Some very low hypnotizable people have been able to learn to control pain with hypnosis, suggesting that it is a skill that can be learned. However, few investigations of improvement of hypnoanalgesia were located. Rather, one must generalize from the fact that other kinds of hypnosis skills have been improved using special training programs, such as the Carleton University program developed by Gorassini & Spanos, 1986). Although most research on improving hypnotic response has been based on operant learning principles, a model that incorporates respondent (classical conditioning) principles might be more useful when it comes to understanding the training of a neurophysiological response, such as inhibitory brain patterns associated with hypnoanalgesia. "Historical success with clinical pain, taken together with newer findings in the neurophysiology of hypnosis, indicate that we should be spending more energy investigating how learning may improve hypnotic analgesia" (p. 43). "We should acknowledge that there are advantages to hypnosis beyond those of relaxation, a good placebo, and psychotherapy. ... Responsible care demands that we provide training or practice in hypnotic analgesia when treating pain, and especially whenever a chronic pain patient initially appears to be nonresponsive" (p. 43).

Jay, Susan (1987, October). Hypnotic susceptibility and response to psychological intervention for distress related to painful procedures in leukemic children. [Paper] Presented at the annual meeting of the Society for Clinical and Experimental Hypnosis, Los Angeles.

#### NOTES

Presented children with a cognitive behavioral intervention package that involved five elements 1. Filmed Modeling (child modeling and talking about it with good coping skills) 2. Positive Reinforcement - trophy 'for doing the best you can,' to change aversive situation to a positive situation 3. Breathing Exercises - 'puff yourself up like a tire' 4. Emotive Imagery/Distraction - super hero image (Superman), or being in a favorite place 5. Behavioral Rehearsal - dollplay, reviewing the procedure with medical equipment.

For Numbers 4 and 5 the therapist would actively guide the procedures; numbers 3, 4 & 5 are hypnotic elements.

Valium had lowered children's distress prior to procedures but not during the procedures. This study involved Valium plus cognitive behavior therapy.

25 Subjects ages 6-12, were measured for hypnotizability

2 groups: (1) Cognitive Behavior Therapy + Valium given just before intervention started, after film ended; (2) Cognitive Behavior Therapy alone.

Dependent Measures: 1. Observation Scale of Behavioral Distress coded every 15 seconds. 2. Faces Scale for Fear (self report) before procedure

Faces Scale for Pain (self report) after procedure 3. Blood pressure

**RESULTS.**

No Significant Differences were found between the two groups (CBT vs CBT + Valium). Pre-Post Analyses: Post intervention scores were significant lower than Pretest on [missed notes]

Jay, Susan M.; Elliott, Charles H.; Katz, Ernest; Siegel, Stuart E. (1987). Cognitive-behavioral and pharmacologic interventions for children's' distress during painful medical procedures. Journal of Consulting and Clinical Psychology, 55, 860-865.

This study evaluated the efficacy of a cognitive-behavioral intervention package and a low-risk pharmacologic intervention (oral Valium), as compared with a minimal treatment-attention control condition, in reducing children's distress during bone marrow aspirations. The subjects were 56 leukemia patients who ranged in age from 3 years to 13 years. The three intervention conditions were delivered in a randomized sequence within a repeated-measures counterbalanced design. Dependent outcome measures included observed behavioral distress scores, self-reported pain scores, pulse rate, and blood pressure scores. Repeated-measures analyses of variance indicated that children in the cognitive-behavior therapy condition had significantly lower behavioral distress, lower pain ratings, and lower pulse rates than when they were in the attention- control condition. When children were in the Valium condition, they exhibited no significant differences from the attention control condition except that they had lower diastolic blood pressure scores.

**NOTES**

Lonnie Zelzer, M.D., in a UCLA Hypnosis Seminar lecture in 1992, stated that in pre-treatment with Valium the patients did worse during the procedure, vs no

pretreatment with Valium, because the medicated patients didn't have clarity of attention during the cognitive behavioral learning.

Jones, M. M. (1994). Apnea in postsurgical hypnotherapy of an esophageal cancer patient: A brief communication. International Journal of Clinical and Experimental Hypnosis, 42 (3), 179-183.

Use of clinical hypnosis in the post surgical psychotherapy of an esophageal cancer patient who could not swallow involved reenactment of the successful surgery and producing hallucinations of taste and smell, as well as working through emotions relating to the surgery and her disease. An apnea that occurred in a late phase of the treatment was addressed with the familiar arm pumping technique that had been used as a deepening technique, resulting in the patient's resuming normal breathing. The experience reminds the practitioner of the possible unexpected professional demands when working in a medical environment. It also provides clues as to the underlying psychological mechanisms and their role in successful symptom removal. A 6-year follow-up confirmed the lasting effect of this brief psychotherapy.

Katz, Ernest R.; Kellerman, Jonathan; Ellenberg, Leah (1987). Hypnosis in the reduction of acute pain and distress in children with cancer. Journal of Pediatric Psychology, 12, 379-394.

Hypnosis has been used as a behavioral approach to help children tolerate aversive medical procedures more effectively, but empirical longitudinal research evaluating the outcome of such interventions has been limited. In the present study, 36 children with acute lymphoblastic leukemia between the ages of 6 and 12 years of age undergoing repeated bone marrow aspirations (BMAs) were randomized to hypnosis or play comparison groups. Subjects were selected on their behavioral performance on baseline procedures and received interventions prior to their next three BMA procedures. Major results indicated an improvement in self-reported distress over baseline with both interventions, with no differences between them. Girls exhibited more distress behavior than boys on three of four dependent measures used. Suggestions of an interaction effect between sex and treatment group were noted. The role of rapport between patient and therapist in therapeutic outcome was also evaluated. Results are discussed in terms of potential individual differences in responding to stress and intervention that warrant further research.

Kaye, J. M.; Schindler, B. A. (1990). Hypnosis on a consultation-liaison service. General Hospital Psychiatry, 12, 379-383.

Studied the use of hypnosis on a consultation-liaison service with a broad spectrum of medically hospitalized patients. Autohypnosis tapes were used for reinforcement. Twenty-nine women and eight men from 24-75 years of age were hypnotized for relief of depression, pain, anxiety, or side effects of chemotherapy. Results were excellent (total to almost total relief of symptoms) in 68%, fair in 22%, and poor in 11%, with no differences among the results with the various conditions. This

demonstrates that hypnotherapy is an extremely useful tool in medical management of patients in consultation-liaison psychiatry.

**Kraft, Tom (1992). Counteracting pain in malignant disease by hypnotic techniques: Five case studies. Contemporary Hypnosis, 9, 123-129.**

Five cases of patients suffering from cancer are described in which hypnotic visualization techniques were successfully employed to relieve pain and anxiety. This study supports the view that hypnosis can be an effective tool for pain relief in malignant disease, particularly when traditional methods have been exhausted.

**Kraft, Tom (1993). Using hypnosis with cancer patients: Six case studies. Contemporary Hypnosis, 10, 43-48.**

Hypnosis can be used in a number of different ways for helping patients suffering from cancer. As well as pain relief, hypnosis may be used to correct insomnia that does not respond to sleeping tablets; for the reduction in skin irritation and dyspnoea when these are due to organic causes, and for treatment-related over-eating. Some patients will use hypnosis in a symbolic way. When this occurs, just as in dream interpretation, it is important to ask the patient for associations, so that these symbols can be understood. Hypnosis can be an extremely useful addition to the medical armamentarium, and should be employed as an adjunct to standard forms of cancer treatment. This paper reports six case studies in which hypnosis was used to help cancer patients.

**LaClave, Linda J.; Blix, Susanne (1989). Hypnosis in the management of symptoms in a young girl with malignant astrocytoma: A challenge to the therapist. International Journal of Clinical and Experimental Hypnosis, 37 (1), 6-14.**

This paper presents the case of a 6.5-year-old girl with malignant astrocytoma of the left brain hemisphere. During the course of her chemotherapy treatment, severe vomiting developed to the degree that on several occasions she became dehydrated. Discontinuation of chemotherapy was being considered when she was referred for hypnotherapy. Despite severe neurological impairments which excluded many traditional techniques, hypnosis was successful in eliminating emesis. Hypnosis was also utilized to decrease pain and to improve sleep patterns. Drawings are presented to help show how this child resolved anxiety associated with treatment and fears surrounding the knowledge of her impending death.

**LeBaron, Samuel; Zeltzer, Lonnie (1982, October). The effectiveness of behavioral intervention for reducing chemotherapy related nausea and vomiting in children with cancer. [Paper] Presented at the annual meeting of the Society for Clinical and Experimental Hypnosis, Indianapolis, IN.**

Eight children (nine to seventeen years, Mean age 12.1) with cancer received behavioral intervention for chemotherapy related nausea and vomiting. Within three to five days after the administration of each course of chemotherapy, patients rated (1-10 scale; 1 = none, 10 = all the time or maximal amount) their nausea and vomiting and the extent to which chemotherapy bothered them and disrupted their daily routine. After a pre-intervention assessment of 2.5 courses of chemotherapy, patients received intervention (Mean = 2.6 courses). Significant reductions following intervention (Wilcoxon matched- pairs signed ranks test) were found in nausea ( $Z = 2.37, p < .02$ ), vomiting ( $Z = 2.52, p < .01$ ), bother ( $Z = 2.24, p < .02$ ), and disruption of activities ( $Z = 2.38, p < .02$ ). This preliminary study indicates that chemotherapy side effects can be reduced through behavioral intervention.

Levitan, Alexander A. (1985). Hypnotic death rehearsal. American Journal of Clinical Hypnosis, 27 (4), 211-215.

Death rehearsal is a technique developed to help terminally ill patients and their families deal with anxieties about death. It has proven useful in demystifying the dying process by answering the question "What is it like to die?" Patients, who are able to hypnotically experience the death process, learn to deal with both grief and anxiety with the help of the hypnotherapist. - Author's abstract

Levitan, Alexander A. (1992). The use of hypnosis with cancer patients. Psychiatric Medicine, 10, 119-131.

Hypnosis has proven to be extremely valuable in the treatment of cancer patients. Specific applications include: establishing rapport between the patient and members of the medical health team; control of pain with self-regulation of pain perception through the use of glove anesthesia, time distortion, amnesia, transference of pain to a different body part, or dissociation of the painful part from the rest of the body; controlling symptoms, such as, nausea, anticipatory emesis, learned food aversions, etc.; psychotherapy for anxiety, depression, guilt, anger, hostility, frustration, isolation, and a diminished sense of self-esteem; visualization for health improvement; and, dealing with death anxiety and other related issues. Hypnosis has unique advantages for patients including improvement of self-esteem, involvement in self-care, return of locus of control, lack of unpleasant side effects, and continued efficacy despite continued use.

Lioffi, Christina; Hatira, Popi (1999). Clinical hypnosis versus cognitive behavioural training for pain management with pediatric patients undergoing bone marrow aspirations. International Journal of Clinical and Experimental Hypnosis, 47 (2), 104-116.

