables reduce EMG better with hypnosis and lows did better with biofeedback.

Our findings also supported notion that highs perform better with sensory imagery instructions and lows do better with biofeedback.

Critical in determining the outcome is the way Ss deploy attention. Qualls & Sheehan, and we, find highs don't like attention drawn away from internal cognitive strategies by the biofeedback signal. However lows find the signal to keep their attention focused.

Author developed model combining biofeedback and hypnosis to capitalize on the attentional characteristics of patients, the specific cognitive and affective characteristics of the pt.

Highs start with using altered state of consciousness to help them to alter their cognition patterns. Some do not relax during hypnosis and biofeedback can be used.

Hypnotic suggestions can be added to biofeedback to emphasize attention to internal discrimination. Attention to stimuli is poor when arousal is too low or too high. Both biofeedback and hypnosis can be used to create a moderate level of attention.

With low hypnotizables, they need to increase awareness of contingencies between cognitions and physiological states; to verbalize and express their feelings. Initially they learn to recognize, label, and express their feelings through biofeedback, which amplifies the physiol. state/body sensations. It provides a means of relaxation. Begin with brief trials of biofeedback to train low arousal states. Duration of training is gradually lengthened to 15 minutes. Patient should be continually questioned about feelings etc. (physical) during exercise, and their response correlated with the feedback signal.

Many lows have difficulty expressing feelings in words. Biofeedback allows the correlation to emerge initially by the instruments. Crystal's "preparatory" treatment: helping patient with affect tolerance prepares them for next stage of verbalizing emotions. Biofeedback facilitates this by deintensifying the effect of discharged affect.

Bruner, Jerome (1992). Another look at New Look 1. American Psychologist, 47, 780-783.

New Look 1 was not initially about the unconscious. It was the new mentalism on its way to becoming the Cognitive Revolution. Its subsequent concern with "unconscious defense mechanisms," although useful, was not its main theoretical thrust. Its principal questions have always been how and where selective processes operate in perception. Obviously, many such processes are unconscious, for consciously guided attention and search become automatized easily in use. And they are fairly flexible as well. So how smart is "the unconscious"? Not very, but a big help anyway.

Dixon, Michael; Laurence, Jean-Roch (1992). Two hundred years of hypnosis research: Questions resolved? Questions unanswered!. In Fromm, Erika; Nash, Michael R. (Ed.), Contemporary hypnosis research (pp. 34-66). New York: Guilford Press.

## NOTES

These notes summarize only that part of the chapter concerning nonvoluntary behavior (pp 38-39; 58-61).

The concept of 'nonvolition' has been and continues to be an important issue in hypnosis research. The concept pertains to the "subjective report that the hypnotic suggestion is enacted without the subject's conscious and willful participation" (p. 38). When hypnosis was attributed to a magnetic fluid, in the days of Mesmer, the issue did not arise (because of course a person would not have control over something that happened to them physically). However, when hypnosis came to be considered a psychological phenomenon, the issue of how a behavior could be the result of motivated action and yet not perceived as being under conscious influence became important. In 1819 Faria wrote that the nonvolition paradox is due to the hypnotized subject's tendency to misattribute the source or reason for one's behaviors; he noted that successful suggestions depended upon the subject falsely attributing to the hypnotist the power to influence them. From that point forward, circular reasoning was used to state that one is hypnotized if one experiences their behavior as nonvolitional, and nonvolitional behavior signifies that a person is hypnotized.

"The observation of the seemingly complete automaticity of response in the highly hypnotizable subject led Liebeault in his 1866 book (followed later on by Bernheim and Liegeois) to describe these subjects as 'puppets' in the hands of the hypnotist. This was a quite unfortunate statement, since it would lead to one of the fiercest legal debates surrounding the use of hypnosis in the last 20 years of the 19th century (Laurence & Perry, 1988). ...

"The most prominent author (if not the only one) who attempted to tackle this difficult question was Pierre Janet, who would make the investigation of automatism the basis of his theory of hypnosis, rather than suggestion or suggestibility. This theoretical orientation is best exemplified by his concept of desagregation psychologique seen in some psychopathologies, or the carrying out of a posthypnotic suggestion in the normal individual (Janet, 1889; see also Ellenberger, 1970; Perry & Laurence, 1984; Prevost, 1973). Nonetheless, until the end of the 19th century, and for a good part of the 20th century, these reports of nonvolition were thought to be the end result of some neurological changes happening during hypnosis--an idea that has not been substantiated by contemporary research." (pp 38-39)

Reports of nonvolition are explained as due to dissociation by Hilgard, or as the results of misattributing the origins of behaviors and experiences by Spanos and by Lynn. Neodissociationists like Hilgard regard misattribution to be a cognitive alteration, mainly an internal triggering mechanism, while social psychologists like Spanos and Lynn regard the misattribution to be the results of situational demands and therefore an external triggering mechanism.

"Regardless of one's preferred metaphor, the issue of nonvolitional reports remains at the core of an integrated view of hypnosis and hypnotizability. The question remains as follows: By which mechanisms does this occur, and how can we predict a priori who will report involuntariness and under what circumstances? Whereas dissociationists have emphasized general cognitive mechanisms and de-emphasized situational factors, social-psychological theorists have emphasized situational variables and de-emphasized individual differences. Given the limitations of both approaches, emphasis will have to be placed not on their continued separation but on their integration, as more and more investigations demonstrate that they clearly interact with each other (see, e.g., Nadon, Laurence, & Perry, 1991)." (p. 60)

"At the height of the confrontation between the two French schools, hypnosis found its way into the legal arena. Following a series of criminal cases in which hypnosis had been allegedly involved, the two schools once again found themselves on opposite sides of the fence. For La Salpetriere, only those who had a propensity toward criminality (and hystericals were prime candidates) could be the victims of hypnosis. For the Nancy school, in highly responsive individuals suggestions could lead to criminal behavior. Unfortunately for the Nancy school, it soon became evident that the concept of suggestion was not sufficient in explaining the questions raised by the courts, and Bernheim was forced to recognize that in cases where suggestions had played a role, other dispositional and situational factors

were probably more important in the genesis of the reprehensible behaviors. His espousing a too extreme position meant that the baby was thrown out with the bathwater. History may indicate that the same fate is now awaiting contemporary theoretical positions that adopt an extreme stance vis-a-vis the phenomenon of hypnosis" (p. 61).

Greenwald, Anthony G. (1992). New Look 3: Unconscious cognition reclaimed. American Psychologist, 47, 766-779.

Recent research has established several empirical results that are widely agreed to merit description in terms of unconscious cognition. These findings come from experiments that use indirect tests for immediate or long-term residues of barely perceptible, perceptible-but-unattended, or attended-but-forgotten events. Importantly, these well-established phenomena--insofar as they occur without initially involving focal attention--are limited to relatively minor cognitive feats. Unconscious cognition is now solidly established in empirical research, but it appears to be intellectually much simpler than the sophisticated agency portrayed in psychoanalytic theory. The strengthened position of unconscious cognitive phenomena can be related to their fit with the developing neural network (connectionist) theoretical framework in psychology.

Hilgard, Ernest R. (1992). Dissociation and theories of hypnosis. In Fromm, Erika; Nash, Michael R. (Ed.), Contemporary hypnosis research (pp. 69-101). New York: Guilford Press.

## NOTES

[These Notes were made from a prepublication copy and the pagination for quotes added later.] The author reviews the history of dissociation theory, the hidden observer, and the credible-skeptical arguments regarding hypnosis. He briefly summarizes alternative theories about hypnosis, and asserts that we can turn aside from debate by examining the common topic studied, the "domain of hypnosis" or what happens when hypnotist, with consent of subject, attempts to induce hypnosis through conventional procedures: production of hallucinations, contractions, paralyzes, age regression, analgesia, posthypnotic amnesia, etc. Even if one disagrees about the nature of these phenomena or the appropriate explanatory concepts, one can agree on the area to be investigated.

The author notes that one never sees these behaviors in the same situation, in any other context. They are distinguishable from other phenomena like meditation, highway hypnosis, responses to a persuasive leader, and even some waking suggestions by several delimiting factors:

1. Hypnosis is not simply a response to suggestion, because that kind of response occurs in other situations. Suggestions can be divided into personal and impersonal (Hull, 1933); and suggestibility can be divided into primary and secondary (Eysenck & Furneaux, 1945). Primary suggestibility includes responses to waking suggestion (e.g. postural sway) that correlate with hypnotizability; secondary suggestibility involves responses to waking suggestion that do not correlate with primary suggestibility. Hypnotizability does not correlate with social suggestibility (i.e. gullibility or conformity) (Burns & Hammer, 1970; Moore, 1964); nor does it correlate with placebo response (McGlashan, Evans, & Orne, 1979).

2. Test-retest correlations are approximately +.70 between scores on hypnotizability scales with and without formal inductions. Thus, responses to the type of suggestion on hypnotizability scales--even when in the waking context--belong within the domain of hypnosis. The individual differences in responsivity to items on hypnotizability scales persist over time (Piccione, Hilgard, & Zimbardo, 1989:  $r = .64$  for 10 years test-retest,  $.82$  for 15 years, and  $.71$  for 25 years, on Stanford Form A); and this persistence is observed in twin studies as well (Morgan, 1973; Morgan, Hilgard, & Davert, 1970).

3. Additional evidence of coherence of the domain comes from reports of hypnotized Subjects about their phenomenological experience.

Hilgard's discussion of the executive and monitoring functions within hypnosis place his theory within the area of cognitive psychology. He presents a theory of a central regulating mechanism, with a hierarchy of subsystems that may be activated (and once activated may continue with some autonomy). When autonomous action occurs, the conscious representation of the control system may recede. Furthermore, the hypnotist's suggestions may alter the relationships within the hierarchy of subsystems and may also influence the executive functions. He gives as a common example, when a bilingual person talks in one language, the other language is temporarily inhibited.

There are a number of concepts or positions in the history of psychology that relate to Hilgard's theory of hierarchical control with executive and subsystems:

1. 'Cognitive structure' (Edward Tolman, 1932; 1938; Kurt Lewin, 1935). There may be communication problems between cognitive structures.
2. 'Habit family hierarchy' (Clark Hull, 1934). Habits are organized in a preferential system, so that if one is blocked the next is activated.
3. 'Cell assemblies' (Hebb, 1949; 1975), which are a physiological counterpart of the 'hidden observer' phenomenon.
4. 'Roles' (Sarbin & Coe, 1972) may be considered cognitive substructures.
5. 'Cognitive networks' (Blum, Geiwitz, & Stewart, 1967) serve similar functions.
6. 'Images' and 'plans' (Miller, Galanter, & Pribram, 1960) provide for control of thought and action and have some kind of hierarchy.
7. 'Subordinate ego-structures' (Gill & Brenman, 1959) with a dominant ego; or the ego-apparatuses in a 'conflict-free ego sphere' (Hartmann, 1958).

In hypnosis, central executive functions may be shared between hypnotist and Subject. Hilgard gives extensive examples of varying degrees of split in the executive control system.

"It can be argued that, except for relinquishing control over the subsystems that are specifically dissociated from control by suggestion, and the readiness for relinquishing control, the central executive functions have not been much modified in hypnosis. In superficial hypnosis, these mild dissociations can occur through waking suggestions, with little alteration of the general state of consciousness. When varied suggestions to a talented hypnotic subject have cumulative effects, as in suggestions of relaxation and detachment from the environment, the more general features of the hypnotic state begin to appear. A more massive dissociation, so far as the executive is concerned, may be the consequence of the summing up of many specific subsystems for which control has been relinquished. Such an interpretation permits hypnosis as a state to be a relative matter, the specific dissociations being identifiable, but the general state being a matter of how many specific dissociations are operative and how pervasive they are. Only when they are sufficiently pervasive is it appropriate to speak of a change of state" (p. 96).

Hilgard also discusses the monitoring function extensively, relating it to trance logic and contrasting it with the waking state. Less of the usual monitor is retained when the hypnotic involvement is greater, as in deep hypnosis, or when the subject becomes more deeply engrossed in an activated system that has been aroused. He also relates the monitoring function to the Hidden Observer phenomenon.

Isenberg, S. A.; Lehrer, P. M.; Hochran, S. (1992). The effects of suggestions and emotional arousal on pulmonary functions in asthma: A review and a hypothesis regarding verbal mediation. Psychosomatic Medicine, 54, 192-216.

This paper reviews the empirical literature on the relation between asthma, suggestion, and emotion, and proposes the hypothesis that these effects are mediated parasympathetically. The literature indicates that, among asthmatics, suggestion can produce both bronchoconstriction and bronchodilation, and that stress can produce bronchoconstriction. The proportion of asthmatic subjects showing bronchoconstriction to both suggestion and stress averages 35%-40% across studies, but, because of methodological considerations, might be conservatively estimated as closer to 20%. The effect is smaller for suggestion of bronchodilation, and is very short-lived among nonasthmatics. No

clear connection has been found between these responses and such subject variables as age, gender, asthma severity, atopy, or method of pulmonary assessment, although some nonsignificant tendencies appear. Most studies in this literature used small n's and did not systematically examine various somatic, environmental, and demographic factors that could influence results. A hypothesis is presented regarding vagal mediation of psychological effects on the airways, as well as possible alternative mechanisms, and recommendations for future research to evaluate these hypotheses.

## 1991

The first part of this paper examines the concept of dissociation in the context of hypnosis. In particular, the neodissociative and social psychological models of hypnosis are compared. It is argued that the social psychological model, in describing hypnotic enactments as purposeful, does not adequately distinguish between behavior that is enacted "on purpose" and behavior that serves or achieves a purpose. 2 recent dissertations (Hughes, 1988; Miller, 1986) from the University of Waterloo are summarized, each of which supports the neodissociative view that hypnotic behavior can be purposeful (in the sense that the suggested state of affairs is achieved) and nonvolitional (in the sense that the suggested state of affairs is not achieved by high level executive initiative and ongoing effort). The second part of the paper employs a neodissociative view of hypnosis to help understand the current epidemic of multiple personality disorder (MPD). In particular, it is argued that many symptoms of MPD are implicitly suggested effects--particularly prone to occur in persons who have a lifelong tendency to use dissociative type defenses. The present author believes that this account is easier to sustain conceptually and empirically than the current view, which states that a secondary (tertiary, etc.) personality accounts for the striking phenomenological discontinuities experienced by MPD patients.

## NOTES

As an example of the fact that behavior that serves a purpose is not always performed on purpose, the author cites not falling out of bed while sleeping, and waking up in response to signals from the bladder to go to the bathroom. Lower levels of control can be dissociated from executive initiative and/or monitoring. "Since the experience of volition is closely tied to executive initiative and effort, suggested behaviors that bypass such initiative and effort are typically experienced as nonvolitional" (p. 157). Dissociated control occurs under waking conditions also, as when one dials a very familiar phone number rather than the one that they intended to dial. In this case, the behavior that is enacted is not what one consciously intended.

Miller's dissertation, also published as Miller & Bowers, 1986, is described on p. 158 ff. Without hypnosis, cold pressor pain (cold water immersion) reduced accuracy of performance on a multiple choice vocabulary test 35%. Both hypnotic analgesia and cognitive pain management strategies were equally effective in reducing pain of cold pressor test (and both interventions were more effective for high than for low hypnotizable Ss). However, the cognitive strategy group showed an additional drop of 30% in vocabulary performance from pre- to posttreatment cold water immersion (despite successfully reducing their pain). In the hypnosis condition, lows showed only a slight additional decrease (8%) while highs showed a slight (10%) \_increase\_ in their vocabulary performance from pre- to posttreatment immersion.

Thus, the effect of hypnosis in pain control "does not depend on S's utilization of high-level cognitive strategies. Rather, hypnotic analgesia seems to involve the dissociated control of pain--that is, control which is relatively free of the need for high- level, executive initiative and effort. ... Because hypnotic analgesia minimizes the degree of executive initiative and ongoing effort required to reduce pain, however, it seems inappropriate to view such reductions as something achieved on purpose" (p. 161).

Hughes' dissertation is described on p. 162 and ff. Instead of performance decrement on a cognitive task like vocabulary testing, she used increased heart rate as an index of cognitive effort. If heart rate

increases when Ss successfully use hypnotic imagery, that would confirm the social psychological view that "suggested effects are achieved by this kind of ongoing allocation of high-level cognitive force or work" (p. 162).

Highs and lows were hypnotized and administered three trials of neutral and three trials of fearful imagery in counterbalanced order. Each imagery trial lasted 1 minute, after which Ss rated vividness of imagery, effort required, and amount of fear experienced.

Average imagery vividness was higher in highs than lows, for both neutral and fear imagery. For lows the correlation between heart rate increases and ratings of cognitive effort were .54 (neutral imagery) and .49 (fear imagery). For highs, the correlations were -.05 (neutral) and -.52 (fear). Thus, "for low but not high hypnotizable Ss, we find the predicted positive relationship between a cardiac indicator of cognitive effort and the ratings of cognitive effort involved in producing neutral imagery" (p. 163).

"First, for low hypnotizables engaged in fear imagery, ratings of effort are correlated .66 with ratings of fear. In other words, the more low hypnotizable Ss work to produce a fearful image, the more frightening the image is. Second, for high hypnotizables engaged in fear imagery, the correlation between ratings of fear and effort is minus .68-- indicating that the less effort highs report in producing fear imagery, the more frightened they become. Finally, for high hypnotizables, the correlation between ratings of fear and heart rate increase is .59, indicating that the more fear high hypnotizable Ss experience when engaged in fear imagery, the more their heart rate increases (the comparable figure for low hypnotizables is .16)" (p. 164).

The authors discuss why the pattern of correlations is different for people high and low in measured hypnotizability, and summarize the implications of both Miller's and Hughes' research. Both investigations indicate that, at least for high hypnotizable people, less initiative and effort are required to effect a response to hypnotic suggestion than one would expect. They show how behavior can be both purposeful and nonvolitional (in the sense of not exhibiting conscious intention and strategic efforts). By noting that the sense of nonvolition that accompanies a response to suggestion is an actual alteration in executive control, they provide a model for dissociative psychopathology such as MPD. For although executive control is dissociated, these experiments do not suggest that there is a second executive system or 'personality' that is responsible for the behavior.

Patients diagnosed with MPD have very high measured hypnotizability (Bliss, 1984). In fact, they seem to engage in self hypnosis, withdrawing into a trance or a dissociated state (Bliss, 1984). The authors quote Wilson & Barber (1983) as indicating that highly hypnotized, fantasy-prone normal individuals may become so absorbed in a character being imagined that they lose awareness of their own identity.

The authors offer a neodissociative account of MPD: "People prone to MPD are very high in hypnotic ability and are, therefore, vulnerable to the suggestive impact of ideas, imaginings, and fantasies; what is more, they are high in hypnotic ability because they have learned to use dissociative defenses as a way of dealing with inescapable threat-- such as physical and sexual abuse (Kluft, 1987). ... Fantasied alternatives to reality (including a fantasied alter ego ... ) can become increasingly complex and differentiated. Gradually, these fantasied alternatives begin to activate subsystems of control more or less directly--that is, with minimal involvement of executive level initiative and control. Such 'dissociated control' of behavior does not necessarily eliminate consciousness of it, though one's actions are apt to be experienced as increasingly ego-alien. If and when the activating fantasies and resulting behaviors become sufficiently threatening, however, they can also be repressed into an unconscious (i.e., amnesic) status, thus further separating high-level executive and monitoring functions from the dissociated, ego-alien aspects of oneself. The fully realized result of this process is an individual who is subject to profound discontinuities in his or her sense of self. ... The experience of behaving in an outwardly uncharacteristic manner requires only that subsystems of control are more or less directly activated by ideas and fantasies in a manner that effectively bypasses executive initiative and control" (pp. 168-169).

923, Bowers, 1992 NOTES: Tart allegedly taught ESP skills based on reinforcement, using a machine that projected display and gave feedback immediately, so the subjects could learn to anticipate the picture better. But the picture presented next was time-linked to the S's response (so S could learn it). 1987 Behavioral and Brain Sciences review, with 2 target articles, makes one doubt strength of findings. ESP research doesn't distinguish between description of an observation and it's proposed cause.

MPD shares with ESP a tendency to predispose toward a certain explanation. Feeling like one has a separate personality leads to finding evidence for one. But an MPD account is wrong-headed because the diagnosis misconstrues a notion of personality, which is a developmental concept (a pattern of thought, feeling, and behavior). Mischel's (1968) account of human functioning competed with trait theory, so "personality" concept became extraneous.

Defining personality in terms of one's experiences or beliefs about oneself has led to further problems, encouraged by the descriptive approach of DSM III (which depends on patient reports). Drew Weston distinguished between the self and self representation. One can't argue that a computer programmed to describe itself is the same as it's descriptions.

Personality can't be reduced to person's beliefs about themselves. A secondary personality cannot be reduced to bizarre experiences a person believes are due to a second personality. Clinicians do not accept as valid the beliefs of a paranoid schizophrenic; or of an anxious neurotic. With multiple personality disorder (MPD) the patient becomes the expert and the clinician the student.

William Smith's 1986 SCEH paper: case study of patient who was convinced her problems were due to unresolved problems from a previous life. He didn't challenge her system but still worked with her successfully, communicating respect without validating her belief.

Advocates of MPDs think the observation that it is associated with high hypnotizability indicates great dissociation; critics think the association indicates great suggestibility. There is a historical parallel: Mesmer probably didn't suggest seizure-like episodes, but implicit suggestions for seizures were probably partially responsible. Mistaken attribution permitted Mesmer to see this as validation of his theory of animal magnetism.

Clinicians are not the only ones to "suggest" MPD syndrome. High profile cases are in the media. We should also remember Orne's 1959 research showing that students who received false information a week earlier in lecture on hypnosis showed the behavior when they were hypnotized.

Janet's disaggregation (dissociation) theory said hysterics and hypnotized people responded to ideas dissociated from the main stream of consciousness. So his contemporaries thought that spontaneous amnesia was a defining feature of hypnosis; yet it is not thought to be so in our era. The idea may have circulated in Janet's time, by popular culture.

MPDs are always highly suggestible so can respond to circulating accounts in the media, and every account that reaches the media can influence these people.

We could abandon the diagnosis of MPD in favor of Spiegel's "disorder of self integration." It is less provocative, does not imply any clinical benefit in the benefits of seeking out more personalities. This might reduce the incidence of this disorder, or likelihood that a suggestible person would develop the disorder iatrogenically.

Brown, Jason W. (1991). Self and process: Brain states and the conscious present. New York: Springer-Verlag.

## NOTES

Author, from the Department of Neurology at New York University Medical School, presents a theory about the genetic unfolding of mental content (mind) through stages, from mental state into consciousness or into behavior. He relates the genesis of mind to brain development but avoids assuming that there is a straightforward correlation between brain development (e.g. myelination) and cognitive development or perception. To some degree, the theory is based on subjective report data

and psychological symptoms. The author discusses issues that bear on the phenomena of nonvoluntary responding and dissociation that are reported or described by hypnotized persons.

"The nature of the mental state will determine the relation between self and world, and thus the interpretation given to agency and choice. ... The crossing of the boundary from self to world is a shift from one level in mind to another" (pp. 10-11).

"... if we begin with mind as primary and seek to explain objects from inner states and private experience, the discontinuity between inner and outer evaporates: mind is everywhere, a universe. ... Whereas before we thought to perceive objects, now we understand that we think them" (p. 19).

"The concept of a stratified cognition is central to the notion of a mental state .... This entails an unfolding from depth to surface, not from one surface to the next, a direction crucial to agency and the causal or decisional properties of consciousness" (p. 52). By unfolding from depth to surface, he means from Core, through Subconscious, then Conscious Private Events, and finally Extra-Personal Space.

He goes on to provide a definition of mental states. "A mental state is the minimal state of a mind, an absolute unit from the standpoint of its spatial and temporal structure. ... The state also has to include the prehistory of the organism. ... The concept of a mental state implies a fundamental unit that has gestalt-like properties, in that specific contents-- words, thoughts, percepts--appear in the context of mind as a whole (p. 53).

"The entire multitiered system arborizes like a tree, with levels in each component linked to corresponding levels in other components. For example, an early (e.g., limbic) state in language (e.g., word meaning) is linked to an early stage in action (e.g., drive, proximal motility) and perception (e.g., hallucination, personal memory) .... In sum, a description of the spatial and temporal features of a single unfolding series amounts to a description of the minimal unit of mind, the absolute mental state" (p. 54).

The author's discussion of an individual's physical movement relates to the concept of nonvoluntary movement (or movement without awareness of volition) in hypnosis. "More precisely, levels in the brain state constitute the action structure. As it unfolds, this structure generates the conviction that a self-initiated act has occurred. This structure--the action representation--does not elaborate content in consciousness. ... As with the sensory-perceptual interface, the transition to movement occurs across an abrupt boundary. In some manner, perhaps through a translation of cognitive rhythms in the action to kinetic patterns in the movement, levels in the emerging act discharge into motor (physical) events" (p. 57).

"The self has the nature of a global image or early representation within which objects-to-be are embedded. ... The self is the accumulation of all the momentary cognitions developing in a brain configured by heredity and experience in a particular way (p. 70).

"The deposition of a holistic representation ... creates the deception of a self that stands behind and propagates events. The feeling of the self as an agent is reinforced by the forward thrust of the process and the deeper locus of the self in relation to surface objects. The self appears to be an instigator of acts and images when in fact it is given up in their formation. The self does not cause or initiate, it only anticipates (p. 70).

The foregoing notes cover only the first five chapters, less than half the book. Other chapters relevant to hypnosis would be those titled 'The Nature of Voluntary Action,' 'Psychology of Time Awareness,' 'From Will to Compassion,' and 'Mind and Brain.'

## NOTES

Notes are taken from a review of this book: Diamond, Michael (1993). Book review. *Bulletin of the Menninger Clinic*, 57 (Winter), 120-121.

Brown "posits that because the fundamental matrix of the human brain is metaphoric, hypnosis results from skillful matching of metaphorical communication with the brain's biological, rhythmic alterations. The most significant feature of trance experience is thereby located in the hypnotist-subject interaction" (p. 120).

"The middle section [of the book is comprised largely of] literature reviews in support of Rossi's (1986) ultradian rhythm theory of hypnosis and Lakoff and Johnson's (Johnson, 1987; Lakoff & Johnson, 1980) experientialist theory of conceptual thought" (p. 120). The final section includes "research evidence on medical uses of hypnosis, a theory of dissociation and multiple personality disorders, and an uncritical discussion of Milton Erickson's naturalistic hypnotherapeutic approach ... [and also] a brief discussion of the social-cultural functions of possession states among the Mayotte culture" (p. 120).

Erxleben, Jan; Cates, Jim A. (1991). Systemic treatment of multiple personality: Response to a chronic disorder. American Journal of Psychotherapy, 45 (2), 269-278.

Proposes a treatment approach for multiple personality disorder (MPD) in which the personality fragments are viewed from a systemic perspective. MPD is considered the result of a dissociative defense in response to severe trauma during the formative period of personality. As the child dissociates to defend against the trauma, the fragments of personality develop as separate entities. The traditional focus of therapy is integration, or fusion of the various fragments of the personality. The alternative treatment process attempts to maintain balance within the system as a short-term goal, and strives for integration as a long-term goal.

## NOTES

"We are a unity of cells. Every cell is a citizen with it's own jobs, communicating all the time; cells send messages; the way we communicate with them is by suggestions. Each cell is a mind-body.... When I do it now [hypnotic inductions], I say, 'We're going to go into hypnosis, we're both going to go into hypnosis. I'm going to close my eyes (etc.)' - modeling hypnosis for them."

Counts, R. M. (1990). The concepts of dissociation. Journal of American Academy of Psychoanalysis, 18, 460-479.

Reviews conceptualizations of dissociation. Dissociation is the underlying mechanism in a number of defensive mechanisms. Repression, intellectualization, splitting, and other defense mechanisms rely upon dissociation to accomplish their specific tasks. Dissociation is thus believed to be the underlying and basic mechanism of many aspects of mental functioning.

Fellows, Brian J. (1990). Current theories of hypnosis: A critical overview. British Journal of Experimental and Clinical Hypnosis, 7, 81-92.

The present state of theory in hypnosis is reviewed and observations are made concerning future prospects. The state- non-state issue continues to dominate theoretical debate, although no satisfactory reply has yet been made to T. X. Barber's criticisms of the 'hypnotic trance' concept. The impact of social-psychological theory has been considerable and the results of Spanos's hypnotic training

programme could have significant implications for our understanding of hypnosis. Future theorizing should see a move towards a more integrated sociocognitive approach. Neodissociation theory has generally not fulfilled its early promise and is encumbered with the 'hidden observer' concept. The role of imaginative processes continues to be a dominant theme in hypnosis theory, although the relatively small correlation between imaginative and hypnotic abilities remains a problem. The links between hypnosis, sleep and relaxation deserve further research, although, as theories of hypnosis, their scope seems limited. Suggestibility and role enactment theories have shown few signs of development in recent years. Theoretical problems over the interpretation of hypnosis need to be more widely recognized and the use of question-begging terminology curtailed. One advantage of the imagination hypothesis is that it provides a bridge, or a point of convergence, between state and non-state approaches (Spanos & Barber, 1974). It also handles certain hypnotic phenomena very well. For example, the known facts of age regression can be readily interpreted, together with the oddities of age progression and past life regression, as imaginative reconstructions (Barber, 1979). However, other phenomena, such as amnesia and analgesia, are less easily explained.

Gauld, Alan (1990). Mesmeric analgesia and surgery: A reply to Spanos and Chaves. British Journal of Experimental and Clinical Hypnosis, 7, 171-174.

#### NOTES

Spanos and Chaves' criticisms of the author's paper in this journal (vol. 5, 1988, pp 17-24) on mesmeric analgesia are considered. Spanos and Chaves are unnecessarily dismissive of nineteenth century reports of mesmeric analgesia and, in order to bring these cases within the compass of their theory, they make assumptions about them that are not supported by the facts.

Heyneman, Nicholas E. (1990). The role of imagery in hypnosis: An information processing approach. International Journal of Clinical and Experimental Hypnosis, 38 (1), 39-59.

Imagery is widely agreed to be an important component of hypnosis. The theoretical framework from which to conceptualize the role of imagery in hypnosis, however, has remained controversial. A model is presented which attempts to reconceptualize hypnotic imaginal processing in terms of current theory and research in cognitive psychology and psychophysiology. This model draws from a propositional approach to imagery (e.g. Pylyshyn, 1973), particularly as adapted by Lang's (1979) bioinformational theory. It is argued that the hypnotic image is fundamentally more complex than simple iconic mental representation, containing instead both stimulus and response components. It is proposed that the critical properties of the hypnotic image are not the stimulus components or propositions which give rise to the experience of the image but instead are response propositions which are associated with overt behavior. Processing of these response propositions is conceptualized as a negative feedback system between the brain and effector site. Some preliminary sources of support as well as implications and research suggested by this model are discussed.

#### NOTES

The author notes that the brain does not store a kind of "photograph," but rather stores "meanings" (Anderson, 1978); and that images actually represent response processes, as observable in physiological concomitants (Lang, 1977).

The hypnotic suggestion that a Subject's arm is being pulled up into the air by a large helium balloon is represented by two separate propositions: "There is a helium balloon tied to your arm" (a stimulus proposition) and "Your arm is moving up into the air" (a response proposition). According to Peter Lang (1979), an image is not a mental stimulus to which a response is made, but is in itself an active response process, accompanied by physiological activity. Verbal instructions to a Subject determine whether they will access stimulus propositions or response propositions. "Lang et al. (1980) found that only those Ss given response training coupled with response proposition scripts showed significant

physiological arousal. These Ss were presumably better able to access and process that portion of the propositional network which controls visceral and motoric responding" (p. 46).

This author proposes that cognitive processing of a hypnotic image involves (internal) responding, and that 'responsive propositions' provide the basis for understanding the function of imagery in hypnosis, and are more important to hypnotic imagery than stimulus propositions. "In other words, the experience of a visual image and thus the vividness or controllability of that image is not critical for hypnosis. What is important to note is that the hypnotic behavior is not a response to a visual image but is instead a function of the processing of the image itself (cf. Lang, 1979)" (pp. 47-48).

In explaining how an image might facilitate amplification of a subtle response (such as in arm levitation), the author suggests that physiological and external feedback systems are involved--principally a neural feedback loop between brain and target organ (in this case, arm muscles). "Efferent signals, which are activated by processing response propositions, initiate the overt behavior while afferent signals feed back to the brain and modulate further input to the effector system. The process progressively reduces the mismatch between the image instructions and behavior until the hypnotic task is completed" (p. 48). The feedback loop "provides information on the discrepancy between desired behavior and actual behavior:  $e = B_d - B_a$ , where  $e$  = error,  $B_d$  = desired behavior, and  $B_a$  = actual behavior (Arbib, 1972). The error signal generated by this discrepancy modifies the efferent output so as to eventually approximate  $e = 0$ " (p. 49). The author notes that this complex process of physiological feedback may be "augmented by external feedback such as modified verbal instructions or vocal intonations of the hypnotist and self-observation by S" (p. 49).

The author's model is summarized as: "1. The context, setting, and expectations implied by being hypnotized as well as the wording of the hypnotic suggestions provides S with: (a) explicit or implicit instructions to use imagery, (b) repetitious wording which may increase the probability of fully accessing the relevant propositions, and (c) instructions that task completion is expected. This may function to increase the probability that the deep structure of the response propositions will be processed. 2. The hypnotic suggestion proper is composed of stimulus and response propositions embedded within a propositional network. 3. Stimulus propositions give rise to the phenomenological characteristics or the percept- like experience of the image but may be unimportant in determining hypnotic behavior. 4. Processing of the response propositions includes an active response. This response process is facilitated by S's expectation to become actively involved in the imagined scene. Response propositions are the critical features of hypnotic imagery. 5. During hypnosis, the propositional network may be systematically modified by physiological or external feedback regarding the relative progress of the behavior toward task completion. This processing of response propositions is conceptualized as a negative feedback system. Efferent signals are delivered to the appropriate effector site while afferent signals feed back to the brain in order to modify further neural input, functioning to reduce the error between image and behavior. While the initial feedback is probably physiological, additional feedback may be obtained from the hypnotist's instructions and S's self-observations. 6. If stimulus propositions are simultaneously accessed, S experiences an image" (p. 51).

Alexieva, A.; Nicolov, N.A. (1989). Brain mechanisms in classical conditioning. Behavioral and Brain Sciences, 12, 137.

## NOTES

This is a Commentary on article by J. S. Turkkan (1989), Classical Conditioning: The new hegemony. In Behavioral and Brain Sciences.

Commentators note that the objective of the target article is to show how current thinking about Pavlovian conditioning differs substantially from the historical view; also that this has been recently emphasized by Rescorla (1988). Commentators note that the neural pathways and neural mechanisms

involved in Pavlovian conditioning are of great interest and are investigated by many neuroscientists all over the world (Grigoryan & Tchilingaryan 1988; Kositsyn N.S. & Dorochoy 1986; Onifer & Durkovic 1988; Storzuk 1986; Vartanyan & Pirrgov 1986). Commentators also note the work of Ramachandran & Pearce (1987) and Uryvaev Yu.V. et al. (1988).

They express the opinion that Turkkan's review affords a thorough description and interpretation not only of basic data and new conceptual views, but also of certain key notions in the modern theories of Pavlovian associative learning.

Blum, Gerald S. (1989). A computer model for unconscious spread of anxiety-linked inhibition in cognitive networks. Behavioral Science, 34, 16-45.

Unconscious inhibitory processes, triggered by a potential anxiety reaction, are reviewed in the context of an emerging rapprochement between psychodynamic and cognitive approaches in experimental psychology. Conditions underlying spread of inhibitory action to other cognitive networks are first explored in three tachistoscopic experiments utilizing words posthypnotically tied to a potential anxiety, pleasure, or neutral reaction. Response times of subjects, instructed to ignore those words while naming pictures or solving anagrams as quickly as possible, reveal a highly differentiated pattern of circumstances governing likelihood of inhibitory spread from anxiety-linked words to target stimuli. Next a computer model is constructed to simulate cognitive processes from onset of display to eventual response, and the model is then tested for its fit to the empirical data. Finally, an illustrative study shows that a subset of computer-generated predictions for spread of inhibitory action is verifiable experimentally.

Buss, A. H. (1989). Personality as traits. American Psychologist, 44, 1378-1388.

Personality traits have been challenged as unimportant determinants of behavior, but evidence suggests that traits may carry as much variance as experimental manipulations. Asking whether traits or manipulations control more variance is useless because researchers can plan paradigms that favor one or the other. When traits and manipulations complement each other there are several major kinds of interaction. The trait-manipulation dichotomy is analogous to the person-environment dichotomy, and both are related to active versus passive models of behavior. Trait variance is increased by aggregating across responses, situations, and time. Underlying aggregation are the issues of units and classes of behavior. Individual responses are on a continuum of breadth that extends successively upward to response classes, personality traits, and higher order traits. Broad and narrow traits each have advantages and disadvantages. Recent research has led to novel personality traits and to knowledge about the origin and maintenance of traits. If there is to be a specialty called personality, its unique and therefore defining characteristic is traits.

Gardner, Beatrix T.; Gardner, Allen R. (1989). Beyond Pavlovian classical conditioning. Behavioral and Brain Sciences, 12, 143-144.

## NOTES

This is a commentary on the article by Turkkan (1989) entitled "Classical conditioning: The new hegemony" in Behavioral and Brain Sciences, 12, 121-179. (Pavlov's theory of hypnosis was based on a conditioning model, which is why this material may be relevant.)

"Traditionally, the mechanism of stimulus association proposed by Pavlov early in this century is invoked to account for conditioning that is independent of the positive and negative consequences of responding. ... Pavlov attributed this result to stimulus substitution (i.e., the subject responds to the Sa as if it were the S\*) and this has been the dominant view throughout this century" (p. 143).

'In Pavlov's classical procedure, only increases and decreases in the original consummatory or defensive response are counted as conditioned responses. ... Pavlov's classical procedure is only a special case of a much broader case of a phenomena" (p. 143).

**"Key-pecking by pigeons and lever-pressing by rats are responses that were long held up as prototypes of arbitrary behaviors that could only be shaped by response- contingent reinforcement. In the autoshaping procedure, however, these same responses have been easily conditioned to an arbitrarily selected stimulus (Sa) when the delivery of food was entirely independent of the response of the subjects. Not only that, but robust rates of responding have been maintained when food was withheld if the pigeons pecked the key or the rats pressed the lever, that is, when the contingency was negative (Williams & Williams 1969)" (p. 143).**

**"Turkkan follows a grand tradition when she discusses the similarities between associative conditioning and fundamental aspects of human verbal behavior. Yet an essential characteristic of verbal behavior is the difference between the response to an object and the response to a word for the object. The response to the spoken or written word 'apple' must be distinctly different from the response to an actual apple. Whatever we learn when we acquire vocabulary, it cannot be the simple stimulus-stimulus connection advocated in Pavlov's classical theory. Even the popular Rescorla (1967) design for separating stimulus-stimulus contiguity from stimulus-stimulus contingency only succeeds in comparing two sources of stimulus-stimulus association. Meanwhile, the recently discovered autoshaping experiment does offer us a laboratory model in which associative conditioning can result in a response to the Sa that is different from the consummatory response to the S\*" (p. 144).**

**"The theory of stimulus-stimulus association that Pavlov built upon the results of his special procedure is inadequate to deal with the wide range of phenomena of associative conditioning that have been discovered since his time.**

**"We wholeheartedly agree with Turkkan regarding the enormous theoretical and practical significance of the new discoveries but we are convinced that the terms 'Pavlovian conditioning' and 'classical conditioning' serve us best in their historical usage. ... The new discoveries seem to us to show that a wide range of significant phenomena fall outside the boundary conditions of traditional Pavlovian and Skinnerian theories" (p. 144).**

**Baker, Elgan L. (1988). The contributions of Milton Erickson: Reflections on the forest and the trees. International Journal of Clinical and Experimental Hypnosis, 36, 125-127.**

## **NOTES**

**This is the introduction to a special issue of International Journal of Clinical and Experimental Hypnosis, which is devoted to the contributions of Milton Erickson. "The conclusions of these analyses are sometimes surprising. The usual understanding of Erickson's work and the hallmarks of the Ericksonian tradition emphasize such parameters as indirect suggestion; naturalistic or permissive trance induction; confusional strategies; 'unconscious learning'; and the focal use of metaphor, analogy, anecdote, and storytelling. These authors suggest, however, that Erickson's work frequently did not entail the use of hypnotic trance in any conventional sense and attribute many of the crucial variables in his therapeutic work to a variety of nonhypnotic phenomena" (p. 126).**

**Several consistent themes emerge, which Baker refers to as perhaps the "essence" of Erickson's contributions: "(a) the charismatic power of Erickson's personal presentation and style; (b) the marked influence of social variables; (c) consideration of primitive, unconscious relationship variables; (d) the evocative use of language, symbolism, and nuances of communication; (e) the ingenious tailoring of therapeutic interventions to the perceived uniqueness of each patient; and (f) the central influence of nonhypnotic variables rooted in social learning and cognitive-behavioral paradigms" (p. 126).**

**Diamond, Michael Jay (1988). Accessing archaic involvement: Toward unraveling the mystery of Erickson's hypnosis. International Journal of Clinical and Experimental Hypnosis, 36, 141-156.**

The "essence" underlying Milton Erickson's unique style and uncommon technical maneuvers inheres in his uncommon skill at eliciting patients' archaic involvement. Archaic involvement, as characterized by perspectiveless overevaluation, is explicated and America's beloved tale, *The Wonderful Wizard of Oz*, is used to evoke further perspectives. The importance of such regressive object-representations are noted. Erickson's uncanny ability to access archaic involvement and thereby profoundly influence his client is analyzed in terms of his: (a) relationship style; (b) therapeutic "persona"; (c) theoretical orientation; and (d) specific micro-techniques and interventions. Clinical findings derived from a case transcript and videotaped work are employed throughout to substantiate the argument that Erickson fosters regressive interpersonal shifts. Implications of this skill are discussed, and further avenues for investigation are suggested.

## NOTES

Shor (1959, 1962, 1979) introduced the concepts of archaic involvement, trance (fading of the generalized reality orientation or altered state of consciousness) and nonconscious involvement (or fulfillment of the role of hypnotic subject, dissociated role taking) to account for experienced hypnotic depth. Shor (1979) defined archaic involvement as "'the extent to which at any given moment in time there are archaic, primitive modes of relating to the hypnotist that echo back to the love relationships of early life [p. 126]' (p. 143)."