A randomized controlled trial was conducted to compare the efficacy of clinical hypnosis versus cognitive behavioral (CB) coping skills training in alleviating the pain and distress of 30 pediatric cancer patients (age 5 to 15 years) undergoing bone marrow aspirations. Patients were randomized to one of three groups: hypnosis, a

package of CB coping skills, and no intervention. Patients who received either hypnosis or CB reported less pain and pain-related anxiety than did control patients and less pain and anxiety than at their own baseline. Hypnosis and CB were similarly effective in the relief of pain. Results also indicated that children reported more anxiety and exhibited more behavioral distress in the CB group than in the hypnosis group. It is concluded that hypnosis and CB coping skills are effective in preparing pediatric oncology patients for bone marrow aspiration.

Lyles, Jeanne Naramore; Burish, Thomas G.; Krozely, Mary G.; Oldham, Robert K. (1982). Efficacy of relaxation training and guided imagery in reducing the aversiveness of cancer chemotherapy. Journal of Consulting and Clinical Psychology, 50, 509-524.

Fifty cancer patients receiving chemotherapy, 25 by push injection and 25 by drip infusion, were assigned to one of three conditions for their chemotherapy treatments: (a) progressive muscle-relaxation training plus guided-relaxation imagery; (b) therapist control, in which a therapist was present to provide support and encouragement but did not provide systematic relaxation training; and (c) no-treatment control. Patients participated in one pretraining, three training, and one follow-up session. Results indicated that during the training sessions, patients who received relaxation training, relative to patients in either of the other two conditions, (a) reported feeling significantly less anxious and nauseated during chemotherapy, (b) showed significantly less physiological arousal (as measured by pulse rate and systolic blood pressure) and reported less anxiety and depression immediately after chemotherapy, and (c) reported significantly less severe and less protracted nausea at home following chemotherapy. The attending nurses' observations during chemotherapy confirmed patient reports. In general, patients in the therapist control condition and the no-treatment control condition did not differ significantly from each other. The differences among conditions generally remained significant during the follow-up session. The data suggest that relaxation training may be an effective procedure for helping cancer patients cope with the adverse effects of their chemotherapy.

Margolis, Clorinda G. (1982-83). Hypnotic imagery with cancer patients. American Journal of Clinical Hypnosis, 25 (2-3), 128-134.

This is a clinical report on the use of hypnotic imagery to reduce pain and discomfort in cancer patients. Deep relaxation, ego strengthening, imagery, and suggestions for changes in perception and awareness are the principal techniques used to reduce suffering and to produce a sense of well-being among cancer patients treated at different stages of disease. Hypnotic intervention involving six patients is described, with emphasis on the ease with which positive transference is established and the effectiveness with which it may be used to enhance therapeutic effects.

Margolis, Clorinda G. (1984). Hypnosis and cancer: An overview of the field. [Unpublished manuscript]

## NOTES

This paper apparently was presented either at American Psychological Association or the Society for Clinical and Experimental Hypnosis. The author has two tables summarizing types of cancer associated with pain, and pain syndromes in patients with cancer.

Table 3 is a list of Erickson's procedures for Controlling Pain: --Direct hypnotic suggestion for total abolition of pain --Permissive indirect hypnotic abolition of pain --Amnesia --Hypnotic analgesia --Hypnotic anesthesia --Hypnotic replacement or substitution of sensations --Hypnotic displacement of pain --Hypnotic dissociation Time and body disorientation --Hypnotic reinterpretation of pain experience --Hypnotic time distortion --Hypnotic suggestions effecting a diminution of pain (from Rossi, Ed., *Innovative Hypnotherapy*, Vol. IV of the Collected Papers of Milton H. Erickson on Hypnosis, 1980)

Table 4 is a list of Sacerdote's Procedures for Controlling Pain: --Teleological approach --Reinterpretation of signals --Associating and conditioning --Dissociation --Simile of electric wiring --Development of amnesia --Positive and negative hallucinations --Induction of dreams --Time and space distortion, and elicitation of mystical states --Relaxation techniques --Glove anesthesia and analgesia --Pain management through control of autonomic functions (from Barber & Adrian, Eds., *Psychological Approaches to the Management of Pain*, 1982)

The author describes cases treated by Erickson (one in which he used 12 hours of training, in one session, reported in Rossi's 1980 edited writings of Milton Erickson, Vol. IV) and by Sacerdote.

Author notes that the Hilgards, in *Hypnosis in the Relief of Pain* (1975), describe the use of hypnosis in treating patients with cancer pain. In all three--Butler (1954), Lea, Ware, and Monroe (1960), and a larger study by Cangello (1961), both success and failure are reported. As the Hilgards point out, about 50% of the patients studied were able to reduce their pain--a percentage the Hilgards remark is rather close to what successful clinicians tend to report.

McCue, Peter A. (1991). Key Paper Review: Prophylactic therapy for cancer and coronary heart disease. [Comment/Discussion] .

## NOTES

This is a commentary on two papers by Grossarth-Maticek and Eysenck, in which they report on 'creative novation behaviour therapy' to prevent cancer and heart disease in people with personalities associated with the development of those diseases. Therapy may involve hypnosis and/or relaxation, with suggestions that facilitate modification of unhealthy expectancies. The papers are:

Grossarth-Maticek, R. & Eysenck, H.J. (1991). Creative novation behaviour therapy as a prophylactic treatment for cancer and coronary heart disease: Part I - Description of treatment. *Behaviour Research and Therapy* 29, 1-16.

Eysenck, H.J. & Grossarth-Maticek, R. (1991). Creative novation behaviour therapy as a prophylactic treatment for cancer and coronary heart disease: Part II - Effects of treatment. *Behaviour Research and Therapy* 29, 1, 17-31.

Meares, Ainslie (1982-83). A form of intensive meditation associated with the regression of cancer. *American Journal of Clinical Hypnosis*, 25 (2-3), 114-121.

Elsewhere I have reported a number of cases of regression of cancer following intensive meditation. This type of meditation is characterized by extreme simplicity and stillness of the mind, and so differs from other forms using a mantra, awareness of breathing or visualization of the healing process. Any logical verbal communication by the therapist stimulates intellectual activity in the patient. So communication is by unverballed phonation, reassuring words and phrases, and most important, by touch. There follows a profound reduction in the patient's level of anxiety which flows on into his daily life. The non-verbal nature of the meditative experience initiates a non-verbal philosophical understanding of other areas of life.

Morrow, Gary R. (1984). Appropriateness of taped versus live relaxation in the systematic desensitization of anticipatory nausea and vomiting in cancer patients. *Journal of Consulting and Clinical Psychology*, 52 (6), 1098-1099.

Investigated the suggestion that the relaxation part of systematic desensitization--an effective treatment for the nausea and vomiting experienced by approximately 25% of cancer patients in anticipation of chemotherapeutic treatments-- could be learned from a prerecorded audiotape prior to meeting a psychologist for treatment. 10 cancer patients who had developed anticipatory nausea or vomiting were assigned to either a live-relaxation or a tape-relaxation group. Results show that 4 of 5 Ss assigned to the tape-relaxation group experienced nausea while listening to the prerecorded audiotape, while none of the patients in the live-relaxation group reported nausea when subsequently listening to an audiotape made during the live presentation of relaxation.

Newton, Bernauer (1984, October). The use of imagery in the treatment of cancer patients. [Paper] Presented at the annual meeting of the Society for Clinical and Experimental Hypnosis, San Antonio, TX.

Several hundred cancer patients were treated with the Simonton visualization method, with the additional factor that they were hypnotized for the visualization. In a long term follow-up study, those patients who were treated for at least 6 months and are still alive had imagery that was vivid, persistent, positive, and passive ("passive" here meaning an underlying sense of calm). Those who died had the opposite kind of images, and retrospective review of clinical notes indicates their aggressive images reflected desperation. Of the patients who were treated less than six months, a few lived. Their images also were vivid, persistent, and positive.

Newton, Bernauer W. (1982-83). The use of hypnosis in the treatment of cancer patients. American Journal of Clinical Hypnosis, 25 (2-3), 104-113.

For nearly eight years, cancer patients have been treated at this outpatient facility using hypnosis and psychotherapy. Basic concepts, assumptions and procedures are presented and the issues and problems encountered are discussed. Results are given as they relate to the three goals of treatment.

Oliver, George W. (1982-83). A cancer patient and her family: A case study. American Journal of Clinical Hypnosis, 25 (2-3), 156-160.

In recent years, increasing numbers of mental health workers have been attempting to use techniques of psychotherapy to influence the course of malignant disease. This paper reviews in detail the course of treatment of one female patient with an inoperable malignancy and conveys a sense of the clinical experience of working intensively with a cancer patient and her family. It shows the complex levels of interaction within the patient herself, between the patient and her family, and between the therapist and her family and within the therapist himself during different phases of the therapeutic journey.

Petrucci, Ralph J.; Harwick, Robert D. (1984). Role of the psychologist on a radical head and neck surgical service team. Professional Psychology: Research and Practice, 15, 538-543.

Surgery for head and neck cancers often produces disfiguration and a sense of hopelessness in patients, and it may also results in a lack of self-acceptance, depression, and covert hostility. Psychologists are often called on to help such patients deal with drug abuse, suicidal behaviors, strong characterological disorders, noncompliance, and overall adjustment. Behavioral management and anxiety-reduction strategies, such as relaxation exercises and visual imagery, are often helpful. (17 ref).

Rapkin, David A.; Straubing, Marsha; Holroyd, Jean (1991). Guided imagery, hypnosis and recovery from head and neck cancer surgery. International Journal of Clinical and Experimental Hypnosis, 39, 215-226.

The value of a brief, preoperative hypnosis experience was explored with a sample of 36 head and neck cancer surgery patients. 15 patients volunteered for the experimental hypnosis intervention. 21 patients who received usual care (no hypnosis) were followed through their hospital charts and were used as a comparison group. Hypnotic intervention and usual care groups were comparable in terms of relevant demographic variables. Postoperative hospitalizations for the hypnotic intervention group were significantly shorter than for the usual care group. Within the hypnotic intervention group, hypnotizability was negatively correlated with surgical complications and there was a trend toward a negative correlation between hypnotizability and blood loss during surgery. Findings suggest that imagery-hypnosis may be prophylactic, benefitting patients by reducing the

probability of postoperative complications and thereby keeping hospital stay within the expected range. Recommendations are presented for a controlled, randomized, clinical trial with a sufficiently large sample to provide the opportunity for statistical analysis with appropriate power.

#### NOTES

Actual stay in hospital, post-surgery, was 8.7 days (SD = 3.7) for the Hypnosis group and 13.9 days (SD = 9.7) for the Usual Care group; the range was 3-17 days for the Hypnosis group and 5-42 days for the usual care group.

The hypnosis script included an indirect, permissive induction; positive suggestions for relaxation and healing imagery; images of calm situations that would lead to expectation for healing (e.g. a 'healing pool'); suggestions for patients to develop their own images of pleasurable, comforting situations. The only direct suggestions were for minimal blood loss during surgery, modeled after those given in the waking situation by Bennett, Benson, and Kuiken (1986).

As measured by the Stanford Hypnotic Clinical Scale, there were five highly hypnotizable patients (scores 4-5), six mediums (scores 2-3), and four lows (scores 0-1). "Hypnotizability correlated negatively with complications ( $r = -.54, p < .04$ , two-tailed test). There was a trend toward a negative correlation with length-of-stay ( $r = -.37, p < .18$ , two-tailed test) and estimated blood loss ( $r = -.40, p < .15$ , two-tailed test). Note that these correlations represent moderate to large effects, and the significance levels are due in part to low power associated with a small N (Cohen, 1988). The means for blood lost during surgery for the three hypnotizability groups were: highs = 904 cc, mediums = 1465 cc, and lows = 2056 cc" (p. 222).

Data on cost could not be published in this article but later was published in a letter to the Editor of the Newsletter of the Society of Clinical and Experimental Hypnosis (February 1994, Vol. 35, No. 1, p.8). "The average savings for the intervention group was \$6,725. While this difference fell short of statistical significance on the Wilcoxon test ( $Z = -1.5402, p < .10$ ), it is rather striking on its face. The range actually was \$7849 to \$27,782 for Intervention Group patients and \$9,390 to \$53,627 for Usual Care group patients.

"In 1990 a semi-private room at UCLA Center for the Health Sciences cost \$405 to \$529 per day, depending on quality; standard ICU care (one nurse for two patients) was \$1236 per day, and more intensive care (one nurse for one patient) was \$2471/day. Head and neck surgery patients may remain in the ICU, driving up costs, solely because they have not learned to suction their own tracheostomies, usually a motivational factor that might be affected by hypnosis. UCLA is a tertiary care hospital in a high-cost area (and is therefore reimbursed at higher rates than many other hospitals), and costs may be driven up by the many additional procedures required for long-stay patients. Therefore the cost savings could not be expected to be as great where expected length of stay is brief, ICU use is limited, and community costs are lower" (p. 8).

Redd, William H.; Andresen, Graciela V.; Minagawa, Rahn Y. (1982). Hypnotic control of anticipatory emesis in patients receiving cancer chemotherapy. Journal of Consulting and Clinical Psychology, 50 (1), 14-19.

## **NOTES**

**Deep muscle relaxation hypnosis controlled nausea, gagging, retching in all cases. Anticipatory emesis recurred when hypnosis was not used. During subsequent sessions in which hypnosis was reinstated, anticipatory emesis was again controlled.**

**Redd, William H.; Andrykowski, Michael A. (1982). Behavioral intervention in cancer treatment: Controlling aversion reactions to chemotherapy. Journal of Consulting and Clinical Psychology, 50 (6), 1018-1029.**

**During the protracted course of cancer chemotherapy, approximately 25% of patients develop aversion reactions to treatment by becoming nauseated and/or vomiting before their chemotherapy treatments. This phenomenon has been conceptualized as a result of respondent conditioning. Since commonly used antiemetic drugs do not reliably control anticipatory nausea/emesis, behavioral techniques of control have been studied. They include hypnosis used in conjunction with guided-relaxation imagery, progressive muscle relaxation with guided imagery, and systematic desensitization. (67 ref)**

**Redd, William H.; Rosenberger, Patricia H.; Hendler, Cobie S. (1982-83). Controlling chemotherapy side effects. American Journal of Clinical Hypnosis, 25 (2-3), 161-172.**

**Severe nausea and vomiting are commonly experienced by cancer patients after receiving chemotherapy treatments. Moreover, approximately 25% of these patients develop conditioned aversions to treatment and become nauseated before they receive their chemotherapy injections. The use of deep muscle relaxation hypnosis in conjunction with guided imagery to control pre- and post-chemotherapy nausea and emesis is discussed. Theoretical and clinical issues raised by this application of hypnosis in cancer treatment are also addressed.**

**Rosenberg, Simon W. (1982-83). Hypnosis in cancer care: Imagery to enhance the control of the physiological and psychological 'side-effects' of cancer therapy. American Journal of Clinical Hypnosis, 25 (2-3), 122-127.**

**The use of surgery, radiation, and chemotherapy has resulted in increased control of malignancy and prolonged survival for cancer patients. These modalities also carry significant morbidity. Normal physiological homeostasis is often altered by both the neoplasm and its treatment. The diagnosis, treatment, and social stigma of cancer exact profound psychological impact. Hypnosis effectively can control the range of both physiological and psychological 'side-effects' of cancer and its therapy. This paper will delineate those effects of hypnosis of proven value to the cancer patient. Incorporation of images into each phase of a hypnosis session will be demonstrated with an actual case history and annotated transcript. Imagery as a therapeutic modality will be discussed in general, and specific suggestions and images will be given.**

Sacerdote, Paul (1970). Theory and practice of pain control in malignancy and other protracted or recurring painful illnesses. International Journal of Clinical and Experimental Hypnosis, 18 (3), 160-180.

Recent neuroanatomical and neurophysiological experimental data suggest absence or presence of pain and changes in pain intensity as expressions of the balance between sensory (peripheral) and central (centrifugal) inputs at synaptic stations. Psychological activities by contributing to the centrifugal input influence conduction, transduction, and perception of pain stimuli. Hypnotically induced analgesia and anesthesia are therefore acceptable as neurophysiological realities. Methods for hypnotic alterations of pain based upon these premises are described utilizing neurophysiological mechanisms, psychodynamic changes, establishment of new behavioral patterns, or changes in time-space concepts and percepts. Case presentations illustrate some of these multiple psychological and physiological approaches to pain control. (Spanish & German summaries) (28 ref.) (PsycINFO Database Record (c) 2003 APA, all rights reserved)

Shapiro, Arnold (1982-83). Psychotherapy as adjunct treatment for cancer patients. American Journal of Clinical Hypnosis, 25 (2-3), 150-155.

During the past ten years psychotherapy as adjunct treatment for cancer patients has become increasingly common. The use of hypnosis as an integral part of that treatment has also burgeoned. This report will follow the progress of two cancer patients in psychotherapy. While each is highly individual, the commonalities which allow treatment to be systematic will be quite apparent. The ability to minimize pain and discomfort, the ability to keep the white cell count high despite ongoing chemotherapy, and augmenting the ability of the body's immune system to fight the disease are utilized by both of the patients. All of the above are accomplished through the use of visual imagery in the trance state. Visual imagery is also used to reach feelings which patients are often unable to verbalize, and of which they often claim to be unaware. Other aspects of therapy such as the gradual shift from despair to hope and even confidence, and the development of more assertive behavior are discussed.

Slater, Roger C.; Flores, Louis S. (1963). Hypnosis in organic symptom removal: A temporary removal of an organic paralysis by hypnosis. American Journal of Clinical Hypnosis, 5 (4), 248-255.

#### NOTES

Summary and Conclusions. A detailed case study is reported on the use of hypnosis with beneficial results in an instance of eventually proved organic brain disease. Three other confirmatory case reports of organic disease definitely benefitted by the use of hypnosis are briefly cited.

The first patient had been adequately studied repeatedly for organic brain disease. Because the studies led to an uncertain indefinite unconfirmed suspicion of psychogenic epilepsy, the patient was returned with a recommendation for

continued treatment and observation by the author, a general practitioner. Hence, she was, after still further study for organic disease, treated symptomatically by hypnosis with beneficial results. This led to the erroneous conclusion that the patient's disability was probably functional. A sudden fatal outcome of the actual but unrecognized brain disease led to a correct but post- mortem diagnosis of astrocytoma of the brain, Grade IV.

"This report and those given to supplement it raise significant questions about the importance and value of hypnosis in organic disease. These include the challenging question of the extent to which the use of hypnosis can potentiate the natural corrective forces of the body; the need to recognize the value of hypnosis in effecting beneficial results in organic disease; the need to qualify the reliability of hypnosis as a differential diagnostic procedure in relation to psychogenic and organic disability; and the possibility and extent of the amelioration or actual correction of known organic illness" (p. 254).

Spiegel, David (1992, October). Hypnotizability. [Paper] Presented at the annual meeting of the Society for Clinical and Experimental Hypnosis, Arlington, VA.

#### NOTES

Dr. Spiegel announced that this was a last minute substitution for Fred Frankel's presentation on Hypnotizability. We have ongoing a major replication of the study that we published on group therapy with terminally ill breast cancer patients. The matched control patients get educational materials but not psychotherapy. We are looking at NKC cytotoxicity and delayed hypersensitivity.

Tasks: spend 15 minutes discussing list of problems; 15 minutes discussing things like, "What is your spouse doing that doesn't help; what can we do to help it?" We get drop in NKC cytotoxicity immediately afterward, returning after 24 hrs to usual levels. Controls don't drop in NKC cytotoxicity. This measure of stress may be a predictor of survival time.

In Fawzy's study of group therapy with melanoma patients, they noted a significant difference at 6 months in interferon augmented activity of NK, which didn't hold up at a year. But at 6 years there were 10 of 40 deaths in control group vs 3 of 40 deaths in treated group. This is a vigorous effect.

Cohen's study of colds in New England J. of Med is another good clinical study.

There are two broad areas of relevance of hypnotizability to healing: 1. Hypnotizability as a trait: do highs differ in way they regulate body or mind? 2. Is there something you do when in hypnotized state that is different? Studies of treatment of warts with hypnosis are important 3. Transition between states, e.g. circadian rhythms; is there a shift in wakefulness between trance and nontrance states that affects health?

Psychiatric Diagnosis and self regulation. High hypnotizability is associated with certain psychiatric disorders (dissociative reaction, PTSD, MPD, etc.). Schizophrenics score much lower than normals (av. = 4 vs 7; replicated with the Hypnotic Induction Profile (HIP). Stanford Hypnotizability Scales show no difference in means, but do show a difference in range). I don't know what this

means. But schizophrenics can falsely pass some Stanford Scale items, e.g. amnesia which they don't however reverse; so schizophrenics' hypnotizability scores may be inflated on Stanford scales. We don't see extremely high scores in schizophrenics.

Psychoactive medication doesn't affect scores of schizophrenics, but improves scores of anxiety neurotics (by reducing anxiety). Frischholz has an article coming out in a psychiatry journal that confirms this.

There is a lot of evidence that patients with dissociative disorders are more hypnotizable than other groups. Frischholz et al couldn't replicate Frankel's finding of higher scores in phobics. Pettinati et al found higher scores in bulimia and I haven't seen anything to counter that. Another idea is that high hypnotizables are very good at internal regulation

Spiegel & Ken Kline selected Ss who could regulate gastric activity. They got an 80% increase in gastric acid output while imagining eating; got 40% decrease in output when imagining something pleasant that wasn't imagining eating. Injected with pentagastrin, which induces gastric output, they still got a decrease in gastric acid output in the relaxation condition.