Archaic involvement develops as a hypnotist actively encourages the subject to regard the hypnotist with the role of parent, teacher, guru. Charismatic authority, protector, etc. Erickson fostered these attitudes in his patients, and his apparent magical expertise can be attributed to his ability to tap into these archaic ties, which are 'ubiquitous.' "Freud (1919/1955) long ago noted that human beings' irresolution and craving for authority should never be underestimated. Fenichel (1945) stressed the universal yearning for 'omnipotent beings whose help, comfort, and protection he could depend on [ p. 491].' Kaiser (1965) considered the 'universal psychopathology' of attempting to create in real life the fantasy of fusion. Still others (Kohut, 1971, 1977; Kriegman & Solomon, 1985; Newman, 1983) suggested that the motivation to yield to or to create such charismatic leaders stems from the desire to lose all boundaries and become lost within a greater whole--an experience elsewhere termed a fusional or symbiotic alliance (Diamond, 1987). This 'search for oneness' (cf. Silverman, Lachman, & Milich,, 1982) is engaged by charismatic leaders as we become enticed by our own archaic wishes to avoid uncertainty, ambivalence, and the complexities of maturation, perhaps even creating such leaders to save us from ourselves" (p. 145). There remains the question of how archaic involvement facilitates or impedes psychotherapy.

In addition to archaic involvement, Erickson's behavior as a hypnotherapist during the later years of his career stressed the evocation of nonconscious role-playing, while underplaying the evocation of the trance dimension. He relied on his reputation and interventional skills, stressing 'naturally occurring trance' of everyday life. (In his earlier years he spent more time on developing profoundly altered states of consciousness.)

"Erickson's \_therapeutic 'persona'\_ and style of engaging were consistently parental and authoritative, albeit frequently permissive, supportive, flexible, and benevolent. He always remained in control and typically insisted that his orders be carried out strictly and without question (Hilgard, 1984). ... Archaic wishes are further gratified by Erickson's gentle and soothing parental tone and stance, while control is maintained as he invites his patient to 'enjoy being irritable with me'" (pp. 147-148). To further psychotherapeutic goals, he sometimes assumed the role of surrogate parent, in hypnosis, to supply the patient with needed (childhood) experiences, as in the famous case referred to as the 'February Man.'

Erickson's implicit theory of an autonomous and omnipotent unconscious further encouraged "more primitive modes of perceiving and construing consensual and historical reality" (p. 148). "For

example, he tells his patient in the Lustig (1975) videotape that: 'Your unconscious knows all about it; it will inform the conscious mind when it is ready to know'" (p. 149).

Regarding his technical maneuvers (intonation, wording, nonverbal communication, indirect suggestion, metaphor, and anecdote), "contrary to popular belief, he frequently spent long periods of time thinking about and planning his interventions (Hammond, 1986). In addition to using these patterns to evoke both patient resources and archaic alliances, he adopted an exceptionally confident manner, even when prescribing unusual assignments (McCue, 1984). Thus, patient faith and positive expectation in the efficacy of his interventions were maximized" (p. 149).

Erickson's pacing of his speech was slow, at the same rate as President Reagan's speeches. He was tone deaf, which may have contributed to the arrhythmia and unusual intonation observed in his speech. He used the patient's language, typically, which "undoubtedly provides a narcissistically gratifying identification with a hypnotist felt to be inside one's own psychic system (Diamond, 1987)" (p. 150). When he would say to patients, "My voice will go with you," he was inviting a "bodily-level incorporation" (p. 150). When he created mental confusion through his maneuvers, he increased the likelihood that the patient would "respond to subsequent direction in order to bind anxiety" (p. 150). "Thus, an archaic object relationship is recapitulated by an invoked regression to earlier, primary phases of cognitive processing, and in turn, Erickson provides a safe, 'holding environment' (cf. Winnicott, 1965) for his now regressed patient" (p. 150).

Erickson used what Watzlawick (1978) has called 'the language of change'--puns, metaphors, indirect communication, analogies. He finessed the defensive functions of secondary processes (Kalt, 1986) by allying himself with the patient's secondary processes, as when he used anecdotes and teaching tales in the role of a 'Dutch uncle' giving advice. The teaching tales usually affirmed basic American values (common sense, pragmatism, self-sufficiency, resiliency, achievement; Diamond, 1983). However, this kindly grandfather approach "recreates an archaic relational situation wherein adult-level defenses and secondary processes are realigned while Erickson the storyteller permits expression and oftentimes symbolic gratification of instinctual drives. This archaic recapitulation occurs as a result of the relaxing of defenses through metaphorical communication (cf. Schafer, 1983), in addition to the revival of opportunities for mastery within this safe and often enchanting context (cf. Bettelheim, 1977)" (p. 151).

The author concludes by addressing clinical issues pertaining to an Ericksonian approach that relies on archaic involvement. "An essential question for clinicians concerns the long-term effects on the patient of the therapist's fostering such regressive involvement. There are both pluses and minuses of therapeutic relationships which maximize archaic involvement. Consequently, we need to empirically determine the efficacy of Ericksonian interventions both in offering short-term relief from suffering, and in potentiating developmental maturation in the long run. Not only must we ascertain how much archaic involvement is required for lasting change, but what is done with the regressive involvement (i.e., is it merely evoked, managed, utilized, or ultimately worked through?) is critical in assessing the value of Erickson's contribution" (p. 152).

Gorassini, Donald R.; Hooper, Cynthia L.; Kitching, Kathleen J. (1988). The active participation of highly susceptible hypnotic subjects in generating their hypnotic experiences. Imagination, Cognition and Personality, 7 (3), 215-226.

Hypnotized individuals have traditionally been considered to be detached from the control of their own suggested behavior. We tested this and the alternative notion that hypnotized subjects attempt to self-generate the experiences (i.e., mainly of involuntariness) as well as produce the behaviors thought to be prototypical of high hypnotic ability. In an experimental investigation, highly susceptible hypnotic subjects were found to engage in the kind of imaginative activity that would be expected of individuals who were attempting deliberately to generate their experiences of involuntariness; they

engaged as actively in imagery-generation as did subjects who were specifically instructed to imagine during suggested responding, and they experienced as much involuntariness as subjects in whom suggested movements were produced by an external physical force. The implications of these findings for the neodissociation and social psychological theories of hypnotic responding are discussed.

Hawkins, Russell; Le Page, Keith (1988). Hypnotic analgesia and reflex inhibition. Australian Journal of Clinical and Experimental Hypnosis, 16, 133-139.

The major change in thinking about models of analgesia over the last decade or so may be seen as a shift away from the earlier emphasis on a one-way afferent transmission sequence. Analgesia was effected, according to the older models, by a simple blocking of afferent impulses at some level (as achieved by local anaesthesia). Recent models suggest that there are at least two CNS analgesia control systems, each operating via an active mechanism for the inhibition of nociception which includes reciprocal efferent impulses able to respond to input from lower centres by sending control signals which modify their output. One CNS analgesia system has now been quite well described. This "opiate" analgesia system has proved to be naloxone reversible and seems to be mediated by reciprocal pathways between brain stem structures and the dorsal horn and trigeminal caudalis. This is not likely to be the system responsible for all cases of hypnotic analgesia, since the common experience of continued awareness of some elements of a normally painful stimulus, in spite of a freedom from pain, implicates a higher level involvement such as input from the prefrontal cortex.

#### NOTES

The authors present a surgery case (of a cystoscopy and urethrotomy performed under hypnotic analgesia, with a highly hypnotizable patient) as an illustration of their position. The patient grimaced when the urethrotome was inserted into the urethra and dilated, but she denied discomfort and did not exhibit a reflex adduction of the thighs that is often observed even under standard general anaesthesia. She had spontaneous amnesia for the entire surgery. Later, under hypnosis, the patient could remember "discomfort and a sharp pain" which lasted for "seconds, if that" (p. 134).

The authors refer to Melzack and Wall's (1965) gate control theory as well as Hilgard's (1973) neodissociation interpretation of pain reduction in hypnosis. They review research by Hardy and Leichnetz (1981) with monkeys, in which they "traced the projections of the periaqueductal gray (PAG) to determine the extent of any possible cortical involvement in the endogenous analgesic system. Their work showed that the prefrontal cortex was the principal source of projections to the PAG" (p. 136). They quote the latter as writing that, "Patients who have had prefrontal lobotomies for relief of chronic pain report that while they still feel the pain they are no longer bothered by it ... the prefrontal cortex by virtue of its projections to the PAG may play a role in modulating nociception at the spinal level" (Hardy & Leichnetz, 1981, p. 99).

"Hardy and Leichnetz have also suggested that there may be more than one analgesic system within the CNS. The first system is a naloxone-reversible mechanism which can be activated by opiates (presumably both endogenous and exogenous) and by acupuncture. Since hypnotic analgesia has shown itself not to be naloxone-reversible (Goldstein & Hilgard, 1975) it may have little to do with the opiate reception analgesia system. Instead the mechanism of hypnotic analgesia may lie in Hardy and Leichnetz's second system which is sensitive to affective and cognitive influences" (pp. 136-137).

The authors include a review of the work by Mayer and Price (1976) which established the importance of brain stem structures in analgesia, especially for eliciting stimulation-produced analgesia. They cite Mayer and Price as drawing a distinction between "analgesia achieved by incapacitating a component in a pain transmission system or by activating a pain inhibition system" (p. 137). They also report that Mayer and Price conclude that stimulation-produced analgesia does not result from a "functional lesion" in the brain stem, but results from stimulation of a pain-inhibiting mechanism, suggesting the

dorsal horn and trigeminal nucleus caudalis may be involved. This would be consistent with the inhibition of spinal reflexes (the adductor reflex) observed in their urethrotomy case, and the spinal reflex to nociception has also been reported by Finer (1974).

"The concomitant inhibition of reflexes in humans during hypnotic analgesia can be interpreted as evidence that nociception is probably not ascending to the cerebral cortex and that therefore the source of analgesia can be localized to the brain stem areas. It may be the case, however, that the locus of effect of hypnotic analgesia is not uniform across cases and may be identified by the overall pattern of subjective reports and physiological responses. Hypnotic analgesia may be experienced in more than one way subjectively and these differences may be attributable to differing underlying physiological mechanisms. On some occasions the relevant body part may be experienced as totally anaesthetised and all sensation (not only painful sensation) may be lost. This experience matches well with a brain stem involvement, which presumably inhibits any further afferent action. On other occasions, however, and more commonly, patients are still aware of a variety of sensations, which might include pressure in the case of childbirth or even cutting in the case of surgery, but these sensations are not described as painful. This is reminiscent of the effect of frontal lobotomy and it is tempting to focus on the frontal lobe as the locus of hypnotic analgesia effects in such instances" (p. 138).

Hilgard, Ernest R. (1988). Milton Erickson as playwright and director. International Journal of Clinical and Experimental Hypnosis, 36, 128-140.

Milton Erickson in his therapeutic practice can be characterized as a playwright who plans a little play for each patient and then leads that patient to accept and enact the assigned role. This arrangement permits him to be authoritarian as playwright and director by providing the staging and the strategy, while the patient then provides the tactics by carrying out the assignment in his or her own way. Several examples are given from published cases. The first is a case of enuresis in both husband and wife, selected because in this instance no mention is made of hypnosis as Erickson sets the circumstances and gives direct orders for carrying out the instructions. 3 pairs of cases are described to indicate how differently Erickson has treated cases with similar symptoms. Finally, 1 case is discussed more extensively because the treatment extended over a 6-year period. Its interpretation shows how difficult it is to distinguish what belongs to the strategic drama and what to hypnosis. All cases had successful outcomes.

The essence of Erickson's therapy lay in the unexpectedness of his comments or instructions, the shock element, the surprises, and the tasks that he assigned the patient to carry out in the real space-time world or in fantasy. There was often doubt whether other than light hypnosis was involved" (p. 129).

As an example, Hilgard reports on a published case in which both the husband and wife had enuresis and Erickson treated them in a very authoritarian fashion. Erickson told them that he "would make a bargain with them: If they got well, they would not have to pay; if they did not benefit from the therapy, they would have to take full financial responsibility for the time he gave to them. He obtained their promise that they would do what he told them, and then he proceeded to tell them: 'This is what you are to do.' He then laid out the scenario. The most important part was that they were to take fluids frequently, drink a glass of water 2 hours before going to bed, and then lock the bathroom door. At bedtime, they were to get into their pajamas, kneel side by side on the bed and deliberately and jointly wet the bed. Wetting the bed would then be over for the night, and they could sleep through the night in the wet bed. They must do this every night for 2 weeks; on the Sunday night to follow, they may lie down and sleep in a dry bed. If the bed is wet the next morning, they will have to kneel and wet the bed each night for another 3 weeks.

**"You have your instructions. There is to be no discussion and no debating between you about this, just silence. There is to be only obedience, and you know \_and will know what to do\_. I will see you again in five weeks' time. You will then give me a full and amazing account. Goodbye! [Volume IV, 1954, p. 100, emphasis in original].**

**"When they reported--cured after the first 2 weeks--they asked whether Erickson had used hypnosis. He dodged their question by saying that they were entitled to full credit for what they accomplished" (p. 130).**

**Hilgard makes the point that Erickson's authoritarianism might seem to contradict claims made that he had a high degree of respect for patients, their autonomy, and their responsibility for solving their own problems. "There need be no contradiction, if it is recognized that the planned behavior may not in itself be the cure, but may only be the occasion that leads to patient to reorient and solve the personal problems that led to the seeking of therapy. Another way of putting this is that the \_strategy\_--that is, the plot of the drama--was entirely Erickson's, although the \_tactics\_--that is, beyond the fixed actions required by him, how the part was played--were left to the resources of the patient. This is not the permissiveness of Rogers (1951) with respect to the patient's responsibility for his or her own life, nor does it have the freedom of expression of Moreno's (1946) spontaneity theater" (p. 131).**

**Hobson, J. Allan (1988). The dreaming brain. New York: Basic Books.**

**Hypnosis and Sleep\_ Ramon y Cajal and Freud shared an interest in hypnosis, as an experimental method of inducing an altered state of consciousness, introducing dynamic principles into both neurology and psychiatry (rather than simply static descriptions). The author contrasts the hypnosis "artificially altered state of consciousness" with sleep as a "naturally altered state of consciousness, asking whether similar rules govern the transition of state change in both cases. He notes that induction of both states involve rhythmic stimulation and eye fixation, and both may facilitate gaining control over brain-stem centers implicated in conscious-state regulation.**

**The brain stem is the nightly battleground of warring neuronal factions, and REM sleep and dreaming are the result of temporary domination of one neuronal population over another. Victorious is a troop of reticular-formation neurons concentrated mainly in the pontine portion of the brain stem; owing to their fusillades of firing in association with REM-sleep events, these pontine reticular neurons are likely to play the executive role in the generation of REM sleep and dreaming. Sharing the white flag of temporary surrender is a population of aminergic neurons located in the locus ceruleus, the raphe nuclei, and the peribrachial regions of the anterior pontine brain stem; hardly a shot is fired by this neuronal phalanx during REM sleep. By virtue of this cease-fire, these aminergic neurons are likely to play a permissive role in the generation of REM sleep" (p. 183).**

**The Reciprocal-Interaction Model suggests that "the continuous competition between the excitatory reticular neurons and the inhibitory aminergic neurons is the basic physiological process underlying sleep-cycle alternation" (p. 184). Neurotransmitters (aminergic for inhibition, cholinergic for excitation) are implicated as well. The width of the brain stem correlates with sleep-cycle. The brain seems to "undergo a periodic shift in neurotransmitter ration, from a predominantly aminergic mode in waking to a predominantly cholinergic mode during REM sleep" (p. 192). Thus, there is a major shift in metabolic orientation as we change from waking externally generated information and action to REM-sleep internally generated information and suppressed action.**

**The author proposes an activation-synthesis hypothesis to account for dreaming and envisions the brain as a "Dream Machine." "The recognition that the brain is switched on periodically during sleep answers the question of where dreaming comes from: it is simply the awareness that is normal to an auto-activated brain-mind. This causal inference is continued in the term \_activation\_ in the new**

dream theory's title. The question of why dreams are paradoxically both coherent and strange is in turn suggested by the term \_synthesis\_, which denotes the best possible fit of intrinsically inchoate data produced by the auto-activated brain-mind.

"The original dream theory thus had two parts: activation, provided by the brain stem; and synthesis, provided by the forebrain, especially the cortex and those subcortical regions concerned with memory. The physiology that is now in hand best supports the first part of the theory; much more work needs to be done on the synthetic aspects of the process. But I now add a third major component to the theory, the concept of \_node switching\_, which accounts for the \_differences\_ in the way the activated fore-brain synthesizes information in dreaming (compared with waking): for the twin paradoxes of dream bizarreness and insight failure (where the system has lost self-reference as well as its orientation to the outside world) and for dream forgetting" (p. 204).

The author assumes a formal isomorphism between subjective (dream report) and objective (brain activity) levels of investigation. Thus, the report of experiencing visual images in dreams implicates the brain's visual system.

In terms of psychophysiology, Hobson proposes that "the on-off switch for dream mentation is the reciprocal-interacting neuronal populations comprising the aminergic neurons and the reticular neurons of the brain stem" (p. 205). For sleep (and dreaming) to be maintained, stimulation from the outside world must be minimized. This is accomplished in at least two ways. There is active inhibition of nerves at the pre-synaptic level (e.g. by depolarization by signals coming from the brain stem; Pompeiano, 1978) so that the nerves are less efficient in transmitting information from the environment, as there is less neurotransmitter available. Secondly, there is competition among higher levels of sensory and associative circuits, so that they ignore incoming signals (or incorporate them into internally generated dreaming activity). Hobson refers to these mechanisms as the sensory input blockade.

Hobson also describes the motor output blockade, which prevents us from taking actions based on dream content. There seems to be inhibition of motor-command neurons in the brainstem and spinal cord.

When dreams arise, there seems to be brain activation as evidenced by PGO (Pons, lateral Geniculate, Occipital cortex) waves originating in the brain stem. They are found in association with REM sleep and go via independent pathways to both visual and association cortex. "According to the activation-synthesis hypothesis of dreaming, the now auto-activated, disconnected, and auto-stimulated brain-mind processes these signals and interprets them in terms of information stored in memory" (p. 207).

Hobson states that the activation-synthesis hypothesis can account for five aspects of dreaming: visual and motor hallucinations, the acceptance of these hallucinations as 'real', bizarre spatial and temporal distortion, strong emotions, and amnesia for the events after waking up. The experiences of dreams are accepted as real because there is no concomitant external input.

1987

Bandura, A.; O'Leary, A.; Taylor, C. B.; Gauthier, J.; Gossard, D. (1987). Perceived self-efficacy and pain control: Opioid and non-opioid mechanisms. Journal of Personality and Social Psychology, 53, 563-571.

Subjects who were trained to use psychological coping strategies (e.g. imagery, distraction, dissociation, sensation transformation) had both better pain tolerance on a cold pressor test and higher self efficacy ratings. Those subjects who were given naloxone (which blocks pain reduction effects of beta endorphins) showed more pain tolerance than subjects not given the cognitive training experiences. They attributed much of the pain tolerance increase associated with cognitive

interventions to opiate release, suggesting that cognitive interventions may have physiological mediating effects on pain perception.

Gorassini, Donald R. (1987). Use of concurrent verbalization to assess the dissociation of conscious controls. Journal of Abnormal Psychology, 96 (3), 218-222.

The degree of dissociation of conscious controls that occurred when, according to the neodissociation theory (Hilgard, 1977, 1979), conditions were optimal for such an event was assessed. A task that required subjects to locate specified sentences in a textbook was conducted under these optimal conditions, as well as under conditions that were expected to mitigate against the occurrence of dissociation. The sentence-search task necessitated rehearsal for its successful completion. The correspondence between task rehearsal and task performance did not differ between optimal and mitigating conditions, thus suggesting a failure to dissociate. Nevertheless, search behavior was self-rated as substantially more involuntary under the optimal than under the mitigating conditions. The implications of these findings for the neodissociation and social role theories of hypnosis were discussed.

Hilgard, Ernest R. (1987). Research advances in hypnosis: Issues and methods. International Journal of Clinical and Experimental Hypnosis, 35, 248-264.

There are substantial areas of agreement upon the classical phenomena of hypnosis, illustrated by what we now have learned about hypnotic talent, amnesia, hallucinations, analgesia, and dissociative processes. While genuine advances in knowledge about hypnosis have been made in recent decades, differing orienting attitudes have kept some controversy alive, particularly in the interpretation of empirical findings. Differences of interpretation of the phenomenal and behavioral facts are to be expected in the present stage of developmental, cognitive, and social psychology.

## NOTES

The author writes of the "domain of hypnosis" as within the larger domain of social psychology (because it is usually interpersonal); cognitive psychology (because of alterations in perception, imagination, memory, and thought); developmental and personality psychology (because of individual differences); and physiological psychology (because of neurophysiological aspects).

In terms of what we know about hypnotic talent, he notes that high hypnotizability is not generally associated with psychopathology; that it may however be associated with a personality measure called absorption; and that there may be some inherited ability (Morgan, 1973). In the author's view, hypnosis is no longer considered simply a response to suggestion, since imagination and/or fantasy are very important.

In reviewing evidence of posthypnotic amnesia the author writes, "Subtleties in language require making careful distinctions among concepts such as compliance, suggestion, compulsivity, belief, self-deception, automaticity, the voluntary, the involuntary, and a happening. If these distinctions are glossed over, the choice of words (e.g., substituting compliance for response to suggestion) may give the impression that a finding departs more widely from conventional views than it does. We, too, have found that Ss used varied strategies or skills during amnesia, but this need not deny augmentation by suggestion.

"It takes genuinely high Ss to illustrate truly high posthypnotic amnesia... Many of the truly high hypnotizable individuals cannot break amnesia, no matter how hard they try" (p. 253).

Regarding the evidence for hypnotic hallucinations and trance logic, the author suggests that trance logic is not a clear concept because the Subject is capable of good logic while tolerating some inconsistencies. "It is ordinary logic to assume that if your hallucination is your own construction, it is

you who can influence it by your own wishes. In the rare cases of transparent or diaphanous hallucinations there is still an 'out there' quality. People who report that they see wispy ghosts also see them as 'out there,' so that they qualify as hallucinations. The distinction appears to be one of perception and perception-like experiences within hypnosis rather than of logic" (p. 256).

In reviewing the evidence for hypnotic analgesia, the author acknowledges that pain relief is available with other kinds of interventions, or by using other kinds of psychological processes, but that does not diminish the contribution of hypnosis (which has a long and impressive clinical history). Following laboratory studies, it is noted that "the amount of alleviation of pain through hypnosis is positively correlated with the hypnotizability of the candidate for pain reduction. This result is not universally accepted, because some clinicians are convinced that those unsuccessful in hypnotic pain reduction are resisting hypnosis" (p. 256-257). In the present paper he acknowledges but does not review physiological literature on hypnoanalgesia.

Regarding the concept of dissociation, the author indicates that he considers it a more useful concept than the concept of trance or hypnotic state "when a person is only slightly or moderately involved in hypnosis ... . The advantage is that dissociations, as compared with altered states, can be described according to limited or more pervasive changes in the cognitive or motor systems that are being activated or distorted through suggestion in the context of hypnosis. Perhaps when all-inclusive enough, such changes can justify the use of the term trance or altered state, but I believe that these terms should be used, if at all, only for those for whom the immersion in the hypnotic experience is demonstrably pervasive" (pp. 258-259).

The author goes on to describe his initial discovery of the 'hidden observer' in an experimental context, and to relate the 'hidden observer' to others' earlier observations of a secondary report of an experience previously concealed from S's consciousness (Binet, 1889-1890/1896; Estabrooks, 1957; James, 1899; Kaplan, 1960). "The issues are still being worked on, but as in the case of trance logic the heart of the problem is not whether to speak of a hidden observer, but to recognize that there may be cognitive distortions in hypnosis even while some more realistic information is being processed in parallel, so that everything is not reportable by S" (p. 260).

1986

Goldberg, Benjamin Mark (1986, October). The role of selective attention in hypnotic susceptibility: An empirical study (Dissertation, City College of New York). Dissertation Abstracts International, 47 (4), 1774-1775-B.

This study tested the hypothesis that in hypnotic situations high as opposed to low susceptible subjects evidence a more pronounced restriction of attention to hypnotic suggestions. Also tested was the hypothesis that high susceptible subjects evidence attentional behavior aimed at enhancing the subjective reality of these suggestions. Fifteen high susceptible and 15 low susceptible subjects participated in a hypnotic procedure while ostensibly extraneous phrases emanated from an adjacent cubicle. Hypnotic suggestions coincided with phrases that were consonant, neutral, and dissonant with the theme of each suggestion. In a control condition, high and low susceptible subjects performed nonhypnotic tasks while exposed to the same phrases which were neutral with relation to the theme of each task. Contrary to the present hypothesis, subsequent phrase recognition was equal and poor for all groups. Moreover, all groups showed an identical pattern of differential phrase recognition which consequently precluded thematic value as an organizing factor. The findings suggest that selective attention is not a critical factor, underlying hypnotic responsiveness. Alternatives to attentional conceptions of hypnosis are discussed" (pp. 1774-1775).

**Bowers, Kenneth S. (1984). On being unconsciously influenced and informed. In Bowers, Kenneth S.; Meichenbaum, D. (Ed.), The unconscious reconsidered (pp. 227-273). New York: John Wiley & Sons.**

**Research on confirmatory bias has uncovered additional cognitive processes that are frequently automatic in function and significant in modifying behavior, affect, and cognition. Snyder and Swann (1976, 1978) provided subjects with set inducing hypotheses about the personalities of certain target individuals. Subjects were then asked to test these hypotheses by interviewing the target individuals. It was found that subjects regularly looked for and found evidence that was consistent with their initial hypotheses rather than for evidence which could show these hypotheses to be incorrect. This biased search strategy of the subjects had more profound effects as well, for it also influenced the behaviors of the target individuals in a manner leading them to produce behaviors that seemed to confirm the original mental set of the subjects. Subjects were unaware that their manner of interviewing was producing a biased sample of behavior from the targets. Here too an automatic cognitive process was affecting perception and thinking without conscious awareness" (p. 280).**

## **NOTES**

**Provides summary of the history of associationism. Refers to Beddoes' essays (1802-03) which state that (1) emotions play a significant role in strengthening associations, and a study of emotions would be the 'chief secret for unriddling the inconsistencies of dreams,' and (2) variations could occur in associations (from very strong to very weak).**

**In the 19th century there was an ongoing debate about the role of the reflex in the nervous system, about how high up it could function, and whether it could still take place if it reached areas that subserved consciousness. Dr. William Carpenter postulated three levels: (1) excitomotor reflex (spinal, and maybe lower brain), (2) sensorimotor or consensual (midbrain) which was unconscious, (3) ideomotor (cerebral) - based on evidence from hypnosis in which volition appeared suspended and the subject became 'a mere thinking automaton' whose flow of ideas resulted from external suggestions only. The ideomotor response could be unconscious.**

**In the 1830's and 40's Thomas Laycock brought Associationism together with the concept of reflex. "By bringing the reflex into 'cerebral processes,' he proposed a model that made fast and automatic responses possible in the realm of ideas. Automatic thinking, speaking, writing, and more complex actions became topics of increasing interest to psychologists later in the century. As early as 1868, Prosper Despine had been speaking of 'psychological automatisms.' Laycock proclaimed most of these responses as being unconscious, that ideas could be charged with varying amounts of energy, and that ideas could act as causes of human disturbances, both psychological and physiological" (pp. 25- 26).**

**1860's - 90's saw the rise of hypnotism, with Eugene Azam using it in surgery and psychiatry; Durand de Gros's book on Braid; Liebeault publishing a book; Bernheim launching his career; Charcot**

shifting interest from organic neurological conditions to functional conditions; and Charcot teaching both Janet and Freud.

The author notes that "in July 1880, a bright and educated young woman of 20 started to nurse her dying father. Like the shamans before her, she had to grapple with the spectre of death and in her own fashion, she developed a creative illness. Her symptoms were myriad, but many had to do with changes in her consciousness (including 'absences,' clear-cut trances) and splits in her memory, including the loss of an entire language. At one point her current personality disappeared and another took its place: in this case it was herself but existing a year before in a state in which she lived without any apparent awareness of what had happened to her in the interim. It is this case of Anna O. and her doctor, Josef Breuer, which became important to the next epoch in our review and who had so much to do in inspiring the studies that followed" pp. 27-28.

Critelli, Joseph W.; Neumann, Karl F. (1984). The placebo: Conceptual analysis of a construct in transition. American Psychologist, 39, 32-39.

The placebo in psychotherapy has unfortunately retained the negative connotation of an inert "nuisance variable," a label that it originally incurred in the field of medicine. In addition, the transition toward more cognitive models of psychotherapy, particularly Bandura's theory of self-efficacy, has led to problems in defining the placebo within psychology. This transition has resulted in an awkward interface between certain preferred cognitive metaphors and the negative connotations of a presumably cognitive placebo construct. As a result, suggestions have recently been made to dismiss the placebo construct from psychology and to do away with the use of true placebo controls in outcome research. The present analysis maintains that (a) the placebo can be adequately defined within psychology, (b) the negative connotation of the placebo label is largely undeserved, (c) the placebo retains a continuing conceptual and empirical utility for evaluating psychotherapy, and (d) the therapeutic efficacy of current therapies is well established even though they have not generally been shown to be more effective than nonspecific treatment.

Heide, F. J.; Borkovec, T. D. (1984). Relaxation-induced anxiety: Mechanisms and theoretical implications. Behaviour Research and Therapy, 22, 1-12.

Literature evidence documenting the occurrence of relaxation-induced anxiety is reviewed, and several hypothesized mechanisms to explain the phenomenon are discussed. Possible avenues for circumventing the problem in therapy are offered. Finally, a theoretical model is presented wherein the phenomenon is viewed with a broader framework designed to explain the development and maintenance of the more generalized anxiety disorders. That framework emphasizes the emergence of fear of somatic anxiety cues and fear of loss of control from more fundamental interpersonal anxieties.

Baars, B. J. (1983). Conscious contents provide the nervous system with coherent, global information. In Davidson, Richard J.; Schwartz, Gary E.; Shapiro, David (Ed.), Consciousness and self regulation (3, ). New York: Plenum Press.

## NOTES

We are conscious of some content when there exists an internal representation that is global, stable, and informative.

Author views nervous system as a distributed information. processing system, in which highly complex & efficient processing is performed by specialized processors in a relatively independent way. These processors may be 'data driven'--i.e. they may decide by their own criteria what is worth processing...' p. 41 [See also Gazzaniga's (1985 Psychology Today article) idea that mind/brain consists of modules.]

p.44 gives references substantiating the above, e.g. Geschwind, Hilgard, La Berge, Shiffrin & Schneider.

p. 45 We are in habit of thinking hierarchically about nervous system rather than distributively.

p. 45 "Consciousness seems to be closely associated with a mechanism that permits interaction between specialized, dedicated processors" The 'global' data base' is like a TV station sending out information that can be processed or not by the viewer. It is not an executive, and in fact can sometimes be controlled by the processors. 'Consciousness ...[is] a certain operating mode of this medium, & consciousness can likewise be used by processors acting as executives, without itself being an executive "(p.49).

The global data base is a lingua franca, so that one sense modality can communicate with others. p. 51. [Synesthesia reported by high hypnotizables implicates this system--either the communicating tracks are greased between color and smell, or the name of the destination, in computer language, is lost, or equivalent.]

p. 52 Repression and the dynamic unconscious. explained in terms of controlled access to the global data base, with certain specialized processors given high priority.

Context, taken by itself, is unconscious; & input, taken by itself & in the absence of the appropriate context, is also unconscious. Only when both of these conditions exist- -when there is input that can be organized within a current context--are we conscious of some percept.

Contextual factors become conscious only when they are challenged.

Fromm, Erika; Brown, Daniel P.; Hurt, Stephen W.; Oberlander, Joab Z; Boxer, Andrew M.; Pfeifer, Gary (1981). The phenomena and characteristics of self-hypnosis. International Journal of Clinical and Experimental Hypnosis, 29 (3), 189-247.

Self-hypnosis and hetero-hypnosis were compared, and self-hypnosis was studied longitudinally. Results indicated that absorption and the fading of the general reality orientation are characteristics of both hetero-hypnosis and self-hypnosis. The differentiating characteristics lie in the areas of attention and ego receptivity. Expansive, free-floating attention and ego receptivity to stimuli coming from within are state-specific for self-hypnosis, while concentrative attention and receptivity to stimuli coming from one outside source--the hypnotist on whom the subject concentrates his attention--are state-specific for laboratory defined hetero-hypnosis. Attempts to produce age regression and positive or negative hallucinations are markedly more successful in hetero-hypnosis. Imagery is much richer in self-hypnosis than in hetero-hypnosis. Self-hypnosis requires adaptation to the state: in the beginning of self-hypnosis there is a good deal of anxiety and self-doubt. As the subject feels more comfortable in the self-hypnotic state, he spends less time worrying about failures in self-suggestion, his ability to enter trance quickly and easily increases, as does the fading of the general reality orientation, trance depth, and absorption. An attempt was also made in the present study to find personality characteristics related to the ability to experience self-hypnosis.

**1980**

Hilgard, Ernest R. (1980, October). Hypnotic modification of sensitivity and control. [Paper] Presented at the annual meeting of the Society for Clinical and Experimental Hypnosis, Chicago.

The author presents a factor analysis of several scales in the hypnosis domain: HGSHS:A, Wilson-Barber CIS, Stanford Hypnotic Susceptibility Scale Form C, Questionnaire on Mental Imagery (Sheehan's modification of Betts) and the Tellegen- Atkinson Absorption Scale. Scales were broken down into components first. He didn't report all of the factors, but shows how these tests fall on a

graph defined by Factor 1 (Amnesia/Cognitive) and Factor 4 (Absorption/Imagery). "Capacity for fantasy and amnesia are so different that hypnosis probably includes both."

Hilgard concludes that he doesn't like a state theory for hypnosis or the idea of "trance" because it is unidimensional. He prefers "dissociation" because we think of it as a continuum. Even Highs differ one from another in the nature of their responses. Altered- state-of-consciousness theories don't readily explain partial dissociation (e.g. persistence of a suggestion such as arm rigidity after hypnosis is terminated; or hysterical paralysis).

## **TINNITUS**

Attias J, Shemesh Z, Sohmer H, Gold S, Shoham C, Faraggi D Comparison between self-hypnosis, masking and attentiveness for alleviation of chronic tinnitus. *Audiology* 1993;32(3):205-12 The efficacy of self-hypnosis (SH), masking (MA) and attentiveness to the patient's complaints (AT) in the alleviation of tinnitus was evaluated. Forty-five male patients close in age with chronic tinnitus related to acoustic trauma were assigned to three matched subgroups: SH, AT or MA. The therapeutic stimuli in the SH and MA sessions, recorded on audio cassettes, were given to the patients for use when needed. SH significantly reduced the tinnitus severity; AT partially relieved the tinnitus; MA did not have any significant effect.

Marks NJ. Karl H. Onisiphorou C. A controlled trial of hypnotherapy in tinnitus. *Clinical Otolaryngology* 1985;10(1):43-6 A group of 14 patients with unilateral tinnitus were selected because of the constant nature of their tinnitus, and its resistance to all other forms of therapy. They were subjected to hypnosis in three forms in random order. The induction of a trance state alone formed the control arm of the trial. Compared to this were the effects of 'ego boosting' and active suppression of tinnitus whilst in a trance state. One of the 14 patients showed a highly significant response to the latter treatment as judged by visual analogue scales. Five of the 14 patients (36%) found the induction of a hypnotic state of value.

This seemed to help them tolerate their tinnitus better, although its loudness and quality were unaltered.

Mason JD. Rogerson DR. Butler JD. Client centred hypnotherapy in the management of tinnitus--is it better than counselling?. *Journal of Laryngology & Otology*. 1996;110(2):117-20 The aim of this study was to assess whether client centred hypnotherapy (CCH) which required three sessions with a trained therapist was superior to a single counselling session in reducing the impact of tinnitus. Patients were randomly allocated to receive either counselling (n = 42) or CCH (n = 44). The outcome measures were: tinnitus loudness match, subjective tinnitus symptom severity score, trend of linear analogue scale, request for further therapy and whether the patient had an impression of improvement in their tinnitus after treatment. CCH was no better than counselling in reducing the impact of tinnitus using the three quantitative measures of tinnitus, and requests for further follow up. The only significant difference between the two therapies was that 20 (45.5 per cent) of the CCH group reported a general sense of improvement compared to six (14.3 per cent) in the counselling group, this is significant  $p < 0.01$ . The study did not demonstrate whether this was a genuine hypnotic effect or simply a response to the additional attention from the therapist.

## **U RESEARCH**

### **Ulcers**

1991

Schwarz, Shirley P.; Blanchard, Edward B. (1991). Evaluation of a psychological treatment for inflammatory bowel disease. Behaviour Research and Therapy, 29 (2), 167-177.

Compared the effectiveness of a multicomponent behavioral treatment package, which included inflammatory bowel disease (IBD) education, progressive muscle relaxation, thermal biofeedback, and training in use of cognitive coping strategies, with the effectiveness of symptom-monitoring as a control condition. The treatment group consisted of 11 IBD patients (aged 25-62 yrs); 8 of 10 persons (aged 25-71 yrs) in the control group completed treatment. At posttreatment, the treatment group showed fewer reductions in symptoms (5) than the symptom-monitoring controls (8). However, treated Ss perceived themselves as coping better with IBD and as feeling less IBD-related stress. It is hypothesized that the differences in treatment responses may be related to differences between Ss with ulcerative colitis and Ss with Crohn's disease.

Whorwell, P. J. (1991). Use of hypnotherapy in gastrointestinal disease. British Journal of Hospital Medicine, 45, 27-29.

Recent controlled studies in the field of gastroenterology have shown that hypnotherapy is unequivocally beneficial in conditions such as irritable bowel syndrome and peptic ulceration. There is also some evidence for influence on certain physiological functions. Further research should help to define more clearly the role of this controversial form of therapy.

#### NOTES

This is a summary of work the authors are doing in gastroenterology. The authors are doing pilot work with inflammatory bowel disease and also ulcerative colitis. Patients are given an idea of the pathophysiology. "First subjects are asked to place a hand on their abdomen and feel warmth and then to relate this sensation to the relief of pain, spasm, bloating etc. Second they are asked to visualize a river and imagine that it is their gut. They are then told to modify the flow in order to achieve a more satisfactory bowel habit. For instance it would be suggested to a subject with loose bowels that a fast-flowing river with broken water is changed into a much more slow, smoothly flowing one. To the trainee therapist these suggestions sound very unconvincing but they do seem to work.

Patients often take many weeks to respond and this can be very testing for the resolve of both patient and doctor alike. Some patients seem to adopt a very passive approach to treatment, expecting the therapy to work rather akin to taking a tablet--they attend once a week and wait for something to happen." (p. 29). [They have to be taught that they must make the treatment work for themselves.]

1990

Schwarz, Shirley P.; Taylor, Ann E.; Scharff, Lisa; Blanchard, Edward B. (1990). Behaviorally treated irritable bowel syndrome patients: A four-year follow-up. Behaviour Research and Therapy, 28 (4), 331-335.

A 4-yr longitudinal study evaluated 19 patients (aged 23-60 yrs) suffering from Irritable Bowel Syndrome (IBS) who had completed a multicomponent treatment involving progressive muscle relaxation, thermal biofeedback, cognitive therapy, and IBS education at baseline. 17 Ss rated themselves as more than 50% improved. Six of the 12 Ss who submitted symptom monitoring diaries met the criteria for clinical improvement, (i.e., achieving at least a 50% reduction in primary IBS symptom scores). The means on all measures at long-term follow-up were lower than those obtained prior to treatment. When follow-up symptom means were compared with pretreatment means, significant reductions were obtained on abdominal pain/tenderness, diarrhea, nausea, and flatulence.

1989

Klein, Kenneth B.; Spiegel, David (1989). Modulation of gastric acid secretion by hypnosis. Gastroenterology, 96, 1383-1387.

#### NOTES

The ability of hypnosis to both stimulate and inhibit gastric acid secretion in highly hypnotizable healthy volunteers was examined in two studies. In the first, after basal acid secretion was measured, subjects were hypnotized and instructed to imagine all aspects of eating a series of delicious meals. Acid output rose from a basal mean of 3.60 to 6.80 ... with hypnosis, an increase of 89% ( $= .0007$ ). In a second study, subjects underwent two sessions of gastric analysis in random order, once with no hypnosis and once under a hypnotic instruction to experience deep relaxation and remove their thoughts from hunger. When compared to the no-hypnosis session, with hypnosis there was a 39% reduction in basal acid output ... and an 11% reduction in pentagastrin-stimulated peak acid output ...  $p < .05$ . We have shown that different cognitive states induced by hypnosis can promote or inhibit gastric acid production, processes clearly controlled by the central nervous system. Hypnosis offers promise as a safe and simple method for studying the mechanisms of such central control

Tosi, D. J.; Judah, S. M.; Murphy, M. A. (1989). The effects of a cognitive experiential therapy utilizing hypnosis, cognitive restructuring, and developmental staging in psychological factors associated with duodenal ulcer disease: A multivariate experimental study. Journal of Cognitive Psychotherapy, 3, 273-290.

This study evaluated the effects of a Cognitive Experiential Therapy (CET)--in the past referred to as Rational Stage Directed Hypnotherapy--Cognitive Restructuring (CR), Hypnosis Only (HO), and a no-treatment control condition on the duodenal ulcer syndrome. CET is a systematic, stage-directed therapy that employs hypnosis and the cognitive restructuring of self-defeating cognitive, emotional, physiological, and behavioral tendencies. Seven criterion variables were assessed using two standardized instruments and questionnaire data. The standardized instruments included the Millon Behavioral Health Inventory (MBHI) and the Common Beliefs Survey III (CBS). Twenty-five volunteer duodenal ulcer patients were subjects in a 4 x 3 factorial design with repeated measures consisting of the four treatments and pretest, posttest, and follow-up. There was a significant treatment effect, and effects were observed on personality coping styles, beliefs and locus of control scales, and on gastrointestinal disturbance. CET appeared to have an ameliorative effect on psychological factors associated with duodenal ulcer.