This suggests that hypnotizability should be a selection criterion for some research. See also Katz et al. 1974 (?) with acupuncture; and McGlashan, Evans & Orne on the placebo response.

Herbert Spiegel found that 2/3 of highs but 1/3 of lows were cured of phobia. Eye roll sign on the HIP, living with spouse/lover, rating self as hypnotizable, and giving a postcard follow-up response at one week post treatment were associated with 89% rate abstinence at 2 years follow-up, when only 23% overall of 223 were abstinent. Absence of those positive predictors was associated with only a 4% rate of abstinence.

Spiegel, David; Bloom, J. R.; Kraemer, H. C.; Gottheil, E. (1989, October 14). The beneficial effect of psychosocial treatment on survival of metastatic breast cancer patients: A randomized prospective outcome study. Lancet, 888-891.

The effect of psychosocial intervention on time of survival of 86 metastatic breast cancer patients was studied using randomized prospective design. The one-year treatment consisted of weekly supportive group therapy with training in self-hypnosis for pain management, and resulted in significant reductions in mood disturbance and pain. Both the treatment and control groups had routine oncologic care. At ten-year follow-up, only three of the original 86 patients were still alive, and death records were obtained for the other 83. Survival from the time of randomization and onset of intervention was 36.6 (sd = 37.6) months for the treatment group, compared with 18.9 (sd = 10.8) months for the control group, and this difference was highly significant ( $Z = 3.94$ ,  $p < .0001$ ) using the Cox life table regression model. Kaplan-Meier survival analysis indicated that the divergence in survival began at 20 months after entry into the study, or 8 months after the treatment intervention ended. These unexpected findings suggest that intensive psychosocial support affects the course of the illness, although the mechanism by which it does so is not clear.

Spira, James L.; Spiegel, David (1992). Hypnosis and related techniques in pain management. Hospice Journal, 8, 89-119.

Hypnosis has been used successfully in treating cancer patients at all stages of disease and for degrees of pain. The experience of pain is influenced not only by physiological factors stemming from disease progression and oncological treatment, but also from psychosocial factors including social support and mood. Each of these influences must be considered in the successful treatment of pain. The successful use of hypnosis also depends upon the hypnotizability of patients, their particular cognitive style, their specific motivation, and level of cognitive functioning. While most patients can benefit from the use of hypnosis, less hypnotizable patients or patients with low cognitive functioning need to receive special consideration. The exercises described in this chapter can be successfully used in groups, individual sessions, and for hospice patients confined to bed. Both self-hypnosis and therapist guided hypnosis exercises are offered.

Stokvis, B. (1956). The application of hypnosis in organic diseases. Journal of Clinical and Experimental Hypnosis, 4 (2), 79-82.

#### SUMMARY.

Hypnotherapy, applied as a symptomatic treatment, is especially indicated in those cases of organic diseases in which the patient has neurotically elaborated his physical suffering. In cases presenting neither etiological nor secondary psychic factors one may try to improve the patient's condition by hypnotic treatment. Description of a case (hypnotherapy in a woman with carcinoma mammae)[sic]. The writer's lack of appreciation of hypnotherapy in organic diseases does not include the treatment of diseases which are definitely psychosomatically determined" (pp. 81-82).

Syrjala, Karen L.; Cummings, Claudette; Donaldson, Gary W. (1992). Hypnosis or cognitive behavioral training for the reduction of pain and nausea during cancer treatment: A controlled clinical trial. Pain, 48, 137-146.

Few controlled clinical trials have tested the efficacy of psychological techniques for reducing cancer pain or post-chemotherapy nausea and emesis. In this study, 67 bone marrow transplant patients with hematological malignancies were randomly assigned to one of four groups prior to beginning transplantation conditioning: (1) hypnosis training (Hypnosis); (2) cognitive behavioral coping skills training (CB); (3) therapist contact control (TC); or (4) treatment as usual (TAU; no treatment control). Patients completed measures of physical functioning (Sickness Impact Profile; SIP) and psychological functioning (Brief Symptom Inventory; BSI), which were used as covariates in the analyses. Biodemographic variables included gender, age and a risk variable based on diagnosis and number of remissions or relapses. Patients in the Hypnosis, CB, and TC groups met with a clinical psychologist for two pre-transplant training sessions and ten in-hospital "booster" sessions during the course of transplantation. Forty-five patients completed the study and provided all covariate data, and 80% of the time series outcome data. Analyses of the

principal study variables indicated that hypnosis was effective in reducing reported oral pain for patients undergoing marrow transplantation. Risk, SIP, and BSI pre-transplant were found to be effective predictors of inpatient physical symptoms. Nausea, emesis and opioid use did not differ significantly between the treatment groups. The cognitive behavioral intervention, as applied in this study, was not effective in reducing the symptoms measured.

#### NOTES

1:

NOTES: Hypnotizability was not measured in this study.

The authors hypothesized that "(1) patients receiving hypnosis training would report the least pain, but the cognitive behavioral group would report less pain than the untreated group; and (2) both treatment groups would report less nausea and emesis than the control groups" (p. 138). The adult patients were undergoing their first marrow transplant, had survived at least 19 days post-transplant, and had participated in at least the first 8 of 10 possible inpatient sessions; five additional patients completed the study but had missing data.

Each patient in the TC (therapist contact), CB (cognitive behavioral coping skills), and Hypnosis groups participated in two 90 minute training sessions with a psychologist, 2-4 days apart, on an outpatient basis. Once admitted to hospital, twice each week they participated in a total of ten 30-minute sessions designed to reinforce use of the interventions. The TAU (treatment as usual) group had no psychologist contact. For the TC control group, the psychologist simply talked with the patients about whatever was on their minds.

The CB group received multiple interventions: training in relaxation (2 techniques-progressive muscle relaxation and abbreviated autogenic relaxation) with tapes provided; cognitive restructuring (Turk et al., 1983) which included training in attention redirection and restructuring self-defeating cognitions; preparing coping self-statements or affirmations, by focusing attention on neutral or pleasant events or objects, or by occupying their attention through mental repetition of affirmations, songs or prayer; encouragement to think of negative events as time limited; provision of information, especially the beneficial effects of reducing physiological arousal and attention to pain and nausea; assistance in setting short-term progress-related goals for self-care such as exercise, caloric intake, and mouth care; exploration of the meaning of their illness and of bone marrow transplant.

For the Hypnosis group, individually tailored Ericksonian inductions (Lankton & Lankton, 1983) with relaxation and multi-sensory imagery were taped and given to the patient to use in daily practice, in between sessions. The suggestions were directed at reducing pain, nausea, and the emotional reactions to those symptoms; there also were suggestions about health, well-being, self-control and enhanced coping capabilities.

The results were analyzed by ANCOVA (except where non-parametric analysis was required with the opioid data). Due to gender differences in reported pain (men experiencing more) and the fact that the TAU group had an over-representation of men, the TAU group could not be used in the pain analyses. However, there were no gender differences in nausea reports, so that all four groups could be used for nausea outcome analyses.

The Hypnosis group evidenced the lowest amount of post-transplant pain, and used (nonsignificantly) less opioids than the other groups. No significant treatment effects were observed for either nausea or emesis.

In their discussion, the authors noted that "The hypnosis group's peak pain was lower and of a shorter duration than the other three groups. Opioid use closely followed the course of pain intensity. ... The gender effect may be characteristic of this particular sample [since it was unexpected].

"Nausea and emesis followed a less predictable course than pain. ... nausea fluctuated dramatically from day to day within treatment groups. As nausea moderated after completion of conditioning, the day to day fluctuations remained striking. This lack of symptom predictability may have contributed to the difficulty patients had in using the interventions effectively" (p. 143).

"The lack of significant differences between treatment groups in opioid use indicates that lower pain report in the hypnosis group cannot be explained by increased opioid use. Results do not support the second hypothesis that both hypnosis and cognitive behavioral training would reduce chemotherapy or radiation-induced nausea and emesis.

"In MT patients, several factors may limit the impact of either cognitive behavioral training or hypnosis on nausea and emesis. First, MT patients receive higher doses of emetogenic agents than are given to most other cancer patients. Second, patients in this study had only two sessions in which to learn relaxation techniques; this may not have provided adequate training. Third, the most severe emetic challenge began immediately with the first dose of chemotherapy rather than having a gradual onset. This did not permit patients to master the techniques with milder symptoms before applying training to intense symptoms. Fourth, for all patients, psychological interventions were provided as adjuncts to medications rather than as substitutes for antiemetics or opioids. Both antiemetics and opioids have substantial cognitive side effects which, in high doses, may impact patients' abilities to implement interventions which are in essence cognitive. This combination of factors may have provided too severe a challenge to a newly learned skill. In contrast to nausea, oral pain developed over a number of days, permitting practice while symptoms were mild and before administration of opioids.

"Results suggest that the imagery component of the hypnosis intervention was central to its efficacy. Not only was the cognitive behavioral intervention without imagery not effective in reducing the symptoms measured, but we found in clinical practice that patients intermittently began to refuse sessions with relaxation alone. Even hypnosis patients, when under the physical stresses of treatment, had shortened attention spans that necessitated briefer inductions, less time spent on relaxation, and more active, engaging imagery.

"... Since, in clinical practice, imagery is frequently a component of cognitive behavioral treatment, these results would not generalize to those settings where imagery is combined with other skill training.

"Several other possible limitations of the cognitive behavioral intervention merit consideration. Our experience indicates that the number of components used in the two training sessions were more than patients could competently learn in a short time. ... A further possibility is that maladaptive cognitions, which are the targets of

cognitive restructuring, may be the exception rather than the rule among MT patients who tend to focus, with their families, on positive, hopeful attitudes toward their treatment" (pp. 144- 145).

The authors note that the relatively small sample size may have provided inadequate statistical power to demonstrate effects with some of the outcome variables.

Walker, Leslie G. (1992). Hypnosis with cancer patients. American Journal of Preventative Psychiatry & Neurology, 3, 42-49.

Overviews the uses of hypnosis with cancer, for example to ameliorate side effects of treatment, help patients adjust to having cancer and its symptoms, reduce the distress caused by painful procedures, and to attempt to alter mechanisms of immunity with a view to improving prognosis. Studies in these areas are reviewed.

Wall, Valerie J.; Womack, William (1989). Hypnotic versus active cognitive strategies for alleviation of procedural distress in pediatric oncology patients. American Journal of Clinical Hypnosis, 31 (3), 181-191.

#### NOTES

The authors compared the effectiveness of a standardized hypnosis instruction vs and active cognitive strategy.

Zeltzer, Lonnie K.; Dolgin, M. J.; LeBaron, Samuel; LeBaron, C. (1991). A randomized, controlled study of behavioral intervention for chemotherapy distress in children with cancer. Pediatrics, 88, 34-42.

Subjects were randomly assigned to hypnosis, nonhypnotic distraction/relaxation, or attention placebo control. children in the hypnosis group reported the greatest reduction in both anticipatory and postchemotherapy symptoms. Distraction/relaxation kept symptoms from getting worse, but they did not get better, and the control children's symptoms became much worse.

#### CARDIOLOGY/CARDIOVASCULAR

2000

Lang, E. V.; Benotsch, E. G.; Fick, L. J.; Lutgendorf, S.; Berbaum, M. L.; Berbaum, K. S.; Logan, H.; Spiegel, D. (2000, Apr 29). Adjunctive non-pharmacological analgesia for invasive medical procedures: A randomised trial. Lancet, 355 (9214), 1486-90.

**BACKGROUND:** Non-pharmacological behavioural adjuncts have been suggested as efficient safe means in reducing discomfort and adverse effects during medical procedures. We tested this assumption for patients undergoing percutaneous vascular and renal procedures in a prospective, randomised, single-centre study.

#### METHODS

241 patients were randomised to receive intraoperatively standard care (n=79), structured attention (n=80), or self-hypnotic relaxation (n=82). All had access to

patient-controlled intravenous analgesia with fentanyl and midazolam. Patients rated their pain and anxiety on 0-10 scales before, every 15 min during and after the procedures.

#### **FINDINGS**

Pain increased linearly with procedure time in the standard group (slope 0.09 in pain score/15 min,  $p < 0.0001$ ), and the attention group (slope 0.04/15 min;  $p = 0.0425$ ), but remained flat in the hypnosis group. Anxiety decreased over time in all three groups with slopes of -0.04 (standard), -0.07 (attention), and -0.11 (hypnosis). Drug use in the standard group (1.9 units) was significantly higher than in the attention and hypnosis groups (0.8 and 0.9 units, respectively). One hypnosis patient became haemodynamically unstable compared with ten attention patients ( $p = 0.0041$ ), and 12 standard patients ( $p = 0.0009$ ). Procedure times were significantly shorter in the hypnosis group (61 min) than in the standard group (78 min,  $p = 0.0016$ ) with procedure duration of the attention group in between (67 min).

#### **INTERPRETATION**

Structured attention and self-hypnotic relaxation proved beneficial during invasive medical procedures. Hypnosis had more pronounced effects on pain and anxiety reduction, and is superior, in that it also improves haemodynamic stability.

Abstract from National Library of Medicine, PubMed

1999

Rainville, P.; Hofbauer, R. K.; Paus, T.; Duncan, G. H.; Bushnell, M. C.; Price, D. D. (1999). Cerebral mechanisms of hypnotic induction and suggestion. Journal of Cognitive Neuroscience, 11 (1), 110-125.

The neural mechanisms underlying hypnotic states and responses to hypnotic suggestions remain largely unknown and, to date, have been studied only with indirect methods. Here, the effects of hypnosis and suggestions to alter pain perception were investigated in hypnotizable subjects by using positron emission tomography (PET) measures of regional cerebral blood flow (rCBF) and electroencephalographic (EEG) measures of brain electrical activity. The experimental conditions included a restful state (Baseline) followed by hypnotic relaxation alone (Hypnosis) and by hypnotic relaxation with suggestions for altered pain unpleasantness (Hypnosis-with-Suggestion). During each scan, the left hand was immersed in neutral (35 degree C) or painfully hot (47 degrees C) water in the first two conditions and in painfully hot water in the last condition. Hypnosis was accompanied by significant increases in both occipital rCBF and delta EEG activity, which were highly correlated with each other ( $r = 0.70$ ,  $p < 0.0001$ ). Peak increases in rCBF were also observed in the caudal part of the right anterior cingulate sulcus and bilaterally in the inferior frontal gyri. Hypnosis-related decreases in rCBF were found in the right inferior parietal lobule, the left precuneus, and the posterior cingulate gyrus. Hypnosis-with-suggestions produced additional widespread increases in rCBF in the frontal cortices predominantly on the left side. Moreover, the medial and lateral posterior parietal cortices showed suggestion-related increases overlapping partly with regions of hypnosis-related decreases. Results support a state theory of hypnosis in which occipital increases in rCBF and delta

activity reflect the alteration of consciousness associated with decreased arousal and possible facilitation of visual imagery. Frontal increases in rCBF associated with suggestions for altered perception might reflect the verbal mediation of the suggestions, working memory, and top-down processes involved in the reinterpretation of the perceptual experience. These results provide a new description of the neurobiological basis of hypnosis, demonstrating specific patterns of cerebral activation associated with the hypnotic state and with the processing of hypnotic suggestions.

Wickramasekera, Ian E.; Kolm, Paul; Pope, Alan; Turner, Marsha (1998). Observation of a paradoxical temperature increase during cognitive stress in some chronic pain patients. Applied Psychophysiology and Biofeedback, 23 (4), 233-241.

A total of 224 chronic pain somatoform disorder patients without obvious pathophysiology or psychopathology were found to have colder hands than nonpatients. A paradoxical temperature increase (PTI) in response to a cognitive stressor (mental arithmetic) was noted in a subset of these chronic pain patients. Patients were defined as "PTI" responders if, during cognitive stress, an increase in digital temperature occurred over a prior eyes closed resting condition. It was found that 49.4% of males and 42.6% of females in a total sample of 224 patients demonstrated PTI. The PTI patients had significantly colder hands than non-PTI patients prior to stress. A concurrent SCL measure of sympathetic activation found no difference between the PTI and non-PTI groups either at baseline or during cognitive stress. It appears from this data that PTI is specific to the peripheral vascular system of these patients and may be a marker of psychophysiological dissociation or trauma blocked from consciousness.

Bayot, A.; Capafons, A.; Cardega, E. (1997). Emotional self-regulation therapy: A new and efficacious treatment for smoking.. American Journal of Clinical Hypnosis, 40 (2), 146-156.

We described emotional self-regulation therapy, a recently-developed suggestion technique for the treatment of smoking, and present data attesting to its efficacy. Of the 38 individuals who completed treatment, 82% (47% of the initial sample) stopped smoking altogether and 13% (8% of the initial sample) reduced their smoking. A follow-up at 6 months showed that 66% (38% of the initial sample) of those who had completed the treatment remained abstinent and reported minimal withdrawal symptoms or weight gain. In a no-treatment comparison group, only 8% reduced their smoking or became abstinent.

Lang, Elvira V.; Joyce, Janet S.; Spiegel, David; Hamilton, Donna; Lee, Kelvin K. (1996). Self-hypnotic relaxation during interventional radiological procedures: Effects on pain perception and intravenous drug use. International Journal of Clinical and Experimental Hypnosis, 44 (2), 106-119.

The authors evaluated whether self-hypnotic relaxation can reduce the need for intravenous conscious sedation during interventional radiological procedures. Sixteen patients were randomized to a test group, and 14 patients were randomized to a control group. All had patient-controlled analgesia. Test patients additionally had self-hypnotic relaxation and underwent a Hypnotic Induction Profile test. Compared to controls, test patients used less drugs (0.28 vs. 2.01 drug units;  $p < .01$ ) and reported less pain (median pain rating 2 vs. 5 on a 0-10 scale;  $p < .01$ ). Significantly more control patients exhibited oxygen desaturation and/or needed interruptions of their procedures for hemodynamic instability. Benefit did not correlate with hypnotizability. Self-hypnotic relaxation can reduce drug use and improve procedural safety.

1995

Enqvist, Bjorn; von Konow, L.; Bystedt, H. (1995). Pre- and perioperative suggestion in maxillofacial surgery: Effects on blood loss and recovery. International Journal of Clinical and Experimental Hypnosis, 43 (3), 284-294.

The basic assumption underlying the present study was that emotional factors may influence not only recovery but also blood loss and blood pressure in maxillofacial surgery patients, where the surgery was performed under general anesthesia. Eighteen patients were administered a hypnosis tape containing preoperative therapeutic suggestions, 18 patients were administered hypnosis tapes containing pre- and perioperative suggestions, and 24 patients were administered a hypnosis tape containing perioperative suggestions only. The patients who received taped suggestions were compared to a group of matched control patients. The patients who received preoperative suggestions exhibited a 30% reduction in blood loss. A 26% reduction in blood loss was shown in the group of patients receiving pre- and perioperative suggestions, and the group of patients receiving perioperative suggestions only showed a 9% reduction in blood loss. Lower blood pressure was found in the groups that received pre- and perioperative and perioperative suggestions only. Rehabilitation was facilitated in the group of patients receiving perioperative suggestions only.

1993

Blankfield, Robert P. (1993, October). Suggestion, hypnosis, and relaxation as adjuncts for surgery patients: Lessons from studies involving cardiac surgery patients. [Paper] Presented at the annual meeting of the Society for Clinical and Experimental Hypnosis, Arlington Heights, IL.

NOTES

The author stated that his research and the few other studies of cardiac surgery patients do not support idea that cardiac surgery patients benefit from hypnosis and suggestion.

Types of intervention have varied: hypnosis, suggestion, relaxation; pre-op, during, or post-op; with many different outcome variables.

Aiken & Henrichs (1971) study was nonrandomized, nonblinded, for 30 patients getting open heart surgery. Treated patients had benefits.

Surman, Hackett, Silverberg, & Behrendt (1974) had a randomized, single-blind design for 40 patients taught Self Hypnosis (S-H), for elective mitral valve surgery. No difference in benefits. But 45% of patients taught S-H reported a subjective sense of benefit (though objective indicators didn't support that). [He says the difference between subjective/objective outcome ratings is important.]

Hart (1980) used randomized, single-blind design for 40 patients who had open heart surgery. No differences found except initial 3 days post surgery.

Greenleaf et al (1992) - see her paper presentation of this date.

Blankfield et al (presented at Society of Clinical and Experimental Hypnosis meeting in 1992) used a randomized, single-blind design for 95 patients, who were randomly assigned to taped suggestions, music, or controls. No differences were found in benefits.

Our data were re-analyzed: patients who felt tape was helpful were compared to the remaining 62 patients, but there again were no differences in amount of narcotics used for pain, though there was a trend in the right direction; nursing assessments failed to identify less anxiety.

The point is, whereas the bulk of publications suggest benefits, there is little evidence with this population. Could these patients be different in personality, ability to respond to intervention, amount of external stimuli? They should be studied because there are a lot of these patients with only a few surgeons and you don't have to gain the cooperation of a lot of different surgeons to do this kind of research. Also, there is uniformity in cardiac surgery whereas standard operating surgery is in a state of flux in other areas (e.g. movement from generous incisions to micro procedures, and patients receiving this type of surgery remain in hospital for a week whereas this opportunity to study them during inpatient post-surgical period is disappearing in other areas). It is my opinion that cardiac patients may not be highly receptive to suggestion.