1988

Colgan, S. M.; Faragher, E. B.; Whorwell, P. J. (1988, June 11). Controlled trial of hypnotherapy in relapse prevention of duodenal ulceration. Lancet, 1299-1300.

30 patients with rapidly relapsing duodenal ulceration were studied to assess the possible benefit of hypnotherapy in relapse prevention. After the ulcer had healed on treatment with ranitidine, the drug was continued for a further 10 weeks during which time patients received either hypnotherapy or no hypnotherapy. The two randomly selected groups were comparable in terms of age, sex, smoking habits, and alcohol consumption. Follow-up of both groups of patients was continued for 12 months after the cessation of ranitidine. After 1 year, 8 (53%) of the hypnotherapy patients and 15 (100%) of the control subjects had relapsed. The results of this study suggest that hypnotherapy may be a useful therapeutic adjunct for some patients with chronic recurrent duodenal ulceration.

#### NOTES

The aetiology of duodenal ulceration is poorly understood but it is probably multifactorial. ... Stress, both psychological and physical, has since been shown to affect gastric emptying and the secretion of acid and pepsin, but attempts to causally link stress and peptic ulcer disease have produced conflicting results.

"Hypnotherapy can modify the response to betazole-stimulated gastric acid secretion, although the mechanism by which this is mediated remains unclear" (p. 1299).

"The active [treatment] group received 7 sessions of hypnotherapy and were given an audio tape for daily autohypnosis; the other group were seen as often, but did not receive any hypnotherapy. The ranitidine was then stopped and both groups were reviewed every 3 months for a further year, with the active group receiving hypnotherapy at their follow-up visits. All subjects had an endoscopy at the end of the study, or sooner if a symptomatic relapse occurred.

"Hypnosis was induced as previously described, with attention focused on the abdomen by the use of the patient's hand. They were asked to imagine warmth beneath the hand and to relate this to the control of gastric secretion. Reinforcement by visualization was used if the patient had this ability" (p. 1299).

At the end of a year, on follow up, the patient relapse rate was 53% and controls relapse was 100%, a difference significant at  $p = 0.01$ .

In their Discussion, the authors state, "This study shows that hypnotherapy is helpful in maintaining remission in those patients with duodenal ulceration who are particularly prone to relapse. ... In this model, hypnotherapy might operate at a variety of levels in the disease process: it could act in a nonspecific psychotherapeutic sense increasing 'coping' capacities and decreasing perceived stress. Alternatively, hypnotically induced relaxation may affect gastric acid secretion, and there is some experimental evidence for this.

"The early relapse rate in the hypnotherapy subjects was similar to that of controls, but subsequently the curves showed a much greater separation. This finding could indicate that there is a subgroup of subjects who are particularly responsive to therapy. However, a detailed review of psychological and clinical parameters did not reveal any specific feature that could be used to predict a response to this form of treatment" (pp. 1299-1300).

## NOTES

2:

Current etiology of duodenal ulcers includes the presence of bacteria *Helicobacter pylori* which is important in relapse. In order to compare treatments we must know what is the status of each group regarding the presence of this bacteria. Current treatment of duodenal ulcer includes metronidazole, amoxicillin and tetracycline to kill it. [Editor's Note: This appears to be a critique of the research methodology rather than notes on the article itself.]

1966

Zane, M. D. (1966). The hypnotic situation and changes in ulcer pain. International Journal of Clinical and Experimental Hypnosis, 14 (4), 292-304.

This is a study of internal and external hypnotic conditions associated with changes in pain developed during 5 hypnosis sessions in a patient with an acute duodenal ulcer. The 12 increases and 8 decreases in pain studied were found to be related to the interaction of coexisting reactions directed toward shifting social and private goals. Pain was associated with conflict among these reactions; intensification of pain occurred as a train of self-propagating internal events increased the conflict; relief of pain accompanied a reduction in the conflict. Increasing bodily disorganization resulted as shifts in focus of attention among social and private goals resulted in the rapid growth of conflicting mental and physical processes. An external stimulus, in the form of a highly individualized hypnotic suggestion, was often required to stop the disorganizing processes.

#### Unconscious

1995

Pribram, Karl H. (1995). Brain in perception: From Kohler's fields to Gabor's quanta of information. In Proceeding of the 39th Congress of German Society for Psychology (pp. 53-69).

[The following material was taken from a paper provided by the author as a replacement for a presentation he made on the same topic at the Annual Meeting of the American Psychological Association, 1994, Los Angeles.]

Pribram presents the view that neuroelectric field theory (similar to theories proposed by Kohler and by Lashley earlier in this century) account for complexities observed in the relationship between awareness/perception and sensation. "Nerve impulse generation and transmission in neuronal circuits is but one of the important electrical characteristics of neural tissue. Another characteristic is the production of patterns of pre- and post-synaptic polarizations in axonal and dendritic arborizations. ... [which] are produced everywhere in the brain cortex when nerve impulses arrive at synapses as a result of the fact that the impulses become attenuated due to decreased fiber size resulting from the branching of axons" (p. 53). The polarizations develop a wave front.

Georg von Bekesy performed experiments on tactile perception that demonstrated the complex relationship between sensation and awareness. We often 'perceive' an object as external to us, even though the immediate specific neural stimulation is of receptors and from there activity is transmitted to the neurons of the brain. Thus we 'see' an object as external to us, even though the light reflected from that object produces an image on our retina. The same kind of externalized projection occurs for hearing. Touch is ordinarily perceived as at the same location as the stimulation (i.e. in the body), except that the von Bekesy experiments demonstrated that touch could also be perceived at a distance, that is, outside the body, if conditions were appropriate.

In the von Bekesy experiments, a pair of vibrators were used to stimulate two fingers, with each vibrator actuated by the same series of clicks and with the delay of time between the clicks varied. "The interesting point in this experiment is that for the condition in which there is no time delay the vibrations are localized between the two fingers where no skin is present" (p. 55). When two vibrators are placed on the thighs, the experimental subject can, by moving the knees apart, experience the vibratory sensation localized in the open space between the knees! Such an externalization of tactile perception is observed in everyday life, as when in using a knife we seem to sense the edge of the knife in order to make the appropriate movements.

Following from von Bekesy's work, it seems that only some neural processes lead to awareness. "In fact, instrumental (often automatized) behavior and awareness are to a large extent opposed; the more efficient a performance, the less aware we become. ... for the neuroscientist, the question becomes: What kinds of neural activity allow awareness to be inversely related to automatized action?"

"Patterns of synaptodendritic polarizations and nerve impulses are two kinds of processes that function reciprocally. A simple hypothesis states that the more or less persistent designs of dendritic field polarization patterns are coordinate with awareness (Pribram, 1971, Chapter 6). This view carries the corollary that circuits of nerve impulses per se and the behavior they generate are unavailable to immediate awareness. Even the production of speech is 'unconscious' at the moment the words are spoken" (pp. 55-56).

Some additional information comes from the experimental work of Ben Libet (1966, 1994), in which direct stimulation of brain tissue in waking subjects yields reports of awareness (of a particular part of the body tingling or being in a certain position). However, the awareness occurs 0.5 to 5 seconds post-stimulus, indicating that "electrical stimulation must set up some state in the brain tissue, and only when that state has been attained does the patient become aware" (p. 56).

The evidence of electrical fields comes from using both high pass filters and low pass filters on the electrical activity generated by the brain and picked up on EEG. There are 'bursts' of spikes, and onset of the field effect precedes the initiation of spikes. "Just as depolarization of axon membranes is a necessary precursor of the generation of action potentials, so also is the local build up of synaptodendritic field potentials a precursor to the recruitment of action potentials in post synaptic neurons" (p. 57).

Maps of the receptive field of an axon can be developed (e.g. using Kuffler's procedure). However, stimulation outside of that receptive field can change that axon's response--a field effect "produced in a more extended field of potentials occurring in neighboring synaptodendritic fields" (p. 58). In this investigation, the relationship between local field potentials of the rat somatosensory system (whisker stimulation) is studied using the Kuffler procedure. Whiskers were stimulated by rotating cylinders which varied in spacing of grooves and speed of rotation. The resulting variation in density of stimulation yielded a map or manifold of cortical bursts/spikes. Pribram's research fits the experimentally generated data to a theoretical model derived from signal processing theory, using "a rectangular window in the spatiotemporal domain to constrain the two dimensional sinusoidal signal" (p. 62). They noted that the manifolds obtained from somatosensory cortex recordings were similar to receptive field characteristics measured at the primary visual cortex, which "suggests that this process is ubiquitous in the cortical synaptodendritic network" (p. 63).

Referring to the Fourier theorem (that "the original pattern can be reconstituted, reconstructed, by performing the inverse transform" p. 65), the author notes that experimental data are more complex than would be predicted. The author suggests that it would be helpful to employ the Gabor uncertainty principal, in which Gabor (1946) described as a fundamental unit a 'quantum' of information. "Gabor became interested in describing a joint spacetime-spectral domain because he noted that there is a limit on the precision to which simultaneous measurement of spectral components and [space]time can be made. ... the Gabor relation describes the composition of a sensory channel, and the residual uncertainty defines the limits of channel processing span" (p. 65). The Gabor relationships are similar to those described in quantum physics by Heisenberg, so Gabor referred to a quantum of information, which he named a Logon.

The author describes his experimental results as exhibiting Gabor elementary functions, which "are composed in dendritic arborizations, receptive fields of the neurons from which we are recording. ... Each logon, i.e. each such receptive field module, is a channel. According to Gabor, the ensemble of such channels is a measure of the degrees of freedom, the number of distinguishable dimensions or features (e.g., spatial and temporal frequency, degrees of orientations, preferred direction, color). The minimum uncertainty relation expressed by Gabor elementary functions sets the limits on the information processing competence of each of these channels" (pp. 65-66).

In a Coda to this chapter, the author notes that there is a discrepancy between fields (composed of arrival and departure patterns of synapto-dendritic polarizations) and perceptual awareness which "occurs within spacetime coordinates." Discussion of the discrepancy may be found in Pribram and

Carlton (1986). Holonomic brain theory in imaging and object perception. *Acta Psychologica*, 63, 175-210; and in Pribram (1991), Lecture 6 of *Brain and Perception*. Basically, there is top-down organization imposed by the cortical system on peripheral sensation/perception. "These various systems not only relate to one another in a hierarchical manner but that the higher order systems operate on lower order systems by interpenetrating. Thus, we ordinarily, immediately perceive named and categorized objects, not just sets of images (though we are capable of 'imaging' by suspending the higher order processes). There is abundant evidence of such top-down penetration in the visual, auditory and somatosensory neural systems" (p. 66).

Erickson III, James C. (1994). The use of hypnosis in anesthesia: A master class commentary. [Comment/Discussion] .

#### NOTES

The author answers questions sent by a reader: "When and how can I use hypnosis or hypnotic principles in preparing patients for surgery and while undergoing surgery? Are there studies or experiential evidence to use as guides for the selection of appropriate cases or types of operations?" (p. 8). SUMMARY "There are unequivocal benefits derived from the use of positive suggestion and hypnotic techniques in all patients who must submit to surgical and obstetrical procedures with modern general or regional anesthesia. We must learn, and we must teach our colleagues, the advantages of consistent use of the semantics of positive suggestion. When we help patients focus on the desired comfort, safety, and satisfaction obtained with well-managed modern anesthesia and surgery, they will enjoy great benefit, especially when we use the auditory perception that often exists during general anesthesia. Rather than regarding hypnotic suggestion as a mere adjunct to anesthesia, it should be regarded as an integral part of surgical and obstetrical care" (pp. 11-12).

Tellegen, Auke (1994, October). Comments on Symposium "Hypnosis Reconsidered". [Comment/Discussion] Presented at the annual meeting of the Society for Clinical and Experimental Hypnosis, San Francisco, , as part of Symposium titled: Hypnosis reconsidered.

#### NOTES

I agree that the topography of issues has become more complicated. I would want to look at the distinction between "special process" theories and other views. I still think there is some non-trivial element of difference between the two groups; but it's not one well defined group vs another, with people now distributed across a continuum and to some degree moving around. At the poles of these theoretical positions are real differences (e.g. in favorite hypotheses, research methods). But there has been some closing of the gap between these two poles.

Historically, rapprochement in psychological theories has been the result of hard nosed behaviorism going soft and cognitive in the last 15 years. The behavioral paradigm is the ancestor of the social cognitive view within hypnosis research. You can see the evolution in Ted Barber, and eventually it was carried forward by Spanos. Today all major views of hypnosis have become systems models, requiring flow diagrams. We are comparing more parsimonious (social cognitive) with more surplus meaning positions. Parsimony is a good way to advance knowledge, making a theory more complex only when you have to. The major social psychological positions are widely shared; many are close to common sense. The question is, are they sufficient to the data? The behavioral approach recognizes individual differences but doesn't weight them heavily; it may treat individual differences as a curve fitting issue, or may treat them as training outcome. Associated with the behavioral approach is a tendency not to explore fully individual differences from a naturalistic perspective. The difference in

research approaches between the two poles is loosely aligned with Cronbach's correlational vs experimental approaches to psychology.

The role of individual differences in hypnotizability however may be structural, in which case different flow diagrams may be needed, depending on trait levels, on the eliciting circumstances, etc. Thus we might need different flow diagrams for different levels of hypnotizability.

The role of imagination remains unexplicated across theoretical positions. Everyone since the Franklin committee thinks imagination is important in hypnosis; it is urgent to explore it. Even the most constructivist perspective on perception doesn't equate perception with imagination.

We now must turn the flow diagrams into neurobehavioral models, like Helen Crawford is attempting to do.

#### COMMENTS FROM THE AUDIENCE:

**Kenneth Bowers:** The people flowing out from the neodissociation camp are going in different directions. I think that ideas are directly activated, Helen Crawford and John Kihlstrom would think it involves more effort on the part of the hypnotized Subject. Irving Kirsch agrees that at some level the words have to be processed, but doesn't imply great effort. There is some kind of preattentive processing in hypnosis, the kind of processing which allows you to turn when you hear your name, in normal circumstances. Does it still make sense to talk about the field of hypnosis research or theory in terms of the two camps? I fear a return to the situation when the term "two camps" was justified.

1993

Miller, Mary E.; Bowers, K. S. (1993). Hypnotic analgesia: Dissociated experience or dissociated control?. Journal of Abnormal Psychology, 102, 29-38.

High-hypnotizable subjects were found superior to low-hypnotizable subjects in degree of pain reduction produced by hypnotic analgesia and by a stress-inoculation (cognitive-therapy) procedure. But, stress inoculation and not hypnotic analgesia impaired performance on a cognitively demanding task that competed with pain reduction for cognitive resources. This outcome implies that hypnotic analgesia occurs with little or no cognitive effort to reduce pain, challenging the social psychological theory of hypnotic response, at least in high-hypnotizable individuals. The findings are also incompatible with the concept of dissociated experience wherein the pain and cognitive efforts to reduce it are separated from consciousness by an amnesia-like barrier. But the results do support the concept of dissociated control, which proposes that suggestions for hypnotic analgesia directly activate pain reduction and thereby avert the need for cognitive strategies to reduce pain.

Woody, Erik Z. (1993, October). Factors, facets, and fiddle-faddle. [Paper] Presented at the annual meeting of the Society for Clinical and Experimental Hypnosis, Arlington Heights, IL.

#### NOTES

The classic suggestion effect implies involuntary behavior. A theory by Norman & Tim Shallice (published in a book on cognitive neuropsychology by Shallice) explains the classic suggestion effect in terms of underlying control processes.

There are 2 complementary systems: 1. contention scheduling (routine acts that don't require conscious control, activating schemas through environmental events and other schemas) for well learned habitual tasks. 2. supervisory attentional system - nonroutine actions in centralized processes, accessing unique information, operating only indirectly by modulating lower level control system, biasing their selection of schemas by system #1.

These two systems permit the sense of behavior being automatic or willed. The theory can be used to explain hypnotic nonvolition. For highs, hypnosis may partly disable System #2, dissociating lower

levels of control and resulting in genuine changes in behavior because System #1 would be more enabled, triggered directly by co-active schemas and environmental stimuli. This increased dependence on a lower level of control would not rule out a wide range of behavior. It's mainly novel or very complex behaviors that would diminish, plus exercise of will.

The model also illuminates our understanding of behavioral rigidity and the tendency for thought/action to be triggered by [suggestions?]. Spontaneous voluntary behavior would be diminished. (See for example Orne's studies of the effect of apparent power outage during an experiment, in which high hypnotizable Ss did not move or leave the room but sat passively, whereas low hypnotizable simulating Ss simply got up and left.)

Also a weaker "supervisor" would lead to disinhibition of inappropriate or peculiar associations or behavior. In labs one sees few such triggers, although Hilgard observed drug flashbacks. The phenomena of hypnosis sequelae appear like a disinhibition of experiences.

Hypnotic analgesia follows this model too, an automatic and controlled processing of perceptual input. Amnesia that follows hypnosis can be explained by this theory. Shallice has a model of how memory is affected: memory is a higher control system, enabling the handling of non-routine situations. Confronted by a nonroutine memory problem, the supervisory system formulates a model of what [the information] should look like, pulls out memories, and compares the model. If hypnosis interferes with the supervisor function it should interfere with memory (the description and verification phases) leading to [hypnotic amnesia?]. [With hypnosis one would predict]: 1. Poor access to memories requiring description (not overlearned material). Recall should demonstrate good cued memory but poor free recall. [It has been observed that] hypnotic amnesia selectively impairs free recall rather than recognition recall. 2. Hypnotized Ss should show poorer verification (the ability to discriminate irrelevant from correct associations). Many studies have shown this, with impoverished verification (e.g. the "discovery" of elaborate previous lives).

A dissociated control theory of hypnosis is thus possible, emphasizing a loss of control of supervisory system processes. It would implicate changes in frontal lobe processing. The essence of hypnosis, according to this approach, is the bypassing of executive control, and the frontal lobe is viewed as a center of executive control.

There are several ways that hypnosis suggests inhibition of frontal lobe functioning: 1. impoverishment of self initiated behavior 2. other-directedness 3. frontal amnesia (unable to distinguish true memories from irrelevant memories; prone to confabulation, especially when probed with false information) 4. poorer in temporal or sequential organization in memory.

How do we proceed to make this theoretical approach useful? We should do more neuropsychological studies, as Helen Crawford does. They emphasize the inhibition of frontal lobe functions.

Testable hypotheses arise: 1. Hypnotizable Ss should show the same kind of problem solving problems as frontal lobe patients. 2. Memory of hypnotized Ss should be like patients with frontal amnesia.

**1992**

Anonymous (1992, May). Studies: Learning can occur while under anesthesia. Daily Breeze (South Bay, Los Angeles County).

Surgical patients can absorb information while they're knocked out, and even learn tips that help with recovery, researchers reported Friday at a symposium on memory and anesthesia.

"Researchers at Papworth Hospital in Cambridge, England, studied 51 cardiac patients, one-third of whom heard a tape of positive 'therapeutic suggestions' during surgery. Another third heard batches of word associations; the rest heard a blank tape.

"Patients who were played the suggestion tape - which told them they were doing well, or wouldn't feel much pain - left the hospital 1 1/2 days earlier on average than other patients.

"Another study, from the University of Arizona College of Medicine, found that surgical patients who heard specific pain-relief suggestions recovered more easily than those hearing vague advice such as, 'Think of being well.'

"These are still early days to invest in every operating suite buying a tape recorder to play for the patients,' said Dr. Sunit Ghosh, a researcher with the Papworth team. 'But this definitely does hold promise.'

"Scholars at the second annual Symposium on Memory and Awareness in Anesthesia said patients rarely wake up recalling - unprompted - something that happened during anesthesia.

"But several studies showed subconscious learning while the patients were out cold.

"Not everyone accepted the findings.

"It shows an enormous sensitivity on the part of the brain, if it can be shown,' said Eugene Winograd, an Emory University psychologist and organizer of the Emory- sponsored conference. 'I'm not confident it has been shown yet.'

"Some researchers in other studies found no association between messages heard during anesthesia and learning.

"Dr. Alan Aitkenhead, professor of anesthesia at the University of Nottingham in England, found no significant difference between patients who heard recuperative suggestions and patients who were treated to a deliberately dull history of the hospital where they were.

"Aitkenhead said his study kept all patients quite deeply anesthetized, and that may be why they might not have learned as much as patients in other studies.

"By far, most likely, it's a difference in levels of anesthesia,' he said.

"The Papworth researchers, in another study, found that some patients showed strong word associations after hearing tapes of groups of words during surgery; but other patients under a different anesthesia didn't.

"There needs to be standardization of our testing,' Ghosh said. 'I think it's partly related to the anesthesia technique and partly related to the way in which material is presented to the patient.'

"Dr. Peter Sebel, an Emory anesthesiologist and conference organizer, said that if patients can retain information about a speedy recovery, they probably retain other information, too - for example, a surgeon's discouraging operating-room assessment of their prognosis."

Blankfield, Robert; Scheurman, Kathleen; Bittel, Sue; Alemagno, Sonia; Flocke, Sue; Zyzanski, Stephen (1992, October). Taped therapeutic suggestions and taped music as adjuncts in the care of coronary artery bypass graft patients. [Paper] Presented at the annual meeting of the Society for Clinical and Experimental Hypnosis, Arlington, VA.

## NOTES

18 studies have explored the issue with an experimental design; half used tapes, half didn't; majority of studies found benefits; 2 were of heart surgery patients.

This study used taped suggestions with coronary bypass patients. Used tape recorder rather than person delivering suggestions because it was more convenient; used tape intra-surgery and post-operatively for more impact.

We hypothesized: shorter length of stay, less narcotic analgesia, less anxiety, faster recovery, more positive mental outlook, resume activities sooner, have less symptoms postoperatively, etc.

Used a prospective, randomized, single-blind trial in 2 community hospitals in Cleveland with coronary artery bypass graft surgery patients. Study was done between Dec 1989 - Feb 1992.

3 groups were involved: (1) Suggestion, (2) music, and (3) tape. Control subjects had a blank tape. Tapes were played continuously and repeatedly with headphones. Postoperatively, a different tape was played.

**Excluded:** Patients with emergent surgery, hearing impairment, poor comprehension of English, patients who died in hospital, patients whose hospital stay lasted longer than 14 days (3 of them). 5% of sample were eliminated for last 2 reasons.

**Music:** Herb Ernst, Dreamflight II. **Suggestions:** Music background, permissive, based on Evans & Richardson's study.

**Outcome Measures:** Nurse assessment of anxiety and progress post operatively, Symptom scale, Depression scale.

Mean age 62, 3/4 men, 92% white, 75% married. The groups were same on a variety of preoperative variables (status of heart and arteries). Length of stay was 6.5 in all 3 groups. No difference in narcotics use, in nurse assessment of anxiety or of progress; of depression scale, or activities of daily living.

Recategorized data into patients who said the tapes were helpful (both music and suggestion) N = 33 vs the other patients N = 62. No difference in the variables evaluated.

**Bruner, Jerome (1992).** Another look at New Look 1. American Psychologist, 47, 780-783.

New Look 1 was not initially about the unconscious. It was the new mentalism on its way to becoming the Cognitive Revolution. Its subsequent concern with "unconscious defense mechanisms," although useful, was not its main theoretical thrust. Its principal questions have always been how and where selective processes operate in perception. Obviously, many such processes are unconscious, for consciously guided attention and search become automatized easily in use. And they are fairly flexible as well. So how smart is "the unconscious"? Not very, but a big help anyway.

**Erdelyi, Matthew, Hugh (1992).** Psychodynamics and the unconscious. American Psychologist, 47, 784-787.

The original New Look integrated the constructivist-psychodynamic traditions of Bartlett and Freud. The unconscious (Greenwald's "New Look 3") is a logically different idea, although in practice it is often intertwined with constructivist - psychodynamic approaches. The unconscious is a pretheoretic term with a variety of problems: It has multiple and unsettled meanings; null reports need not signify null awareness; the conscious-unconscious dichotomy implied by the limen may not exist; even "absolute subliminality" (chance-level accessibility) is relative to the time interval of testing, as accessibility can increase to above-chance levels over time (hypermnnesia). Yet, the phenomena that the unconscious sloppily subsumes are not simple or dumb. The capacity of subliminal perception should not be confused with the capacity of subliminal (unconscious) memory and cognition.

## NOTES

The 1976 Chowchilla kidnaping case in California stimulated interest in using hypnosis for forensic investigation; in the same year, it was used in a case of airline hijacking in the Mediterranean to Uganda. Hypnosis is used for obtaining "leads" and doesn't claim to develop "the truth."

Other uses include: lifting amnesia of witnesses and victims of trauma--including but not limited to crime; obtaining additional information in nonamnesic Ss; evaluation of a subject's mental condition (e.g. multiple personality disorder vs malingering, as in the Bianchi case). In each use, hypnosis is not infallible, is not complete. But no procedure is. Motivation, resistance, transference are all critical.

Historic questions: 1. whether coercion is entailed 2. impact of hypnosis on memory 3. possible harm to subject, physically and mentally

The coercion issue dates to Mesmer, whose procedures led to accusations of immoral suggestions. In the 1880s Charcot said no one could be forced to do anything while the Nancy school (Liebeault) said they could. Since then we have seen laboratory studies using student volunteers, fake "poison," rubber daggers, etc., as well as recent "real life" studies where Ss were induced to violate their morals (see Watkins). Review articles include those by Jacob Conn of Baltimore and the 1985 JAMA article written by a panel headed by Martin Orne.

For impact of hypnosis on memory, see the Orne report which did not fully support using hypnosis for memory enhancement.

Regarding possible harm to a hypnotic subject in the 19th century, a young man's death was attributed to nervousness and exhaustion and diabetes due to repeated hypnosis. Other studies of death (of chickens, of a frog) due to repeated hypnotization were published. Now the consensus is that hypnosis is not dangerous (but incompetence using hypnosis may be dangerous).

#### **LEGAL PRECEDENTS.**

In 1897 a California court refused to accept testimony of a Subject who had been hypnotized. *People vs Eubanks*.

The 1950's Cornell case established that a person can be hypnotized for their own defense.

In 1963 the California supreme court ruled that a lower court made a mistake in not admitting testimony from someone who had been hypnotized.

In *Harding* (a Maryland case), the trauma victim, amnesic, was hypnotized one month later. The testimony was accepted. A 1983 Maryland appeals court overturned it, influenced by the California *Shirley* case.

In 1983 *Hurd* case, a victim, hypnotized, identified her husband as attacker. Lower court didn't permit the testimony; then a higher court reversed it. The court issued what are known as the Hurd rules, governing testimony that is acceptable: 1. hypnotist is licensed psychologist or psychiatrist with training in hypnosis 2. hypnotist must be independent of both the prosecution and defense 3. all information given to the hypnotist about the case must be written 4. hypnotist must obtain a nonhypnotic account of the memory before hypnosis is used. 5. must have taped record of the hypnosis sessions (preferably videotaped) 6. only hypnotist and subject should be present in the room

Soon after, California had the *Shirley* case. The California court ruled hypnosis per se is unreliable because it produces confabulation. This decision had a chilling effect throughout the country for several years.

In 1987 we had *Rock vs Arkansas*, the first and only case involving hypnosis to come before the U. S. Supreme Court. Vicky Rock shot her husband. Under hypnosis, she remembered she did not have her finger on the trigger, and her husband grabbed her and shook her. Lower court wouldn't admit the testimony of the gun expert, who testified the trigger was sensitive to jarring. Supreme Court ruled defendants (not necessarily others) could use hypnosis in their own defense.

Greenwald, Anthony G. (1992). New Look 3: Unconscious cognition reclaimed. *American Psychologist*, 47, 766-779.

Recent research has established several empirical results that are widely agreed to merit description in terms of unconscious cognition. These findings come from experiments that use indirect tests for immediate or long- term residues of barely perceptible, perceptible-but-unattended, or attended-but-forgotten events. Importantly, these well-established phenomena--insofar as they occur without initially involving focal attention--are limited to relatively minor cognitive feats. Unconscious cognition is now solidly established in empirical research, but it appears to be intellectually much simpler than the sophisticated agency portrayed in psychoanalytic theory. The strengthened position of unconscious

cognitive phenomena can be related to their fit with the developing neural network (connectionist) theoretical framework in psychology.

Jacoby, Larry L.; Lindsay, D. Stephen; Toth, Jeffrey P. (1992). Unconscious influences revealed: Attention, awareness, and control. American Psychologist, 47, 802-809.

Recent findings of dissociations between direct and indirect tests of memory and perception have renewed enthusiasm for the study of unconscious processing. The authors argue that such findings are heir to the same problems of interpretation as are earlier evidence of unconscious influences--namely, one cannot eliminate the possibility that conscious processes contaminated the measure of unconscious processes. To solve this problem, the authors define unconscious influences in terms of lack of conscious control and then describe a process dissociation procedure that yields separate quantitative estimates of the concurrent contributions of unconscious and consciously controlled processing to task performance. This technique allows one to go beyond demonstrating the existence of unconscious processes to examine factors that determine their magnitude.

Kihlstrom, John F.; Barnhardt, Terrence M.; Tataryn, Douglas J. (1992). The psychological unconscious. American Psychologist, 47, 788-791.

In response to Greenwald's article on contemporary research on unconscious mental processes, the authors address three issues: (a) the independence of much recent research and theory from psychodynamic formulations; (b) the broad sweep of the psychological unconscious, including implicit perception, memory, thought, learning, and emotion; and (c) the possibility that the analytic power of unconscious processing may depend both on the manner in which mental contents are rendered unconscious and the manner in which they are to be processed.

Lewicki, Pawel; Hill, Thomas; Czyzewska, Maria (1992). Nonconscious acquisition of information. American Psychologist, 47, 796-801.

The authors review and summarize evidence for the process of acquisition of information outside of conscious awareness (covariations, nonconscious indirect and interactive inferences, self-perpetuation of procedural knowledge). Data indicate that as compared with consciously controlled cognition, the nonconscious information - acquisition processes are not only much faster but are also structurally more sophisticated, in that they are capable of efficient processing of multidimensional and interactive relations between variables. Those mechanisms of non-conscious acquisition of information provide a major channel for the development of procedural knowledge that is indispensable for such important aspects of cognitive functioning as encoding and interpretation of stimuli and the triggering of emotional reactions.

Loftus, Elizabeth F.; Klinger, Mark R. (1992). Is the unconscious smart or dumb?. American Psychologist, 47, 761-765.

How sophisticated is unconscious cognition? This is one of the most fundamental questions about the unconscious that has been posed by research psychologists over the past century. Anthony Greenwald takes a contemporary look at this classical problem and concludes that unconscious cognition is severely limited in its analytic capability. In response, other leading scholars agree that the reality of unconscious processes is no longer questionable. Although there is some disagreement about just how sophisticated these processes are, the consensus is that exciting times are ahead for both research and theory concerning the mental processes involved in unconscious cognition.

Merikle, Philip M. (1992). Perception without awareness: Critical issues. American Psychologist, 47, 792-795.

## NOTES

This is the introduction to a group of articles. "To a large extent, this entire controversy over perception without awareness has centered on the issue, What constitutes an adequate behavioral measure of conscious perceptual experience? Depending upon one's answer to this question, the evidence for perception without awareness is either overwhelming or nonexistent.

The distinction is much more significant and interesting if conscious and unconscious processes lead to qualitatively different consequences than if unconscious processes are simply quantitatively weaker versions of unconscious processes. Three different qualitative differences have been established: 1. Groeger (1984, 1988) has demonstrated that words are coded differently depending on whether they are perceived with or without awareness. 2. Stroop effect research showed that prediction based on stimulus redundancy only occurs when subjects consciously perceive the predictive stimuli (Cheesman & Merikle, 1986). The fact that the color word predicted the name of the color patch on 75% of the trials was only used by the subjects to facilitate naming of the color patches when the words were clearly visible. 3. Marcel (1980) showed that conscious awareness is necessary for the selection of a context-relevant interpretation of a stimulus.

The important findings are that performance differs qualitatively across the aware and non aware conditions.

Rondi, Glenys (1992, October). Postoperative impact of information presented during general anesthesia. [Paper] Presented at the annual meeting of the Society for Clinical and Experimental Hypnosis, Arlington, VA.

We tried to improve on the methodology in the literature. Thus we included a limited range of surgery procedures; standardized anesthesia; monitoring of anesthesia; suggestions that were only positive (the suggestions did not mention pain or nausea); patient-controlled analgesia in order to have a more accurate measure; and hypnotizability was measured. They do not equate the hypnotic state with the anesthesia state, but there may be an overlap in the ability to perceive and respond to suggestions in these two states.

All hysterectomy and bilateral [missed word ...ectomy] patients were approached, excluding those without English language, etc.

Bowers and she phrased simple, positive suggestions to maximize benefits; Suggestions lasted 3 minutes, and were repeated 3 times on a 60 minute tape. Brief melodies alternated with suggestions or with silence. Conditions included: 1. Suggestions 2. Melody 3. Suggestions + melody 4. Blank tape Half of the tapes contained suggestions; half not. It was a counterbalanced design. Double blind ratings were made by students.

State-trait Anxiety and Profile of Mood States were measured before surgery. Patients were reminded to listen to suggestions for recovery just before they fell asleep. MDs ordered premedication for the surgery "only if very necessary."

Patients rated their own recovery as -3 worse than expected to +3 better than expected; and completed a visual analogue scale. Then 24 hours later the researchers asked them if they remembered the tape, and if they had been given suggestions or not.

On Day 5 post operation they administered the Stanford C hypnotizability scale.

## RESULTS.

None of the patients recalled or dreamed anything that could be attributed to the period of anesthesia. There was a response bias to say "Yes" to "Did you have suggestions?" (34 of Suggestion patients and

28 of non-suggestion patients said "Yes" and there were 48 in each group. Taking response bias into consideration, patients with suggestions were above chance in saying "Yes" to "Did you have suggestions?"

Only 73 of the 96 completed the hypnotizability scale. Duration of the tape (therefore of surgery) was longer for the suggestion group (90 vs 72 minutes). So authors also did a univariate measure.

They divided morphine use by patient weight for each post operative day. The difference in dose for suggestion and no suggestion groups did not reach significance on Day 1 but on Day 2 patients who had suggestions used significantly less morphine.

The correlation matrix showed that patient age was negatively correlated with morphine use; subjected to 1-way ANOVA of covariance; the effect of suggestions remains significant.

Surgery time was covaried out, as it was associated with more negative post operative symptoms; patient age was a second covariate. None of the main effects or 2- way interactions were significant.

Hypnotizability, suggestion group, and their interaction were analyzed. Neither hypnotizability nor its interaction with suggestion contributed to any outcome variable.

Using only highs (13) and lows (12) for another analysis and 2x2 ANOVAS to examine suggestion by hypnotizability. Highs used significantly less morphine in the first hours, whether or not they received suggestions.

Even when weight is taken into account, hypnotizability accounted for significant amount of variance in first 24 hours. Highly hypnotizables' guesses about whether they were played a tape with suggestions was 100% accurate; guesses of lows were 42% accurate.

#### CONCLUSIONS.

Some patients show evidence of hearing, and of responding to suggestions. Hypnotic ability did not mediate the response; but patients with high ability showed 100% accuracy in guessing whether they were played suggestions, in the absence of confidence in their response. They may be particularly sensitive to their environment during general anesthesia.

1991

Block, Robert I.; Ghoneim, M. M.; Sum Ping, S. T.; Ali, M. A. (1991). Efficacy of therapeutic suggestions for improved postoperative recovery during general anesthesia. Anesthesiology, 75, 746-755.

There have been claims that the postoperative course of patients may be improved by presentation during general anesthesia of therapeutic suggestions which predict a rapid and comfortable postoperative recovery. This study evaluated the effectiveness of such therapeutic suggestions under double-blind and randomized conditions. A tape recording predicting a smooth recovery during a short postoperative stay without pain, nausea, or vomiting was played during anesthesia to about half the patients (N = 109), while the remaining, control patients were played a blank tape instead (N = 100). The patients were primarily undergoing operations on the fallopian tubes, total abdominal hysterectomy, vertical banding gastroplasty, cholecystectomy, and ovarian cystectomy or myomectomy. The anesthesia methods consisted of either isoflurane with 70% nitrous oxide in oxygen to produce end-tidal concentrations of 1.0, 1.3, or 1.5 MAC; or 70% nitrous oxide in oxygen combined with high or low doses of opioids. Assessments of the efficacy of the therapeutic suggestions in the recovery room and throughout the postoperative hospital stay included: the frequency of administration of analgesic and antiemetic drugs; opioid doses; the incidence of fever; nausea, retching, and vomiting; other gastrointestinal and urinary symptoms; ratings of pain; ratings of anxiety; global ratings of the patients' physical and psychological recoveries by the patients and their nurses; and length of postoperative hospital stay. There were no meaningful, significant differences in postoperative recovery of patients receiving therapeutic suggestions and controls. These negative results were not likely to be due to insensitivity of the assessments of recovery, as they showed

meaningful interrelations among themselves and numerous differences in recovery following different types of surgery. Widespread utilization of therapeutic suggestions as a routine operating room procedure seems premature in the absence of adequate replication of previously published positive studies. (Key words: Anesthesia, depth: Awareness, Memory, Recall, Learning.)

## NOTES

Patients ages 19-55 were accepted into the study and they were paid for participation. (Older patients were excluded to guard against memory or hearing problems.) Other criteria for exclusion were: ASA physical status 4 or 5 indicating significant systemic disease, visual or hearing problems, middle ear disease (because it increases probability of nausea and vomiting), if their condition might require heavy sedation, if they were currently taking medication that interferes with memory (e.g. benzodiazepines, if there were intolerance to opioids, or if there were a likelihood of using postoperative pain treatment other than opioids.

The Spielberger State-Trait Anxiety Inventory was administered before surgery. Either suggestions (lasting 6 minutes) or a blank tape were played through headphones, starting 5 minutes after the surgical incision. The tape was played once for the first 59 patients, continuously for the remaining 150 patients. The first 139 patients received additional verbal materials on the tape, for memory tests to test possibility of learning under anesthesia. Operating room sounds were recorded by a tape recorder near the patient's head, throughout period of unconsciousness (except when tape was being played).

After the first 25% of cases, the team decided that lack of effect on therapeutic suggestions attributable to type of anesthesia did not warrant restriction to a single anesthetic method; also, multiple presentations of the suggestions on tape did not show an effect different from a single presentation.

After the patient regained consciousness and was reoriented, pain, nausea, retching, and vomiting were assessed every 30 minutes. Pain was rated orally on a scale from 1 to 10 in the recovery room, then on visual analogue scales every 2 hours on the day of surgery and the second day, and every 4 hours on subsequent hospital days during waking hours. Variables that were rated by staff every 24 hours included: opioids, other analgesics, antiemetics, nausea, vomiting, retching, presence or absence of nasogastric tube, passage of flatus, bowel movement, fluid intake, solids intake, urination. Temperature was recorded every 4 hours for the first 2 days after surgery, and after that less often. The anxiety measures were repeated on Day 3 postsurgery, as well as self ratings and nurse ratings on physical and psychological recovery. Staff recorded length of postoperative hospital stay and reasons for any delay of discharge. Separate analyses were performed for patients receiving opioids via patient-controlled analgesia (52%) vs traditional administration (48%), but no differences were found for effects of therapeutic suggestions except on postoperative Day 8.

"The inability to detect beneficial effects of therapeutic suggestions probably was not due to insensitivity of the measures of recovery. These measures were sensitive enough to show numerous significant differences in recovery after different types of surgery" (p. 751). The authors supported their contention that the measures were sufficiently sensitive by demonstrating meaningful correlations among the measures themselves; and by demonstrating adequate statistical power for detecting the effects of theoretical interest--at least 1 day in postoperative hospital stay or one half day in fever.

Discussion: The authors note that a recent investigation that found positive results in a double-blind, randomized design with 39 hysterectomy patients (Evans & Richardson, 1988. Improved recovery and reduced postoperative stay after therapeutic suggestions during general anaesthesia. *Lancet*, 2:491-493) may not have controlled for variables such as presence of malignancy, physical status of patients before surgery, or ethnicity. Authors note that Evans and Richardson observed shorter periods of pyrexia despite there being no relevant suggestions, but no differences in pain intensity, nausea, vomiting, or urinary difficulties despite there being suggestions relating to those symptoms. There also

were no differences in mood and anxiety test scores postoperatively for the experimental and control groups.

The authors note that McLintock, Aitken, Downie, & Kenny (Postoperative analgesic requirements in patients exposed to positive intraoperative suggestions. *Br M J* 301:788-790. 1990) reported a 23% reduction in opioids by patients receiving suggestions, but no reduction in pain, nausea, or vomiting. They contrast the present study with these earlier studies that had obtained positive results.

"We studied patients who had more than one type of surgery to obtain a large sample size and to assess the possibility that beneficial effects of therapeutic suggestions would be restricted to certain types of operations. Had this been the case, interactions of therapeutic suggestions with type of surgery would have been significant in the overall analyses, and follow-up analyses would have indicated that they were attributable to beneficial effects of therapeutic suggestions for certain surgeries. This did not occur. The two types of surgeries involving the largest numbers of patients seemed particularly promising for demonstrating beneficial effects. It has been reported that therapeutic suggestions presented during anesthesia are likely to be less successful with major and extensive surgery. Certainly, surgery on the fallopian tubes and gastric stapling did not involve a great deal of tissue trauma and blood loss. Patients were motivated to have the surgery and to recover quickly; particularly motivated were those having operations on the fallopian tubes, who were very eager to become pregnant, and those having vertical banding gastroplasties, who wanted desperately to lose weight" (pp. 753-754).

"In practice, we observed no beneficial effects of therapeutic suggestions, and there was no hint that anesthesia methods influenced the efficacy of the therapeutic suggestions. Interestingly, anesthetic methods also did not influence learning under anesthesia in the implicit memory tests we have used previously. Patients anesthetized with nitrous oxide and opioids did not differ from those anesthetized only with inhalational agents. In general, implicit or unconscious memory occurs in patients regardless of anesthesia methods or dosages of drugs" (p. 754).

"The few significant effects of therapeutic suggestions in our study did not point toward a beneficial influence of these suggestions. We found, in fact, an increased frequency of retching (but not nausea or vomiting) in the experimental group. The multiple variables examined in this study increased the likelihood of significant differences arising by chance, such that the null hypothesis was rejected when it should have been accepted. This is the way we interpret the effect on retching---i.e., as a type I error. We used in our therapeutic suggestions one negative or exclusionary sentence, 'You won't feel nauseous or have to vomit', among several positive or affirmative statements, e.g., 'You will enjoy eating, drinking...You will swallow to clear your throat and everything will go one way, straight down. . . The food will taste good....Your stomach will feel fine.' We do not think that the negative sentence led to paradoxical results. Evans and Richardson (personal communication) used in their therapeutic suggestions a negative sentence ('You will not feel sick'), which they repeated, yet the reported incidence of nausea and vomiting did not differ between the experimental and control groups" (p. 754).