Curiously, according to Surman and my research, 1/2 the subjects report benefits. Either some benefits are subtle, or they are reporting a placebo effect.

Future studies need more patients, and the investigators must stratify on personality inventory variables such as Type A personality, hypnotizability, motivation, anxiety, depression, family support, social support systems. This is labor intensive, to determine which characteristics determine differing outcomes. The patients used in this type of research require more presurgery evaluation than previously has occurred.

The MMPI can be self administered and is widely acceptable, but is cumbersome, not well suited to people who are acutely ill. Assessment of Type A personality is important because Type A's might be less receptive to suggestion. Structured

interview is time consuming, but a 52-item questionnaire can be self administered. Other factors listed above are important.

Crawford, Helen J.; Gur, Ruben C.; Skolnick, Brett; Gur, Raquel E.; Benson, Deborah M. (1993). Effects of hypnosis on regional cerebral blood flow during ischemic pain with and without suggested hypnotic analgesia. International Journal of Psychophysiology, 15, 181-195.

Using <sup>133</sup>Xe regional cerebral blood flow (CBF) imaging, two male groups having high and low hypnotic susceptibility were compared in waking and after hypnotic induction, while at rest and while experiencing ischemic pain to both arms under two conditions: attend to pain and suggested analgesia. Differences between low and highly-hypnotizable persons were observed during all hypnosis conditions: only highly-hypnotizable persons showed a significant increase in overall CBF, suggesting that hypnosis requires cognitive effort. As anticipated, ischemic pain produced CBF increases in the somatosensory region. Of major theoretical interest is a highly-significant bilateral CBF activation of the orbito-frontal cortex in the highly-hypnotizable group only during hypnotic analgesia. During hypnotic analgesia, highly-hypnotizable persons showed CBF increase over the somatosensory cortex, while low-hypnotizable persons showed decreases. Research is supportive of a neuropsychophysiological model of hypnosis (Crawford, 1991; Crawford and Gruzelier, 1992) and suggests that hypnotic analgesia involves the supervisory, attentional control system of the far-frontal cortex in a topographically specific inhibitory feedback circuit that cooperates in the regulation of thalamocortical activities.

Greenleaf, Marcia; Fisher, Stanley; Miaskowski, Christine; Du Hamel, Katherine (1993). Hypnotizability and recovery from cardiac surgery. American Journal of Clinical Hypnosis, 35, 119-128.

#### NOTES:

Notes were taken from author's presentation of this material at the Annual Meeting of the Society of Clinical and Experimental Hypnosis, Arlington Heights, Illinois. The paper presentation was part of a Symposium: Towards a Theory of Surgery: Hypnosis, Suggestion, Anesthesiology and Surgery, Methodological and Theoretical Issues and Dilemmas.

Authors outlined the reported advantages of using hypnosis. Their review found problems in much of the research on this topic published to date: many single subject studies, subjects were often selected and trained by the investigator, hypnotizability wasn't evaluated.

Used the Hypnotic Induction Profile (HIP) before assignment of patients to groups, and also equated groups for age. Groups 1 & 2 had formal hypnosis and then either relaxation-imagery (Jancks' autogenic training) or specific outcome suggestions (e.g. to have a clean dry wound, and to look forward to being able to function well); Group 3 were controls.

No differences were found in outcome measures of length of time in ICU, time on respirator, length of stay, and cumulative index of recovery. Didn't publish our data on pain medications because learned it was poorly charted.

Only difference found was: the relaxation imagery group got more wound drainage. It was degree of hypnotizability, independent of group, that made a difference in total number of hours on Nipride - highs were on it almost twice as long. On cumulative stability (having need of medications or respirator) the mid-range people did better. Not statistically significant but nevertheless clinically important, the lows were in the hospital 5 days longer.

This was counter-intuitive though it supports Herbert Spiegel's theory. We, as experimenters, were independent of the treatment team. We didn't have DRGs then and now we may have hit a ceiling effect in the amount of time people stayed in the hospital, because they had excellent pre-surgery education.

We had difficulty continuing the study because the intervention seemed to other staff to be so useful: after 6 months the surgeons began requesting hypnosis for their anxious patients; the chief anesthesiologist had started using it routinely.

Sample size is problematic. They were patients who were actively recruited, not people who sought hypnosis.

#### **CONCLUSIONS**

High hypnotizables in the hospital intensive care unit (ICU) demonstrate sensitivity to external stimuli without critical ability to screen; we see this reversed in the postoperative period. Mid range hypnotizables can decide which external cues to pay attention to. Lows are less able to incorporate new suggestions. They are bound by pre-existing views and also vigilance.

Hypnosis = Dissociation + Absorption + Suggestibility (Spiegel's theory)

We must focus more on the state-trait phenomena, the context, and then select the treatment.

Harris, Ruth M.; Porges, Stephen W.; Carpenter, Myrna E. Clemenson; Vincenz, Lilli M. (1993). Hypnotic susceptibility, mood state, and cardiovascular reactivity. American Journal of Clinical Hypnosis, 36 (1), 15-25.

In this study we explored the relationship between hypnotic susceptibility measured with the Harvard Group Scale of Hypnotic Susceptibility (HGSHS) and cardiovascular parameters. After assessing their degree of hypnotic susceptibility, we induced 21 female students into happy mood states and into sad mood states. During the mood state induction we monitored blood pressure, heart rate, and cardiac vagal tone continuously. The study demonstrated a strong relationship between hypnotic susceptibility and both cardiac vagal tone and heart rate reactivity. Subjects with lower heart rate and greater vagal tone during baseline and greater heart rate increases during mood induction were more susceptible to hypnosis. Multiple regression analyses indicated that approximately 40% of the individual difference variance of hypnotic susceptibility was accounted for by baseline cardiac vagal tone and heart rate reactivity during mood state. The data demonstrate that autonomic tone, assessed by cardiac vagal tone and heart rate

reactivity, are related to hypnotic susceptibility as measured by the HGSHS. -  
Journal Abstract

Morgan, William P. (1993, October). Use of hypnosis in exercise and sport psychology. [Paper] Presented at the annual meeting of the Society for Clinical and Experimental Hypnosis, Arlington Heights, IL.

#### NOTES

Performance of exercise is rated as equal effort with hypnosis and waking conditions; but with hypnotic suggestion they will perceive it as more or less effortful (uphill exercise vs going down the hill). When they think they are going up hill both cardiac and respiratory response increase physiologically, with catecholamine differences.

Mitchell (1981) suggests that respiration changes with exercise do not result from muscle feedback, but that central motor brain signals go to both the cardiovascular centers and to exercising muscle. Actually, it appears that both muscle and cortex give signals, and their synergy governs whether ventilation or heart rate increase.

Wang & Morgan, Psychophysiological responses to imagined exercise, Sport Psychology Lab, University of Wisconsin-Madison. Reported that both external (watching someone else) and internal (imagining oneself) visualizing give responses similar to actual exercise.

We have done research on the prediction of respiratory distress (dyspnea) - work we have done with fire fighters. The best predictor of this on treadmill with air supply is trait anxiety. Sometimes the firefighters who took off face mask even though they had air did not know why they did. It is an opportunity to use hypnotic age regression. SCUBA divers described in Lynn & Rhue also were age regressed to obtain information that was repressed. They have demonstrated stress responses like panic in a 12 foot tank also.

For active people and athletes there is an "iceberg" profile on the POMS, below average on tension, depression, anger, fatigue, and confusion, but higher on vigor. But the divers who panic have a flat profile, around the 50th percentile on all POMS scales.

Middleman et al used Navy divers in 25 degree C. water and used hypnosis to increase and decrease their body temperature--one of the best papers on the topic. Ss who were best able to use imagery, to think of a beach, had the poorest responses; the ones who could relax did poorest, because shivering produces heat and keeps you warm. It is opposite of what is needed.

In our work, we took 5 highest and 5 lowest anxiety Ss; the latter had higher rates of respiration than the former.

All Ss are similar in oxygen use whether volunteers or not. When people volunteer for research before they know hypnosis will be used, the males are lower than females [on hypnotizability?] when they finally volunteer. [He presents a lot of different tests on which volunteers do not differ from nonvolunteers personality wise.]

Ikai & Steinhaus is a classic study of Disinhibition of Inhibitory Mechanisms. Taking Ss up to their maximum (in weight training) to a plateau, Ikai & Steinhaus

said this is a pseudomaximum. They showed that strength increases if - you fire a starter pistol behind them - you ask them to shout just as they do it - they have alcohol - they have amphetamine sulfate - they have hypnosis It is disinhibition of the inhibitory mechanisms.

[He referred to the book *Mind of the Marathoner*.]

In Tibet an anthropologist was amazed to see a man running into their camp, and he ran straight through--a monk carrying messages. He created a non-cultic form of meditation in the laboratory (trained to visually "fix" on mountaintop, to have respiration in synchrony with locomotion, and to use a pseudo mantra "down" each time they put their foot down). Placebo condition was used also. Ss were tested by blinded lab assistants. Endurance time increased from 16 minutes to 20, while controls decreased a minute.

Now we can predict who will win a race. Elite runners do not dissociate; they use association strategy. They pay close attention to race strategy, they monitor themselves constantly (they slow down when they feel bad), and attempt informally to stay loose, not get tight, and relax. Dissociation has, however, been used for the last 300 meters of a marathon (New Zealander Dixon).

Kostka, Marion (1992). Personal experience with 'Use of Hypnosis Before and During Angioplasty' [Letter]. *American Journal of Clinical Hypnosis*, 34, 281-282.

#### NOTES

Author read the article referred to after his/her heart attack and before angioplasty. Goal was to control preprocedure anxiety and assist by being relaxed and cooperative; also to be able to tolerate inflations of the balloon for as long as needed. Used self-hypnosis "and by the time I entered the laboratory my anxiety was under control. ... None of the physiological responses that can occur (i.e., nausea, pain, etc.) did occur and, for the most part, my postprocedure recovery was uneventful. ... Had two procedures because the artery again occluded. ... My cardiologist commented later that the time of inflation was longer than he had even attempted with any of his patients and he attributed this to my lack of symptoms. I felt this was due in part to the use of self- hypnosis. .... my subjective feeling was that both my discomfort and anxiety were minimal" (Pp. 281-82). No blood was sampled to measure catecholamine levels.

Morse, Donald R.; Martin, John; Moshonov, Joshua (1992). Stress induced sudden cardiac death: Can it be prevented?. *Stress Medicine*, 8, 35-46.

Previously, psychosomatically induced death relative to stress, hypnosis, mind control, and voodoo was discussed. In this article, emphasis is on one aspect of that - stress induced sudden cardiac death (SCD). A brief review is presented of the sympathetic aspects of the acute stress response and stress induced SCD. Findings from previous studies are presented to highlight sympathetic aspects of the acute stress response. This is followed by a presentation of various strategies to prevent or decrease the possibilities for stress induced SCD. These include long-term measures

(e.g. diet control, smoking control, hypertension control, stress management strategies) and immediate measures (e.g. calm, controlled approach, elicitation of the relaxation response, selected use of drugs, and heart rate variability monitoring). Relative to prevention strategies, findings are presented both from previous studies and new investigations.

Tosi, D. J.; Rudy, D. R.; Lewis, J.; Murphy, M. A. (1992). The psychobiological effects of cognitive experiential therapy, hypnosis, cognitive restructuring, and attention placebo control in the treatment of essential hypertension. Psychotherapy, **29**, 274-284.

Evaluated the effects of cognitive experiential hypnotherapy (CEH), which includes hypnosis, cognitive restructuring, and developmental staging, on essential hypertension. CEH, Hypnosis alone, cognitive restructuring, and attention-placebo control conditions were randomly assigned to 39 subjects. There was a significant interaction effect with the nine psychobiological outcome measures. Discriminant analysis found a stronger overall effect over time for CEH when compared with its components.

Grossarth-Maticek, R.; Eysenck, H. J. (1991). Creative novation behaviour therapy as a prophylactic treatment for cancer and coronary heart disease: Part II - Effects of treatment. Behaviour Research and Therapy, **29**, 17-31.

#### NOTES

Reports on what they call creative novation behavior therapy or "autonomy training" to prevent cancer and coronary heart disease in prone individuals. This individually tailored cognitive-behavioral program includes the use of hypnosis and of imagery. When administered individually (20-30 hours) in a group (6-15 sessions of up to several hours) or via bibliotherapy with 4-6 hours of individual therapy, the outcome was better than that of control subjects. After 13 years, 45 of 50 cancer-prone subjects in individual treatment were still alive (and none of the 5 deaths were from cancer), while among 50 control subjects, 31 died, 16 from cancer. This study along with Spiegel et al. (1989) article in Lancet have important implications for health care.

Hopkins, Mildred B.; Jordan, Jeanette M.; Lundy, Richard M. (1991). The effects of hypnosis and of imagery on bleeding time: A brief communication. International Journal of Clinical and Experimental Hypnosis, **39**, 134-139.

2 studies are reported, one using hypnotized Ss selected on hypnotizability and one using Ss selected on imagery vividness, whose purpose is to examine whether non-patient Ss can control their bleeding in a laboratory setting. All Ss were cut on both arms with the "Surgicutt" device, an instrument that automatically makes a cut that will bleed from 2 to 10 minutes. Results suggest that Ss, who are instructed to

reduce the bleeding time in one arm and to let the other arm bleed normally, are not able to control bleeding time.

**McCue, Peter A. (1991). Key Paper Review: Prophylactic therapy for cancer and coronary heart disease. [Comment/Discussion] .**

This is a commentary on two papers by Grossarth-Maticek and Eysenck, in which they report on 'creative novation behaviour therapy' to prevent cancer and heart disease in people with personalities associated with the development of those diseases. Therapy may involve hypnosis and/or relaxation, with suggestions that facilitate modification of unhealthy expectancies. The papers are:

**Grossarth-Maticek, R. & Eysenck, H.J. (1991). Creative novation behaviour therapy as a prophylactic treatment for cancer and coronary heart disease: Part I - Description of treatment. *Behaviour Research and Therapy* 29, 1-16.**

**Eysenck, H.J. & Grossarth-Maticek, R. (1991). Creative novation behaviour therapy as a prophylactic treatment for cancer and coronary heart disease: Part II - Effects of treatment. *Behaviour Research and Therapy* 29, 1, 17-31.**

**Weinstein, Edwin J.; Au, Phillip K. (1991). Use of hypnosis before and during angioplasty. *American Journal of Clinical Hypnosis*, 34, 29-37.**

In this study, 16 patients matched with 16 controls were hypnotized prior to angioplasty. The hypnotized patients had a 25% increase in the time the cardiologist was able to keep the balloon inflated compared to the controls. Of the hypnotized patients, 13% required additional narcotic pain medication during the procedure as compared to 44% for the controls. Although we found no differences in rhythm, ischemia, blood pressure, or pulse between the two groups, the results of arterial catecholamine levels drawn at the start and at the end of the procedure were unexpected and seemed paradoxical. Norepinephrine levels were significantly higher in the hypnotized group (432 pg/ml, SE 51) than in the control group (281 pg/ml, SE 23) at the start of the procedure and fell more during the procedure than in control patients. Because catecholamines reportedly act as a barometer of neuroanxiety, further studies defining their role are needed.

#### **NOTES**

While sedatives and tranquilizers may reduce anxiety on a coronary care unit, occasionally they result in confusion, agitation, and ataxia (Kornfeld, 1980). Hypnosis can be used in acute medical care settings (Deltito, 1984) and is beneficial in reducing pain, suffering, and anguish (Hilgard & Hilgard, 1975). There is some suggestion that hypnosis may help regulate heart rate and blood pressure (Hilgard & Morgan, 1975).

In this study, patients with even chart numbers were in the control group, while odd-numbered patients were in the hypnosis group. Patients who were deaf or senile were excluded. All patients received their usual medications before angioplasty, and both the hypnosis group and the control group received identical treatment other than the hypnosis intervention. However, only the hypnosis group was interviewed

by the first author, on the night before angioplasty, and he was also present during the angiograph itself if necessary to help relax the hypnosis patients.

The hypnosis procedure was a modification of Barber's (1977) Rapid Induction Analgesia, and lasted about 1/2 hour. Patients were given a posthypnotic suggestion that they could achieve the same sense of relaxation the next morning during the angioplasty.

"If the patient had severe angina or had an undue amount of discomfort during the procedure, additional pain medication was given as was felt necessary by the cardiologist.

Two of 16 hypnotized and 7 of 16 control patients received pain medication. The difference is significant at  $p = .05$  (Chi Square)" (p. 34).

"In the hypnotized patients the total catecholamine levels (538 pg/ml, SE 60) and the levels of its major component, norepinephrine (432 pg/ml, SE 51), were significantly elevated above their corresponding control levels (361 pg/ml, SE 31 and 281 pg/ml, SE 23) at the start of the angioplasty procedure ( $p < .01$ ). These were unexpected findings. The epinephrine level in the hypnotized group was also higher than the corresponding level in the control group but did not reach a level of significance.

"At the end of the procedure, catecholamine levels had fallen in both groups, but the drop or [sic] total catecholamines in the hypnotized group of 124 pg/ml (SE 33) was greater than the corresponding drop of 37 pg/ml (SE 25) in the control group. This was significant at  $p < 0.025$ . Why the two groups handled catecholamines differently is not clear" (p. 33).

Generally it is hoped that relaxation will permit the cardiologist to keep a balloon inflated longer, not needing to end the procedure because of pain or a complication. The total time required for the procedure was 79 minutes for hypnotized patients and 86 minutes for controls. The inflation time was 353 seconds for hypnotized and 283 minutes for control patients. These differences (which are in the positive direction) did not achieve significance with statistical testing. However, considering the total procedure time, the balloon was inflated 25% longer in the hypnosis than in the control group ( $p = .10$ ).

In their Discussion, the authors note that the reduction in pain medication required by the hypnosis patients is concordant with less pain medication being required by burn patients who are treated with hypnosis (Schafer, 1975; Wakeman & Kaplan, 1978). They do not have an explanation for finding elevated catecholamines in the hypnotized patients. "Catecholamines reportedly act as a barometer of neuroanxiety (Goldstein, 1981; Zaloga, 1988). Turton, Deegan, and Coulshed had already shown in 1977 that prior to catheterization catecholamine levels were elevated and returned to control levels 3 days later. .... One would expect that if hypnosis does cause relaxation, then those patients who were hypnotized would have a lower arterial catecholamine level than their controls. This was not the case. ... It is known that prolonged stress depletes catecholamine stores (Zaloga, 1988), but it is hard to believe that a brief hospitalized stay would cause a difference in depletion between the two groups. There is no literature dealing with the effect of hypnosis on catecholamine levels" (p. 35).

Sletvold, H.; Jensen, G. M.; Gotestam, K. G. (1990). The effect of specific hypnotic suggestions on blood pressure in normotensive subjects. Pavlovian Journal of Biological Science, 26, 20-24.

Twenty normotensive subjects participated in a study of the effects of specific suggestions on blood pressure (BP). After an induction, the experimental group received suggestions presumed to be relatively nonactivating, although capable of lowering or raising BP. A control group was used to record the BP changes over time. All subjects met for one session. Eight subjects from the experimental group met for a second session. Both adaptation and induction resulted in significant BP decreases. A specific suggestion to increase BP gave a significant result when compared to the induction point. There was no significant change from induction to the BP-decrease suggestion. Both systolic and diastolic BP behaved in the same way. A second experimental session resulted in no significant change compared with the first session. Also, no significant difference was found in suggestibility scores from the first to the second session. The results are in line with previously published studies.

Abelson, James L.; Curtis, George C. (1989). Cardiac and neuroendocrine responses to exposure therapy in height phobics: Desynchrony within the 'physiological response system'. Behaviour Research and Therapy, 27 (5), 561-567.

Monitored subjective, behavioral, cardiovascular and neuroendocrine responses in 2 men (aged 19 and 34 yrs) with height phobias over a full course of exposure therapy and at 6 and 8 month follow-up. Both Ss showed rising cortisol responses and stable, nonextinguishing norepinephrine responses to height exposure over the course of treatment, while improvement occurred in subjective and behavioral response systems. They had differing heart rate responses. Despite desynchrony among anxiety response systems and within the physiological system at treatment conclusion, Ss had successful outcomes with general measures of change (phobia rating scales, the Fear Survey Schedule, and the SCL-90) showing substantial improvement for both Ss. These outcomes were preserved at follow-up.

Hall, H.; Minnes, L. (1989). Psychological modulation of auditory responses. International Journal of Psychosomatics, 36 (1-4), 59-63.

Psychological modulation of auditory response, the effects of imagery and suggestion on auditory thresholds were examined in naive subjects. After a hypnosis-like induction, the subjects, who were not aware of the purpose of the study, were asked to generate and maintain a specific set of images before, during, and after which their auditory thresholds were tested. Following the imagery, which represented cooling and vasoconstriction in the cochlea, audiograms revealed a temporary auditory threshold shift (TTS) in the experimental group only. This TTS pattern was similar to that produced by exposure to loud noise. Information carried in the image is suggested as the basis for the observed auditory changes. Although a

hypnosis-like induction was employed, the subjects' level of hypnotizability did not appear to be related to the findings.

Meyer, H. K.; Diehl, B. J.; Ulrich, P. T.; Meinig, G. (1989). Changes in regional cortical blood flow in hypnosis. Zeitschrift für Psychosomatische Medizin und Psychoanalyse, 35, 48-58.