Brown, Jason W. (1991). Self and process: Brain states and the conscious present. New York: Springer-Verlag.

Author, from the Department of Neurology at New York University Medical School, presents a theory about the genetic unfolding of mental content (mind) through stages, from mental state into consciousness or into behavior. He relates the genesis of mind to brain development but avoids assuming that there is a straightforward correlation between brain development (e.g. myelination) and cognitive development or perception. To some degree, the theory is based on subjective report data and psychological symptoms. The author discusses issues that bear on the phenomena of nonvoluntary responding and dissociation that are reported or described by hypnotized persons.

"The nature of the mental state will determine the relation between self and world, and thus the interpretation given to agency and choice. ... The crossing of the boundary from self to world is a shift from one level in mind to another" (pp. 10-11).

"... if we begin with mind as primary and seek to explain objects from inner states and private experience, the discontinuity between inner and outer evaporates: mind is everywhere, a universe. ... Whereas before we thought to perceive objects, now we understand that we think them" (p. 19).

"The concept of a stratified cognition is central to the notion of a mental state .... This entails an unfolding from depth to surface, not from one surface to the next, a direction crucial to agency and the causal or decisional properties of consciousness" (p. 52). By unfolding from depth to surface, he means from Core, through Subconscious, then Conscious Private Events, and finally Extra-Personal Space.

He goes on to provide a definition of mental states. "A mental state is the minimal state of a mind, an absolute unit from the standpoint of its spatial and temporal structure. ... The state also has to include the prehistory of the organism. ... The concept of a mental state implies a fundamental unit that has gestalt-like properties, in that specific contents-- words, thoughts, percepts--appear in the context of mind as a whole (p. 53).

"The entire multitiered system arborizes like a tree, with levels in each component linked to corresponding levels in other components. For example, an early (e.g., limbic) state in language (e.g., word meaning) is linked to an early stage in action (e.g., drive, proximal motility) and perception (e.g., hallucination, personal memory) .... In sum, a description of the spatial and temporal features of a single unfolding series amounts to a description of the minimal unit of mind, the absolute mental state" (p. 54).

The author's discussion of an individual's physical movement relates to the concept of nonvoluntary movement (or movement without awareness of volition) in hypnosis. "More precisely, levels in the brain state constitute the action structure. As it unfolds, this structure generates the conviction that a self-initiated act has occurred. This structure--the action representation--does not elaborate content in consciousness. ... As with the sensory-perceptual interface, the transition to movement occurs across an abrupt boundary. In some manner, perhaps through a translation of cognitive rhythms in the action to kinetic patterns in the movement, levels in the emerging act discharge into motor (physical) events" (p. 57).

"The self has the nature of a global image or early representation within which objects-to-be are embedded. ... The self is the accumulation of all the momentary cognitions developing in a brain configured by heredity and experience in a particular way (p. 70).

"The deposition of a holistic representation ... creates the deception of a self that stands behind and propagates events. The feeling of the self as an agent is reinforced by the forward thrust of the process and the deeper locus of the self in relation to surface objects. The self appears to be an instigator of acts and images when in fact it is given up in their formation. The self does not cause or initiate, it only anticipates (p. 70).

The foregoing notes cover only the first five chapters, less than half the book. Other chapters relevant to hypnosis would be those titled 'The Nature of Voluntary Action,' 'Psychology of Time Awareness,' 'From Will to Compassion,' and 'Mind and Brain.'

Dennett, Daniel C. (1991). Consciousness explained. Boston: Little, Brown & Co..

Material in this book is relevant to discussions about 'nonvoluntary' behavior and (un)conscious experiencing. It combines information from cognitive neuroscience with the philosophy of mind. The author presents a view that consciousness (the 'mind') is the consequence of the brain's activities which give rise to illusions about their own properties. He presents the Multiple Drafts model of consciousness, which reformulates the concept of a 'stream of consciousness.' This provides a basis for

consideration of concepts central to cognitive neuroscience and phenomena associated with hypnosis, e.g. experiential states and the nature of the self.

The author gives various examples of phenomenology and notes that although these examples are familiar to us, they are totally inaccessible to materialistic science; e.g. the way the sunset looks to someone. He treats people's descriptions of what they experience as a record of speech acts. Thus, observing and interpreting speech acts, inferring from them the speaker's inner states, is like a reader who is interpreting a work of fiction. He gives as examples of how one can scientifically study what does not 'exist' (a) literary theorists who describe fictional entities, (b) anthropologists who study cultural artifacts like gods and witches, and (c) physicists who study a center of gravity.

In Dennett's theory, multitrack processes of interpretation of sensory inputs and elaboration of those inputs amounts to a kind of 'editorial revision' by the brain. For example in the phi phenomenon a red dot is displayed, followed by a green dot in a different location; the first spot seems to begin moving and then change color in the middle of its illusory passage toward the second location. He points out that awareness of the change in color must occur after seeing the green spot, but one consciously experiences a single spot first red, then red-turning-to-green, finally green. In an example that relates directly to the words used for his theory, he cites contemporary publishing practices, in which several different drafts of an article are in circulation even while the author is revising it. Deciding on some specific moment of brain processing as the moment of consciousness is arbitrary, according to his Multiple Drafts model.

"Visual stimuli evoke trains of events in the cortex that gradually yield discriminations of greater and greater specificity. At different times and different places, various 'decisions' or 'judgments' are made; more literally, parts of the brain are caused to go into states that discriminate different features, e.g., first mere onset of stimulus, then location, then shape, later color (in a different pathway), later still (apparent) motion, and eventually object recognition. These localized discriminative states transmit effects to other places, contributing to further discriminations, and so forth. The natural but naive question to ask is: 'Where does it all come together'? The answer is: Nowhere. Some of these distributed contentful states soon die out, leaving no further traces. Others do leave traces, on subsequent verbal reports of experience and memory, on 'semantic readiness' and other varieties of perceptual set, on emotional state, behavioral proclivities, and so forth. Some of these effects--for instance, influences on subsequent verbal reports--are at least symptomatic of consciousness. But there is no one place in the brain through which all these causal trains must pass in order to deposit their content 'in consciousness'" (pp. 134-135).

The author describes the evolution of the brain, along Darwinian lines, and introduces the idea of culture as a repository and transmission medium for innovations (including innovations of consciousness) as a medium of evolution. Through learning, we humans evolve an American or a Japanese brain. Once we have evolved the 'entrance and exit pathways' for language, they become 'parasitized' by memes (entities that have evolved to thrive in such a niche).

Richard Dawkins coined the term memes to describe the smallest idea elements that replicate themselves reliably (e.g. wheel, alphabet, wearing clothes, right triangle). "The transformation of a human brain by infestations of memes is a major alteration in the competence of that organ" (p. 209).

Dennett discusses the similarities and dissimilarities of brains and computers. He suggests that human minds are like serial virtual machines implemented on parallel processing hardware. The stream of consciousness results from our rehearsal of brief experiences, to commit them to memory; language then permits us to describe to ourselves the process of thinking which leads to judgement and action.

The author's discussion of how a verbal expression evolves and becomes manifest is related to how so-called intentional action occurs. [This relates to discussions of nonvoluntary actions in hypnosis.] We assume that because our actions make sense, they are the product of serial reasoning. However, there are multiple channels "in which specialist circuits try, in parallel pandemoniums, to do their various things ... (pp. 253- 254). Bernard Baars has suggested "that consciousness is accomplished by a

'distributed society of specialists that is equipped with a working memory, called a *\_global workspace\_*, whose contents can be broadcast to the system as a whole (p. 42)'" (p. 257). Dennett states that there is no line dividing the events that are definitely in consciousness from those that are outside consciousness. He urges scientists to forgo the concept of the 'inner observer' implied by Cartesian materialism.

Examples of perception that is unaccompanied by consciousness include blindsight (in which the subject does better than chance on visual tests but denies consciousness, and the denials are given credence by neurological evidence of brain damage) and hysterical blindness, which is given less credence because subjects often use the visually provided information in ways blindsight Ss do not. Other behaviors not controlled by conscious thought include blinking when things approach the eye, walking without falling over, regulating our body temperature, adjusting our metabolism, etc. "If I am trying to see a bird that I hear, and stare at the spot but do not distinguish the bird from its background, can I say that it is present in the background of my (visual) consciousness or not?" (p. 336).

The author maintains that if an event doesn't linger and the person is unable to identify and reidentify the effect, it cannot be reported. But such reportability can be improved, as with training the palate of wine tasters. Often, however, we continue disregarding stimuli that impinge on us. There are minor oversights, such as our 'blind spots' or proof reading errors, and major oversights such as a brain-damaged patient's hemi-neglect. In the Multiple Drafts theory, the Observer is replaced by 'coalitions of specialists' that are distributed around in the brain, distributed in both time and space.

Though discrimination or discernment happens, there is no one Discerner doing the work. However, Dennett takes the middle ground on the question of whether a self exists: it is simply a creation like the nest of the Bower bird, or the organized colony of termite ants. "So wonderful is the organization of a termite colony that it seemed to some observers that each termite colony had to have a soul (Marais, 1937). We now understand that its organization is simply the result of a million semi-independent little agents, each itself an automaton, doing its thing. So wonderful is the organization of a human self that to many observers it has seemed that each human being had a soul, too: a benevolent Dictator ruling from Headquarters" (p. 416). The sense of self is a creation, like a physicist's center of gravity.

Thus, multiple personality disorder is viewed as a self that has gaps; and our sense of self might include different aspects from one year to the other. Hence, "selves are not independently existing soul-pearls, but artifacts of the social processes that create us, and, like other such artifacts, subject to sudden shifts in status. The only 'momentum' that accrues to the trajectory of a self, or a club, is the stability imparted to it by the web of beliefs that constitute it, and when those beliefs lapse, it lapses, either permanently or temporarily" (p. 423).

Finally, the author has an extensive discussion of the concepts of 'qualia' and of 'epiphenomena' and seems to have little use for either term in trying to understand Mind.

Dixon, Norman F.; Henley, Susan H. (1991). Unconscious perception: Possible implications of data from academic research for clinical practice. *Journal of Nervous and Mental Disease*, 179 (5), 243-252.

Evidence for the reality of unconscious perception and perceptual defense suggests that the experimental paradigms used to investigate these phenomena might play a role in the understanding and treatment of mental disorders. The literature on applying subliminal stimulation to problems of diagnosis and therapy indicates that data support the view that the meaning of external stimuli of which the recipient is unaware may be responded to and determine emotional responses, lexical decisions, overt behavior, and subjective experience. Data confirm the reality of psychopathology as a substrate of emotionally colored, stored information with a potential for producing somatic symptoms and disorders of thinking, affect, and behavior. To the extent that psychopathology is screened from

conscious scrutiny and thus impervious to supraliminal information, it may be accessed and ameliorated by drive-related stimuli of which the S is not aware.

Jansen, C. K.; Bonke, B.; Klein, J.; van Dasselaar, N.; Hop, W. C. J. (1991). Failure to demonstrate unconscious perception during balanced anaesthesia by postoperative motor response. Acta Anaesthesiologica Scandinavica, 35, 407-410.

Eighty patients undergoing a standardized balanced anaesthesia were randomly assigned to either a suggestion group (N = 38) or a control group (N = 42), in a double-blind design. Anaesthesia was maintained with nitrous oxide, enflurane and fentanyl. Patients in the suggestion group were played seaside sounds, interrupted by statements of the importance of touching the ear during a postoperative visit, by means of a prerecorded audiotape and headphones. Tapes containing these suggestions were played from 30 min after the first incision, for a duration of 15 min. Patients in the control group were only played seaside sounds. There were no significant differences between the groups in either the number of patients touching their ears postoperatively or the number and duration of ear touches.

**NOTES**

This research follows upon other studies in which patients carried out postoperative motor responses while still being amnesia for the source of the suggestions for the action (e.g. Bennett, Davis, & Giannini, 1985; Goldmann, Shah, & Hebden, 1987). The earlier studies used widely varied anesthesia techniques, small sample sizes, and did not measure baselines for those responses or clearly delimit the amount of time for recording the responses postoperatively. This investigation was an attempt to improve on the research design of earlier investigations that had obtained positive results.

Patient assignment to groups was stratified over three levels of estimated intensity of pain stimulation during surgery (based on the type of surgery).

The outcome measure, number of ear touches and their duration, was made by the anesthetist and an observer during the first 10 minutes of the pre- and postoperative interviews. (The observer was blind for the patient group assignment.) 75 of the patients were interviewed on the first postoperative day, and the remainder on the second postoperative day. The interview included questions regarding recall of the intravenous administration of drugs and of events during surgery. The outcome data may be seen in the Table below.

Distribution of ear touches during the first 10 min of the preoperative interview and, after the intraoperative suggestion, during the first 10 min of the postoperative interview. -----

No. of patients with		Total no. of ear touches for		Duration of ear touches				Grp		N		Pre		Post		Pre		Post		Pre	
ear touches for all responders																					
-----		-----		-----		-----		-----		-----		-----		-----		-----		-----		-----	
Post	-----	S	38	2	3	2	9	62													
155	C	42	5	3	8	4	38	23													

S = suggestion group C = control group

In discussing their results, the authors offer several reasons why they might not have obtained the same results as those of previous investigators. "First, our anaesthetic techniques were different from those used in the studies of Bennett et al., 1985, and Goldmann et al., 1987" (p. 408).

"A second reason for the discrepancy between our results and those of the other two studies could be that our suggestion was perhaps less meaningful to the patients undergoing surgery than the one used by our fellow researchers. It has been argued that recollection of perioperative events is influenced by the salience of the stimuli [Dubovsky & Trustman, 1976, Anesth Analg; Goldmann & Levey, 1986 (letter) Anaesthesia]. This salience depends largely on the content of the message. It may be that the requested response, i.e., to touch the ear, is one that in our culture, or environment, has insufficient

emotional impact and is thus ignored. It is interesting to note in this context that the percentage of patients touching the ear postoperatively was significantly lower (Fisher's exact test:  $P < 0.01$ ) in our study than in the study by Bennett et al., both for the suggestion group and the control group. On the other hand, recent findings showed robust effects with emotionally neutral stimuli [Jelicic, Bonke, & Appelboom, 1990, *Lancet*; Roorda-Hrdlickova, Wolters, Bonke, & Phaf, 1990, in Bonke, Fitch, Millar, Eds. *Memory and awareness in anesthesia*. Amsterdam: Swets & Zeitlinger]. Salience also depends on the timbre and strength of the requesting person's voice, the manner in which the response is requested and, possibly, many other subtle factors. We tried to increase the emotional impact of the message by adding reassuring phrases, as had been done in the previous studies. Furthermore, we had the message recorded by the anaesthetist who also conducted the pre- and post-operative interviews, assuming this would make the voice more familiar to the patient. During all interviews, as well as on the tape, the anaesthetist clearly introduced himself to the patient, mentioning his name a number of times. This was done to increase the possibility that the voice was 'recognized'" (p. 409).

Rapee, Ronald M. (1991). The conceptual overlap between cognition and conditioning in clinical psychology. *Clinical Psychology Review*, 11, 193-203.

Given the fact that contemporary theories of conditioning regularly utilize information processing concepts such as memory and expectancies, classifying clinical theories as either cognitive or conditioned appears to be outdated. Yet, this dichotomy is still upheld in many clinical writings. Such a false dichotomy seems to serve more of a political function than a theoretical one and thus is likely to interfere with a complete understanding of psychopathology. While the terms conditioning and cognition are often used to imply unconscious learning on the one hand versus conscious, rational learning on the other, this usage is not consistent. A more empirically useful way to describe pathological behavior may be in terms of the amount of attentional resources utilized.

Van Der Kolk, Bessel; Van Der Hart, O. (1991). The intrusive past: The flexibility of memory and the engraving of trauma. *American Imago*, 48, 425-454.

Describes the work of Janet concerning narrative versus traumatic memory, dissociation, and subconscious fixed ideas. Janet (1904) believed PTSD patients suffer from a phobia for the traumatic memory. Repression and dissociation are distinguished. Contemporary concepts of memory processing and the concept of schemas are then reviewed. Finally, a model is presented about how the mind freezes some memories. Evidence for the involvement of autonomic hyperarousal, triggering, and state dependent learning in PTSD is reviewed. They conclude that helplessness and the inability of the PTSD victim to take action (psychological and physical immobilization) facilitates dissociation. Includes practical ideas for the working through of trauma.

## NOTES

p. 443 "Traumatic memories are triggered by autonomic arousal ... and are thought to be mediated via hyper-potentiated noradrenergic pathways originating in the locus coeruleus of the brain... The locus coeruleus is the 'alarm bell' of the central nervous system, which properly goes off only under situations of threat, but which, in traumatized people, is liable to respond to any number of triggering conditions akin to the saliva in Pavlov's dogs. When the locus coeruleus alarm gets activated, it secretes noradrenaline, and, if rung repeatedly, endogenous opioids. These, in turn, dampen perception of pain, physical as well as psychological (van der Kolk et al. 1989). These neurotransmitters which are activated by alarm affect the hippocampus, the amygdala and the frontal lobes, where stress-induced neurochemical alterations affect the interpretation of incoming stimuli further in the direction of 'emergency' and fight/flight responses" (p. 443).

1990

Bornstein, Robert F. (1990). Critical importance of stimulus unawareness for the production of subliminal psychodynamic activation effects: A meta-analytic review. Journal of Clinical Psychology, **46**, 201-210.

Performed meta-analysis that assessed the magnitude of behavior change produced by subliminal vs supraliminal drive-related stimuli (DRS) on 11 subliminal psychodynamic activation (SPA) studies (published 1966-1989) that employed both types of stimuli. The analysis revealed that subliminal presentation of DRS produced significantly stronger effects on behavior than supraliminal presentation of the same stimuli. Stimulus content, type of outcome measure, and S characteristics influenced the magnitude of subliminal/supraliminal response differences. Results support L. H. Silverman's (1983) hypothesis that DRS must be presented subliminally to produce SPA effects.

Kihlstrom, John F.; Schacter, Daniel L.; Cork, Randall C.; Hurt, Catherine A.; Behr, Steven E. (1990). Implicit and explicit memory following surgical anesthesia. Psychological Science, **1**, 303-306.

Paired associates were presented to 25 surgical patients following the induction of anesthesia by thiopental, vecuronium, and isoflurane. Postoperative testing (immediately or after two weeks) showed no free recall for the list; nor was there significant cued recall or recognition, compared to a matched control list. However, a free-association task showed a significant priming effect on both immediate and delayed trials. At least under some conditions, adequate surgical anesthesia appears to abolish explicit, but not implicit, memory for intraoperative events.

Kunzendorf, Robert G.; Jesses, Michael; Dupille, Leonard; Butler, William (1990-91). Subliminal activation of intrapsychic conflicts: Subconscious realms of mind vs subconscious processes of mentation. Imagination, Cognition and Personality, **10**, 117-128.

## NOTES

Cognitive-state monitoring theory asserts that people perceive subliminal stimulation without self-consciously monitoring its external innervation (as opposed to central innervation). Thus monitoring theory predicts that subconsciously perceived discord, in the absence of any 'external location' cues, should be misinterpreted as centrally generated discord and should disrupt self-generated behavior. Consistent with this prediction, mathematical problem-solving in the current experiment was disrupted after mathematically competitive males repeatedly heard the subliminal message IT'S WRONG TO CRUSH DADDY stereophonically localized in the middle of their heads--but not after they repeatedly heard this subliminal 'Oedipal' message binaurally localized on one side of their heads. A subliminal message binaurally localized on one side of the self should not interfere with problem-solving behavior \_because, even though the message's external innervation is not self-consciously 'monitored,' its external location is inferable from subconscious cues.\_

Monitoring theory asserts that subliminal [perceptions] of 'unmonitored' messages are unaccompanied by any self-consciousness that one is perceiving them (rather than imaging them), and that subliminal or 'unmonitored' messages of distress are mistaken for self-generated distress.

Disruption by the 'internal' subliminal word WRONG seems to us consistent with the fact that disruption was limited to mathematically competent males.

Indeed, 'repression' itself is a mode of processing fearful information: a mode in which subjects suspend their self-awareness that they are perceiving fearful stimulation, as research by Kunzendorf and McLaughlin has demonstrated. This selective suspension of monitoring provides immediate relief from fearful stimuli, Freudian or otherwise, but it does so at the risk of turning self-conscious fear into

subconscious anxiety (into consciously lingering fear without a self consciously perceived source). No subconscious realm full of lurking fears is implicated in this 'unmonitored' mode of self-protection. All that is implicated is an unconscious storehouse of potentially fearful memories--potentially fearful but sensationless memories, which can be 'suppressed' from conscious sensory representation or 'constructed' into conscious memory images or 'subconsciously represented' as unself-consciously imaged sensations.

Roediger, Henry L. III (1990). Implicit memory: Retention without remembering. American Psychologist, 45 (9), 1043-1056.

Explicit measures of human memory, such as recall or recognition, reflect conscious recollection of the past. Implicit tests of retention measure transfer (or priming) from past experience on tasks that do not require conscious recollection of recent experiences for their performance. The article reviews research on the relation between explicit and implicit memory. The evidence points to substantial differences between standard explicit and implicit tests, because many variables create dissociations between these tests. For example, although pictures are remembered better than words on explicit tests, words produce more priming than do pictures on several implicit tests. These dissociations may implicate different memory systems that subservise distinct memorial functions, but the present argument is that many dissociations can be understood by appealing to general principles that apply to both explicit and implicit tests. Phenomena studied under the rubric of implicit memory may have important implications in many other fields, including social cognition, problem solving, and cognitive development.

Weinberger, Joel; Hardaway, Richard (1990). Separating science from myth in subliminal psychodynamic activation. Clinical Psychology Review, 10, 727-756.

This paper reviews subliminal psychodynamic activation (SPA). Eight common criticisms are described and evaluated: (a) SPA data analysis is too liberal; (b) there are enough nonsignificant unpublished SPA studies to offset those showing effects; (c) SPA studies are difficult to replicate; (d) the claims of SPA proponents rely on unpublished studies; (e) SPA stimuli are not really subliminal; (f) experimenter expectancy effects and/or demand characteristics can account for SPA effects; (g) the mediating events said to underlay SPA effects have never been evinced; and (h) alternative explanations for SPA effects are superior to the psychoanalytic ones typically offered. Theoretical and statistical analyses revealed that only the argument concerning mediating events has serious merit. The SPA stimulus for which the most support was found was Mommy and I Are One. Oedipal sanction stimuli were also found to yield reliable effects whereas Oedipal prohibition stimuli did not. Suggestions for future research are offered. Resistance to SPA findings are considered in Kuhnian terms.

Wood, W. E.; Gibson, W.; Longo, D. (1990). Moderation of morbidity following tonsillectomy and adenoidectomy: A study of awareness under anesthesia. International Journal of Pediatric Otorhinolaryngology, 20, 93-105.

In a double-blind study, 67 children, ages 3-10, were randomly assigned to one of three groups: tape recorded therapeutic suggestions repetitively recited in English or in French, and a control of continuous white noise. The English condition was associated with more favorable outcome on all parameters, although statistical significance could not be demonstrated. Favorable outcomes appeared most significant for those patients at highest risk for poor convalescence (i.e., poor status preoperative patients).

1989

Blum, Gerald S. (1989). A computer model for unconscious spread of anxiety-linked inhibition in cognitive networks. Behavioral Science, 34, 16-45.

Unconscious inhibitory processes, triggered by a potential anxiety reaction, are reviewed in the context of an emerging rapprochement between psychodynamic and cognitive approaches in experimental psychology. Conditions underlying spread of inhibitory action to other cognitive networks are first explored in three tachistoscopic experiments utilizing words posthypnotically tied to a potential anxiety, pleasure, or neutral reaction. Response times of subjects, instructed to ignore those words while naming pictures or solving anagrams as quickly as possible, reveal a highly differentiated pattern of circumstances governing likelihood of inhibitory spread from anxiety-linked words to target stimuli. Next a computer model is constructed to simulate cognitive processes from onset of display to eventual response, and the model is then tested for its fit to the empirical data. Finally, an illustrative study shows that a subset of computer-generated predictions for spread of inhibitory action is verifiable experimentally.

Kihlstrom, John F.; Register, Patricia A.; Hoyt, Irene P.; Albright, Jeanne Sumi; Grigorian, Ellen M.; Heindel, William C.; Morrison, Charles R. (1989). Dispositional correlates of hypnosis: A phenomenological approach. International Journal of Clinical and Experimental Hypnosis, 37, 249-263.

Attempted to construct and validate a questionnaire measure of hypnotic-like experiences based on Shor's (1979) 8-dimension phenomenological analysis of hypnosis. Separate item pools were developed to measure each disposition: Trance, Nonconscious Involvement, Archaic Involvement, Drowsiness, Relaxation, Vividness of Imagery, Absorption, and Access to the Unconscious. Based on preliminary testing (total Number - 856), a final questionnaire was produced containing 5 items measuring normal, everyday experiences in each domain. Results from a standardization sample (Number - 468) showed that each of the subscales, except for Archaic Involvement, possessed satisfactory levels of internal consistency and test-retest reliability. Factor analysis indicated that 6 subscales loaded highly on a common factor similar to the absorption construct (Tellegen & Atkinson, 1974), while items pertaining to Relaxation and Archaic Involvement formed separate factors. Validation testing on 4 samples receiving the Harvard Group Scale of Hypnotic Susceptibility, Form A (HGSHS:A) of Shor and E. Orne (1962) (total Number = 1855) showed that the Absorption and Trance dimensions correlated most strongly with HGSHS:A; the correlations with Drowsiness, Relaxation, and Nonconscious Involvement approached 0. The scales derived from Shor's analysis, however, did not improve the prediction of hypnotizability over that obtained with the absorption scale (Tellegen & Atkinson, 1974).

## NOTES

Authors discuss a dual memory theory. The first memory system is prominent in early childhood, and is a system in which are organized and evoked by persons, locations, and emotions. Such memories are not easily "transportable" outside the original experience. These memories are accessed through images of face and place, actions, or feelings. The second memory system begins to develop in early childhood, is verbally mediated, and stores experiences in narrative form. Such memories are accessible through verbal interaction, and can be reviewed and shared with others verbally. For a small child, to access all of a memory one would need to tap into both memory systems. The authors

suggest that the first memory system continues to be available throughout one's life, especially when strong emotion was associated so that verbal cues are not attached. [This has implications for retrieval of "lost" memories using imagery-based approaches like hypnosis.]

Suler, John R. (1989). Mental imagery in psychoanalytic treatment. Psychoanalytic Psychology, 6, 343-366.

Mental imagery techniques may facilitate the therapeutic process by stimulating patients' insight into unconscious dynamics, by helping them uncover and master warded-off affect, and by enhancing the clinician's empathic contact and access to countertransference. The history of imagery techniques in the psychoanalytic movement and the effect of these techniques on the traditional psychoanalytic method are reviewed. A conceptual framework based on the theory of primary and secondary process suggests spontaneity, experiential scope, associative elaboration, and object impact as four dimensions for the clinical evaluation of imagery experience.

Van der Hart, O.; Friedman, B. (1989). A reader's guide to Pierre Janet on dissociation: A neglected intellectual heritage. Dissociation, 2 (1), 3-16.

A century ago there was a peak of interest in dissociation and dissociative disorders. Janet (1859-1947) was the most important scientific and clinical investigator of this period, whose work is reviewed in this article. The evolution of dissociation theory and its major principles are traced throughout his writings. His introduction of the term 'subconscious' and his concept of the existence of consciousness outside of personal awareness are explained. The validity and reliability of dissociation as the underlying phenomenon in a wide range of disorders is presented. It is proposed that Janet's theory and methodology of psychological analysis and dynamic psychotherapy are cogent and relevant for today.

1988

Borgeat, Francois; Rezanowicz, Thaddeus; Chaloult, Louis (1988). La stimulation preconsciente et consciente de l'imaginaire erotique. Revue Canadienne de Psychiatrie, 33, 394-398.

The stimulation of erotic fantasies through the association of relaxation and erotic conscious or preconscious suggestions has been evaluated. This study was attempted following positive results in the stimulation of fantasmatic activity in alexithymic subjects with a similar procedure. Thirty female subjects, allocated into three groups practiced relaxation daily for two weeks including three sessions with psychological measures. During the second week, erotic suggestions, preconscious for one group and conscious for another one were added. The third group (control) received only relaxation throughout. Results have shown an increase of sexual arousal and erotic imagery during the sessions with erotic suggestions. Sexual activities and desire increased in the two experimental groups. There was no difference between the effects of the preconscious and conscious suggestions. Possible clinical applications of such a procedure are discussed.

1987

Boswell, Louis K. (1987). Abstract imaging: Abstract imaging as a mode of personality analysis and adjustment. Medical Hypnoanalysis Journal, 2, 175-179.

Describes the use of abstract imaging during hypnosis to circumvent defense mechanisms and arrive at the initial sensitizing event behind a patient's emotional problems. Case examples illustrate how

abstract imaging is also used to explore how the patient relates to the world on a conscious level and forms an idealized self-image to work toward.

Goldmann, Les (1987, October). Ways of maximizing patient memory for events during anesthesia. [Paper] Presented at the annual meeting of the Society for Clinical and Experimental Hypnosis, Los Angeles.

#### NOTES

Reported a series of experiments: 1. Under atropine, we did not get an orienting response to things having to do with the operation, but did get an orienting response to jokes, dogs barking, and the name of a polite anesthetist. 2. Replicated the research by Bennett and didn't get ear pulling response. 3. Studied cardiac patients. Gave subjects a pre-anesthesia speech of importance [of hearing under anesthesia? Notes here are not clear.] and a chin touch suggestion that was successful. 7 of 30 subjects gave reports of recall - usually recalled something of particular interest to them. These 7 subjects appeared more anxious postoperatively than previously. 4. Recognition study: Pre-op "IQ" test. Gave subjects answers to the questions while they were under anesthesia, and postoperatively they had better performance than previously. 5. Recall study, double blind. Interviewer learned something about the patient, and told them something about what was learned about the patient during anesthesia e.g., You have a lovely garden. After surgery they were hypnotized by someone who did not know what information was given, and then recall for information "heard" under anesthesia was tested. 6. 10 female patients who were good hypnotic subjects, all received the same statement under anesthesia, that they would believe for a moment that they had green hair. During the interview, one said she was fascinated by green things, one wanted to go home and wash her hair.

Goldmann, Les; Shah, M. V.; Hebden, M. W. (1987). Memory of cardiac anesthesia: Psychological sequelae in cardiac patients of intra-operative suggestion and operating room conversation. Anesthesia, 42 (6), 596-603.

Thirty elective cardiopulmonary by-pass surgery patients were interviewed pre- and postoperatively. A random selection of patients heard a prerecorded audio tape toward the end of surgery after they were rewarmed to 37 degrees C. The tape contained suggestions for patients to touch their chin during the postoperative interview, to remember three sentences, and to recover quickly. The interviewers were blind to the experimental conditions. The experimental group touched their chins significantly more often than the control group ( $p = .015$ ). Sentence recognition did not reach significance, perhaps due to the small numbers and low salience of the stimuli. Seven patients (23%) recalled intraoperative events, five with the aid of hypnosis. Three reports (10%) were corroborated. Preoperative medication ( $p < .01$ ) and postoperative anxiety ( $p < .05$ ) were significant predictors of those patients who reported recall.

Kihlstrom, John F. (1987). The cognitive unconscious. Science, 237, 1445-1452.

Contemporary research in cognitive psychology reveals the impact of nonconscious mental structures and processes on the individual's conscious experience, thought, and action. Research on perceptual-cognitive and motoric skills indicates that they are automatized through experience, and thus rendered unconscious. In addition, research on subliminal perception, implicit memory, and hypnosis indicates that events can affect mental functions even though they cannot be consciously perceived or remembered. These findings suggest a tripartite division of the cognitive unconscious into truly unconscious mental processes operating on knowledge structures that may themselves be preconscious or subconscious.

Stolzy, Sandra L.; Couture, Lawrence J.; Edmonds, Harvey L., Jr. (1987, October). Partial recall of events occurring during general anesthesia. [Paper] Presented at the annual meeting of the Society for Clinical and Experimental Hypnosis, Los Angeles.

The incidence and causes of awareness during anesthesia are subjects of controversy. It is often assumed that the degree of recall of events occurring during general anesthesia is directly related to the depth of anesthesia. However, patients who are apparently adequately anesthetized have experienced such recall. A randomized double-blind study using a standardized anesthetic protocol was conducted to determine if recall of intraoperative events occurs following deep anesthesia. Fifteen-minute tape recordings consisting of repetitions of either six nonsense words (control) or six uncommon words (target words) were presented to patients under deep surgical anesthesia. Within 48 hours after anesthesia, they were asked to choose the six words that were most familiar from a list of thirty-six uncommon words. When compared with the control group, the patients who heard the six target words selected those words from the list at a rate significantly greater than chance ( $P < 0.04$ ). None of the patients had any conscious recall of an intraoperative event.

1986

Chertok, Leon (1986). Psychotherapeutic transference, suggestibility. Psychotherapy, 23 (4), 563-569.

Discusses suggestion in psychotherapy and defines it as a body-affective process, an indissociable psychosociobiological entity that acts at an archaic unconscious level far beyond that of transference, mediates the influence of one individual on another, and is capable of producing manifest psychological and physiological changes. Present in all types of therapy, indirect (nondeliberate, nonintentional) suggestion is the element that plays an important role in change and can be observed in hypnotic experimentation. It is further argued that transference and suggestion are phenomena that do not altogether overlap. Suggestion is the condition of transference without which transference could not be established.

Kissin, Benjamin (1986). Conscious and unconscious programs in the brain. (1 ). New York: Plenum Press.

## NOTES

Hypnosis is discussed in terms of inhibition/excitation mechanisms in the central nervous system, with both feedback and feedforward controls and lateralizing controls. The author employs a concept of engrams (neural representations of an idea, represented throughout the neocortex) to discuss sensation and perception as well as conscious and unconscious processes. Sensory information is processed serially with encoding of information mostly on the conscious level (but sometimes, less efficiently, on the unconscious level); and it also is processed in parallel. Parallel processing operates almost entirely at the unconscious level and is basic to perception.

Associative phenomena are explained in terms of overlapping engrams, so that two 'related hypercomplex engrams' could be assumed to have at least one simple engram in common. With Premack, he describes three types of engrams: veridical (primary sensory data perceived), abstract (formalized representations of concepts like line drawings of dog or house; Premack's iconic representations), and symbolic (more complex entities that encompass an entire class of objects, actions, or ideas and may have artificial symbols such as words).

With Neiser he suggests that thinking (verbal and nonverbal) involves logical sequential processing of cognitive engrams of external (environmental), internal (visceral), and intracerebral (ideational) origin. Evoked response investigations shed light on the nature of such engrams, their distribution in brain

tissue. John, Bartlett, Slumokochi, & Kleiman (1973) found that an error in choice discrimination learning (cats learning colors) is accompanied by the cortical evoked potential of the stimulus associated with that (erroneous) behavior, not the evoked potential of the true stimulus. In other words, ERPs represented the idea, not the actual visual stimulus provided to the cat.

Emotional/motivational influences are part of every cognition (R. S. Lazarus's position). Interaction of motivational-emotional and cognitive engrams seems to occur primarily in the inferior temporal lobe and the entorhinal cortex. The interaction involves the upper rhinencephalon, the amygdaloid-hippocampal complex, the septal region, the cingulate gyrus, and the inferior and medial aspects of temporal lobe of the cortex. He also explains classical and operant conditioning (on pp. 75-76) in terms of the association of engrams.

The author's position is that consciousness is the subjective equivalent of brain activity in the 'alerting' and 'awareness' systems. Awareness of the environment ('general, vague') appears to involve the limbic area (thalamus and basal ganglia), while more specific awareness of the self entails a system stretching from the basal ganglia through the parietal lobe (posterior aspect).

Normal alert consciousness involves the noradrenergic reticular activating system, as well as associated excitation of the general awareness system in the involved thalamic- basal gangliar nuclei and the self-awareness system in the posterior inferior parietal lobe system. Altered states of consciousness characterized by a relaxed hazy sense of the world involves thalamic activation of the self-awareness system. Dreaming involves activation from cholinergic cells in the pons. "Impaired general awareness occurs with lesions of the thalamic-basal gangliar centers while impaired self-awareness occurs with lesions in the posterior inferior parietal lobes. Finally, in certain physiological states such as sleep, hypnosis, and so on, the entire awareness system--the thalamic-basal gangliar and posterior inferior parietal nuclei--may be activated by different activation systems, such as the cholinergic in the pons or the dopaminergic in the thalamus, to produce different states of consciousness" (p. 82).

Consciousness is described as having seven dimensions: alertness, attention, arousal (heart rate, GSR), activation (EEG, evoked potential), affect, and the two awarenesses. The seven are related, so that changes in any one usually are correlated with changes in others (though dissociation among the seven also can be demonstrated). Motivational-emotional arousal produces electrophysiological activation of the brain, which is translated epiphenomenally into alertness and awareness; awareness is focused through attention onto the cognitively and motivationally significant events in the internal and external environments to determine the final sequence of drive-oriented behavioral responses.

The EEG is useful for diagnosing different states of consciousness: beta and gamma waves alertness, stemming from locus coeruleus and

reticular activating system delta (2-4/sec) waves coma alpha synchronized relaxing influences stemming from

thalamus; low level of awareness as in twilight sleep

or hypnagogic states theta, delta inactivity due to less stimulus from locus coeruleus

reticular activating system influences; associated

with increased inhibitory thalamic and septal-

hippocampal impulses radiating upward to the

cortex.

In some altered states of consciousness there is theta-wave activity, indicating influences from the inhibitory septal-hippocampal circuit.

The reticular activating system (RAS) and thalamus interact in complex ways. The RAS is essential to maintain consciousness, but if destroyed stepwise (in animal research) a low-grade type of consciousness can be maintained by thalamus and basal ganglia. The thalamus has two kinds of influence: it inhibits the cortex, as in sleep; and stimulates the cortex in the form of activating alpha waves. "The median thalamus is also related in a feedforward-feedback circuit with the inhibitory

septal-hippocampal complex which generates theta-wave activity, thus accounting for the close association between alpha and theta wave activity in sleep and in other altered states of consciousness" (p. 86).

Thus there are two different activating systems originating in the lower brain stem: the norepinephrine locus coeruleus system that is associated with normal behavior, and the cholinergic FTG neurone system of REM sleep. The relationship of the latter to consciousness, awareness, self awareness, etc. is unknown, since the only time that it is readily observed is during REM sleep. The author reports that altered states of consciousness (e.g. hypnosis, fugue, alpha state) resemble Stage 1 sleep, rather than REM sleep, physiologically, with the central locus of activation in the medial thalamus rather than the RAS and locus coeruleus.

"It appears then that consciousness may be driven by one or another of three different activation centers: the norepinephrine RAS (emanating from the locus coeruleus), the cholinergic FTG cell system in the pons, and the dopaminergic alpha rhythm system radiating upward from the thalamus (Fig. 6-2). Brain activation by each of these centers is associated with a different state of awareness" (p. 91). The relative contribution from each center determines qualitative aspects of awareness.

The author refers to Mesulam and Geschwind (1978) who traced the self-awareness system from amygdala/hippocampus/midbrain to the inferior parietal lobe where they converge with the body's proprioceptive neural tracts. What results is "a sense of self that was not necessarily present in the sense of general awareness stemming from the median thalamic-basal gangliar complex" (p. 97).

The thalamic-basal gangliar complex is both a center for emotional reception and a relay station for somatosensory events. Both somatic sensory reception and somatosensory elements of emotion are also represented in the parietal lobe. "Affective and somatosensory stimuli, which are constant and persistent even though we are unaware of them most of the time, produce the sense of one's body which is the most basic element in the 'sense of self.'... It is most probable that a major component of the sense of self is produced by the constant barrage of affective and somatosensory stimuli converging from all parts of the body; the majority of these stimuli may not reach consciousness most of the time but they must register a sense of feeling in the thalamus and parietal cortex even though the individual may be unconscious of it" (p. 100).

The author presumes that most of the incoming stimuli that define self are unconscious. "Whether sense-of-self stimuli are unconscious because of constant habituation ... or whether they are unconscious because they are transmitted predominantly to the right hemisphere ..., it appears that the major components of the self-concept are unconscious rather than conscious" (p. 102).

"Even the acutely self-aware component of the self-concept, by definition conscious, varies markedly in different altered states of consciousness. The conscious awareness of oneself in the alert condition is different from (1) that in the twilight state, (2) that in dreams, (3) that in hypnosis, (4) that under the influence of alcohol, (5) that under the influence of other sedatives, (6) that under the influence of stimulants, and (7) that under the influence of hallucinogens. In that sense the acute sense of self is a function of the momentary chemical and physiological state of the brain" (p. 102).

"... the decision-making apparatus of the brain is lodged largely in a consortium of neocortical centers including the prefrontal lobes (integration), the posterior inferior lobes (motivation and emotion), the anterior and posterior associational areas (cognition), the posterior inferior parietal lobes (self-awareness), the left-hemispheric language centers (language), and the precentral frontal lobe motor area (motor). Within the context of this integrated cortical complex, self-awareness functions are somewhat stronger on the right hemisphere while language and decisional activities are somewhat stronger on the left" (pp. 102-103).

The Chapter titled "Attention as directed consciousness" is relevant for investigations of hypnosis but is not included in these notes.

Miller, Mary E.; Bowers, Kenneth S. (1986). Hypnotic analgesia and stress inoculation in the reduction of pain. Journal of Abnormal Psychology, 95, 6-14.

Investigated the influence of hypnotic ability on 3 methods of reducing cold-pressor pain. Following a baseline immersion, 30 high- and 30 low-hypnotizable undergraduates were randomly assigned to 1 of 3 treatment groups: stress inoculation training, stress inoculation training defined as hypnosis, or hypnotic analgesia. Analysis of pain reports indicated a significant hypnotic ability x treatment interaction. Among Ss receiving hypnotic analgesia, high-hypnotizables reported significantly less intense pain than lows. There was no differential response for high- and low-hypnotizable Ss receiving stress inoculation training, whether or not it was defined as hypnotic. Moreover, Ss in the stress inoculation condition (whether or not defined as hypnosis) reported using cognitive strategies to reduce pain, whereas this was not the case for Ss in the hypnotic analgesia condition. The present findings seem inconsistent with the social psychological account of hypnosis and are discussed from a dissociation perspective, which views hypnosis as involving changes in the way information is processed.

Eich, Eric; Reeves, John L.; Katz, Ronald L. (1985). Anesthesia, amnesia, and the memory/awareness distinction. Anesthesia and Analgesia, 64, 1143-1148.

Several studies have shown that surgical patients cannot consciously recall or recognize events to which they had been exposed during general anesthesia. Might evidence of memory for intraoperative events be revealed through the performance of a postoperative test that does not require remembering to be deliberate or intentional? Results of the present study, involving the recognition and spelling of semantically biased homophones, suggest a negative answer to this question and imply that intraoperative events cannot be remembered postoperatively, either with or without awareness.

## NOTES

In this experiment, we attempted to apply the distinction between memory and awareness of memory to the question of whether adequately anesthetized and apparently unconscious patients can register and retain what is said in their presence during surgery. Prior research relating to this question has focused, for the most part, on the ability of postoperative patients to recall or recognize a specific item....The inference need not be drawn, however, that 'patients in so-called surgical planes of anesthesia cannot hear' (15, p. 89) or that anesthetized patients cannot encode and store in memory events that transpire during their surgery. The possibility remains that even though the effects of memory for intraoperative events may not--and probably cannot--be revealed in postoperative tests of retention that require remembering to be deliberate or intentional, such effects might be evident in the performance of tests that do not demand awareness of remembering.

"To explore the possible dissociation between memory and awareness of memory for intraoperative events, we modeled our experiment after a recent neuropsychological study by Jacoby and Witherspoon (5)" (p. 1143).

"...it appears that the prior presentation of a word has a substantial impact on its subsequent interpretation and spelling, regardless of whether or not the word is correctly classified as 'old' in a later test of recognition memory" (p. 1144).

"Approached from the standpoint of anesthesia theory and practice, the idea that recognition and spelling tap different memory processes or systems raises an interesting question for research. Specifically, suppose that during surgery, an anesthetized patient listens to a series of short, descriptive phrases, each consisting of a homophone and one or two words that bias the homophone's less common interpretation (e.g., war and PEACE, deep SEA). Suppose further that several days after surgery, the patient is read a list composed chiefly of old and new homophones (i.e., ones that either had or had not been presented intraoperatively) on two successive occasions. On one occasion, the patient is simply asked to spell each list item aloud; on the other occasion, the patient is asked to state aloud which list items he or she recognizes as having been presented during surgery. Given the situation sketched above, might the patient spell significantly more old than new homophones in line with their less common interpretations, and yet fail to reliably discriminate between the two types of items in the test of recognition memory" (p. 1144).

Kaplan, Rosalind (1985). Further data on the effects of subliminal symbiotic stimulation on schizophrenics. Journal of Nervous and Mental Disease, 173 (11), 658-666.

Examined the effects of activating unconscious symbiotic fantasies in 128 hospitalized schizophrenic men (aged 18-65 years) who qualified as relatively differentiated on an adjective rating scale and were randomly assigned to 4 groups. Each group was assessed for pathological thinking, pathological nonverbal behavior, and self-esteem before and after the subliminal exposure of an experimental and control stimulus. The control stimulus for all groups were the messages "Mommy and I are one," "Mommy is always with me," "Mommy feeds me well," and "I cannot hurt Mommy""(one for each group). One-half of each group was subliminally exposed to verbal messages only and one-half to verbal messages accompanied by congruent pictures. The 1st stimulus ("Mommy and I are one") was intended to activate unconscious symbiotic fantasies that in a number of prior studies reduced pathology in groups of relatively differentiated schizophrenics. The other stimuli were intended to activate reassuring unconscious fantasies about "Mommy" that were not specifically symbiosis-related. Only the "Mommy and I are one" stimulus led to more adaptive behavior and did so on all 3 dependent variables. This supported the supposition that it is specifically symbiosis-related gratifications that are ameliorative for schizophrenics. (23 ref.)

Oliver, J. M.; Burkham, Robert (1985). 'Comments on three recent subliminal psychodynamic activation investigations': Reply to Silverman. Journal of Abnormal Psychology, 94 (4), 644.

Contends that the present authors' (see PA, vol 69:1571) failure to replicate L. H. Silverman's (1976) description of subliminal psychodynamic activation, which was disputed by Silverman (see PA, vol 73:12007), can be traced in part to Silverman's (1978) description of the "symbiotic" stimulus (MOMMY AND I ARE ONE"), 1 of the 2 experimental stimuli used, as a "ubiquitous therapeutic agent". It is suggested that, although Silverman's willingness to modify his theory in light of empirical findings is commendable, modifications that are too frequent and numerous will pose problems for both theory and research. (5 ref)

Porterfield, Albert L.; Golding, Stephen L. (1985). Failure to find an effect of subliminal psychodynamic activation upon cognitive measures of pathology in schizophrenia. Journal of Abnormal Psychology, 94 (4), 630-639.

Replicated the work of L. H. Silverman and colleagues (see PA, vols. 43:14557 and 46:1566) using 30 21-59 year old schizophrenics. Ss were exposed to an aggressive, a merging, and a meaningless lexical stimulus in a within-S design. Dependent variables were inkblot through pathology and form quality, as measured on Rorschach and Holtzman Inkblot Techniques, and performance on the interference task of the Stroop Color-Word Test. Analyses of variance conducted on simple poststimulation scores, rather than on unreliable change scores, revealed no effect of stimulus content. Predicted interactions between stimulus content, Ss self-object differentiation, and temporal position of the assessment tasks did not emerge. Findings do not support Silverman's hypothesis that subliminal tachistoscopic presentations of stimuli with aggressive content temporarily increase thinking disorder in schizophrenics. (44 ref.)

Porterfield, Albert L. (1985). 'Comments on three recent subliminal psychodynamic activation investigations': Reply to Silverman. Journal of Abnormal Psychology, 94 (4), 645-646.

#### NOTES

Contends that in defending his nonverbal pathology measure against the claim that it lacks demonstrated validity, L. H. Silverman (see PA, vol 73:12007) painted a misleading picture of its face validity. A correction to that picture is presented, and the impact of the present author and S. L. Golding's (see PA, vol 73:11992) findings on subliminal psychodynamic activation explanations of schizophrenic thought disorder is defended, despite the absence of a nonverbal pathology measure. (5 ref)

Silverman, Lloyd H. (1985). 'Comments on three recent subliminal psychodynamic activation investigations': Rejoinder to Oliver and Burkham and to Porterfield. Journal of Abnormal Psychology, 94 (4), 647-8.

Considers the replies of A. L. Porterfield (see PA, vol 73:11991) and J. M. Oliver and R. Burkham (see PA, vol 73:11985) to the critique of the present author (see PA, vol 73:12007). The original criticisms are seen as valid. A critical deficiency in the design of Porterfield and S. L. Golding's (see PA, vol 73:11992) study is viewed as disqualifying it as a fair attempt at replication. It is suggested that although Oliver and Burkham's (see PA, vol 69:1571) study was well-designed, statements made in their write-up are unwarranted. (12 ref)

Silverman, Lloyd H. (1985). Comments on three recent subliminal psychodynamic activation investigations. Journal of Abnormal Psychology, 94 (4), 640-643.

Contends that unwarranted statements about subliminal psychodynamic activation research by the present author (1976, 1983, 1984) were made in the work of J. M. Oliver and R. Burkham (see PA, vol. 69:1571); K. C. Haspel and R. S. Harris (see PA, vol 69:4952) and A. L. Porterfield and S. L. Golding (see PA, vol 73:11992). Issues considered include the choice of subliminal stimuli, the present author's statistical analyses, and the necessity of a nonverbal measure of psychopathology in this research (17 ref).

Silverman, Lloyd H. (1985). Research on psychoanalytic psychodynamic propositions. Clinical Psychology Review, 5 (3), 247-257.

Discusses a research program in which the present author has been involved that deals with the subliminal psychodynamic activation method. In this method, verbal and/or pictorial stimuli, some of which contain content related to unconscious wishes, fears, and fantasies and other of which are (relatively) neutral, are presented to Ss at 4-msec exposures. A variety of psychoanalytically based hypotheses have been tested on various clinical and nonclinical populations. Two major findings have emerged: (a) a number of clinical groups (e.g., schizophrenics, depressives, stutterers) have shown intensifications of their symptoms after the subliminal exposure of stimuli designed to stir up particular unconscious conflicts; and (b) various clinical and nonclinical groups have manifested enhanced adaptive behavior after the subliminal exposure of the message "Mommy and I are one," conceived as activating unconscious symbiotic fantasies.

Tranel, Daniel; Damasio, Antonio R. (1985, June). Knowledge without awareness: An autonomic index of facial recognition by prosopagnosics. Science, 208 (4706), 1453-1454.

Prosopagnosia, the inability to recognize visually the faces of familiar persons who continue to be normally recognized through other sensory channels, is caused by bilateral cerebral lesions involving the visual system. Two patients with prosopagnosia generated frequent and large electrodermal skin conductance responses to faces of persons they had previously known but were now unable to recognize. They did not generate such responses to unfamiliar faces. The results suggest that an early step of the physiological process of recognition is still taking place in these patients, without their awareness but with an autonomic index.

#### NOTES

Research on confirmatory bias has uncovered additional cognitive processes that are frequently automatic in function and significant in modifying behavior, affect, and cognition. Snyder and Swann (1976, 1978) provided subjects with set inducing hypotheses about the personalities of certain target individuals. Subjects were then asked to test these hypotheses by interviewing the target individuals. It was found that subjects regularly looked for and found evidence that was consistent with their initial hypotheses rather than for evidence which could show these hypotheses to be incorrect. This biased search strategy of the subjects had more profound effects as well, for it also influenced the behaviors of the target individuals in a manner leading them to produce behaviors that seemed to confirm the original mental set of the subjects. Subjects were unaware that their manner of interviewing was

producing a biased sample of behavior from the targets. Here too an automatic cognitive process was affecting perception and thinking without conscious awareness" (p. 280).

Bryant-Tuckett, Rose; Silverman, Lloyd H. (1984). Effects of the subliminal stimulation of symbiotic fantasies on the academic performance of emotionally handicapped students. Journal of Counseling Psychology, 31 (3), 295-305.

Divided 64 10.8 - 19.3 yr old emotionally disturbed residents of a treatment school into an experimental and control group matched for age, IQ, and reading ability. Both groups were seen 5 times/week for 6 weeks for tachistoscopic exposures of a subliminal stimulus. The stimulus for the experimental group was the phrase, "Mommy and I are one," conceived of as activating symbiotic fantasies that in a number of previous studies with varying groups of Ss had led to greater adaptive behavior. The control group was exposed to the phrase, "People are walking." Results show that experimental Ss manifested significantly greater improvement on the California Achievement Tests--Reading than did the controls. On 5 of 6 secondary variables--arithmetic achievement, self-concept, the handing in of homework assignments, independent classroom functioning, and self-imposed limits on TV viewing--the experimental Ss showed better adaptive functioning. It is suggested that activation of unconscious symbiotic fantasies can increase the effectiveness of counseling and teaching. (42 ref)

Crabtree, Adam (1984, October/1986). Explanations of dissociation in the first half of the twentieth century. In Quen, Jacques M. (Ed.), Split minds/split brains (pp. 85-108). New York: New York University Press. (Based on symposium in Bear Mt., N.Y., by Section on the History of Psychiatry of Cornell University Medical Center)

In 1907 Morton Prince, Editor of Journal of Abnormal Psychology, introduced a symposium by listing 6 meanings of subconscious: 1. that portion of our field of consciousness which is outside the focus of attention 2. (Janet's idea) - split off ideas which may be isolated sensations like the lost tactile sensation of anesthesia, or maybe aggregated into groups or systems. The author quotes Janet as stating that "they form a consciousness coexisting with the primary consciousness and thereby a doubling of consciousness results" (p. 87). The primary consciousness is usually dominant, but sometimes is reduced under exceptional conditions (e.g. automatic writing). 3. the subconscious self or hidden self -- a part of every human, not just seen in psychopathology; this is a personalized entity; every mind has a double, with the unconscious self having powerful effects on feelings, thoughts, and reactions of the conscious self 4. extends #3 to include not only ideas that remain active below surface but also those which are inactive -- forgotten or out of mind 5. Frederic Myers' concept of the 'subliminal self' which had 3 functions:

- a) inferior - seen in processes of dissociation
- b) superior - seen in works of genius, arising from 'subliminal rush' of information, feelings, and thoughts which lie below consciousness
- c) mythopoeic - the unconscious tendency to create fantasies 6. physiological meaning, e.g. William Carpenter's 'unconscious cerebration' in which unconscious phenomena are interpreted in terms of pure neural processes unaccompanied by mental activity.

Prince suggested some redefinitions to clarify unconscious and subconscious. He would replace Janet's subconscious with co-conscious and reserve unconscious for physiological processes that lack the attributes of consciousness. Prince noted that co-conscious ideas have been called unconscious (e.g. by Freud) but said that is confusing and to be avoided.

"Coconscious ideas include states we are not aware of because they are not the focus of our attention, and also pathologically split-off and independently active ideas or systems of ideas, such as occur in hysteria and reach their most striking form in co-conscious personalities and automatic writing.

"Prince prefers the term coconscious to Janet's subconscious for two reasons. First, because it expresses the simultaneous coactivity of a second consciousness. And second, because the coactive ideas or idea systems may not be outside the awareness of the personal consciousness at all. They may be recognized by the personal consciousness as a distinct consciousness existing alongside it.

"Thus, through his redefinition of terms, Prince makes simultaneous activity of two or more systems of consciousness in one individual the key element in dissociation. He thereby moves the issue of amnesia or lack of awareness by one system of another into the background, making it a secondary, nonessential element. Prince was one of the few to provide a theoretical framework for dissociation in which any combination of interawareness among the coconscious systems was possible" (p. 91).

Two researchers at the turn of the century came to opposite conclusions about the nature of the Subconscious Self that every human has. Morris Sidis saw it as "a brutelike consciousness with a tendency toward personalization. Frederic Myers held that it included those functions and much more, being the source of all that is human, including the highest intuitive powers" p. 96.

Bernard Hart, in 1910, did an analysis of Janet and Freud. Janet's work is essentially descriptive: "he is always talking about a consciousness which manifests itself in a way we can perceive, whether by listening to it talk, reading its written communications, or watching its movements" (p. 97). However Janet's spatial model of dissociation cannot explain the presence of the same material (e.g. memories) in two or more dissociated systems. According to Hart, Freud offered the conceptualization that Janet lacked, in his idea of the Unconscious .

Freud's Unconscious is not in competition with Janet's subconscious. "Janet's subconscious is the arena of dissociated phenomena which manifest in observable form as elements coactive with the personal self. Freud's unconscious is a conceptual, nonobservable construction put forward to explain certain facts of human experience. In this way Hart equates the unconscious with the atomic theory in physics or the theory of heredity in biology" p. 99. But Hart also thought Freud's theory did not do justice to dissociative phenomena. Not only do psychoanalysts show little interest in double personality or multiple personality, they also neglected dissociation on the phenomenal level.

In 1915 Freud denied the existence of a second consciousness and wrote, "there is no choice for us but to assert that mental processes are in themselves unconscious, and to liken the perception of them by means of consciousness to the perception of the external world by means of the sense organs" (p. 101). Janet claimed that Freud had simply taken over his own system and given it a new terminology, and in 1924 Freud wrote an angry rebuttal. For him, "dissociated systems are simply separate groups of mental but unconscious elements. As our consciousness turns now to one group, now to another, as a searchlight shines now on one object and now on another, the dissociated groups manifest in conscious life. ... There exists no doubling of consciousness" p. 102.

Jung's ideas were closer to those of Janet, and like Janet he made dissociation a key concept in his theory. The complex is unconscious, has an archetypal core clothed in personal experience, is like a self-contained psyche within the big psyche, sometimes called a fragmentary personality dwelling inside us. Dissociation for him meant being cut off from the Ego, which is the center of an individual's field of consciousness. "Dissociated or autonomous complexes are those which have no direct association with the ego" (p. 103). If complexes are charged with enough energy they will become manifest--as a neurotic symptom, as projected into idea of a god or demon, or perhaps as an alternate personality. Therefore Jungian treatment aims at assimilating dissociated complexes into the ego.

Decker, Hannah S. (1984, October/1986). The lure of nonmaterialism in materialist Europe: Investigations of dissociative phenomena, 1880-1915. In Quen, Jacques M. (Ed.), Split minds/split brains (pp. 31-62). New York: New York University Press. (Based on symposium in Bear Mt., N.Y., by Section on the History of Psychiatry of Cornell University Medical Center)

NOTES

**Emphasizes spiritism, hypnotism, and the career of Pierre Janet.**

**Janet's career paralleled an increased interest in dissociation, because he had contact with scientists studying spiritism, used hypnosis, and insisted on a scientific approach. He coined the words "subconscious" and "dissociation." As his sphere of influence declined, so did scientific interest in dissociation--especially multiple personality disorder.**

**Scientific study of dissociation began with investigations into religious exorcism and spirit possession. For example, at the behest of Prince Max Joseph of Bavaria, Mesmer duplicated the exorcisms of Father Gassner (causing convulsions) using hypnosis. Following Mesmer, there were reports of multiple personalities (e.g. an "exchanged personality" in Germany, reported in 1791 by Eberhardt Gmelin).**

**"Partly because of this growth of knowledge of multiple personality, a new model of the mind developed during the early 19th century: the mind was dual; there were conscious and unconscious mental states. Later, it was said that there was a dominant conscious personality with a group of underlying subpersonalities. Eventually it was declared that split fragments of personality could act autonomously" p. 37.**

**The scientific study of these phenomena continued under the leadership of Frederic Myers of The Cambridge Society for Psychical Research. According to William James, Myers was the first to consider the phenomena of hallucination, hypnotism, automatism, double personality, and mediumship as connected parts of one whole subject. The Cambridge Society was involved in the transition from the use of automatic writing by mediums to its use for clinical purposes and experimental research in the 1880's and 1890's.**

**Increasing numbers of multiple personalities reported in the literature in late 19th century led to increased interest in hypnosis and to the concept of dissociation. The author details the contributions of Janet, and then explains how interest declined in dissociation and in hypnosis due to the following:**

**1. Experimental psychologists in Germany (e.g. Wundt) refused to deal with anything that resembled the "unconscious," and neglected the point of view of the experiencing person. 2. Those few psychologists interested in the unconscious found projective tests (Rorschach, TAT) an easier avenue than hypnosis or automatic writing. 3. Many mediums were exposed as frauds, e.g. Flournoy's popular "From India to the Planet Mars". 4. Janet himself was very critical of parapsychology. 5. When Charcot died suddenly, it was discovered that some of his assistants had rehearsed the behavior of hypnotized patients. 6. Hypnotists' extravagant claims (e.g. past life age regression) led to a wave of reaction against them. 7. Questions were raised about the iatrogenic nature of multiple personality. 8. Conscientious hypnotists discovered drawbacks**

**- not everyone could become good hypnotists (e.g. Freud)**

**- not everyone could be hypnotized**

**- some patients faked hypnosis**

**- extreme sensitivity of hypnotized patients to the hypnotist's wishes led to biased results**

**- hypnotist sometimes was conditioned to things in certain way by his first patient**

**9. Janet didn't have the personality of a leader, and he argued with the psychoanalysts about who should get credit for certain ideas**

**Frauman, David C.; Lynn, Steven Jay; Hardaway, Richard; Molteni, Andrew (1984). Effect of subliminal symbiotic activation on hypnotic rapport and susceptibility. Journal of Abnormal Psychology, 93 (4), 481-483.**

**L. H. Silverman's subliminal symbiotic activation paradigm (Silverman, 1982) was used to manipulate unconscious affective factors in hypnosis to determine whether gratification of symbiotic fantasy would enhance hypnotic susceptibility and rapport with the hypnotist. Seventy-two male undergraduates were divided into two groups matched for susceptibility (high, medium, low). The experimental group**

received symbiotic, MOMMY AND I ARE ONE, subliminal stimulation via tachistoscope in a double-blind design. The comparison group received a psychodynamically neutral stimulus, PEOPLE ARE WALKING. Following subliminal stimulation, subjects were hypnotized individually. Projective tasks that indexed rapport with the hypnotist and the mother were administered during hypnosis. Rapport was also measured by rated intimacy of self-disclosure topics and by valence of topics selected to disclose to the hypnotist. A significant multivariate group selected more positively valenced topics to disclose on. The effect for symbiotic activation on hypnotic susceptibility was not quite significant ( $p < .056$ , two-tailed).

## NOTES

2350, Frauman, Lynn, Mare, & Kvaal, 1992 NOTES: [Paper presented by Lynn.] A number of observations and conclusions are based on literature reviews done with Brentar (British Journal of Experimental and Clinical Hypnosis; Chapter in Rhue, Lynn, & Kirsch [Eds.] Handbook of Clinical Hypnosis) and 15 years of training students in hypnotherapy. Some of this may seem elementary to some of you.

For half a century there have been reports of negative effects after hypnosis: minor, serious, transient, and chronic. Clinicians need be as wary (but no more wary) of negative effects in hypnosis as in other therapies. There are more negative effects in clinical situations than non clinical situations.

Therapists must be prepared to recognize negative effects and intervene.

Too often hypnosis is seen as a technique divorced from psychotherapy. The hypnotist must be a competent psychotherapist. What makes you a good therapist will make you a good hypnotherapist.

There should be careful assessment of the client for: 1. those with history of unusual experiences following anesthesia or drugs 2. those with a history of dissociation

People may recapitulate a previous bad experience with anesthesia, based on the unusual physiological feelings. The dissociative client must be stabilized before using hypnosis. Depressed clients may also have problems, with the imagery becoming dysphoric. Those vulnerable to psychotic decompensation, with paranoid or borderline character structures, must be evaluated carefully. A lot depends on your comfort zone in therapy.

Life experiences with parents and authority figures may also play into the reaction.

Many clients, and experimental Ss, are ambivalent about hypnosis. This ambivalence must be acknowledged and one must work with the ambivalence before proceeding. One may: - explain hypnosis - reframe in terms of self hypnosis or relaxation - explain as a state of awareness with full consciousness - offer active induction which is just as effective as the passive induction - do induction with eyes open

Research clearly shows that Subjects can monitor events outside the framework of a suggestion-- especially if you suggest they can do so with ease.

We do not use ideomotor suggestions because they aren't necessary. We tell them to open their eyes and communicate with us during hypnosis.

We always assess their feelings about hypnosis, have them have a fantasy about what hypnosis would be like, do an informal semantic analysis of the descriptors clients use (and then reframe them), inquire about previous experiences with counseling and psychotherapy, and do a mental status. Don't make assumptions. We want to know about early life experiences to know about transference and form an alliance.

Hypnosis procedures employed must have explicit informed consent (cf MacHovic book), which also provides opportunity to demystify the experience. Our research shows the great majority of Ss find it relaxing, invigorating. Even perceptual distortions can be created without hypnosis. Can create confidence by sharing the research information on hypnosis.

Elicit cooperation with easier suggestions, then use graded suggestions. We want to titrate the demands on clients, move at a pace that keeps anxiety low, promote self efficacy and mastery through ... [missed a few words] and graduated tasks.

Carefully monitor clients for frowns, lack of attention, etc. It is important to ask them what they are experiencing. Rarely, a client appears unable to talk, in which case the therapist can offer hypotheses to the hypnotized client.

Don't terminate hypnosis if there is a problem (Orne also says this); instead, offer reassurance to explore/release the feelings. It is beneficial to work through what is being experienced. There is a somewhat higher risk of emotional reactions with age regression or induced dreams. We simply tell people they can tell us at any time about what they are experiencing, without going through any ritual. When we give suggestions about amnesia, we ask what they would like to remember and suggest that they forget what they would like to forget. The usual permissive suggestion doesn't work; find out what it is, exactly, that they want to forget and then devise strategies for it. Follow for 2 weeks after any abreactive experience that may have occurred. Let them know they can contact you.

Forceful suggestions to abandon symptoms can promote resistance and the therapist may generate negative transference. (See their chapter in book edited by Rhue, Lynn, and Kirsch, *Handbook of Clinical Hypnosis*, published by the Amer Psychological Association.)

Palumbo, Robert; Gillman, Irene (1984). Effects of subliminal activation of oedipal fantasies on competitive performance: A replication and extension. *Journal of Nervous and Mental Disease*, 172 (12), 737-741.

Conducted a subliminal psychodynamic activation experiment in which the effects of 5 subliminal stimuli were sought on the dart-throwing performance of 40 male Ss (aged 22-46 years). The stimuli consisted of the following messages, each accompanied by a congruent picture: "beating dad is ok," "beating dad is wrong," "beating him is ok," "beating him is wrong," and "people are walking." The 1st 2 stimuli were intended to activate competitive motives within the context of the Oedipus complex; the next 2, competitive motives outside that context; and the last message was intended as a control stimulus. Findings show that "beating dad is ok" led to greater dart-throwing accuracy than each of the other 4 conditions, which, in turn, did not differ from each other. This finding replicates a result reported by L. H. Silverman et al (1978) and is in keeping with the formulation that the activation of oedipal motives can affect competitive performance (7 ref)

Smith, Mark Scott; Kamitsuka, Michael (1984). Self-hypnosis misinterpreted as CNS deterioration in an adolescent with leukemia and Vincristine toxicity. *American Journal of Clinical Hypnosis*, 26 (4), 280-282.

A thirteen year-old girl with leukemia was taught self-hypnosis techniques for symptom control. She was hospitalized with probable vincristine toxicity and a superimposed hyperventilation syndrome. Her spontaneous use of the self- hypnosis technique was misinterpreted as central nervous system deterioration until her apparently comatose state resolved with suggestions from the therapist.

Zamansky, Harold S.; Bartis, Scott P. (1984). Hypnosis as dissociation: Methodological considerations and preliminary findings. *American Journal of Clinical Hypnosis*, 26, 246-251.

Three criteria are proposed to be met by any experience labeled as "dissociation." A preliminary experiment is described that illustrates one way in which two of these criteria may be operationalized, and that assesses the relationship between successful performance on the two criteria and hypnotic

susceptibility. The results are viewed as consistent with Hilgard's (1977) hypothesis that hypnotic susceptibility and the ability to dissociate are positively related.

## NOTES

The authors propose that for dissociation to be present: "1) The individual must be engaged in two or more cognitive processes concurrently. 2) These processes must occur simultaneously, i.e., without recourse to alternation between them. 3) One of these processes must be perceived (by the subject) to occur below the level of conscious awareness, i.e., must seem to be autonomous or nonvolitional" (p. 247). In this study they focus on the first two criteria, as well as the relationship between ability to perform two cognitive tasks simultaneously and Subjects' hypnotizability.

The authors used a dichotic listening task, with Ss instructed to listen to both auditory inputs at once. One input was a short story that was to be followed with 12 multiple choice questions. The other ear received 3 tones every 2 seconds (the higher tone 60% of the time, lower tone 40% of the time) and S was to press a button in response to the low tones. Speed of presentation of tones was intended to reduce the opportunity for alternating back and forth between tasks.

Of 28 volunteer students, 22 passed criteria for accuracy on both tasks when performed singly: 10 high hypnotizables (Harvard Group Scale of Hypnotic Susceptibility; HGSHS > 8); 10 medium hypnotizables (HGSHS 5-8); and 2 low hypnotizables who were dropped from the data analysis. They were considered 'dissociators' if they met the criterion of passing 9 or more items of the story and simultaneously having fewer than 15% errors on the tones, on two separate trials with two different stories.

"Of the 20 subjects, four scored above criterion on both test trials and were classed as dissociators; these four also scored as highly hypnotizable on the HGSHS. Accordingly, 40% of the highly hypnotizable subjects met our criteria, while not one of the moderately hypnotizable subjects reached this level of performance" (p. 249).

In their Discussion, the authors wrote, "The results demonstrated that highly hypnotizability Ss are significantly better able to attend to two inputs simultaneously than are moderately hypnotizability Ss. These results provide preliminary empirical evidence that dissociative ability, assessed independently of hypnosis, may be an important factor underlying hypnotic behavior" (p. 249).

The authors speculated about why only 40% of the highly hypnotizable people performed successfully, suggesting that it may be because they had misclassified Ss with the HGSHS which may be less demanding than other scales, or that "while dissociation represents an important cognitive factor in hypnosis, the Harvard measures mostly ideomotor performance" (p. 250). They suggest using a hypnotizability scale that uses more cognitive items to select highly hypnotizable Subjects who would demonstrate a high degree of dissociative ability. The other possibility that they mention is that dissociation may be only one of several alternate paths to hypnosis, citing Hilgard (1965).

The Experimenters added two control groups, one given the stories without the competing tones, the other given identical questions but without actually hearing the stories. The first group answered a mean of 9.7 and 8.6 questions correctly; the second control group answered a mean of 2.9 and 3.8 questions correctly.

1982

Chertok, Leon (1982). The unconscious and hypnosis. International Journal of Clinical and Experimental Hypnosis, 30 (2), 95-107.

This paper reviews Soviet approaches to the unconscious and to hypnotic phenomena, before examining psychoanalytic theories of hypnosis which are generally based on transference. The author believes the existing theories are inadequate, arguing that there is a psychophysiological dimension to

hypnosis; but what unconscious processes does this conceal? Psychoanalysis opened one road to the unconscious, but affect, nonverbal communication, and psychophysiological process are still uncharted territories towards which hypnosis may yet prove to be another royal road.

#### NOTES

The author concludes, "hypnosis and the unconscious ... are closely linked. Historically, experiments on posthypnotic suggestion were in fact the starting point for the discovery of the unconscious. Posthypnotic suggestion is in effect one of the most irrefutable proofs that psychical contents can influence behavior, albeit eluding the subject's consciousness.

"In this paper, the present author provides a description of Soviet researchers' conceptions of the unconscious, and of the point of view from which they approach hypnotic phenomena. Psychoanalytic theories of hypnosis are then presented, which are essentially based on transference. It is shown why this notion seems to the present author powerless to account for the specific nature of the hypnotic relationship. There is, in effect, a psychophysiological dimension to hypnosis. It lies at the crossroads between the instrumental and the relational dimension. But nothing is known about what unconscious processes hide at the psychophysiological level. Psychoanalysis has brought to light the laws governing the functioning of unconscious representations. But the realm of the affect, the nonverbal communication, and bodily processes still remain beyond our knowledge. This is a hidden side of the unconscious, in relation to which hypnosis may serve as another 'royal road'" (pp. 104-105).

1980

Fromm, Erika (1980). Values in hypnotherapy. Psychotherapy: Theory, Research and Practice, 17 (4), 425-430.

Hypnosis is an altered state of consciousness characterized by a regression in the service of the ego along with increased access to the unconscious. This makes it possible to achieve lasting therapeutic results faster in hypnosis than in the waking state. Hypnosis is also a state of decreased vigilance, a vulnerability that involves dangers if a patient is in the hands of a poorly trained, incompetent, or unscrupulous therapist. In general, the same human and moral values that guide responsible therapists with patients in the ordinary waking state must guide them with patients in hypnosis, only more so. Contemporary permissive hypnotherapists do not superimpose their own wills or personalities onto patients but provide support, help patients face the frightening parts of the unconscious, and thus aid them in coping with conflicts and gaining full autonomy and freedom from fear. (11 ref).

Shevrin, Howard; Dickman, Scott (1980). The psychological unconscious: A necessary assumption for all psychological theory?. American Psychologist, 35 (5), 421-434.

The notion of complex psychological processes operating outside of awareness has traditionally been associated with the concept of the unconscious used by psychodynamically oriented clinicians; it has never found an equivalent place in the mainstream of American experimental psychology. However, mounting evidence from several rather diverse fields of empirical research (e.g., selective attention, cortical evoked potentials, subliminal perception) provides support for such a concept, and, in fact, explanatory constructs of a similar nature have been embodied in several current models of perceptual processing. While there clearly remains an enormous gap between the clinically based conception and the experimentally based conception of the nature of these unconscious processes, they nevertheless seem to provide an interface between two seemingly disparate approaches to the understanding of personality.

Stam, Henderikus J.; Radtke-Bodorik, Lorraine; Spanos, Nicholas P. (1980). Repression and hypnotic amnesia: A failure to replicate and an alternative formulation. Journal of Abnormal Psychology, 89 (4), 551-559.

In an attempt to replicate and extend a study by S. R. Clemes, 2 groups of 10 undergraduate hypnotic Ss learned a list of 18 words and were given an amnesia suggestion telling them they would be able to remember only 10 of these words. Half of the list words were critical (i.e., considered to be related to repressed conflictual material) and half were neutral (unrelated to conflictual material) as determined by Ss' responses to a word association test. Experimental Ss received their own critical and neutral words and yoked control Ss received the critical and neutral words of experimental Ss. Neither the experimental nor the yoked control group exhibited selective amnesia in favor of critical words, thus constituting a failure to replicate Clemes's result. However, variables affecting the degree to which words were initially learned (e.g., imagery value, serial position) predicted their resistance to amnesia. These findings are inconsistent with a repression hypothesis but congruent with an inattention hypothesis of suggested amnesia. (41 ref).

1979

Bennett, Henry L.; Giannini, Jeffrey A.; Kline, Mark D. (1979, September). Consequences of hearing during general anesthesia. [Paper] Presented at the annual meeting of the American Psychological Association, New York.

A double blind 2X2 study exposed 23 herniorrhaphy and cholecystectomy patients to either a 45 minute suggestion tape or to the actual sounds of the operation. Structured interviews conducted postoperatively assessed hypnotic susceptibility and regressed patients under hypnosis to operative events. Ten patients accurately recalled significant events from surgery but only under hypnosis. Recall was greater and more accurate in patients scoring high on the Stanford Clinical Hypnosis Scale. Fewest number of pain medications were given postoperatively to patients receiving the suggestion tape. Hernia patients showed better recall than gallbladder patients.

Thompson, Kay F. (1979). The case against relaxation. In Burrows, G. D.; Collison, D. R.; Dennerstein, L. (Ed.), Hypnosis 1979 (pp. 41-46). Amsterdam: Elsevier/North-Holland Biomedical Press.

NOTES

One wonders why facilitators continue to talk about and insist on relaxation as a precondition for hypnosis. Do we need to see this relaxation to believe our patients are truly in a hypnotic state?" (p. 43). "The advantages of eliminating relaxation as a precondition for trance include the elimination of the need to re-learn the non-relaxed state, the admission of more natural responses to the therapeutic situation, the recognition of spontaneous trance, and a freer communication between the doctor and patient which should result in a more comfortable use of hypnosis and its more widespread acceptance in medicine" (p. 45).

1978

Bowers, Patricia G. (1978). Hypnotizability, creativity and the role of effortless experiencing. International Journal of Clinical and Experimental Hypnosis, 26, 184-202.

NOTES

Creative people and highly hypnotizable people describe their experience of finding creative solutions or responding to hypnotic suggestions as "effortless." It is suggested that receptiveness to subconscious work accounts for the experience of effortlessness in both tasks. An experiment using 32 high and low

hypnotizable men and women was designed to explore the hypothesis that the aptitude for such effortless experiencing accounts for the relationship found between creativity and hypnotizability. Analyses of variance indicate highly significant effects of level of hypnotizability on composite scores reflecting effortless experiencing of several tasks and creativity. Intercorrelations of these indices are about .60. As predicted, effortless experiencing accounts for much of the relationship between high versus low hypnotizability and composite creativity. The role of imagery vividness and of absorption in both hypnotizability and creativity were also explored.

1977

Avila, Donald; Nummela, Renate (1977). Transcendental meditation: A psychological interpretation. Journal of Clinical Psychology, 33 (3), 842-844.

The authors suggest that Transcendental Meditation offers a great deal of promise for use in helping relationships. They also suggest that the technique might receive wider acceptance if it could be explained in other than a purely philosophical or mystical way. For that reason, in their article they offer a psychological interpretation of the TM process.

Trustman, R.; Dubovsky, S.; Titley, R. (1977). Auditory perception during general anesthesia -- myth or fact. International Journal of Clinical and Experimental Hypnosis, 25 (2), 88-105.

Reports have appeared periodically in the literature indicating that surgical patients can hear and be influenced by remarks occurring while they are under general anesthesia. Much of the evidence has been obtained by postoperatively studying patients under deep hypnosis. The present article discusses the empirical status of this phenomenon, "auditory perception during anesthesia." 14 selected studies regarding auditory perception during general anesthesia were critically reviewed. All were found to have serious deficiencies as evidence for or against the occurrence of auditory perception during general anesthesia. Methodological and theoretical difficulties of conducting research into auditory perception during general anesthesia were discussed, and suggestions for future research were offered.

1974

Galín, David (1974). Implications for psychiatry of left and right cerebral specialization: A neurophysiological context for unconscious processes. Archives of General Psychiatry, 31 (4), 572-583.

A brief review is presented of hemispheric specialization for different cognitive modes, and of the symptoms that follow disconnection of the two hemispheres by commissurotomy. Our present knowledge of the hemispheres' cognitive specialization and potential for independent functioning provides a framework for thinking about the interaction of cognitive structures, defensive maneuvers, and variations in awareness. Parallels are noted between some aspects of the mental processes of the disconnected right hemisphere and some aspects of primary process thinking and repression. The hypothesis is proposed that in normal intact people mental events in the right hemisphere can become disconnected functionally from the left hemisphere (by inhibition of neuronal transmission across the cerebral commissures), and can continue a life of their own. This hypothesis suggests a neurophysiological mechanism for at least some instances of repression and an anatomical locus for the unconscious mental contents.

1972

Sacerdote, Paul (1972). The nature of the hypnotherapeutic process. American Journal of Clinical Hypnosis, 15 (1), 1-11.

The author presents several clinical cases where hypnosis was successfully utilized. Through detailed description of what takes place during sessions it is shown how various approaches are adapted to the intellectual, cultural, emotional and hypnotic capabilities of the patient and to the progress of therapy. The author analyzes what takes place during and after hypnotic intervention and draws some conclusions about the nature of the hypnotherapeutic process which, he feels, is essentially a convergence of the patient's and therapist's conscious and subconscious expectations and goals. The importance of the therapeutic ego of the doctor is brought into proper focus. One of the clinical cases illustrates how the therapist can convert a therapeutic relationship that may appear sterile or even hostile into a productive one by utilizing the patient's responses, while avoiding stubborn insistence upon expectations of preconceived hypnotic responses. It is suggested that the hypnotherapeutic model may present, in clearer focus, what takes place in other psychotherapeutic exchanges which do not utilize hypnosis.

1968

**Reyher, Joseph; Smeltzer, William (1968). Uncovering properties of visual imagery and verbal association. Journal of Abnormal Psychology**

21 young males were asked to 'image' or to 'associate' to 10 words from each of 3 categories representing sex, hostility, and family relationships. Imagery was found to produce heightened GSR activity, more primary process, more direct representation of drives, and less effective defense. The superiority of visual imagery over verbal association as an uncovering technique was attributed to the relative ease with which unconscious processes can influence imagery

1961

**Hatfield, Elaine C. (1961). The validity of the LeCron method of evaluating hypnotic depth. International Journal of Clinical and Experimental Hypnosis, 9, 215-221.**

The purpose of this study was to check the relationship between estimations made by the LeCron measure of hypnotic depth and scores secured by the same S on the Stanford Hypnotic Susceptibility Scale. The correlations between the two measures were low, though significant. The mean of estimates requested from the Ss' "unconscious" correlated .84 with those made by the "conscious," suggesting that the 2 judgments may not be independent. From Psyc Abstracts 36:04:4II15H. **Pearson, R. E. (1961). Response to suggestion given under general anesthesia. American Journal of Clinical Hypnosis, 4, 106-114.**

Employed a double-blind design with placebo control. Audio tapes containing therapeutic suggestions were played to 43 experimental patients during anesthesia. The main theme of the suggestions was that the patient would cope better and recover faster if he could become relaxed. Placebo tapes (music or blank tapes) were played to the 38 control patients. Only E, who had no contact with the patients, knew which tape was played to a given patient. Three postoperative variables were studied: (a) number of doses of narcotics in the first 5 postoperative days; (b) a numerical rating by the surgeon of the postoperative course; and (c) number of postoperative days until release. Although no significant differences were found between the suggestion group and placebo group on need for narcotics or rated course of recovery, patients receiving suggestions were discharged an average of 2.42 days sooner (p < .05).

Raginsky, Bernard B. (1961). The sensory use of plasticine in hypnoanalysis (sensory hypnoplasty). International Journal of Clinical and Experimental Hypnosis, 9 (4), 233-247. (Abstracted in Psychological Abstracts, 62: 4 II 33R)

Modelling with plasticine under hypnosis (hypnoplasty) allows the patient to give plastic expression to suppressed or repressed material. The author claims that this approach finds the patient quite unprepared to use his usual defenses, resulting in a very rapid and remarkable ventilation of unconscious material. Several clinical cases demonstrating the use of sensory hypnoplasty are presented. From Psyc Abstracts 36:04:4II33R. (PsycINFO Database Record (c) 2002 APA, all rights reserved)

1960

Weitzenhoffer, Andre M. (1960). Reflections upon certain specific and current uses of the unconscious in clinical hypnosis. International Journal of Clinical and Experimental Hypnosis, 8 (3), 165-178.

(Author's Summary)

"Three examples of the use of "unconscious" manifestations by medical hypnotists have been examined and questions raised with regard to the interpretation which has been placed upon the results. Certain basic weaknesses inherent in the procedures employed have been pointed out and shown to be a source of confounding. A final question has been raised with regard to the so-called "wisdom" of the "unconscious." The main conclusion derived in each case considered is that there is little justification for assuming that some sort of psychic entity, "the unconscious" has been communicated with or is responsible for the observed phenomena" (p. 177).

1955

Meares, Ainslie (1955). A note on the motivation for hypnosis. Journal of Clinical and Experimental Hypnosis, 3 (4), 222-228. (Abstracted in Psychological Abstracts 57: 1129)

"Summary. The logical reasons of the patient for desiring hypnosis, and of the therapist in advising it, operate on a background of unconscious mechanisms. These mechanisms are important factors in determining whether or not the logical reasons become effective. An understanding of such motivation helps the therapist in the selection of cases and the choice of the particular form of hypnotherapy to be used" (p. 228).

Patient motivations for hypnosis include magical expectations, paranoid belief that one is under the control of a malevolent influence, a (paradoxical) belief that hypnosis will be ineffective with neurotic symptoms and therefore justify continuation of the symptoms, latent aggression ("hypnotize me if you can" attitude) or an excess of passivity ("humiliate me"), erotic motivation or a wish for a more intimate relationship with the therapist, search for new or unusual experiences in life, a last ditch effort to cope with chronic pain and illness, etc.

Patient motivations against hypnosis include fear of being overpowered or the threat of authority, aggressive feelings that would be motivated if the hypnotist seems to be an authority, or association of hypnosis with the erotic. The author has observed "a surprising number of people" with the latter association. "With these people, it is more of an attitude of mind in which any close or intimate relationship is regarded as erotic. They see in hypnosis an intimate relationship with the therapist, and they avoid it without being aware of their reasons for doing so" (p. 226).

Therapist motivations for hypnosis include unconscious mechanisms as well, such as a drive for power (sometimes manifested in desire to demonstrate the technique to a wider audience than simply colleagues in a workshop). When tinged with eroticism the drive can become sadistic. Also, erotic

drives can find vicarious expression as "The intensity of the rapport between patient and psychotherapist in waking psychotherapy, is increased many times in hypnosis" (p. 227).

Therapist motivations against hypnosis include fear of failure (which is more obvious when a patient doesn't follow a suggestion than in lack of response to medicine), fear of erotic involvement, fear of one's own aggression, etc.

Stokvis, Berthold (1955). Hypnosis and psychoanalytic method. Journal of Clinical and Experimental Hypnosis, 3, 253-255. (Abstracted in Psychological Abstracts, 57: 1157)

The author distinguishes between hypnosis/psychoanalysis and 'hypno-analysis' which Hadfield previously described as a combination of hypnotic catharsis and re-educative suggestions.

At the Leyden Clinic the author uses one of several methods to "apply hypnosis together with the utilization of psychoanalytic principles. ... [It] consists in a cathartic-analytic treatment of the patient in the waking state, while endeavouring to re-enact repressed psycho-traumatic events of the past, in the hypnotic state. The experiences in question are subsequently discussed with the patient and elucidated" (p. 253)

1954

LeCron, Leslie M. (1954). A hypnotic technique for uncovering unconscious material. Journal of Clinical and Experimental Hypnosis, 2, 76-79. (Abstracted in Psychological Abstracts, 54: 7497)

"Summary. A technique is given whereby unconscious material and information may be learned under hypnosis through automatic movements of the fingers, or of Chevreul's pendulum. The movements are controlled by the unconscious mind of the patient. Questions are asked which can be answered either 'yes' or 'no.' With most people the movements of the pendulum can even be elicited in the waking state. Essentially, the method is a variation of automatic writing with movements substituted for writing. A brief case history is given wherein knowledge was gained in this way as to the causes for severe menstrual pains" (p. 79).

1953

## NOTES

The author presents a case in which the patient complained of headaches to illustrate a theoretical position, described as follows in the Introduction: "For example, many psychotherapists regard as almost axiomatic that therapy is contingent upon making the unconscious conscious. When thought is given to the unmeasurable role that the unconscious plays in the total experiential life of a person from infancy on, whether awake or asleep, there can be little expectation of doing more than making some small parts of it conscious. Furthermore, the unconscious as such, not as transformed into the conscious, constitutes an essential part of psychological functioning. Hence, it seems more reasonable to assume that a legitimate goal in therapy lies in promoting an integrated functioning, both singly and together, and in complementary and supplementary relationships, as occurs daily in well-adjusted living in contrast to the inadequate, disordered and contradictory manifestations in neurotic behavior" (p. 2).

Raz, Amir; Shapiro, Theodore; Fan, Jin; Posner, Michael (2002). Hypnotic suggestion and the modulation of Stroop interference. Archives of General Psychiatry, 59, 1155-1161.

**This study was designed to determine whether a hypnotic suggestion to hinder lexical processing could modulate the Stroop effect. Behavioral Stroop data were collected from highly suggestible and 16 less suggestible subjects; both naturally vigilant and under posthypnotic suggestion. Subjects were urged to only attend to the ink color and to impede reading the stimuli under posthypnotic suggestion. Whereas posthypnotic suggestion eliminated Stroop interference for highly suggestible subjects, less suggestible control subjects showed no significant reduction in the interference effect. This outcome challenges the dominant view that word recognition is obligatory for proficient readers, and may provide insight into top-down influences of suggestion on cognition. **This study was designed to determine whether hypnosis can modulate color perception. Such evidence would provide insight into the nature of hypnosis and its underlying mechanisms. Eight highly hypnotizable Ss (aged 20-35 yrs) were asked to see a color pattern in color, a similar gray-scale pattern in color, the color pattern as gray scale, and the gray-scale pattern as gray scale during positron emission tomography scanning by means of [<sup>-sup-1-sup-50</sup>]C0-sub-2. The classic color area in the fusiform or lingual region of the brain was first identified by analyzing the results when Ss were asked to perceive color as color vs when they were asked to perceive gray scale as gray scale. The results show that when Ss were hypnotized, color areas of the left and right hemispheres were activated when they were asked to perceive color, whether they were actually shown the color or the gray-scale stimulus. These brain regions had decreased activation when Ss were told to see gray scale, whether they were actually shown the color or gray-scale stimuli. These results were obtained only during hypnosis in the left hemisphere, whereas blood flow changes reflected instructions to perceive color vs gray scale in the right hemisphere, whether or not Ss had been hypnotized. **Dane, Joseph R. (1996). Hypnosis for pain and neuromuscular rehabilitation with multiple sclerosis: Case summary, literature review, and analysis of outcomes. International Journal of Clinical and Experimental Hypnosis, 44 (3), 208-231.**

Videotaped treatment sessions in conjunction with 1-month, 1-year, and 8-year follow-up allow a unique level of analysis in a case study of hypnotic treatment for pain and neuromuscular rehabilitation with multiple sclerosis (MS). Preparatory psychotherapy was necessary to reduce the patient's massive denial before she could actively participate in hypnosis. Subsequent hypnotic imagery and posthypnotic suggestion were accompanied by significantly improved control of pain, sitting balance, and diplopia (double vision), and a return to ambulatory capacity within 2 weeks of beginning treatment with hypnosis. Evidence regarding efficacy of hypnotic strategies included (a) direct temporal correlations between varying levels of pain relief and ambulatory capacity and the use versus nonuse of hypnotic strategies, (b) the absence of pharmacological explanations, and (c) the ongoing presence of other MS-related symptoms that remained unaltered. In conjunction with existing literature on hypnosis and neuromuscular conditions, results of this case study strongly suggest the need for more detailed and more physiologically based studies of the phenomena involved. - Journal Abstract

Crawford, Helen J.; Kapelis, Lia; Harrison, David W. (1995). Visual field asymmetry in facial affect perception: Moderating effects of hypnosis, hypnotic susceptibility level, absorption, and sustained attentional abilities. International Journal of Neuroscience, 82 (n1-2), 11-23.

Effects of hypnotic level, affect valence and cerebral asymmetry on reaction time (RT) in the discrimination of Ekman and Friesen (1978) stimuli of angry and happy faces were studied in counterbalanced conditions of waking and hypnosis. Assessed previously on two hypnotic susceptibility scales (Harvard Group Scale of Hypnotic Susceptibility; Stanford Hypnotic Susceptibility Scale, Form C (SHSS:C)], non-depressed subjects were 16 low (0-4 SHSS:C) and 17 highly (10-12 SHSS:C) hypnotizable, right-handed college students. Subjects were required to identify affect of faces, presented tachistoscopically to left (LVF) or right (RVF) visual fields, by using a forced-choice RT paradigm. Highs were significantly faster than lows in angry and happy affect recognition. Hypnosis had no significant effects. For highs only, angry emotional valence was identified faster when presented to the right hemisphere (RVF), but there were no significant hemispheric effects for happy emotional valence. For lows there were no hemispheric differences. Gender was a nonsignificant factor. Significant correlations showed that faster reaction times to angry and happy stimuli, in both LVF and RVF in waking and hypnosis, were obtained by subjects who reported more deeply absorbed and extremely focused and sustained attention on the Tellegen (1982) Absorption Scale and a subscale of the Differential Attentional Processes Inventory (Grumbles & Crawford, 1981). Vividness of Visual Imagery Questionnaire (Marks, 1973) and Affect Intensity Measure (Larsen, 1985), in general, did not correlate with RTs. The potential role of the fronto-limbic attentional system in the recognition of external visual sensory affect is discussed.

Atkinson, Richard P. (1993, October). Shifts in Muller-Lyer Illusion difference thresholds: Are high hypnotizables more sensitive than lows in hypnosis?. [Paper] Presented at the annual meeting of the Society for Clinical and Experimental Hypnosis, Arlington Heights, IL

## NOTES

Refers to Wallace (1979) finding that hypnotizability correlates with afterimage persistence. Atkinson showed highs perform better than lows in perceptual tasks in hypnosis only. Also studies indicate highs are more susceptible to illusions. Our study showed difference in threshold and point of subjective equality for highs and lows.

32 undergraduates had Harvard and Group Stanford Form C, were 9-12 or 0-3 on both scales. Counterbalanced conditions of waking and hypnosis. Used computer monitor to compare length of lines. Waking condition Ss had to close eyes for 15 minutes before the trials, same length of time as for hypnosis condition.

Significant interaction between hypnotizability and sessions was observed: highs had significantly decreased difference thresholds in hypnosis compared to waking, and significantly decreased difference thresholds compared to lows in hypnosis. Thus they had greater sensitivity than lows.

The point of subjective equality ANOVA did not yield significant effects.

Highs show higher sensitivity to illusion in hypnosis than in waking, and more than the lows.

McCormack, K.; Gruzelier, J. (1993). Cerebral asymmetry and hypnosis: A signal-detection analysis of divided visual field stimulation. Journal of Abnormal Psychology, 102 (3), 352-357.

These authors studied the effect of hypnosis on brightness discrimination with the aid of a signal-detection procedure in three sessions, the second with hypnosis. After two or three training sessions with hypnosis, which involved listening to a taped hypnotic relaxation induction, subjects were subdivided into high- and medium-susceptible groups on the basis of a 'scale inspired by the Stanford Scales.' High-susceptible subjects were found to show increases in perceptual sensitivity in the left visual field (right hemisphere) with hypnosis, whereas medium-susceptible subjects showed bilateral enhancements. The attitudes, or criterion set by the subjects remained invariant in both groups across the three sessions. It was concluded that the results provided evidence of altered brain function with hypnosis and an association of focal right hemispheric changes with high susceptibility, and through the invariance of motivational factors, failed to support the attribution of perceptual changes to attitudinal, non-state factors.

1992

Atkinson, Richard P.; Crawford, Helen J. (1992). Individual differences in afterimage persistence: Relationships to hypnotic susceptibility and visuospatial skills. American Journal of Psychology, 105 (4), 527-539.

To investigate the moderating role of individual differences in hypnotic susceptibility and visuospatial skills on afterimage persistence, we presented a codable (cross) flash of light to 40 men and 46 women who had been dark adapted for 20 minutes. In an unrelated classroom setting, subjects had previously been given two standardized scales of hypnotic susceptibility (Harvard Group Scale of Hypnotic Susceptibility, Shor & Orne, 1962; Group Stanford Hypnotic Susceptibility Scale, Form C, Crawford & Allen, 1982) and the Mental Rotations Test (Vandenberg & Kuse, 1978). The first afterimage interval and the afterimage duration correlated significantly with hypnotic responsiveness, supporting Wallace (1979), but did not show the anticipated relationships with mental rotation visuospatial skills. Individuals in the high hypnotizable group had (a) significantly longer afterimage intervals between its first appearance and first disappearance than did those in low groups, but those in medium groups did not differ significantly from the other groups. Discriminant analysis using the afterimage persistence measures classified correctly 65.2% of high hypnotizables, 37.5% of medium hypnotizables, and 54.8% of low hypnotizables. Hypothesized cognitive skills that assist in the maintenance of afterimages and underlie hypnotic susceptibility include abilities to maintain focused attention and resist distractions over time and to maintain vivid visual images.

NOTES

Because there is no apparent evidence for physiological differences of the visual system between low and high hypnotizables (e.g., Wallace, 1979), cognitive factors are suggested as possible moderators of afterimage persistence.

"Hypnotic susceptibility per se is not the moderator of afterimage duration. Rather, we argue that hypnotic susceptibility represents a constellation of underlying cognitive skills (e.g., for reviews, see Crawford, 1989; Kihlstrom, 1985) that assist an individual to respond to hypnotic suggestions as well as assist in the persistence of afterimages by interacting with more primary casual mechanisms that are physiological in origin. These cognitive skills are thought to include the abilities to focus attention selectively upon both external stimuli and internally generated images, to maintain vivid visual images, to sustain attention over time and remain absorbed in the experience at hand, and to resist distractions. The relationships between these cognitive skills and hypnotic susceptibility are reported in a large body of literature (e.g., Crawford, 1982, 1989; Crawford et al., 1991; Crawford & Grumbles, 1988; Finke & Macdonald, 1978; Grumbles & Crawford, 1981; Mitchell, 1970; Tellegen & Atkinson, 1974)....

"Sustained and selective attention without interference from extraneous stimuli plays an important role in hypnosis. Individuals who are responsive to hypnosis demonstrate greater skills in extremely focused and sustained attention (e.g., Crawford et al., 1991; Tellegen & Atkinson, 1974). Electrophysiological research had found that high hypnotizables often generate substantially more theta electroencephalogram (EEG) power than do low hypnotizables (e.g., Crawford 1990, 1991; Crawford & Gruzelier, 1992; Sabourin, Cutcomb, Crawford, & Pribam, 1990). Such a relationship may be interpreted as further evidence of greater attentional skills in highs, because certain theta waves have been correlated with enhanced problem solving and attentional task performance (e.g., Crawford & Gruzelier, 1992; Schacter, 1977)....

"Hypnosis is seen often as a condition of amplified attention, where attention can be either more focused or diffuse dependent upon set (e.g., Krippner & Binder, 1974). Increases in vigilant performance during hypnosis have been reported, albeit inconsistently (e.g., Barabasz, 1980; Fehr & Stern, 1967; Kissen, Reifler, & Thaler, 1964; Smyth & Lowy, 1983). Fehr and Stern's results suggest that hypnotized subjects devote more attention to a primary task with less available attentional resources for a secondary task. Hypnosis has been found to have an enhancing effect on the imaginal processing of information-to-be-remembered that consists of literal or untransformed representations of pictorial or nonverbal information for high but not low hypnotizables (Crawford & Allen, 1983; Crawford, Nomura, & Slater, 1983; Crawford, Wallace, Nomura, & Slater, 1986). This may possibly be the result of increased attention and/or shifts in cognitive strategies. Supportive of the hypothesis that sustained attention can be enhanced during hypnosis, Atkinson (1991) recently found that high but not low hypnotizables report significantly more persistent afterimages in hypnosis than in waking.

"Although we have argued for a cognitive explanation for individual differences in afterimage persistence and their possible relationship to hypnotic susceptibility and sustained attentional abilities, as has Wallace (1979, 1990), we must point out the possibility that high hypnotizables may be more suggestible to imagery instructions or more willing to discuss or experience imagery than low hypnotizables, particularly in the context of hypnosis and hypnotic susceptibility testing (e.g., Zamansky, Scharf, & Brightbill, 1964). A contextual account of the longstanding relationship between hypnotic susceptibility and absorption was raised by Council, Kirsch, and Hafner (1986), but was not supported by two independent, and more methodologically sound, studies reported by Nadon, Hoyt, Register, and Kihlstrom (1991). The context of hypnosis was not an issue in the present study, because none of the subjects was aware of the investigated relationship between afterimage persistence and hypnotic susceptibility at the time of recruitment or participation" (pp. 533-535).

Kay, L. M. (1992, October). The effects of hypnosis, relaxation, and suggestion on visual acuity (Dissertation, California School of Professional Psychology, San Diego). Dissertation Abstracts International, 53 (4), 2065-B. (Order No. DA 9221587)

Evaluated the relative efficacy of several aspects of the hypnotic process on facilitating change in hypnotic state-dependent visual acuity in myopic student subjects. Five conditions included hypnosis with suggestions, neutral hypnosis, nonhypnotic suggestion, progressive relaxation, and a control (comedy). Visual acuity was assessed as baseline (a task-motivational situation where they were to try to see as well as possible) and after the experimental condition. Results found that hypnosis facilitated a significant improvement in visual acuity ( $p = .002$ ), although no differences were found in the other conditions" (p. 2065).

Spanos, Nicholas P.; Burgess, C. A.; Cross, P. A.; MacLeod, G. (1992). Hypnosis, reporting bias, and suggested negative hallucinations. Journal of Abnormal Psychology, 101, 192-199.

Examined the role of reporting bias in hypnotic negative hallucinations by using a paradigm in which reporting bias was assessed independently of perceptual change. In Experiment 1, highly hypnotizable subjects reported significant loudness reductions when tested for hypnotic deafness. Later, however, these subjects biased their reported loudness reductions in the absence of perceptual change, and their reporting bias scores were almost as large as their hypnotic deafness reports. Subjects also biased their ratings of strategy use. In Experiment 2, ratings of blindness given in response to a hypnotic negative visual hallucination suggestion were significantly correlated with reporting bias scores obtained in this paradigm. Although hypnotic blindness and hypnotic deafness correlated significantly, the partial correlation between these variables was nonsignificant when reporting bias scores were statistically controlled. Results are used to support a skeptical view of hypnotic response as being based on compliance.

1991

Marzi, C. A.; Bisiacchi, P.; Nicoletti, R. (1991). Is interhemispheric transfer of visuomotor information asymmetric? Evidence from a meta-analysis. Neuropsychologia, 29, 1163-1177.

Using a meta-analytic procedure we have analysed 16 studies employing a simple unimanual reaction time (RT) paradigm and lateralized visual stimuli to provide an estimate of interhemispheric transfer time in normal right-handed subjects. We found a significant overall RT advantage of the left visual field over the right and of the right hand over the left. These asymmetries can be explained by a superiority of the right hemisphere for the detection of simple visual stimuli and by a corresponding superiority of the left hemisphere for the execution of the manual response, respectively. Alternatively, they may be interpreted as related to an asymmetry of interhemispheric transmission of visuomotor information, with transfer from the right hemisphere (side of stimulus entry) to the left (side of response generation) faster than in the reverse direction. Although a direct test of these hypotheses is still lacking, we think that the evidence available is more in keeping with the latter possibility.

1990

Wallace, Benjamin (1990). Hypnotizability and the modification of cognitive search strategies. International Journal of Clinical and Experimental Hypnosis, 38, 60-69.

An experiment was conducted to determine if Ss judged to be low in hypnotizability could be taught the efficient search strategies used by high hypnotizable Ss in the performance of a cognitive search task. Ss were requested to find objects embedded within a variety of pictorial scenes. High

hypnotizable Ss were found to be more adept than low hypnotizables at finding more objects correctly. When low hypnotizable Ss were taught the efficient search strategies used by the high hypnotizables, their performance improved and was not significantly different from that of the high hypnotizable Ss. Implications of these results for teaching search strategies are discussed.

Wallace, Benjamin (1990). Imagery vividness, hypnotic susceptibility, and the perception of fragmented stimuli. Journal of Personality and Social Psychology, 58, 354-359.

Two experiments were conducted to determine the role of hypnotic susceptibility level (high or low) and imaging ability (vivid or poor) in the performance of gestalt closure tasks. In Experiment 1, subjects were required to identify fragmented stimuli in the Closure Speed Test and in the Street Test. In Experiment 2, subjects reported on fragmented stimuli that were projected to the right eye and subsequently produced an afterimage. Individuals were asked to identify the composite if possible and to report on the duration of the afterimage. In both experiments, hypnotic susceptibility level and imaging ability affected reports of gestalt closure. The greatest number of correct closures was reported by those who were both high in hypnotic susceptibility and vivid in imaging ability. In addition, in the second experiment, this group also reported the longest enduring afterimage. These results are discussed in terms of the processes required to perform in a gestalt closure task.

1989

Miller, Scott D. (1989). Optical differences in cases of multiple personality disorder. Journal of Nervous and Mental Disease, 177 (8), 480-486.

Nine patients (aged 24-43 years) diagnosed with multiple personality disorder (MPD) and 9 control Ss role-playing MPD were given complete ophthalmological examinations to test whether the MPD Ss would show greater variability in visual functioning across alter personalities than would control Ss role-playing MPD. An analysis of variability of 8 optical measures in 4 prominent areas of vision was performed by comparing 2 covariance matrices for equality. Analyses showed that MPD Ss had significantly more variability across alter personalities than did their control counterparts on measures of visual acuity with correction, visual acuity without correction, visual fields, manifest refraction and eye-muscle balance. Ratings for clinical significance showed that the MPD Ss had 4.5 times the average number of changes in optical functioning between alter personalities of the control Ss.

1988

Sheehan, Peter W.; Donovan, Paul; MacLeod, Colin M. (1988). Strategy manipulation and the Stroop effect in hypnosis. Journal of Abnormal Psychology, 97, 455-460.

When asked to name the ink color of an incompatible color word (e.g., the word red printed in green ink), people show strong interference from the word. This study examined Stroop interference in subjects who were either high or low in susceptibility to hypnosis. Compared with performance in the waking state, the Stroop effect actually increased under hypnosis, a result particularly evident in the high- susceptible subjects. This contradicts the notion that high susceptibility subjects freely select appropriate strategies when hypnotized, a conclusion strengthened by an analysis of reported strategies in the two states. However, when provided with an attentional focusing instruction under hypnosis, high susceptibility subjects sharply reduced the Stroop effect, whereas low-susceptible subjects decreased it only slightly. One role of hypnosis may be to assist the subject in tuning attention, but only when an appropriate strategy is provided.

Wallace, Benjamin (1988). Hypnotic susceptibility, visual distraction, and reports of Necker cube apparent reversals. Journal of General Psychology, 115, 389-396.

Subjects, either susceptible (n = 50) or resistant (n = 50) to hypnotic suggestion, were asked to report on frequency of apparent reversals (ARs) to the Necker cube illusion. Such reports were made in the presence or absence of various types of visual, geometric surrounds (squares, triangles, crosses, or parallelograms). In agreement with a number of previous experiments, susceptible subjects reported perceiving more ARs than did resistant subjects. This difference held whether visual surrounds were present or absent. The presence of surrounds did serve to reduce AR reports regardless of hypnotic susceptibility level. The results are examined in terms of the ability of subjects to selectively attend when confronted with potential visual distractors.

1987

Friedman, Howard; Taub, Harvey A.; Sturr, Joseph F.; Monty, Richard A. (1987). Visual information processing speed in hypnotized and nonhypnotized subjects. Journal of General Psychology, 114 (4), 363-372.

Using a backward-masking paradigm with a bias-free and ceiling-free psychophysical task, we tested hypnotized and control subjects for speed of visual information processing. Approximately half of each group received visual imagery suggestions in an attempt to influence attention. Imagery produced no significant differential effect. Although an absence of a hypnotizability-performance relationship was in keeping with findings of a previous study, those subjects in the present study who performed under hypnosis were, as a group, significantly superior to the other subjects in speed of information processing.

1986

Friedman, Howard; Taub, Harvey A.; Sturr, Joseph F.; Church, Katherine L.; Monty, Richard A. (1986). Hypnotizability and speed of visual information processing. International Journal of Clinical and Experimental Hypnosis, 34, 234-241.

Following the determination of the luminance threshold of each S, high and low hypnotizable Ss were tested for speed of information processing using a backward masking paradigm with a bias-free and ceiling-free psychophysical task. No significant relationship between hypnotizability as measured by the Stanford Hypnotic Susceptibility Scale, Form A (SHSS:A) of Weitzenhoffer and Hilgard (1959) and speed of information processing was observed. The order of administering SHSS:A, pre- or postthreshold task, was significantly related to luminance threshold. Results were compared to other studies wherein some evidence for a relationship between hypnotizability and speed of visual information processing had been offered.

## NOTES

106 college students were tested using tachistoscopic presentation of stimuli. 52 Ss received the SHSS:A immediately prior to the experimental tasks, 54 immediately after, and testing was terminated for each Subject after they failed 3 successive items. The test flash was set at 0.3 log units above threshold, i.e. double the threshold intensity. A trial consisted of 2 observation intervals, separated by warning tones. The test flash occurred randomly in one of the two intervals. The S indicated which observation interval contained the test flash by pressing a button. Feedback tones gave S information about the correct response.

"The masking experiment was begun with the suprathreshold test flash occurring 250 milliseconds prior to the onset of the larger bright masking stimulus. As before, a two-interval forced -choice

staircase procedure was used, but this time the test intensity was constant, and ISI was changed. If S 'hit' three trials in a row, ISI was decreased by 10 milliseconds. The ISIs continued to decrease in 10-millisecond steps, until S "missed," causing an increase in ISI" (p. 348).

RESULTS were analyzed by 2 x 2 x 2 ANOVA (Hypnotizability, sex, and order of hypnotizability measurement). High hypnotizables = 7-12 on the SHSS:A, and low hypnotizables = 0-6. Ss receiving SHSS:A prior to the tasks had a significantly lower luminance threshold (-1.99 log mL) than did those having it after tasks (-1.93 log mL),  $p < .05$ . None of the other analyses were significant. No significant relationships were observed vis a vis the masking task, and the mean masking thresholds were almost identical for the lows and highs.

DISCUSSION. "Spanos (1982), in studying the effects of hypnotizability and suggestions in altering auditory sensitivity, reviewed the difficulties inherent in the measurement of perceptual accuracy and emphasized the role of response bias in the confounding of results" (p. 239). Secondly, these tasks reflect more fundamental, central processes and use more neutral stimuli than letter recognition used earlier. "Thus, while the masking effects of both the previous recognition tasks (masking by pattern) and the current detection tasks (masking by nearby contours) are presumably mediated through similar high level central processes, the differences in findings could possibly have been related to additional processing cues required in letter recognition" (p. 239). A footnote mentions, "Other studies have shown that with stimulus configurations similar to that used in the present study, there are significant central masking effects (Battersby & Wagman, 1962; Markoff & Sturr, 1971; Turvey, 1973)" (p. 239).

"Quite intriguing is the luminance threshold finding which, although not as robust as one would desire, suggests that a hypnotic induction procedure given prior to a task may significantly affect sensitivity on that task. Speculatively, the relaxation suggestions inherent in SHSS:A may account for the changes in luminance threshold" (p. 239).

Wallace, Benjamin (1986). Latency and frequency reports to the Necker cube illusion: Effects of hypnotic susceptibility and mental arithmetic. Journal of General Psychology, 113 (2), 187-194.

An experiment (N = 32) was conducted to assess latency of first apparent reversal (AR) and AR frequency while observing the Necker cube illusion. Subjects who were either high in hypnotic susceptibility (susceptibles) or low in hypnotic susceptibility (resistant subjects) observed the cube either while performing or not performing mental addition problems. Susceptibles reported perceiving the first AR more quickly and a greater frequency of ARs than did resistant subjects. Also, latency of the first AR was negatively correlated with AR frequency. These results were interpreted in terms of the ability of susceptibles to allocate concentrative or selective attention in a manner that was conducive to faster performance when faced with competing tasks.

1985

Nogrady, Heather; McConkey, Kevin M.; Perry, Campbell (1985). Enhancing visual memory: Trying hypnosis, trying imagination, and trying again. Journal of Abnormal Psychology, 94 (2), 195-204.

Tested visual recall memory of high (n = 24) and low (n = 24) hypnotizable undergraduates (screened under the Harvard Group Scale of Hypnotic Susceptibility and the Stanford Hypnotic Susceptibility Scale) for black and white line drawings of common objects in either hypnosis, imagination, or control conditions. Memory performance in terms of both correct and incorrect items increased appreciably across the recall tests. Neither hypnosis nor imagination enhanced recall beyond that of normal repeated testing. Hypnotizability was not related to the amount of correct material recalled but was related to the amount of incorrect material reported. High hypnotizable Ss in the hypnosis condition were more likely than other Ss to confidently rate the incorrect material as correct. Findings are

discussed in terms of the impact of hypnosis on and the relevance of hypnotizability to enhancing visual memory.

1984

Magnavito, F.; Gaupp, L. (1984, October). Absorption, hypnotic susceptibility, and automatization of visual attention. [Paper] Presented at the annual meeting of the Society for Clinical and Experimental Hypnosis, San Antonio, TX.

#### NOTES

Absorption (Tellegen Scale) correlated .62 with SHCS and -.45 with a measure of visual automatization. They conclude that highly absorption-prone individuals attend more to sensory information, processing their environment in a childlike, less automatized manner. The measure of visual automatization, H, was obtained by camera recorded eye movements and fixations as Ss viewed slides in any way they desired.

Venn, J. (1984). The spiral technique of hypnotic induction: A brief communication. International Journal of Clinical and Experimental Hypnosis, 32 (3), 287-289.

The spiral method directs the patient's attention to a sequence of body locations. During 3 years of clinical trials, the method proved valuable in hetero-hypnotic induction and in training patients in self-relaxation. The spiral technique is compared with progressive relaxation, and advantages of this method are discussed. A brief case report is presented.

#### NOTES

The induction is based on a technique published in W. B. Joy (1979), *Joy's Way*. Los Angeles: Tarcher. It guides patient in a (spiral) focused awareness of locations in and around the body, e.g. heart, solar plexus, middle chest, lower abdomen, throat, left shoulder, left hip, base of spine, right hip, right shoulder, center of forehead, left elbow, left knee, right knee, right elbow, center of scalp, left hand, left foot, right foot, right hand, and point in midair several inches above the center of the scalp.

1983

Crawford, Helen J.; Allen, Steven N. (1983). Enhanced visual memory during hypnosis as mediated by hypnotic responsiveness and cognitive strategies. Journal of Experimental Psychology: General, 112 (4), 662-685

To investigate the hypothesis that hypnosis has an enhancing effect on imagery processing, as mediated by hypnotic responsiveness and cognitive strategies, four experiments compared performance of low and high, or low, medium, and high hypnotically responsive subjects in waking and hypnosis conditions on a successive visual memory discrimination task that required detecting differences between successively presented picture pairs in which one member of the pair was slightly altered. Consistently, hypnotically responsive individuals showed enhanced mean number of correct performance during hypnosis, whereas nonresponsive ones did not. Hypnotic responsiveness correlated .52 ( $p < .001$ ) with enhanced performance during hypnosis, but it was uncorrelated with waking performance (Experiment 3). Reaction time was not affected by hypnosis, although high hypnotizables were faster than lows in their responses (Experiments 1 and 2).

#### NOTES

Subjects reported enhanced imagery vividness on the self-report Vividness of Visual Imagery Questionnaire during hypnosis. The differential effect between lows and highs was in the anticipated direction but not significant (Experiments 1 and 2).

Two cognitive strategies appeared to mediate visual memory performance: (a) detail strategy (memorization and rehearsal of individual details) and (b) holistic strategy (looking at and remembering the whole picture with accompanying imagery). Both lows and highs reported predominantly detail-oriented strategies during waking; however the highs shifted to a more holistic strategy during hypnosis. It appears that high hypnotizables have a greater capacity than lows for cognitive flexibility (Battig, 1979).

Results are discussed in terms of Paivio's (1971) dual coding theory and Craik and Tulving's (1975) depth of processing theory. The authors also discuss whether hypnosis involves a shift in cerebral dominance, as reflected by the cognitive strategy changes and enhanced imagery processing.

Nash, John (1983). Negative visual hallucination and concomitant changes in cortical event-related potentials (Dissertation, University of California, Santa Barbara). Dissertation Abstracts International, 45 (2), 716-B. (Order No. DA 8411224)

"The purpose of this investigation was to examine the effects of negative visual hallucination (NVH) on cortical event-related potentials (ERPs), and to compare these effects with those of selectively attending to and ignoring stimuli. Five highly hypnotically susceptible subjects, four female and one male, were trained to block from subjective experience, i.e., negatively hallucinate, a ring of strobe-illuminated circles surrounding a central, independently strobe-illuminated circle. This stimulus array was modeled after part of the Titchener-Ebbinghaus circle illusion, since previous research had shown that subjects could attenuate the effects of the optical illusion via NVH of the outer, illusion-producing circles. "Analysis of the ERP data revealed amplitude and latency changes in various ERP components across the three experimental conditions (Attend, Ignore, NVH) for the four female subjects, a negative result which is explained in motivational terms. "The most noteworthy finding was the selection of the P3 amplitude variable at C2 by stepwise discriminant analysis for the four females, and the fact that this amplitude systematically decreased across conditions from largest in Attend to smallest in NVH. A variety of individual patterns were observed in terms of other ERP components which allowed discrimination (successful classification) among the three conditions. The results suggest that both Ignoring and NVH of a stimulus result in a decrease in the subjective certainty of perception of the stimulus. Individual differences in patterns of ERP changes are interpreted in terms of differing strategies for execution of the experimental instructions. The results support the view that NVH instructions produce distinctive ERP effects and that NVH generally can be viewed as an extreme level of ignoring" (p. 716).

Spanos, Nicholas P.; Dubreuil, Debra L., Saad, Carol L., Gorassini, Donald (1983). Hypnotic elimination of prism-induced aftereffects: Perceptual effect or responses to experimental demands?. Journal of Abnormal Psychology, 92 (2), 216-222.

Two experiments assessed adaptation to displacing prisms in hypnotically limb-anesthetized Ss. Experiment I with 18 college students disconfirmed the hypothesis that the displacement aftereffect is eliminated in limb-anesthetized hypnotic Ss who adapt to prisms in the absence of a visual target. Such Ss showed as large a displacement aftereffect as control Ss who received neither a hypnotic induction procedure nor an anesthesia suggestion. Experiment II with 30 undergraduates demonstrated that under some testing conditions hypnotic Ss complied with experimental demands and eliminated the behavioral but not the perceptual component of the aftereffect.

Wagstaff, Graham F. (1983). Suggested improvement of visual acuity: A statistical reevaluation. International Journal of Clinical and Experimental Hypnosis, 31 (4), 239-240.

This is a re-analysis of data presented by Sheehan, E.P., Smith, H.V., & Forrest, D.W. (1982), A signal detection study of the effects of suggested improvement on the monocular visual acuity of myopes. International Journal of Clinical and Experimental Hypnosis, 40, 138-146. "In sum, a more appropriate conclusion to be drawn from Sheehan et al.'s (1982) results is that suggestions for improving visual acuity have little effect, but listening to music actually appears to reduce sensitivity. This reinterpretation of Sheehan et al.'s (1982) result is purely a comment on their conclusions, not their methodology.

1982

Cunningham, Paul V.; Blum, Gerald S. (1982). Further evidence that hypnotically induced color blindness does not mimic congenital defects. Journal of Abnormal Psychology, 91, 139-143.

Six undergraduate women, highly skilled in hypnotic techniques, were trained under hypnosis with a color mixer to experience red, green, blue, and total color blindness and were then programmed for the same responses in the posthypnotic state under conditions of amnesia. After awakening they were shown pseudoisochromatic plates as a preliminary check on the efficacy of the prior hypnotic instructions. The experiment consisted of successive administrations of the Farnsworth-Munsell 100-hue test, initially under normal baseline viewing conditions followed by each of the color-blind conditions in turn. Results indicate that although the observers subjectively experienced the varieties of color blindness as instructed, their responses differed from specimen responses of individuals with congenital defects in color discrimination. Implications for interpreting hypnotic alterations of perception are discussed.

Saccuzzo, Dennis P.; Safran, Deborah; Anderson, Virginia; McNeill, Brian (1982). Visual information processing in high and low susceptible subjects. International Journal of Clinical and Experimental Hypnosis, 30, 32-44.

High and low hypnotically susceptible Ss were compared in their ability to identify a briefly exposed informational target stimulus consisting of a letter when it was preceded (forward masking) or followed by (backward masking) a noninformational mask stimulus. There were 4 intervals between the target and mask and a no mask control for both forward and backward masking. The experiment was replicated in 2 independent sessions. In Session 1 high susceptible Ss were superior to lows in identifying the target stimulus. The superiority was not maintained in Session 2. Implications of the findings and directions for future research are discussed.

Sheehan, Eugene P.; Smith, Howard V.; Forrest, Derek W. (1982). A signal detection study of the effects of suggested improvement on the monocular visual acuity of myopes. International Journal of Clinical and Experimental Hypnosis, 30, 138-146.

2 groups of 8 Ss each, matched for suggestibility and degree of myopia, were assessed by a signal detection method in their ability to make a monocular spatial discrimination, both before and after 15 minutes of listening either to music or to taped suggestions that vision would improve. There was a significantly greater improvement in sensitivity on the part of the group of Ss listening to suggestions, and within this group, but not within the group of Ss listening to music, there was a significant negative correlation ( $r = -.67$ ) between S's initial sensitivity and the amount by which it increased. There was no significant difference between the amounts by which the criterion changed in the 2

groups. In contrast with the results reported by Graham and Leibowitz (1972), there was no evidence in the present study to indicate that the amount of improvement shown by Ss depended upon either their suggestibility as measured by BSS or their refractive error.

#### NOTES

In contrast with the results reported by Graham and Leibowitz (1972), there was no evidence in the present study to indicate that the amount of improvement shown by Ss depended upon either their suggestibility as measured by BSS or their refractive error (p. 144).

Wallace, Benjamin; Fisher, Leslie E. (1982). Hypnotically induced limb anesthesia and adaptation to displacing prisms: Replication requires adherence to critical procedures. Journal of Abnormal Psychology, 91 (5), 390-391.

N. P. Spanos et al. (see PA, vol 66:7289) reported a failure to confirm the results of an experiment on prism adaptation reported by the present authors (see PA, vol 65:6956) that required Ss to adapt to a prismatically displaced environment when their adapting limb was hypnotically anesthetized. The present authors argue that the failure of Spanos et al to replicate their findings is due to their failure to duplicate the critical conditions of the experiment. (7 ref)

#### 1981

Blum, Gerald S.; Nash, John; Jansen, Robert D.; Barbour, John S. (1981, June). Posthypnotic attenuation of a visual illusion as reflected in perceptual reports and cortical event-related potentials. Academic Psychology Bulletin, 3, 251-271.

Highly selected and trained hypnotic subjects, capable of ablating portions of visual stimuli from conscious awareness, showed varying degrees of ability to attenuate the Titchener-Ebbinghaus circles illusion post-hypnotically under a negative visual hallucination instruction. The presence or absence of such inhibitory skill, inferred from perceptual reports, was differentially reflected in changes in cortical event-related potentials not typically associated with shifts in selective attention. These findings point to the cognitive operation of a distinctive mechanism of selective inattention.

#### NOTES

Blum et al. postulate an inhibitory mechanism of the central nervous system with stages of amplification and attenuation. They suggest that individual differences in inhibitory skill may be improved with practice even for very skilled Subjects. They studied this type of inhibition using a visual illusion (the Titchener-Ebbinghaus circles) because the neural locus of such illusions is thought to be more central in the nervous system rather than at the level of the retina.

Experiment 1. Three Ss trained in using hypnosis viewed stimuli in waking and posthypnotic negative visual hallucination (NVH) conditions. All three had previously passed a negative hallucination item (not seeing a playing card of three such cards placed on a table). Training included practice sessions applying NVH to the experimental stimuli. S1 reported immediate success; S2 experienced some initial difficulty ("I have a feeling something's there") but then reported success; S3 required a couple of long practice sessions.

The classic Titchener-Ebbinghaus illusion stimuli were used. Stimuli were ten slides with drawings of a standard 17-mm-diameter black circle on the left and a comparison black circle on the right. The black circle on the right was either 14, 15, 16, 17, or 18 mm in diameter, skewed intentionally around 17, to compensate for the proportion of smaller and larger judgments applied to the comparison figure in relation to the standard. One black comparison figure was surrounded by seven 15-mm diameter white circles; the other by seven 10 mm diameter white circles. The key drawings were both black

circles of 17 mm. The second set of five drawings, used as a control, contained the same black circles but lacked outer rings of white circles.

The Subject was to state whether the black circle on the right appeared larger, smaller, or the same as the standard black circle on the left. Slides were shown for 4 seconds each, with 6 seconds in between slides.

Alternating blocks of trials were given under baseline (B) condition and a posthypnotically programmed negative hallucination condition (NVH). In the NVH condition, "the rings of white circles surrounding the standard and comparison black inner circles were 'ablated' from consciousness. The observers were amnesic in the waking state for their prior hypnotic instructions and were cued in advance of a block of trials simply by the phrases 'This will be a mixed series' (referring to B, in which the stimuli appeared as they really were, some with outer rings of white circles present and others not), or 'This will be a black only series' (referring to NVH, in which all stimuli appeared to the observer as black circles only, whether the outer rings were physically present or not)" (pp. 254- 255). Sessions were spread out over 8-12 months for each observer, interspersed with a variety of other experiments. In one session the Experimenters used a selective attention instruction, with Ss given posthypnotic suggestions to regulate their cognitive arousal to a peak of mental alertness and concentration (+AA) and focus on the inner black circles but not to negatively hallucinate the outer white circles.

Although all three Ss showed the illusion effect, they varied in ability to attenuate the illusion when negative visual hallucination suggestions were given. "S1 showed a very greatly reduced frequency of reports in the illusory direction under the NVH condition, a less marked reduction under +AA concentration, and no reduction at all under a waking instruction to ignore the outer circles; S2 revealed a moderate but significant reduction under NVH but not under +AA; S3 gave no evidence of attenuation in either condition" (p. 258). The response times for the two more successful Ss (1 and 2) with the 17 mm stimuli under NVH conditions were not different when the outer circles were either present or absent.

Experiment 2. The next year S1 and S2 returned but S3 was no longer available as a Subject; S4 and S5 were added and trained in hypnosis skills. EEG evoked response potentials (ERPs) were recorded while Ss made size judgments as in Experiment 1. Averaged ERPs for each block of 100 stimulus presentations were obtained for the first 500 milliseconds following stimulus onset. Judges blind to the experimental conditions evaluated the ERP records.

All Subjects experienced the Titchener-Ebbinghaus illusion, but again there were individual differences in ability to attenuate the illusion: S1 was the most successful; S2 gave significantly fewer responses in the larger category under NVH than B conditions; and both S1 and S2 improved attenuation performance over the previous year. S4 fell between S1 and S2 in ability; S5 was unable to attenuate the illusion in the NVH condition.

Results. "All three observers whose perceptual reports indicated some attenuation of the visual illusion during the NVH condition also showed a consistent reduction of the P2-N2 amplitude during NVH" (p. 262) at the Occipital sites. Median amplitude reduction was 36%, 40%, and 36% for S1, S2, and S4; only 7% for S5. There were no similar reductions for the other electrode sites, though "enhancement of P2-N2 amplitudes occurred in the lateral prefrontal and frontal areas in the two most successful individuals, S1 and S4" (p. 263). There was also a lag in N2 peak latencies for the three best subjects. The Experimenters noted that the N2 peak occurred 50 msec later in the frontal and prefrontal areas than in the occipital area.

In their Discussion, the authors express the view that it is not likely that faking could have occurred, for several reasons: 1. The Subjects were trained to report honestly, and they often had reported failures to experience hypnotic phenomena suggested during training sessions. 2. The task elicited rapid responses, usually in less than 2 seconds, to 10 different slides in randomized blocks of 100 trials, which would make self monitoring of responses extremely difficult. 3. Subjects exhibited a consistency of responses over experimental sessions that were widely separated in time, making conscious or

unconscious deception unlikely. 4. The finding of no difference in latency between 17 mm stimuli with and without outer rings of white circles supports an interpretation of reliable reporting. 5. Differences in ERP data between the B and NVH conditions were obtained only for those Ss who successfully attenuated the illusion.

The authors also state, "In terms of our conceptual model of the mind, inhibitory skill is attributable to the capacity for invoking inhibitory action earlier in the sequence as signals are processed through stages of amplification and attenuation en route to consciousness (Blum & Barbour, 1979). In the NVH condition of the present task, first- stage attenuation ... [Subject 1] ... occurs in time to negate the illusion as well as preventing conscious awareness of the outer white circles, second-stage attenuation takes place too late to disrupt the illusion but still in time to keep the outer circles from consciousness" (p. 265). Note that the unsuccessful Subject 5 had the highest score on the screening hypnotizability tests. The variation among very high hypnotizables casts doubt on the practice of grouping Ss who score between 9 and 12 on the SHSS. "It is perhaps not surprising that many previous hypnotic studies involving alterations in such subtle phenomena as visual illusions have yielded negative results." p. 266.

N.B. None of the Ss was able to eliminate the illusion under a strong waking instruction to ignore the outer circles while judging the inner black ones. "These different results for AA and NVH instructions pinpoint the contrast between selective attention (+AA) and selective inattention (NVH)" (p. 266).

The ERP changes seen in occipital and frontal areas were in opposite directions. Thus "the data suggest an effect which seems to parallel both investment of attention (increases in late components over frontal cortex) and withdrawal of attention (relative decreases in late components over occipital cortex). This parallel leads us to speculate that our occipital decreases may have been due to active inhibition of information-processing in the occipital regions, and that the late component enhancement over frontal areas may have been due to the mobilization of resources in these areas necessary to accomplish the tonic inhibition of visual input. ... Activity in the frontal cortex apparently 'programs' inhibition on the specific sensory nuclei of the thalamus, in a modality specific and topographical way, accomplishing gating of sensory information to primary sensory cortex" (p. 268).

Zakrzewski, Kajetan; Szelenberger, Waldemar (1981). Visual evoked potentials in hypnosis: A longitudinal approach. International Journal of Clinical and Experimental Hypnosis, 29 (1), 77-86.

Visual Evoked Potentials (VEP's) were recorded in 5 healthy 20-24 year-old-females during hypnosis, hypnosis after the suggestion of blindness, and in 3 waking conditions. VEP's were recorded in these conditions 10 times within each S on different days. Both within-Ss and between-Ss analyses showed a tendency of VEP N-250 latencies (and possibly also amplitudes) to increase in hypnosis when compared to the waking state. Overall, these changes tended to be rather small. No changes were found in the earlier VEP waveform components, and some tendencies noted in the later P-300 component were largely nonsignificant. Decrease in N-250 amplitudes after the hypnotic suggestion of blindness was significant for the whole group, but was difficult to interpret, since amplitude in this condition was not significantly different from the wake control condition N-250 amplitude.

The results are considered preliminary, and a few possibilities of confirming and/or explaining them using somewhat more stringent methodology are discussed. The within-Ss approach is recommended for future studies of evoked potentials in hypnosis.

Erickson, Milton H. (1980). Hypnotic alteration of sensory, perceptual and psychophysical processes. (2). New York: Irvington Publishers, Inc..

NOTES

This second volume of four has five sections, with chapters as follows. **I. Visual Processes**

1. The hypnotic induction of hallucinatory color vision followed by pseudonegative afterimages (written with E. M. Erickson)
2. Discussion: Critical comments on Hibler's presentation of his work on negative afterimages of hypnotically induced hallucinated colors (written by E. M. Erickson)
3. The induction of color blindness by a technique of hypnotic suggestion
4. An experimental investigation of the hypnotic subject's apparent ability to become unaware of stimuli
5. The development of an acute limited obsessional hysterical state in a normal hypnotic subject
6. Observations concerning alterations in hypnosis of visual perceptions (written by E. M. Erickson)
7. Further observations on hypnotic alteration of visual perception (written by E. M. Erickson)
8. An investigation of optokinetic nystagmus
9. Acquired control of pupillary responses **II. Auditory Processes**
10. A study of clinical and experimental findings on hypnotic deafness: **I. Clinical experimentation and findings**
11. A study of clinical and experimental findings on hypnotic deafness: **II. Experimental findings with a conditioned response technique**
12. Chemo-anaesthesia in relation to hearing and memory
13. A field investigation by hypnosis of sound loci importance in human behavior **III. Psychophysiological Processes**
14. Hypnotic investigation of psychosomatic phenomena: Psychosomatic interrelationships studied by experimental hypnosis
15. Hypnotic investigation of psychosomatic phenomena: The development of aphasia-like reactions from hypnotically induced amnesias (written with R. M. Brickner)
16. Hypnotic investigation of psychosomatic phenomena: A controlled experimental use of hypnotic regression in the therapy of an acquired food intolerance
17. Experimentally elicited salivary and related responses to hypnotic visual hallucinations confirmed by personality reactions
18. Control of physiological functions by hypnosis
19. The hypnotic alteration of blood flow: An experiment comparing waking and hypnotic responsiveness
20. A clinical experimental approach to psychogenic infertility
21. Breast development possibly influenced by hypnosis: Two instances and the psychotherapeutic results
22. Psychogenic alteration of menstrual functioning: Three instances
23. The appearance in three generations of an atypical pattern of the sneezing reflex
24. An addendum to a report of the appearance in three generations of an atypical pattern of the sneezing reflex **IV. Time Distortion**
25. Time distortion in hypnosis, I (written by L. F. Cooper)
26. Time distortion in hypnosis, II (written with L. F. Cooper)
27. The clinical and therapeutic applications of time distortion
28. Further considerations of time distortion: Subjective time condensation as distinct from time expansion (written with E. M. Erickson) **V. Research Problems**
29. Clinical and experimental trance: Hypnotic training and time required for their development
30. Laboratory and clinical hypnosis: The same or different phenomena?
31. Explorations in hypnosis research (with a discussion by T. X. Barber, R. Dorcus, H. Guze, T. Sarbin, and A. Weitzenhoffer)
32. Expectancy and minimal sensory cues in hypnosis
33. Basic psychological problems in hypnotic research

**Leibowitz, H. W.; Lundy, R. M.; Guez, J. R. (1980). The effect of testing distance on suggestion-induced visual field narrowing. International Journal of Clinical and Experimental Hypnosis, 28 (4), 409-420.**

The size of the suggestion restricted visual field was determined among 3 groups consisting of hypnotized Ss, simulators and "instructed fakers." Instructions were designed to produce narrowing of the visual field. Visual field size was tested by 3 differently designed perimeters each incorporating a different testing distance. The group data were indistinguishable from each other. Some Ss in each group exhibited field sizes which would have been expected if they were suffering from a true scotoma. Other Ss responded as if the functioning area of the visual field were a real object, while still other Ss produced intermediate functions. Implications for theory and for visual field testing are discussed.

**Wallace, Benjamin (1980). Autokinetic movement of an imagined and an hypnotically hallucinated stimulus. International Journal of Clinical and Experimental Hypnosis, 28 (4), 386-393.**

Autokinetic movement (AKM) of an imagined or an hallucinated stimulus was assessed as a function of hypnotic susceptibility level. 3 groups of Ss were asked to produce an image of a small, pinpoint spot of light and to monitor any activity of the stimulus. The stimulus was produced by imagination for a group of Ss judged high in hypnotic susceptibility and for a second group of Ss judged low in hypnotic susceptibility. A third group of Ss, highly susceptible to hypnosis, was asked to hallucinate the pinpoint spot stimulus with the aid of instructions administered by E. Instructions by which movement reports were elicited were kept equal and open-ended for all 3 groups of Ss. Results indicated that form of the stimulus (imagined or hallucinated) did not affect reports of AKM. Hypnotic susceptibility level, however, was a major factor in influencing resultant reports. The Ss judged high in hypnotic susceptibility reported a significantly greater number of direction changes of AKM than Ss low in hypnotic susceptibility. The data are interpreted in terms of the possible differences in stimulus monitoring ability as a function of hypnotic susceptibility level.

**1979**

**Spanos, Nicholas P.; Ansari, Ferhana; Stam, Henderikus J. (1979). Hypnotic age regression and eidetic imagery: A failure to replicate. Journal of Abnormal Psychology, 88 (1), 88-91.**

Walker, Garrett, & Wallace (1976) reported the restoration of eidetic imagery in hypnotically age-regressed subjects. In an attempted replication of that study, 60 subjects who previously scored high on hypnotic susceptibility were 'hypnotically regressed' to age 7. Before administration of the hypnotic procedures and again after age regression, subjects were tested for eidetic imagery using the random-dot stereograms employed by Walker et al. None of our subjects including those who were age regressed according to standard criteria and who reported having been eidetikers as children, were successful at the stereogram tasks. Although these results fail to replicate those of Walker et al., they are consistent with the available evidence concerning the performance of children on stereogram tasks. Contrary to the impression conveyed by Walker et al., children tested to date, including those classified as eidetikers by Haber and Haber's criteria, have been unsuccessful at stereogram tasks.

**1978**

**Blum, Gerald S.; Porter, M. L.; Geiwitz, P. J. (1978). Temporal parameters of negative visual hallucination. International Journal of Clinical and Experimental Hypnosis, 26, 30-44.**

Negative visual hallucination was investigated by hypnotically programming two highly trained undergraduates not to see the colored lines of consonants while perceiving clearly a set of dots superimposed on the lines in another color. Effects of three temporal parameters were noted in tachistoscopic presentations of the consonants: priming time, i.e., opportunity for the subject to prepare to execute the negative visual hallucination after the posthypnotic cue was flashed and before the consonant appeared; duration of consonant exposure; and intensive practice over protracted periods of time. Signal strength and inhibitory skill emerged as significant variables.

#### **NOTE**

This paper reports 4 experiments with two highly trained subjects. The authors conclude, "From these observations, signal strength and inhibitory skill emerge as major determinants of the outcome in NVH. The stronger the input, the greater the likelihood of insufficient inhibitory action. Differences in skill show up at both the intra- and inter-individual levels of analysis. Even the initially skilled F1 improved her NVH ability with practice, as inferred from the disappearance of undercalling. The lesser skill of F2 was evidenced in her longer required priming time, higher accuracy of color guesses, greater number of color breakthroughs, and reported feeling of mental strain" (p. 42).

Spanos, Nicholas P.; Rivers, Stephen M.; Gottlieb, Jack (1978). Hypnotic responsivity, meditation, and laterality of eye movements. Journal of Abnormal Psychology, 87 (5), 566-569.

Right-handed male subjects were pretested on a number of person variables; they then meditated for eight sessions. Measures of hypnotic responsivity, meditating skill, imaginal abilities, and attitudes toward hypnosis loaded on a common factor that was labeled sustained nonanalytic attending. However, laterality of eye movement (left moving) failed to load on this factor. The implications of these findings for current theorizing concerning hypnosis and meditation are discussed.

t'Hoen, P. (1978). Effects of hypnotizability and visualizing ability on imagery mediated learning. International Journal of Clinical and Experimental Hypnosis, 26, 45-54.

The Ss selected for hypnotizability and visualizing ability were tested for their performance on an imagery-mediated, paired-associates task in which the stimulus materials were varied in imagery and concreteness. Imagery and concreteness showed significant main effects and an additive interaction facilitating learning. Neither hypnotizability nor visualizing ability showed main effects, thereby contradicting the conjecture that those 2 factors would facilitate imagery-mediated learning. However, high hypnotizable Ss learned more high imagery words than the low hypnotizables, and visualizing ability was shown to interact with word concreteness. It is concluded that the effects of hypnotizability and visualizing ability on verbal learning are, at least in part, a function of the content of the words to be learned.

1977

Reyher, Joseph (1977). Spontaneous visual imagery: Implications for psychoanalysis, psychopathology, and psychotherapy. Journal of Mental Imagery, 253-274.

Prolonged free imagery eventually is accompanied by anxiety, symptoms and/or resistance. This is puzzling to clients when these pathogenic images or scenes appear to be innocent. Their curiosity thus piqued, they are invited to revisualize these images. Anxiety and resistance is intensified and symptoms are exacerbated as the underlying strivings become depicted with increasing clarity. This method is called emergent uncovering psychotherapy. The variegated phenomenon produced is relevant to both

Sullivanian and orthodox Freudian constructs. Except for gratification drive discharge, these fare very well. The constructs of psychoanalytic ego psychology did not achieve relevance.

1972

Graham, Charles; Leibowitz, Herschel W. (1972). The effect of suggestion on visual acuity. International Journal of Clinical and Experimental Hypnosis, 20, 3.

In experiment one, all subjects participating attained the maximum score on the BSS. The subjects were hypnotized and post-hypnotic suggestions were given to the effect that the subject really knew how well they could see, and this was contingent upon relaxation. The patient was now given an opportunity to re-read the eye charts. It was found that in this experiment, myopic visual acuity was significantly improved through the use of hypnosis and positive suggestion.

In experiment two, subjects who scored the maximum and the minimum on the BBS were used. The same procedure was used as in number one except that the highly susceptible subjects were told that "various studies had demonstrated that being hypnotized was not a pre-requisite for obtaining improvement." The insusceptibles were told that "acuity improved under hypnosis, but like many other phenomena associated with hypnosis, improvement in vision was also well within the reach of the non-hypnotizable subjects, if they simply learned to relax their eyes." It was found that myopic visual acuity was significantly improved in the absence of a formal hypnotic induction. This improvement was for the highly hypnotizable subjects only, and did not transfer to outside the experimental situation.

In experiment three, subjects were used who scored the maximum on the BSS and the Harvard Group Scale. Testing was done in both the hypnotized and waking state. It was found that the rank order correlation between initial and final acuity levels was .98 ( $p < .001$ ), indicating the effect of suggestion was selective.

Sutcliffe, J. P. (1972). Afterimages of real and imaged stimuli. Australian Journal of Psychology, 24 (3), 275-289.

Tested 45 university students and 15 7-10 yr. olds for after-images of images and of real stimuli. 8 different colored stimuli were used and observations made enabled a check on reliability. Real stimuli typically produced negative afterimages in most Ss. Only half the Ss could project images of the stimuli, only 1/3 reported afterimages of those images, and of those images only 7% were negative. Afterimages of images had a longer latency and a shorter duration than afterimages of real stimuli. Thus qualitatively and quantitatively afterimages of images differ from afterimages of real stimuli. Findings are related to individual differences in general vividness of imagery. (18 ref.) 1969

Graham, Kenneth (1969). Brightness contrast by hypnotic hallucination. International Journal of Clinical and Experimental Hypnosis, 17, 62-73.

Tested the veridicality of a hypnotic hallucination elicited by a buzzer through a conditioning procedure. The stimulus to be hallucinated consisted of 2 gray circles, 3 in. in diameter, mounted on a white card. 11 highly susceptible Ss were able to produce this hallucination upon hearing the buzzer during a series of test trials following the training. Following a 2nd training series, a black and white background was provided for the hallucination and Ss tended to report the hallucinated circles as a brightness contrast. A 2nd group of highly susceptible Ss was not hypnotized, but was asked to

respond as if hypnotized. These Ss tended not to report the contrast. (Spanish & German summaries) (PsycINFO Database Record (c) 2002 APA, all rights reserved)

1968

Dittborn, Julio M.; Shor, Ronald E. (1968). A test of the effectiveness of intermittent photic stimulation on hypnotic performance. International Journal of Clinical and Experimental Hypnosis, 16, 165-178.

ATTEMPTED TO CONFIRM THE FINDINGS OF A. G. HAMMER AND W. J. ARKINS (SEE 39:1) OF SIGNIFICANTLY GREATER IMPROVEMENT IN HYPNOTIC PERFORMANCE AS A RESULT OF 11-CPS INTERMITTENT PHOTIC STIMULATION THAN WITH FREQUENCIES OUTSIDE THE RANGE OF EEG ALPHA ACTIVITY. USING THE BRAIN WAVE SYNCHRONIZER, 3 GROUPS OF SS WERE GIVEN STIMULATION AT 5, 11, AND 30 CPS. TESTS OF HYPNOTIC PERFORMANCE WERE MADE DURING AND IMMEDIATELY AFTER STIMULATION, AND A WEEK OR MORE LATER. NO EVIDENCE OF FREQUENCY-SPECIFIC EFFECT WAS OBTAINED, AND THE ORIGINAL FINDING WAS NOT CONFIRMED. (SPANISH + GERMAN SUMMARIES) (PsycINFO Database Record (c) 2002 APA, all rights reserved)

1967

Bowers, Kenneth S. (1967). The effect for demands of honesty upon reports of visual and auditory hallucinations. International Journal of Clinical and Experimental Hypnosis, 15, 31-36.

SS, UNSELECTED FOR HYPNOTIC SUSCEPTIBILITY AND SIMPLY TOLD TO HALLUCINATE, MADE PRETEST RATINGS ON THE REALITY OF VISUAL AND AUDITORY HALLUCINATIONS. ALL SS WERE THEN TASK MOTIVATED TO HALLUCINATE. BEFORE THE RETEST RATINGS WERE MADE, 1/2 OF THE SS WERE CONFRONTED BY A 2ND E WITH DEMANDS FOR REPORT HONESTY. FOR BOTH SENSORY MODALITIES, THE MEAN CHANGE IN RATINGS FROM PRETEST TO RETEST WAS SIGNIFICANTLY GREATER FOR THE TASK-MOTIVATED THAN FOR THE HONESTY-REPORT CONDITION. RATINGS OF THE REALITY OF HALLUCINATIONS ARE EVIDENTLY HIGHLY SUSCEPTIBLE TO THE CONTEXT OF DEMANDS IN WHICH THE REPORT IS MADE. IT IS ARGUED THAT, IN THIS AND PREVIOUS EXPERIMENTS UTILIZING UNSELECTED SS, REPORTS OF HALLUCINATORY ACTIVITY ARE LESS APT TO REFLECT PERCEPTUAL ALTERATIONS THAN RESPONSE MODIFICATION IN ACCORDANCE WITH REGNANT EXPERIMENTAL DEMANDS. **Andreasen, A. G.; Singer G. (1966). Hypnosis and hypnotizability: Delusion or simulation?. International Journal of Clinical and Experimental Hypnosis, 14 (3), 257-267.**

**Because Sutcliffe (see 36:4) showed that hypnotic suggestions are not comparable in sensory content with real stimuli, the postulated difference between "pseudoperception" and "simulation" as indexed by reported subjective experiences of hypnotic Ss was tested. From 215 undergraduates, 30 high-susceptibility (HS) and 30 low-susceptibility (LS) Ss made kinesthetic and visual judgments of horizontality. A significant response, not attributable to simulation, was found only for the HS-hypnosis induction group; the effect was not attributable individually to susceptibility, hypnosis induction, or motivation. It is concluded that hypnosis, defined by this significant interaction effect between high susceptibility and hypnosis induction can be interpreted as a pseudoperceptual response to suggestion. 1964

Brady, J. P.; Levitt, E. E. (1964). Nystagmus as a criterion of hypnotically induced visual hallucinations. Science, *146*, 85-86.

Hypnotized Ss who report hallucinating a visual situation which would ordinarily elicit optokinetic nystagmus demonstrate nystagmus under these conditions. They and control Ss are unable to feign nystagmus in the waking state, either by imagining the situation or by direct efforts to simulate the eye movements. Thus an objective criterion is provided for the presence of visual hallucinations. (PsycINFO Database Record (c) 2002 APA, all rights reserved)

Hammer, A. G.; Arkins, W. J. (1964). The role of photic stimulation in the induction of hypnotic trance. International Journal of Clinical and Experimental Hypnosis, *12*, 81-87.

The relative effectiveness of the ordinary verbal method of trance induction is compared with 2 forms of induction utilizing mechanical photic stimulation, and with methods combining the personal and mechanical features. The criterion of trance adopted was the compulsive carrying out of a difficult suggestion. Results show that mechanical procedures alone are ineffective. On the other hand, the addition of a particular sort of photic driving probably improves trance induction, which suggests that induction is a complex matter involving both social interactions and relatively nonmeaningful impacts on the brain. Barber, Theodore Xenophon; Deeley, Douglas C. (1961). Experimental evidence for a theory of hypnotic behavior: 1. 'Hypnotic color-blindness' without 'hypnosis'. International Journal of Clinical and Experimental Hypnosis, *9* (2), 79-86.

Barber hypothesizes that a formal hypnotic induction procedure is unnecessary in eliciting alterations in sensory functioning ordinarily thought to characterize hypnotic behavior; similar performances can be elicited from normal persons by instructing them to remain inattentive to visual or auditory stimuli. Substantiating evidence is presented in the area of "hypnotic color-blindness." From Psyc Abstracts 36:02:2II79B. (PsycINFO Database Record (c) 2002 APA, all rights reserved)

#### NOTES

## Conclusions

1. Normal persons who have been instructed to concentrate away from red and green give as many "color-blind" responses on the Ishihara as "deeply hypnotized" subjects who have been given elaborate suggestions to induce color-blindness.

1. Further experiments are necessary to determine if other behaviors which are considered as characteristic of "deeply hypnotized" subjects and which supposedly involve "sensory-perceptual alterations" -- e.g., "hypnotic deafness," "hypnotic blindness," "negative hallucinations" -- can be performed by persons who are simply asked to try to remain in-attentive to visual or auditory stimulation" (pp. 84-85).

1960

Sukhakarn, Khun Vichit (1960/1962). Extra ocular vision [Letter]. British Journal of Medical Hypnotism, 14 (2), 41-47.

## NOTES

The article is in the original form of a letter to Herbert Spiegel, M.D. The author describes experiences training subjects, both blind and with normal vision, to 'see' through the skin of their cheeks. Training involved concentrative meditation (Buddhist) and hypnosis. Simple tests were performed, apparently independently, by two other scientists.

"From information available from our subjects, the Extra Ocular Vision gained through the cheek-skin is different from those through the eyes as best explained here below:-- (1) The vision through the cheek-skin first takes a form of a series of spots somewhat like the image of coarse gain prints. Only after further training the spots are transformed into a clear object, so clear that needle threading is possible. (2) Objects seen through the cheek-skin are as clear as through the eyes. Distant objects can be magnified by the subject's wish, just like looking through an opera glass. (3) The vision gained through the cheek-skin is first 'seen' in black and white, and the 'colour picture' is achieved only after further training. But the colour 'seen' through the cheek is more intense than those through the eyes. (4) The field of vision 'seen' through each side of the cheek is more narrow than those seen through each eye. (5) There is a sign indicating that the vision through the cheek is only two-dimensional, the subjects find it difficult at first to stand the finger to another finger test" (p. 42).

1954

Erickson, Milton H. (1954). The development of an acute limited obsessional hysterical state in a normal hypnotic subject. Journal of Clinical and Experimental Hypnosis, 2, 27-41.

## NOTES

The 25 year old female graduate student in psychology had often been used in hypnosis experiments and as a demonstration subject, and had witnessed induction of hypnotic deafness, blindness, and color-blindness though she had not been given those suggestions herself. Scientific curiosity appeared to be the motivation for volunteering to experience hypnotic blindness, but she was skeptical about her ability to experience it. The author gave a series of "exceedingly tedious" suggestions to develop somnambulism (passively responsive and receptive) followed by suggestions leading gradually to development of "blindness" with the intention of concealing it from the hypnotist, with attendant strong and mixed emotions.

The initial attempts failed because the subject ostensibly was deceiving herself into thinking she had developed hypnotic blindness, but the author also was of the opinion that she was seeking to meet unconscious personality needs. The author then covertly changed the goal of the experiment "to develop in the subject an acute hysterical obsessional compulsive mental state which would be accompanied by hypnotic blindness and which would parallel or resemble the obsessive compulsive

hysterical mental disturbances encountered in psychiatric practice" (p. 32). The author developed a monologue of suggestions based in part on the utterances of hospitalized obsessive patients and in part on trauma relating to traumatic blindness in a kitten and a friend of the subject. In a slow but directed manner the author built up a double-bind situation which eventually led to the experience of hypnotic blindness as well as heightened emotional reactivity, crying etc.

1953

Naruse, Gosaku; Obonai, Torao (1953). Decomposition and fusion of mental images in the drowsy and post-hypnotic hallucinatory state. Journal of Clinical and Experimental Hypnosis, 1 (4), 23-41.

#### Summary of Part I

"From the above we can conclude the following main facts.

- 1) When one sensory stimulus is given to a subject in a drowsy state, images of other objects associated with it often appear.
- 2) These images sometimes have forms, and sometimes are devoid of forms, only light and color being present. This phenomenon resembles the experience of color-hearing, and is called a new type of synaesthesia [sic] by Bachen.
- 3) These images are sure to disappear when they are observed attentively, a passive attitude being necessary for the image observation.
- 4) The remarkable character of these images are such that elements of forms and colors of various objects have been disjointed and connected with each other in different relationships which construct new images.
- 5) The longer and stronger persistence of stimulus, the more easily and clearly conditioned images appear. Conversely if the stimulus is momentary, the recalled images appear also momentarily.
- 6) Not only the visual images but also the sensory images can be elicited in a similar way" (p. 25).

#### Summary of Part II

"The chief results of Naruse's experiments with the various subjects are as follows:

1. When one stimulus (C.S.) is given in the normal waking state after a conditioning procedure in which a conditioned bond is formed between two sensory stimuli in deep hypnotic trance, a mental image corresponding to the other stimulus (U.C.S.) appears with amnesia for the conditioning situation. When the stimulus is removed, the image also disappears.
2. The images attained have various degrees of clearness which may be classified on a continuum from hallucinations to memory images.
3. Such images tend to disappear when subjects try to observe them attentively.
4. Images which are broken into elements of the original figure appear as distinct images.
5. Modifications of images may be made by distortion, vagueness of the image, and by decomposition of the image.
6. When two C.S.'s, which were already conditioned individually to two U.C.S.'s are presented at the same time, the images corresponding to each stimulus appear to overlap. This is the composed image.
7. In image composing, which involves the strong-weak stimulus relationship or the spatial positions of two C.S.'s, the clear-vague or positional relationships of the composed images are changed.
8. In the complex of meaningful images, there are two types, primarily. The one grasps the image as a whole, the other observes it in many mosaic elements. The latter can recall the original figure more correctly in an image form than the former.
9. Some positive and negative reports on sensory conditioning in the normal waking state are reviewed" (p. 36).

#### NOTES

The investigators do not show that hypnosis enhances imagery, compared with the waking state. They studied sensory-sensory conditioning under hypnosis, with amnesia suggestions, followed by testing for the conditioning effect. This study is relevant to studies of amnesia, "repression." In some studies they paired sound of a buzzer or metronome (the Conditioned Stimulus) with images (the Unconditioned Stimuli) as in [Oo, X]; other studies compared a color patch (CS) with an image (Oo, X). Some studies presented both CS's together, in different spatial arrangements (in the instance of the color patch CS). Results (partial) included: "1. When one stimulus (CS.) Is given in the normal waking state after a conditioning procedure in which a conditioned bond is formed between two sensory stimuli in a deep hypnotic trance, a mental image corresponding to the other stimulus (UCS) appears with amnesia for the conditioning situation. When the stimulus is removed, the image also disappears. 2. The images attained have various degrees of clearness which may be classified on a continuum from hallucinations to memory images. 3. Such images tend to disappear when Ss try to observe them attentively. ... 5. Modifications of images may be made by distortion, vagueness of the image, and by decomposition of the image. 6. When two CS's, which are already conditioned individually to two UCS's, are presented at the same time, the images corresponding to each stimulus appear to overlap. ..." (P. 36).

## Volunteers

1992

Brentar, John P.; Lynn, Steven J. (1992, August). The Post-Hypnotic Experience Scale: Validity and reliability. [Paper] Presented at the annual meeting of the American Psychological Association, Washington, DC.

This paper describes the development of the Posthypnotic Experiences Scale (PES), a 57-item scale comprised of four subscales labeled Pleasant, Somatic- Kinesthetic, Irritability/Anger, and Anxiety. It was derived by way of an initial factor analysis using 444 subjects and refined by a second factor analysis using 288 subjects. In three data collection phases, the subscales were found to be internally consistent and to exhibit low to moderate test-retest reliabilities. The PES was also found to evidence excellent content, convergent, and discriminant validity, as measured by indices of hypnotizability, positive affect, depression, anxiety, hostility, sensation seeking, dysphoria, social desirability, perceptual aberration, absorption, and physical symptomatology. Behavioral validity was demonstrated in so far as subjects who were willing to volunteer for a second experiment, without reimbursement, scored higher on the Pleasant subscale than did nonvolunteers. (ABSTRACT from the Bulletin of Division 30, Psychological Hypnosis, Fall, 1992, Vol. 1, No. 3.)

1989

Sanders, Glenn S.; Gansler, David A.; Reisman, Stephen Jr. (1989). The effects of hypnosis on eyewitness testimony and reactions to cross-examination. American Journal of Forensic Psychology, 7, 33-60.

Investigative hypnosis has been a widely used and valuable police technique, but recent court rulings have expressed reservations about the admissibility of hypnotically related testimony. The proposed research is the first directly relevant evaluation of the most serious of the courts' reservations: the allegation that hypnosis produces excessive and unshakable levels of confidence in witnesses, thereby effectively denying opposing counsel the right of cross-examination. Volunteers from the community witnessed a simulated crime, and were then interviewed by a professional police investigator to obtain evidence and testimony. Two-thirds of these witnesses were randomly assigned to have their memory refreshed by one of two hypnotic induction techniques. All witnesses were subsequently examined and cross-examined by a pair of practicing criminal lawyers, and their videotaped testimony was evaluated

by another volunteer sample of community residents serving as jurors. On both objective and subjective measures, hypnotized witnesses provided more complete and internally consistent testimony. However, neither form of hypnotic induction led to greater witness confidence, credibility, or resistance to cross-examination. Our results generally replicate previous findings in a more realistic investigative simulation. The discussion considers artifactual explanations of the confidence null effects, and explores theoretical and policy implications of the data.

#### NOTES

People responding to a newspaper ad asking for volunteers who would be paid for participating in psychology research at the State University were later asked to undergo hypnosis. Of 45 who responded to the ad, six (13%) declined to have hypnosis. This rate of refusal has relevance to research on clinical hypnosis that requires paid volunteer participants.

1987

Gibson, H.B. (1987). Discussion commentary on Imagery and response expectancy as determinants of hypnotic behaviour by Kirsh, I.; Council, J.R. & Mobayed, C. [Comment/Discussion] .

#### NOTES

Discussion of paper by Steven Jay Lynn in same issue. Author criticizes use of random sample of students, as some would be unsusceptible to hypnosis, and calls for a larger sample size. Mentions but does not discuss a great number of other methodological issues.

1986

Hendler, Cobie S.; Redd, William H. (1986). Fear of hypnosis: The role of labeling in patients' acceptance of behavioral interventions. Behavior Therapy, 17, 2-13.

One hundred and five outpatient cancer chemotherapy patients were interviewed to assess their attitudes toward hypnosis and relaxation as well as to determine their beliefs in and willingness to try a behavioral procedure. Patients were randomly assigned to groups receiving identical descriptions labeled "hypnosis," "relaxation," or "passive relaxation with guided imagery." The description stressed the behavioral components of hypnosis and relaxation rather than the nonbehavioral techniques often associated with hypnosis such as age regression and posthypnotic suggestion. Patients believed hypnosis to be a powerful process that involved loss of control and altered states of consciousness. When compared with a group of college students, patients held significantly more fearful, conservative views about hypnosis. Patients who received a description of an intervention labeled "hypnosis" were significantly less likely to believe the procedure would effectively control their nausea and vomiting and were significantly less likely to state they would try the procedure than patients in the other two label conditions. This reaction to the label occurred independently of patients' degree of nausea, vomiting, and pain due to their chemotherapy treatments.

Lambe, R.; Osier, C.; Franks, P. (1986). A randomized controlled trial of hypnotherapy for smoking cessation. Journal of Family Practice, 22, 61-65.

242 patients who were smokers (49% of all patients in this group family practice) were contacted, and 180 (74%) who were interested in hypnosis as a method of helping them quit were included in the study. These 180 were randomly assigned to control and hypnosis groups. Of the 90 assigned to hypnosis: 50% 45 had at least 1 hypnosis session

McConkey, Kevin M. (1986). Opinions about hypnosis and self-hypnosis before and after hypnotic testing. International Journal of Clinical and Experimental Hypnosis, 34, 311-319.

Before hypnotic testing, Ss completed a questionnaire on their opinions about hypnosis and self-hypnosis. Approximately 1 week later, they completed a similar questionnaire that included questions about their experiences of hypnotic testing. Data are presented concerning Ss' agreement with statements about hypnosis and self-hypnosis. Findings are discussed in terms of their generality and in terms of whether Ss' opinions are consistent with scientific evidence.

Sweeney, Carol A.; Lynn, Steven Jay; Bellezza, Francis S. (1986). Hypnosis, hypnotizability, and imagery-mediated learning. International Journal of Clinical and Experimental Hypnosis, 34, 29-40.

The relationship between hypnotizability, imagery utilization ability, and hypnosis was examined in a study described to Ss (N = 157) as an 'imagery experiment.' In Session 1, the Tellegen Absorption Scale (Tellegen, 1976) was completed and the imagery-mediated paired-associate learning task was administered as a baseline measure. In Session 2, either hypnosis, task motivation, or no treatment instructions were administered and the learning task was repeated with a different word list (each 15 high, 15 low imagery pairs). In Session 3, the Harvard Group Scale of Hypnotic Susceptibility, Form A (Shor & E. C. Orne, 1962) was administered. Overall, recall was superior for high imagery words. Hypnotizability was not associated with imagery-mediated recall. Recall performance, however, was correlated with Tellegen Absorption Scale scores. Interestingly, learning and recall performance decreased between Sessions 1 and 2 for hypnotized Ss but remained the same for task motivated and control Ss. The decrease in performance was mediated by less concern for performance and diminished anxiety. Self-reports of imagery utilization did not differ among groups of Ss.

## NOTES

The authors review literature on the relationship between hypnotizability, hypnosis, and imagery abilities, noting that results are conflicting. One reason for differing results may be that imagery scales are self-report measures, subject to reporting bias of varying types. The imagery-mediated paired-associate learning paradigm, using high and low imagery paired associates, may address that reporting bias issue.

This investigation used 157 Ss grouped into high (9-12), medium (5-8), and low (0-4) hypnotizability levels on the basis of the Harvard Scale. Given the fact that high imagery words are usually recalled more easily than low imagery words (Paivio, 1971), a relationship observed between hypnotizability and imagery-mediated recall would elucidate the role of imagery utilization for memory functions.

The experimental conditions included hypnosis, task motivation, and a no treatment control condition, in order to evaluate the possible enhancement effects of hypnosis on imagery utilization for memory functions. The task motivation group was included to control for motivational factors, and the no treatment control condition to control for the practice effects of repeated testing.

The word pair stimuli were from Paivio et al (1968): 30 pairs consisting of 15 high and 15 low imagery noun pairs. Each Subject participated in three experimental sessions.

Session 1. Ss were told that they were in an experiment on imagery to remember pairs of words. They completed the Tellegen Absorption Scale, then were given instructions for using imagery for recalling words, and for rating vividness and clarity of each image immediately after it was formed. Finally they performed the learning task.

Session 2. Ss received either hypnosis, task motivation instructions ("try to form good interacting images of the word pairs" with exhortation to score as high as possible), or control (Like Session 1). No one in hypnosis group refused the induction (despite the fact that they were not forewarned in Session 1 that the experiment might involve hypnosis). Ss completed a questionnaire on the percentage of word

pairs they used images to remember, how easy it was to block out or ignore distractions, how vivid and clear were images of words during recall, how concerned they were about their performance, and how much anxiety, if any, they experienced during the experiment.

Session 3. The Harvard Scale was administered. Three Ss declined to participate in the Harvard Scale administration.

The results were analyzed with a 3 x 2 x 2 x 2 repeated-measures ANOVA: hypnotizability, instruction (hypnotic induction, task motivation, no treatment), session (1 and 2), and pair imagery (high and low). The expected enhanced memory performance of high hypnotizables with high imagery words in the hypnosis condition did not emerge in the results. However, the expected stimulus-imagery effect was observed (a higher proportion of high imagery words than low imagery words recalled). The expected higher imagery ratings for hypnotized high hypnotizable Ss also was not found. Furthermore, there was a significant interaction effect for recall session by hypnotizability: low hypnotizable Ss rated imagery less vivid in Session 2 than in Session 1, while highs rated it more vivid in Session 2 than in Session 1. Thus, low hypnotizable Ss' imagery ratings actually decreased between Recall Session 1 and 2, while high hypnotizable Ss' imagery ratings increased between Recall Session 1 and 2.

While the Absorption Scale correlated with the Harvard (.28,  $p < .001$ ) and with various measures of recall, hypnotizability did not correlate with any of the recall measures. The questionnaires administered during Session 2 suggested that hypnotized Ss were less concerned and anxious than the no treatment control Ss, and less concerned than the Ss receiving task motivation instructions.

In their Discussion, the authors speculate that the strong stimulus-imagery effects might have made it unlikely for them to find differences between high, medium, and low hypnotizable Ss in imagery-based paired associate learning. They suggest including word pairs that range across the continuum of imagery ratings in future research. They also speculate that differences between hypnotizability levels might be found (as 'T Hoen reported in 1978 publication) if Ss were required to respond in a shorter time interval, or if hypnotizability were measured by a scale with more cognitive items than the Harvard Scale--both conditions in 'T Hoen's research protocol.

"The most striking finding of the present research is that instead of facilitating performance in an imagery-mediated recall task, hypnosis resulted in a decrement in recall relative to control conditions. In the hypnotic condition, the amount of learning actually decreased from one session to the next (waking-hypnosis) but remained equivalent in the task motivation (waking-task motivation) and no treatment groups (waking-waking)" (p. 37). The authors note that it is not possible to determine from their research design whether hypnosis interfered with the learning task, the retrieval task, or both.

"The findings suggest that hypnotizability may be related to reported vividness and clarity of imagery but unrelated to the actual ability to utilize imagery in an imagery-mediated paired-associate learning task. ... Although high hypnotizables' self-report ratings of imagery and vividness increased, their recall performance was not accordingly enhanced. The disparity between subjective and objective measures underscores the importance of including both types of measures in studies of imagery abilities" (pp. 37- 38).

To a considerable degree, this study controlled for Ss' expectancies regarding hypnosis better than some earlier studies. This study differs from earlier research in that (1) Experimenters didn't test hypnotizability prior to the imagery-mediation task; and (2) the study was defined as an experiment on imagery, and hypnosis was not mentioned until just before the induction in Session 2.

"In conclusion, the present results indicate that, under certain conditions, hypnosis may decrease Ss' motivation and performance. No support was provided for the ability of hypnosis to facilitate imagery utilization and performance on an imagery-mediated task. The results are compatible with the views proffered [sic] by theoreticians who have emphasized the importance of expectancies and the experimental context (e.g., Barber, 1979; Coe & Sarbin, 1977; M. T. Orne, 1951, 1959; Spanos, 1982)" (p. 38).

1984

Brodsky, Annette M.; McNeil, Daniel W. (1984). Hypnotizability and volunteering for hypnosis experiments. American Journal of Clinical Hypnosis, 26, 206-211.

A class of 145 college students was given Barber's Creative Imagination Scale (CIS) and Spiegel's Eye Roll Sign, and later given several opportunities to volunteer for research projects, some of which specified hypnosis was involved. Those S's who volunteered for the hypnosis experiments took the Harvard Group Scale of Hypnotizability (HGSHS). Hypnosis volunteers differed from the non-hypnosis volunteers by significantly higher grades and more total experimental volunteerism, but were no significantly different on the CIS or Eye Roll Sign. In general, nonwhites scored higher on the CIS. Among hypnosis volunteers, there was a low negative correlation between the Harvard Consciousness scale and volunteering for experiments other than hypnosis.

1982

Friedman, Howard; Taub, Harvey A. (1982). Accessibility: A necessary control for studies of essential hypertension. International Journal of Clinical and Experimental Hypnosis, 30, 4-8.

A study which was planned to compare the relative effects of relaxation and hypnosis upon essential hypertension also offered the opportunity to replicate some of the findings of a previous investigation. A failure in such replication led to consideration of the effect of accessibility to the laboratory, a variable not typically controlled. A significant differential effect of easy versus hard access was observed.

1969

Timney, Brian N.; Barber, Theodore X. (1969). Hypnotic induction and oral temperature. International Journal of Clinical and Experimental Hypnosis, 17, 121-132.

Measured oral temperature in 19 Ss under hypnotic and control conditions. Confirming a study by A. F. Reid and G. Curtsinger (see 42:10), the hypnotic induction procedure gave rise to a significant increase in oral temperature ( $p < .01$ ). This significant rise was due to the data of 10 of the 19 Ss, 6 did no change and 3 dropped in temperature. The temperature change was not related to Ss' responsiveness to suggestions or to their testimony that they were or were not hypnotized. Although good and poor hypnotic Ss manifested the same degree of temperature rise, there was a tendency for those who had the least previous hypnotic experience to show the greatest rise. Data suggest a hypothesis for further research: oral temperature rises during hypnotic induction to the extent that Ss perceive the hypnotic situation apprehensively, i.e., as mysterious or foreboding. Goss, Allen; Morosko, Tom (1968). Stanford Hypnotic Susceptibility Scale, Form A: Score distribution of volunteer subjects. International Journal of Clinical and Experimental Hypnosis, 237-242.

Investigates the applicability of the reported norms of the Stanford Hypnotic Susceptibility Scale, Form A to a population which differs from the normative sample. 40 "true volunteer" dental students were found to score well above the 533 "volunteer" normative sample due mainly to the reduced percentages of low hypnotic susceptibility Ss. The effects of schooling, volunteering, and implications concerning the relationship between personality and hypnotic susceptibility in the volunteer sample are discussed. (French & German summaries) (PsycINFO Database Record (c) 2002 APA, all rights reserved)

1965

Cooper, Leslie M.; Pedersen, Darhl M. (1965). A note on the failure to find personality differences between volunteers and nonvolunteers for hypnotic research. International Journal of Clinical and Experimental Hypnosis, 13 (4), 274-278.

Personality measures were administered to 136 students in an introductory psychology class at Brigham Young University. 30 Ss subsequently volunteered to have their hypnotic susceptibility assessed. There were no significant differences found between the means of the resulting 23 variables for the 30 volunteers and 106 nonvolunteers. 2 variables (age and ego strength) showed significantly different variances for the 2 groups, but these may be attributed to chance because of the number of significance tests made. (PsycINFO Database Record (c) 2002 APA, all rights reserved)

Zamansky, H. S.; Brightbill, R. F. (1965). Attitude differences of volunteers and nonvolunteers and of susceptible and nonsusceptible hypnotic subjects. International Journal of Clinical and Experimental Hypnosis, 13 (4), 279-290.

A form of the Semantic Differential, containing 9 concepts related to hypnosis and research, was administered to 96 hypnotically inexperienced male Ss. The Ss were later asked to volunteer for a hypnotic experiment, and the hypnotic susceptibility of all volunteers (N = 51) was then determined. Semantic Differential responses of volunteers and nonvolunteers and of highly susceptible and un hypnotizable Ss were compared. Differences between groups, in both comparisons, were generally not statistically significant, a finding which suggests that there is no simple relationship between paper-and-pencil measures of attitudes and volunteering for hypnotic experiments or hypnotizability. (PsycINFO Database Record (c) 2002 APA, all rights reserved)

1964

Anderson, Milton L.; Sarbin, T. R. (1964). Base rate expectations and motoric alterations in hypnosis. International Journal of Clinical and Experimental Hypnosis, 12 (3), 147-158.

Degree of responsiveness to "suggestion" in an experiment which did not utilize hypnotic induction (the Berkeley Sample) was comparable to that obtained in an experiment which did utilize hypnotic induction (the Stanford Sample). Procedural differences between the 2 experiments--self-scoring vs. objective-scoring, and group vs. individual testing--were regarded as not crucial in making a comparison of the 2 experiments. The distribution of responses in the Berkeley Sample may be taken as the base rate. The slightly higher degree of responsiveness over the base rate in the Stanford Sample (on some tests) may be attributed to the "degree of volunteering" that characterized the sample. The importance for experiments in the future to create equal levels of motivation and expectation to perform well under both the hypnotic and the nonhypnotic conditions is stressed, and brief mention is made of a new metaphor to be used in the conceptualization of the problems of hypnosis. (25 ref.) (PsycINFO Database Record (c) 2002 APA, all rights reserved)

Melei, Janet P.; Hilgard, Ernest R. (1964). Attitudes toward hypnosis, self-predictions, and hypnotic susceptibility. International Journal of Clinical and Experimental Hypnosis, 12, 99-108.

Correlation of questionnaire results from a sample of 1326 students with hypnotic susceptibility scores of 340 of these later hypnotized showed (a) that those volunteering for hypnosis were more favorable in attitude than those who did not volunteer; (b) attitudes toward hypnosis were predictive of susceptibility for females, not for males; and (c) self-predictions yielded significant low positive correlations with actual susceptibility for both sexes. Other findings concern differences between those

having prior experience with hypnosis and those without such experience. (PsycINFO Database Record (c) 2002 APA, all rights reserved)

Rosenhan, D. L.; Tomkins, S. S. (1964). On preference for hypnosis and hypnotizability. International Journal of Clinical and Experimental Hypnosis, 109-114.

44 male and 44 female coerced volunteers, who either preferred or did not prefer to participate in hypnosis experiments, were compared with regard to (a) scores on the EPPS, (b) birth order, and (c) performance on the Harvard Group Scale of Hypnotic Susceptibility. Sex-specific personality differences were obtained between Ss who preferred and did not prefer hypnosis, but these personality differences were not apparently relevant to hypnotizability. However, for females, preference for hypnosis correlated .41 with hypnotizability; for males no relationship was obtained. Some theoretical and methodological implications of these data are discussed. (PsycINFO Database Record (c) 2002 APA, all rights reserved)

1962

Levitt, Eugene E.; Lubin, B.; Zuckermann, M. (1962). The effect of incentives on volunteering for an hypnosis experiment. International Journal of Clinical and Experimental Hypnosis, 10 (1), 39-42.

The data indicated that neither education about hypnosis nor payment for participating in an experiment are likely to bias a student volunteer group for an hypnotic experiment. (PsycINFO Database Record (c) 2002 APA, all rights reserved)

London, Perry; Cooper, Leslie M.; Johnson, Harold J. (1962). Subject characteristics in hypnosis research. International Journal of Clinical and Experimental Hypnosis, 13-21.

Items of experiences, interests, and attitudes, in London's Survey, tended to cluster among themselves, suggesting a separate factor for each. The items were compared to several objective tests, but correlations were low. The Survey and Shor's Personal Experiences Questionnaire combined, correlated .64 with Stanford Scale A, suggesting the possible development of a paper-and-pencil predictor of hypnotic suggestability. (PsycINFO Database Record (c) 2002 APA, all rights reserved)

1961

London, Perry (1961). Subject characteristics in hypnosis research: Part I. A survey of experience, interest, and opinion. International Journal of Clinical and Experimental Hypnosis, 151-161.

Questionnaire measuring (a) direct and observational experience with hypnosis, and (b) stereotyped attitudes towards hypnosis was administered to 645 undergraduate students of psychology. Results indicate hypnosis considered in generally favorable light. Girls were less willing than boys to be hypnotic Ss. Items regarding the nature of hypnosis reflected a rather sophisticated attitude. From Psyc Abstracts 36:01:3II51L. (PsycINFO Database Record (c) 2002 APA, all rights reserved)

1957

Martin, R. M.; Marcuse, F. L. (1957). Characteristics of volunteers and non-volunteers for hypnosis. Journal of Clinical and Experimental Hypnosis, 5 (4), 176-180.

103 introductory psychology students were tested with the Taylor Manifest Anxiety Scale, the Levinson Ethnocentrism Scale (score already on file), and the Bernreuter Personality Inventory. Later a request for volunteers for an experiment dealing with hypnosis was made (with no reward

promised). A week later the same experimenter informed the class that due to a redesign of the experiment, it was necessary to go through the request for volunteers again (a reliability check for volunteering).

**"Discussion and Conclusion.** There were significant differences between volunteers and nonvolunteers on the variables of intelligence, anxiety, ethnocentrism, dominance-submission, and sociability. Volunteers for hypnosis as a group were found to have a higher mean intelligence score and to be less ethnocentric than nonvolunteers. Male volunteers for hypnosis were more and not, as commonly supposed, less dominant in face-to-face relations and less and not, as commonly supposed, more anxious than nonvolunteers. Female volunteers tend to be more solitary and independent. The very fact that no significant differences were found in any comparison between volunteers and nonvolunteers for hypnosis in self-sufficiency and introversion-extroversion is considered important in that popular belief suggests the contrary.

" ... The data from this study, far from supporting the popular image of the hypnotic subject in terms of inferiority, might be argued to suggest superiority" (p. 178).

## **Vomiting**

**2002**

**Edser, Stuart J (2002, March).** Hypnotically-facilitated counter-conditioning of anticipatory nausea and vomiting associated with chemotherapy: A case study.. *Australian Journal of Clinical Hypnotherapy and Hypnosis*, 23 (1), 18-30.

Presents an account of a cancer patient who suffers from severe anticipatory nausea and vomiting in the lead-up to chemotherapy treatment. The paper briefly contextualises the symptomatology of the presenting problem in the behavioural and hypnotic literature and recounts the rationale and methods that the writer used in assisting the patient to overcome the problem. Counter-conditioning was used to desensitise the patient to the aversive stimuli and hypnosis used to enhance this effect and to facilitate the final outcome.

**1993**

**LaGrone, Randy G. (1993).** Hypnbehavioral therapy to reduce gag and emesis with a 10-year-old pill swallower. *American Journal of Clinical Hypnosis*, 36, 132-136.

10-year-old child experienced severe nausea and psychogenic vomiting that resulted in refusal to take oral medication in pill form. The youngster was treated with hypnbehavioral therapy consisting of mental imagery, relaxation, direct suggestion, adaptive self-talk, self-monitoring, and self-reinforcement. The child's parents were instructed to reinforce approximations of successful pill swallowing while withdrawing attention for avoidance, whining, gagging, and vomiting. A one-year follow-up revealed successful pill swallowing without significant distress.

**1992**

**Levitan, Alexander A. (1992).** The use of hypnosis with cancer patients. *Psychiatric Medicine*, 10, 119-131.

Hypnosis has proven to be extremely valuable in the treatment of cancer patients. Specific applications include: establishing rapport between the patient and members of the medical health team; control of pain with self-regulation of pain perception through the use of glove anesthesia, time distortion, amnesia, transference of pain to a different body part, or dissociation of the painful part from the rest of the body; controlling symptoms, such as, nausea, anticipatory emesis, learned food aversions, etc.;

psychotherapy for anxiety, depression, guilt, anger, hostility, frustration, isolation, and a diminished sense of self-esteem; visualization for health improvement; and, dealing with death anxiety and other related issues. Hypnosis has unique advantages for patients including improvement of self-esteem, involvement in self-care, return of locus of control, lack of unpleasant side effects, and continued efficacy despite continued use.

Walker, Leslie G. (1992). Hypnosis with cancer patients. American Journal of Preventative Psychiatry & Neurology, 3, 42-49.

Overviews the uses of hypnosis with cancer, for example to ameliorate side effects of treatment, help patients adjust to having cancer and its symptoms, reduce the distress caused by painful procedures, and to attempt to alter mechanisms of immunity with a view to improving prognosis. Studies in these areas are reviewed.

1991

Burish, Thomas G.; Snyder, Susan L.; Jenkins, Richard A. (1991). Preparing patients for cancer chemotherapy: Effect of coping preparation and relaxation interventions. Journal of Consulting and Clinical Psychology, 59 (4), 518-525.

60 cancer chemotherapy patients were randomly assigned to 1 of 4 treatments: (a) relaxation training with guided relaxation imagery (RT), (b) general coping preparation package (PREP), (c) both RT and PREP, or (d) routine clinic treatment only. All patients were assessed on self-report, nurse observation, family observation, and physiological measures and were followed for 5 sequential chemotherapy treatments. Results indicate that the PREP intervention increased patients' knowledge of the disease and its treatment, reduced anticipatory side effects, reduced negative affect, and improved general coping. RT patients showed some decrease in negative affect and vomiting, but not as great as in past studies. The data suggest that relatively simple, 1-session coping preparation intervention can reduce many different types of distress associated with cancer chemotherapy and may be more effective than often-used behavioral relaxation procedures.

Madrid, Antonio D.; Barnes, Susan v.d.H. (1991). A hypnotic protocol for eliciting physical changes through suggestions of biochemical responses. American Journal of Clinical Hypnosis, 122-128.

We employed brief hypnotherapy to effect physical changes in patients suffering from medical disorders including allergies, rectal bleeding, systemic lupus, hyperemesis, headache, asthma, and chronic pain. We present, in language appropriate to the individual patient, considerations and suggestions to effect the release of healing biochemicals. Ideomotor signals indicated the patient's awareness of the healing. We hypothesize that the technique triggered novel state-dependent memory, learning, and behavior.

## NOTES

They hypothesize that the technique they use triggers novel state-dependent memory, learning, and behavior (See for example Rossi, 1987, and Rossi & Cheek, 1988).

Hypnotic Protocol: "1. Tell the patient that he can heal himself by allowing his body to supply its own biochemicals needed to make him well. If a specific biochemical is known, such as cortisone or endorphins, name it. "2. Hypnotize the patient. Resistant or hard to hypnotize patients need not be deeply hypnotized because the patients, using this protocol, will automatically go into trance while accomplishing the next task of accessing and using ideomotor signals (Erickson, 1980; Rossi & Cheek, 1988). "3. Tell the patient that his index finger will automatically and involuntarily twitch and float

when his body releases the biochemicals he needs. This ideomotor response (Rossi & Cheek, 1988) is the sole physical response required of the patient. Rossi hypothesizes that the ideomotor response correlates with biochemical changes (Rossi & Cheek, 1988). "4. Next, ask the patient to consider some things (as described below). Present the considerations one after another until one of them triggers the ideomotor response. "5. In some instances, ask the patient to practice on his own. Many patients who have dramatic emotional reactions during or at the completion of the task may not need to practice on their own" (p. 123).

They present several 'considerations' to the patient, one after the other, tailored to the patient's specific case, until his finger twitches or floats, indicating a biochemical response. For example, the following 'considerations' have been used: "1. Psychodynamic: 'Consider that you are not blamed for anything; that you are in fact perfect just the way you are; that you are loved by those you care about.' 'Consider that you can forgive whoever needs forgiving for hurting you.' 'Consider that there are no longer any threats; everything is better; everything is as it used to be.' "2. Autosuggestion: 'Tell your body to heal. It knows what to do; so ask it to do it.' 'Tell your adrenal glands to produce the steroids that your body needs.' 'Allow a glowing light to permeate that injured back, filling it with healing energy.' "3. Incompatible responses: 'Cover yourself with a cool breeze, cooling the injured leg.' 'Imagine your back getting slack and limp and relaxed.' 'Imagine your stomach lining becoming smooth and moving with easy, ocean-like waves.' "4. Emotion calling: 'Consider yourself feeling very happy with everything, for no reason at all.' 'Consider yourself getting angry at someone--your mother, your wife (husband), your boss, your lawyer.' "5. Bargaining: 'Tell yourself that you will heal if you agree to stay away from that job.' 'Tell yourself you will heal by allowing your right arm to begin to hurt when you are over- exerting yourself.' 'Tell yourself that you will heal in exchange for something else, not so serious, to replace this disease and to serve the same function'" (pp. 123-124).

They present seven cases involving, respectively, allergies, rectal bleeding, systemic lupus, hyperemesis of pregnancy, adult onset asthma, chronic pain, and cluster headaches. Two cases were particularly interesting because they represented patients who did not respond initially.

Their procedure involves reframing the state or emotion originally associated with the onset of disease using considerations, and then giving a suggestion that it is within the power of the person, rather than factors outside, to heal the body. First they instruct the patient that the body can heal itself; then they give the list of suggestions for the patient to consider, persisting with different considerations until they get an ideomotor response. Incorporation of the patient's psychodynamic issues appears to be very important.

The authors regard it as unimportant if the patient cannot be hypnotized; "As Cheek (Cheek & LeCron, 1968; Rossi & Cheek, 1988) points out, the patient's inability to be hypnotized may be synonymous with his disease. It is actually beneficial if the patient cannot achieve ideomotor responses at first because both he and the therapist then trust the validity of the response when it does occur after the appropriate consideration" (p. 127).

Zeltzer, Lonnie K.; Dolgin, M. J.; LeBaron, Samuel; LeBaron, C. (1991). A randomized, controlled study of behavioral intervention for chemotherapy distress in children with cancer. *Pediatrics*, 88, 34-42.

Subjects were randomly assigned to hypnosis, nonhypnotic distraction/relaxation, or attention placebo control. children in the hypnosis group reported the greatest reduction in both anticipatory and postchemotherapy symptoms. Distraction/relaxation kept symptoms from getting worse, but they did not get better, and the control children's symptoms became much worse.

Morrow, Gary R. (1984). Appropriateness of taped versus live relaxation in the systematic desensitization of anticipatory nausea and vomiting in cancer patients. Journal of Consulting and Clinical Psychology, 52 (6), 1098-1099.

Investigated the suggestion that the relaxation part of systematic desensitization--an effective treatment for the nausea and vomiting experienced by approximately 25% of cancer patients in anticipation of chemotherapeutic treatments-- could be learned from a prerecorded audiotape prior to meeting a psychologist for treatment. 10 cancer patients who had developed anticipatory nausea or vomiting were assigned to either a live-relaxation or a tape-relaxation group. Results show that 4 of 5 Ss assigned to the tape-relaxation group experienced nausea while listening to the prerecorded audiotape, while none of the patients in the live-relaxation group reported nausea when subsequently listening to an audiotape made during the live presentation of relaxation.

1982

Hoffman, Mark L. (1982/83). Hypnotic desensitization for the management of anticipatory emesis in chemotherapy. American Journal of Clinical Hypnosis, 25 (2-3), 173-176.

A hypnotic treatment employing systematic desensitization was used to alleviate anticipatory nausea and vomiting in a middle-aged man undergoing chemotherapy for Hodgkin's Disease. After four treatment sessions, all nausea associated with chemotherapy was eliminated. Results of this treatment are compared with those of another hypnotic treatment recently reported by Redd et al (1982), and reasons for differences are discussed. [Redd, W. H., Andersen, G. V. & Minagawa, R. Y. (1982). Hypnotic control of anticipatory emesis in patients receiving cancer chemotherapy. Journal of Consulting and Clinical Psychology, 50, 14-19.]

LeBaron, Samuel; Zeltzer, Lonnie (1982, October). The effectiveness of behavioral intervention for reducing chemotherapy related nausea and vomiting in children with cancer. [Paper] Presented at the annual meeting of the Society for Clinical and Experimental Hypnosis, Indianapolis, IN.

Eight children (nine to seventeen years, Mean age 12.1) with cancer received behavioral intervention for chemotherapy related nausea and vomiting. Within three to five days after the administration of each course of chemotherapy, patients rated (1-10 scale; 1 = none, 10 = all the time or maximal amount) their nausea and vomiting and the extent to which chemotherapy bothered them and disrupted their daily routine. After a pre-intervention assessment of 2.5 courses of chemotherapy, patients received intervention (Mean = 2.6 courses). Significant reductions following intervention (Wilcoxon matched-pairs signed ranks test) were found in nausea ( $Z = 2.37, p < .02$ ), vomiting ( $Z = 2.52, p < .01$ ), bother ( $Z = 2.24, p < .02$ ), and disruption of activities ( $Z = 2.38, p < .02$ ). This preliminary study indicates that chemotherapy side effects can be reduced through behavioral intervention.

Redd, William H.; Andrykowski, Michael A. (1982). Behavioral intervention in cancer treatment: Controlling aversion reactions to chemotherapy. Journal of Consulting and Clinical Psychology, 50 (6), 1018-1029.

During the protracted course of cancer chemotherapy, approximately 25% of patients develop aversion reactions to treatment by becoming nauseated and/or vomiting before their chemotherapy treatments. This phenomenon has been conceptualized as a result of respondent conditioning. Since commonly used antiemetic drugs do not reliably control anticipatory nausea/emesis, behavioral techniques of control have been studied. They include hypnosis used in conjunction with guided-

relaxation imagery, progressive muscle relaxation with guided imagery, and systematic desensitization. (67 ref)

Redd, William H.; Andresen, Graciela V.; Minagawa, Rahn Y. (1982). Hypnotic control of anticipatory emesis in patients receiving cancer chemotherapy. Journal of Consulting and Clinical Psychology, 50 (1), 14-19.

#### NOTES

Deep muscle relaxation hypnosis controlled nausea, gagging, retching in all cases. Anticipatory emesis recurred when hypnosis was not used. During subsequent sessions in which hypnosis was reinstated, anticipatory emesis was again controlled.

Redd, William H.; Rosenberger, Patricia H.; Hendler, Cobie S. (1982-83). Controlling chemotherapy side effects. American Journal of Clinical Hypnosis, 25 (2-3), 161-172.

Severe nausea and vomiting are commonly experienced by cancer patients after receiving chemotherapy treatments. Moreover, approximately 25% of these patients develop conditioned aversions to treatment and become nauseated before they receive their chemotherapy injections. The use of deep muscle relaxation hypnosis in conjunction with guided imagery to control pre- and post-chemotherapy nausea and emesis is discussed. Theoretical and clinical issues raised by this application of hypnosis in cancer treatment are also addressed.

#### 1980

Fuchs, K.; Paldi, E.; Abramovici, H.; Peretz, B. A. (1980). Treatment of hyperemesis gravidarum by hypnosis. International Journal of Clinical and Experimental Hypnosis, 28 (4), 313-323.

Nausea and vomiting are the most common complaints in the first trimester of pregnancy. Hyperemesis gravidarum presents a unique challenge to the obstetrician trained in medical hypnosis. Between the years 1965-1977, 138 women suffering from extremely severe vomiting in the first trimester of pregnancy were successfully treated by medical hypnosis. 87 patients were treated in groups and 51 received individual therapy. The results with patients in group hypnotherapy were markedly better than those with patients in individual hypnotherapy. With group hypnotherapy, hospitalization was not necessary; treatment [sic] was given to a number of patients simultaneously and the women felt safer and less lonely. The common motivation of the patients consolidated the psychotherapeutic effect. This made treatment easier and more efficient.

#### 1955

Dorcus, Roy M.; Goodwin, Phillip (1955). The treatment of patients with the dumping syndrome by hypnosis. Journal of Clinical and Experimental Hypnosis, 3 (4), 200-202.

#### NOTES

Psychological tests (MMPI and Manifest Anxiety Scale) were administered to 20 duodenal ulcer patients with successful outcome following subtotal gastrectomy and 20 with an outcome characterized by "one or more of the following symptoms: lack of appetite, aversion to food, aversion to particular kinds of food, nausea, vomiting, dizziness, sweating, cardiac palpitation, weakness, and weight loss" (p. 200). Since the symptoms are supposedly due to food passing more rapidly through the digestive tract the syndrome is called "dumping."

In the unsuccessful outcome group, four patients with symptoms persisting 8-26 months, received hypnosis (2 to 9 sessions). "The suggestions were directed towards reducing tension (production of

relaxation), removal of fear of this condition, enhancing the olfactory qualities of food, and the feeling of comfort with food or liquid intake" (p. 201). All four patients responded with remission of symptoms.

**2002**

**Shenefelt, Philip (2002). Complementary psychotherapy in dermatology: Hypnosis and biofeedback. Clinics in Dermatology, 20 (5), 595-601.**

Hypnosis has been used for millenia to treat medical and dermatologic problems. The use of biofeedback is more recent, being dependent on instrumentation to measure such parameters as galvanic skin resistance (GSR) and skin temperature.

Numerous dermatological disorders may be improved or cured using hypnosis as an alternative or complementary therapy. Examples include acne excoricee, alopecia areata, atopic dermatitis, congenital ichthyosiform erythroderma, dyshidrotic dermatitis, erythromelalgia, furuncles, glossodynia, herpes simplex, hyperhidrosis, ichthyosis vulgaris, lichen planus, neurodermatitis, postherpetic neuralgia, pruritus, psoriasis, rosacea, trichotillomania, urticaria, verruca vulgaris, and vitiligo. Dermatologic procedure anxiety can also be reduced using hypnosis.

Skin problems that have an autonomic nervous system component can be assisted by biofeedback with or without hypnosis. Examples include biofeedback of GSR for hyperhidrosis and biofeedback of skin temperature for Raynaud's syndrome. Hypnosis may enhance the effects obtained by biofeedback.

**2000**

**Shenefelt, Philip (2000). Hypnosis in dermatology.. Archives of Dermatology, 136 (3), 393-399.**

**Background:** Hypnosis is an alternative or complementary therapy that has been used since ancient times to treat medical and dermatologic problems.

**Objective:** To describe the various uses for hypnosis as an alternative or complementary therapy in dermatologic practice.

**Methods:** A MEDLINE search was conducted from January 1966 through December 1998 on key words related to hypnosis and skin disorders.

**Results:** A wide spectrum of dermatologic disorders may be improved or cured using hypnosis as an alternative or complementary therapy, including acne excoricee, alopecia areata, atopic dermatitis, congenital ichthyosiform erythroderma, dishydrotic dermatitis, erythromelalgia, furuncles, glossodynia, herpes simplex, hyperhidrosis, ichthyosis vulgaris, lichen planus, neurodermatitis, postherpetic neuralgia, pruritus, psoriasis, rosacea, trichotillomania, urticaria, verruca vulgaris, and vitiligo.

**Conclusion:** Appropriately trained clinicians may successfully use hypnosis in selected patients as alternative or complementary therapy for many dermatologic disorders.

**Felt, Barbara T.; Hall, Howard; Olness, Karen; Schmidt, Wendy; Kohen, Daniel; Berman, Brad D.; Broffman, Gregg; Coury, Daniel; French, Gina; Dattner, Alan; Young, Martin H. (1998). Wart regression in children: Comparison of relaxation-imagery to topical treatment and equal time interventions. American Journal of Clinical Hypnosis, 41 (2), 130-137.**

Relaxation mental imagery (RMI), standard topical treatment (Top Tx), and equal time-control interventions were compared on measures of wart regression in sixty one, 6-12-year-old children. Subjects chose one common ("index") wart and attended 4 visits over 8 weeks. At each visit, total and "index" extremity wart number were counted and a photo was taken of the "index wart" for later measurement. On average, total wart number decreased by 10% and "index wart" area decreased by 20% with no significant group differences during the first eight weeks. Phone follow [sic] was conducted 6 to 18 months from study entry. At phone follow up, there was a trend for more RMI and Top Tx subjects to report complete wart resolution ( $p = 0.07$ ) with a majority of RMI children reporting use of RMI or no specific treatment pursuit. We conclude there was no significant short-term benefit for RMI in this randomized controlled trial of wart regression in children. However, longer term benefits for RMI and Top Tx groups are suggested.

1995

Holroyd, Jean (1995). Handbook of clinical hypnosis, by Judith W. Rhue, Steven Jay Lynn, & Irving Kirsch (Eds.) [Review]. International Journal of Clinical and Experimental Hypnosis, 43 (4), 401-403.

#### NOTES

"This is a book for the thinking clinician" (p. 401). "The editors are to be congratulated for making this volume much more coherent than most edited books" (p. 402). "My impression is that the book is best suited for an intermediate or advanced course on hypnotherapy, or for people who are already using hypnosis in treatment. Although there is some material on the basics of hypnotic inductions and a few introductory sample scripts for inductions, a beginners' course should probably use a different book, or this book could be accompanied by an inductions manual. ... I recommend it very highly" (p. 403).

1992

Ewin, Dabney M. (1992). Hypnotherapy for warts (*verruca vulgaris*): 41 consecutive cases with 33 cures. American Journal of Clinical Hypnosis, 35, 1-10.

Published, controlled studies of the use of hypnosis to cure warts are confined to using direct suggestion in hypnosis (DSIH), with cure rates of 27% to 55%. Prepubertal children respond to DSIH almost without exception, but adults often do not. Clinically, many adults who fail to respond to DSIH will heal with individual hypnoanalytic techniques that cannot be tested against controls. By using hypnoanalysis on those who failed to respond to DSIH, 33 of 41 (80%) consecutive patients were cured, two were lost to follow-up, and six did not respond to treatment. Self-hypnosis was not used. Several illustrative cases are presented.

"I do not consider self-hypnosis necessary, and I believe it may be contraindicated. Once the change in sensation has been acknowledged by an ideomotor signal, I suggest that the subconscious will take care of healing the warts and that the patient should ignore them and get interested in other things. Self-hypnosis would require regularly giving attention to the warts, and a high rate of cure is obtained without it. In their controlled study using DSIH with adults, Johnson and Barber (1978) included daily self-hypnosis and got cures in only 3 of 11 (27%) of the hypnotic group. This is the poorest result in the published literature. Their control group of 11 patients was given waking suggestions to 'practice imagining that the specified wart(s) were tingling for a few minutes each day until they were gone' and got no change in 3 months. Hellier (1951) got remission in 27 of 74 (36%) patients just using sham x-ray, (waking suggestion without any self-hypnosis). Spanos et al. (1988) instructed their hypnotic group to 'count their warts every day, and after each counting to close their eyes and spend 3 to 4 minutes imagining the warts on their target hand disappearing.' Only 2 of 8 patients (25%) with a

single wart cleared, while 9 of 14 (69%) with multiple warts lost one or more warts at 6- weeks' follow-up. My impression is that conscious daily attention to the lesion is contrary to normal body healing of injuries such as cuts, burns, sprains, in which healing progresses best when ignored while undue attention increases suffering" (pp. 3-4).

All Ss were private patients referred for hypnotherapy; most were diagnosed clinically.

"...I found that there were sexual implications in 7 of the 16 miscellaneous warts in patients over 13, so I separated the cases into pre- and postpuberty to evaluate the results" (p. 4).

"An early success was with a medical student (Case 28) with whom I used suggestions of warmth, with the blood vessels dilating and bringing in antibodies, leukocytes, opsonins, etc. Changes were visible in 3 days. This biased me toward using 'warm,' but two of the children (Cases 6 and 9) got no result until I gave them a choice. Using ideomotor signals they chose cold. Only two healed with 'warm,' while five did with 'cold.' All of them had either had the warts cauterized or frozen previously and had a personal feeling about heat and cold. I've learned to give the patient a choice on the first visit" (p. 5).

"Three... were first treated using DSIH without result and later responded to hypnoanalysis. After obtaining an ideomotor signal that there was no more subconscious value to the warts, the suggestion was given that the body's healing processes would take over without any more conscious attention by the patient. No self-hypnosis was prescribed" (pp 7-8).

Gildston, Phyllis; Gildston, Harold (1992). Hypnotherapeutic intervention for voice disorders related to recurring juvenile laryngeal papillomatosis. International Journal of Clinical and Experimental Hypnosis, 40 (2), 74-87.

Recurring juvenile laryngeal papillomatosis is resistant to cure, and thus usually requires multiple operations which may lead to the extensive proliferation of vocal fold scar tissue. Severe hoarseness, sharply lower pitch, and weak loudness levels are common sequelae. Adjunctive hypnotherapy can increase motivation for change, speed up the acquisition of vocal skills, and possibly even facilitate or sustain remission of growths in selected patients. An 8-year-old girl with severe active eruptions went into remission after 16 sessions, and a 12-year-old boy, already in remission at the beginning of the intervention period, remained free of neoplasms throughout the regimen. Whether or not hypnosis contributed significantly to the sanguine results, it is probable that, at the least, the hypnotic intervention facilitated the achievement of certain technical objectives in voice therapy.

1990

Spanos, Nicholas P.; Williams, Victoria; Gwynn, Maxwell I. (1990). Effects of hypnotic, placebo, and salicylic acid treatments on wart regression. Psychosomatic Medicine, 52, 109-114.

Subjects with warts on their hands and/or feet were randomly assigned to a hypnotic suggestion, topical salicylic acid, placebo, or no treatment control condition. Subjects in the three treated groups developed equivalent expectations of treatment success. Nevertheless, at the six-week follow-up interval only the hypnotic subjects had lost significantly more warts than the no treatment controls. Theoretical implications are discussed.

Study involved 15 females, 25 males (18-35 yrs old) with warts on at least one hand or foot, recruited through posters and newspaper ads; N = 10 in each condition. Hypnotic treatment consisted of 10 minute induction (modified from T. X. Barber's 1969 book) and a suggestion for wart regression that was 2 minutes in duration (the skin around warts was 'beginning to tingle and grow warm'; 'vividly imagine the warts shrinking and dissolving away'; 30 second break; repeated the suggestions). For Ss with warts on more than one limb the complete suggestion procedure was repeated for each wart-infected limb.

Results indicate psychological factors can influence course of some virally produced disorders; that self-medicating with over-the-counter products doesn't explain suggestion-induced wart regression; that expectation of treatment success is the most important variable in psychologically induced wart regression. "Hypnotic subjects attained significantly higher CURSS:S scores than did control subjects. Nevertheless, it is unlikely that between group differences in hypnotizability accounted for the group differences in wart regression. Two previous experiments (3) that used the CURSS found that hypnotizability failed to predict wart loss in either hypnotic suggestion, nonhypnotic suggestion, or placebo treatments, and even in the present study the hypnotic treatment failed to differ from either the real or placebo treatment on CURSS:S scores, and none of the treatments differed significantly on the CURSS:O scores. Our finding and earlier findings that hypnotic subjects reported more intense suggested sensations than placebo subjects is consistent with the hypothesis that vivid suggested imagery facilitates wart loss (7, 8) .

"An alternative hypothesis emphasizes that only our hypnotic suggestion treatment encouraged subjects to see themselves as developing cognitive control over their own wart regression. This hypothesis suggests that subjects' subjective sense of cognitive involvement in and control over treatment outcome (as opposed to the vividness of their suggested imagery) may have been the important psychological factor in wart regression. It would be of interest in a future study to manipulate subjects' sense of cognitive involvement in their treatment independently of suggested imagery in order to assess the relative contributions of these variables to wart regression" (pp. 113-114).

1989

Reid, S. (1989). Recalcitrant warts: Case report. British Journal of Experimental and Clinical Hypnosis, 6, 187-189.

NOTES

Recalcitrant warts which persisted for 5 years despite treatment cleared in 51 days with hypnotherapy. A cause/effect relationship between hypnotherapy and resolution was shown by at first excluding and then including the left hand from the suggestions given.

1988

Noll, Robert B. (1988). Hypnotherapy of a child with warts. Journal of Developmental and Behavioral Pediatrics, 9 (2), 89-91.

Child with 82 warts was treated using hypnosis; suggestions for removal from face only resulted in 8 of 16 facial warts disappearing after one treatment and two weeks. (Child had previous experience with hypnosis for pain and anxiety associated with lumbar punctures and bone marrow aspirates.)

Spanos, Nicholas P.; Stenstrom, Robert J.; Johnston, Joseph C. (1988). Hypnosis, placebo, and suggestion in the treatment of warts. Psychosomatic Medicine, 50, 245-260.

Two experiments assessed the effects of psychological variables on wart regression. In Experiment 1, subjects given hypnotic suggestion exhibited more wart regression than those given either a placebo treatment or no treatment. In Experiment 2, hypnotic and nonhypnotic subjects given the same suggestions were equally likely to exhibit wart regression and more likely to show this effect than no treatment controls. In both experiments, treated subjects who lost warts reported more vivid suggested imagery than treated subjects who did not lose warts. However, hypnotizability and attribute measures of imagery propensity were unrelated to wart loss. Subjects given the suggestion that they would lose warts on only one side of the body did not show evidence of a side-specific treatment effect.

1984

Gould, Sol S.; Tissler, Doreen M. (1984). The use of hypnosis in the treatment of herpes simplex II. American Journal of Clinical Hypnosis, 26, 171-174.

Hypnosis training was used to treat the painful lesions and emotional symptoms associated with Herpes Simplex II in two females, ages 32 and 26. Three weekly sessions of hypnosis and daily practice sessions were initiated in the first case. During this time, the patient experienced a decline in the subjective level of pain and severity of the lesions, as well as an elevation in mood level. On three-month followup, she reported no pain or skin eruptions and significantly less feelings of stress and anxiety. The second case utilized two sessions of hypnosis and daily practice sessions, and similar results were obtained. A traumatic event caused a relapse in the latter patient, but she was again able to use hypnosis to bring the virus back under control and to experience an elevation in mood level as well. A seven-month follow-up indicated no eruptions and an improvement in self-esteem.

In the first case the tape included ego-strengthening suggestions (Hartland, 1971); another tape used the patient's fantasy of water and snow skiing. The patient felt that hypnosis helped her acquire a more positive attitude toward herself and relief of guilt and blame, as well as an improved ability to cope with the unpleasant sensations.

In treatment session, ego strengthening suggestions were followed by 2 minutes of quiet for integration of suggestions, then visualization used in cancer therapy (Simonton): suggestions of a strong cell structure, perfect skin, hormonal balance, cleanliness, and a cooling refreshed feeling in the area of the vagina and perineum; imagery of internally controlled friendly white sharks was used to "devour" the virus; of water and snow skiing, imagery of cool breezes, white refreshing snow, clean fresh water; visualized herself forgiving and releasing her previous boyfriend of guilt, thereby allowing her anger to abate.

For second patient it was similar, plus visualization of being bathed in white lights and traveling through concentric circles radiating peace and protection, being purified as she traveled through the circles until she emerged as flawless as a diamond, reflecting only clarity and light. Both patients scored 4 on Spiegel's Hypnotic Induction Profile (HIP).

## Witchcraft & Voodoo

1994

Mulhern, Sherrill (1994). Satanism, ritual abuse, and multiple personality disorder: A sociohistorical perspective. International Journal of Clinical and Experimental Hypnosis, 42 (4), 265-288.

During the past decade in North America, a growing number of mental health professionals have reported that between 25% and 50% of their patients in treatment for multiple personality disorder (MPD) have recovered early childhood traumatic memories of ritual torture, incestuous rape, sexual debauchery, sacrificial murder, infanticide, and cannibalism perpetrated by members of clandestine satanic cults. Although hundreds of local and federal police investigations have failed to corroborate patients' therapeutically constructed accounts, because the satanic etiology of MPD is logically coherent with the neodissociative, traumatic theory of psychopathology, conspiracy theory has emerged as the nucleus of a consistent pattern of contemporary clinical interpretation. Resolutely logical and thoroughly operational, ultrascientific psychodemonology remains paradoxically oblivious to its own irrational premises. When the hermetic logic of conspiracy theory is stripped away by historical and socio/psychological analysis, however, the hypothetical perpetrators of satanic ritual

abuse simply disappear, leaving in their wake the very real human suffering of all those who have been caught up in the social delusion.

Spanos, Nicholas P.; Burgess, Cheryl A.; Burgess, Melissa Faith (1994). Past-life identities, UFO abductions, and satanic ritual abuse: The social construction of memories. International Journal of Clinical and Experimental Hypnosis, 42 (4), 433-446.

People sometimes fantasize entire complex scenarios and later define these experiences as memories of actual events rather than as imaginings. This article examines research associated with three such phenomena: past-life experiences, UFO alien contact and abduction, and memory reports of childhood ritual satanic abuse. In each case, elicitation of the fantasy events is frequently associated with hypnotic procedures and structured interviews which provide strong and repeated demands for the requisite experiences, and which then legitimize the experiences as "real memories." Research associated with these phenomena supports the hypothesis that recall is reconstructive and organized in terms of current expectations and beliefs.

1992

Morse, Donald R.; Martin, John; Moshonov, Joshua (1992). Stress induced sudden cardiac death: Can it be prevented?. Stress Medicine, 8, 35-46.

Previously, psychosomatically induced death relative to stress, hypnosis, mind control, and voodoo was discussed. In this article, emphasis is on one aspect of that - stress induced sudden cardiac death (SCD). A brief review is presented of the sympathetic aspects of the acute stress response and stress induced SCD. Findings from previous studies are presented to highlight sympathetic aspects of the acute stress response. This is followed by a presentation of various strategies to prevent or decrease the possibilities for stress induced SCD. These include long-term measures (e.g. diet control, smoking control, hypertension control, stress management strategies) and immediate measures (e.g. calm, controlled approach, elicitation of the relaxation response, selected use of drugs, and heart rate variability monitoring). Relative to prevention strategies, findings are presented both from previous studies and new investigations.

1991

Morse, Donald R.; Martin, John; Moshonov, Joshua (1991). Psychosomatically induced death: Relative to stress, hypnosis, mind control, and voodoo: Review and possible mechanisms. Stress Medicine, 7, 213-232.

A common denominator in psychosomatically induced death is stress. Death can occur slowly, as from the preponderance of chronic stressor, or it can come on suddenly, as from an acute stressor. Sudden death is more likely in an individual with preexistent serious medical conditions, which were outlined. Seven types of individuals more prone to sudden death were outlined. Most cases of sudden death are related to the presence of a severely stressful situation in which there appears to be no means of control or escape. With mind control, hypnosis, and voodoo curses, circumstances can be manipulated to achieve severe stress and uncontrollability.

1984

Suryani, L. K. (1984). Culture and mental disorder: The case of bebainan in Bali. In Culture, medicine and psychiatry. D. Reidel Publishing Company.

NOTES

Bebainan is a form of dissociation which is culturally associated with Bali. Thought to be caused by sorcery, a bebainan attack lasts up to an hour and is manifested by confusion, crying, screaming, and shouting, with inability to control one's actions. However, it seems most victims maintain awareness of their own behavior and are not amnesic for it afterwards.

In this study, the author interviewed 27 people, mostly female, most of whom experienced their first attack between 16-30 years of age. The author concluded that the attacks permitted release of feelings of frustration and anger without stigma. Author concluded it is not a form of psychosis, is not organic, and is not a neurosis

1979

Spanos, Nicholas P.; Gottlieb, Jack (1979). Demonic possession, Mesmerism, and hysteria: A social psychological perspective on their historical interrelations. Journal of Abnormal Psychology, 88 (5), 527-546.

Provides a social psychological interpretation of the interrelations among demonic possession, mesmerism, and hysteria. It is argued that the reciprocal role relationship of mesmerist and magnetized S in the 18th and 19th centuries involved the secularization of the role relation that had existed between exorcist and demonically possessed. The commonalities between these 2 sets of social roles are delineated, some of the variables leading an individual to learn and enact the possessed role are outlined, and several lines of historical evidence pertaining to the influence of the exorcist-demonic relationship on the mesmeric relationship are outlined. The influence of the possessed role in shaping the role of the hysterical patient is also discussed. The use of hysteria as a modern explanatory concept in histories of possession and mesmerism, however, is criticized. (198 ref).

1977

Brown, Daniel P.; Fromm, Erika (1977). Selected bibliography of readings in altered states of consciousness (ASC) in normal individuals. International Journal of Clinical and Experimental Hypnosis, 25, 388-391.

The bibliography is divided into the following sections:

I. General Works

II. Reference material on personality in relation to altered states

III. Social and cultural determinants of altered states

IV. Cognition, information-processing, and ego-functioning

V. Methodology in the study of altered states

VI. Differentiation of hyperaroused states

VII. Shamanistic states

VIII. Possession-trance

IX. Psychedelic states

X. The meditative states

XI. Personality differences and meditation

XII. Affective and cognitive change in meditation

XIII. Ordinary Buddhist meditation, concentration, and insight meditation

XIV. The variety of Buddhist meditation traditions