#### NOTES

Regional cerebral blood flow (rCBF) was measured by means of the 133-Xenon inhalation method in 12 healthy male volunteers who had several months of experience in doing self-hypnosis (autogenic training). During hypnotically suggested right arm levitation, as compared to resting conditions, they found an increase in cortical blood flow and an activation of temporal areas; the latter finding was considered to reflect acoustical attention. In addition, a so-far-unexplained deactivation of inferior temporal areas was observed during successful self hypnosis and hypnosis. While there was a global absolute increase of cortical blood flow bilaterally, they could not observe a relative increase of the right as compared to the left hemisphere during hypnosis. Several subjects successfully performed the levitation of the right arm, despite a relative left hemispheric activation, provided the absolute right hemispheric activation remained dominant.

Goldmann, Les; Shah, M. V.; Hebden, M. W. (1987). Memory of cardiac anesthesia: Psychological sequelae in cardiac patients of intra-operative suggestion and operating room conversation. Anesthesia, 42 (6), 596-603.

Thirty elective cardiopulmonary by-pass surgery patients were interviewed pre- and postoperatively. A random selection of patients heard a prerecorded audio tape toward the end of surgery after they were rewarmed to 37 degrees C. The tape contained suggestions for patients to touch their chin during the postoperative interview, to remember three sentences, and to recover quickly. The interviewers were blind to the experimental conditions. The experimental group touched their chins significantly more often than the control group ( $p = .015$ ). Sentence recognition did not reach significance, perhaps due to the small numbers and low salience of the stimuli. Seven patients (23%) recalled intraoperative events, five with the aid of hypnosis. Three reports (10%) were corroborated. Preoperative medication ( $p < .01$ ) and postoperative anxiety ( $p < .05$ ) were significant predictors of those patients who reported recall.

Meyer, von H. K.; Diehl, B. J. M.; Ulrich, P.; Meinig, G. (1987). Kurz- und langfristige Änderungen der kortikalen Durchblutung bei Autogenem Training[Short and long-term changes in cortical circulation caused by autogenic training]. Zeitschrift für Psychosomatische Medizin und Psychoanalyse, 33 (1), 52-62.

The well-known hyperfrontal pattern of hemispheric blood flow measured with 133-Xenon is not found in 12 healthy resting men who have been practicing Autogenic Training at least six months. This might indicate a long-term decrease in the level of activation. Successfully practiced exercises of Autogenic Training lead to an increased blood flow in the Rolandic area representing the body scem (sic) and to a decreased blood flow in regions related to acoustical attention and to autonomic functions. Left hemispheric cerebral blood flow is lower in rest. The relative activation of the left hemisphere during Autogenic Training is discussed.

Ulrich, P.; Meyer, H. J.; Diehl, B.; Meinig, G. (1987). Cerebral blood flow in autogenic training and hypnosis. Neurosurgery Review, 10, 305-307. (Abstracted in American Journal of Clinical Hypnosis, 1989)

In 12 healthy volunteers with at least an experience of 6 months in autogenic training (AT), the cerebral blood flow (CBF) was measured at rest, in AT, and in hypnosis (H). The results were correlated with individual test profiles. The cortical flow pattern at rest of our AT-trained volunteers did not show the hyperfrontality which is described in the literature. This may be interpreted as an effect of better and habitualized relaxation in long-trained AT practitioners. This flow pattern corresponds to the low grades of neuroticism and aggressivity found in the tests. Furthermore, an activation in central cortical areas and a deactivation in regions which are associated with acoustic and autonomous functions occur. Possible explanations for these phenomena as well as for the relatively low perfusion of the left hemisphere at rest and activation in AT are discussed. The global rise of CBF in Hypnosis may be an activation effect caused by resistance against the hypnotizer: the deeper the trance, the smaller the catalepsy of the right arm and in temporal cortical fields processing acoustic inputs.

1986

Suls, Jerry; Sanders, Glenn S.; Labrecque, Mark S. (1986). Attempting to control blood pressure without systematic instruction: When advice is counterproductive. Journal of Behavioral Medicine, 9 (6), 567-577.

Hypothesized that, without assistance, Ss' attempts to keep their blood pressure low would produce increases in blood pressure, compared to Ss asked to respond naturally to an arousing stimulus. 50 male undergraduates watched a videotape containing a neutral (nonarousing) section and an erotic section while their blood pressure was recorded by an automated blood-pressure monitoring device. 22 Ss were asked to relax and keep their blood pressure low during the erotic parts of the videotape, and 28 Ss were asked to respond naturally. Results confirm the hypothesis, suggesting that urging people to relax can be counterproductive if they do not also receive systematic instruction on how to relax or control blood pressure.

Lichstein, Kenneth L.; Eakin, Terry L. (1985). Progressive versus self-control relaxation to reduce spontaneous bleeding in hemophiliacs. Journal of Behavioral Medicine, 8 (2), 149-162.

Investigated the effects of progressive and self-control relaxation on spontaneous bleeding and collateral symptoms with 7 hemophiliacs (average age 32.6 years) in a combined multiple-baseline partial-crossover design. Following 6 or 12 weeks of training in either or both relaxation methods, there was no strong evidence that the treatment affected bleeding or perceived pain in these Ss. Results failed to replicate findings of W. L. LaBow (1975) or J. W. Varni (see PA, Vol 65:13289) (20 ref)

Olness, Karen N.; Conroy, Mary Margaret (1985). A pilot study of voluntary control of transcutaneous PO<sub>2</sub> by children: A brief communication. International Journal of Clinical and Experimental Hypnosis, 33, 1-5.

This pilot study took place to determine whether or not children could voluntarily change tissue oxygen as measured by a transcutaneous oxygen monitor. It tested 2 hypotheses: (a) children can voluntarily change tissue oxygen as reflected by a transcutaneous oxygen monitor and (b) children, experienced in use of self-hypnosis exercises, will be able to change tissue oxygen to a greater degree than children unfamiliar with such exercises. 11 children between the ages of 7 and 17 year were studied. 8 children were previously experienced in the use of self-hypnosis; 3 were not. A Novamatrix transcutaneous O<sub>2</sub>/CO<sub>2</sub> monitoring system provided a constant read-out of PO<sub>1</sub>, PCO<sub>1</sub> and local perfusion. After stabilization, children were asked to attempt increases of oxygen. 9 children increased tissue oxygen significantly. Of those, 8 children had previous self-hypnosis training. 1 had not. Only 2 children with no previous self-hypnosis training were unable to change oxygen values. This pilot study upholds both hypotheses; however, it does not conclude that self-hypnosis mediated the changes noted or that self-hypnosis would be essential to success in voluntary control of tissue oxygen.

Bishay, Emil; Stevens, Grant; Lee, Chingmuh (1984). Hypnotic control of upper gastrointestinal hemorrhage: A case report. American Journal of Clinical Hypnosis, 27, 22-25.

The use of hypnosis for control of bleeding during and after surgical procedures is common practice. It has also been a useful tool for control of bleeding in hemophiliac children, especially during dental procedures, and in traffic accidents. This paper presents the successful treatment with hypnosis of a patient with upper gastrointestinal tract bleeding. After treatment, the patient was discharged from the hospital without the need for surgical intervention

The physician explained to the patient that nothing would hurt her and that nobody would do anything against her will, that if she could "relax," then her unconscious mind would help her control her bleeding. [Gives script used in the hypnosis.] Trance terminated after 20 minutes. "One hour later, endoscopy performed under local anesthesia revealed 'non-bleeding gastritis, no ulcers seen.' She had no bleeding following the hypnotherapy" (p. 23).

1984

Conn, Lois; Mott, Thurman, Jr. (1984). Plethysmographic demonstration of rapid vasodilation by direct suggestions: A case of Raynaud's Disease treated by hypnosis. American Journal of Clinical Hypnosis, 26, 166-170.

Raynaud's Disease is a painful vasospastic disorder of the fingers and toes precipitated by cold or emotional stimuli. Treatment has usually included protection from cold stimuli and vasodilators. Biofeedback, imagery, relaxation, and hypnosis have also been used. The relationship between response to treatment and hypnotizability has been inconclusive. A case of Raynaud's Disease was treated using hypnosis. The patient was highly hypnotizable and responded rapidly to direct suggestion with a fourfold increase in her blood volume. The implications of this rapid response and its relationship to hypnotizability are discussed with suggestions for further studies.

#### NOTES

The authors review experimental literature on the usefulness of hypnosis in modifying peripheral circulation, finding both positive (Barabasz and McGeorge, 1978, Roberts, Kewman, and MacDonald, 1973) and negative (Peters, Lundy, and Stern, 1973; Black, Edholm, Fox, and Kidd, 1963) outcomes. Experiments relating outcome to hypnotizability also have positive (Block, Levitsky, Teitelbaum, and Valletta, 1977) and negative (Crosson, 1980; Roberts et al, 1973) results.

Clinical literature found that peripheral circulation could be influenced (Crasilneck & Hall, 1975; Norris & Huston, 1956; Jacobson et al., 1973) but none of those studies reported the hypnotizability of the patients. In the Crasilneck and Hall (1975) investigation, 60% of their 48 Raynaud's patients experienced marked improvement in symptoms or remission.

Hypnotizability has been investigated with respect to biofeedback results, finding both no relationship (Holroyd et al., 1982) and a positive relationship (Andreychuk and Skriver, 1975).

In this investigation, the highly hypnotizable (Stanford Hypnotic Susceptibility Scale, Form A, score = 11) female patient was treated with hypnosis when the blood vessels in her hands were constricted. Either she had arrived at the office with poor circulation, or a Raynaud's attack was induced with ice water. Hypnosis involved progressive relaxation followed by suggestions to visualize the blood vessels in her hand opening up, the blood warming and nourishing her hands. "With each beat of your pulse your hand becomes warmer as more blood reaches your fingers. It is as though you are lying in the warm sun. Try to visualize the blood vessels in your hand opening up...." (P. 168).

The patient was asked to use self hypnosis and a cassette of the office session twice a week between sessions, but in fact she either failed to practice or did the exercise once between weekly sessions.

With neutral hypnosis (no specific suggestions about circulation) there was little change in pulse volume; with suggestions to open up her blood vessels, there was an increase in blood volume that began within 20 seconds, reaching four times the

baseline in 45 seconds. This increase was reproduced in later sessions, and a somewhat lesser degree of change could be produced with self hypnosis.

In their Discussion, the authors question whether the positive results depend on someone who is high in hypnotizability, and/or on someone with a labile vascular system. They refer to a model of biological information processing to explain how suggestions might have been incorporated by the patient. "Bowers (1977) has speculated that hypnotized patients process information in a way different from when they are not hypnotized. He presents a number of different studies which have shown a significant relationship between hypnotizability and treatment response in patients with illnesses with a clear cut physiological component, including asthma, warts, and ichthyosis. He then speculates that 'suggestions delivered to deeply hypnotized subjects can be transduced into information that is somatically encodable, thereby producing a selective and specific impact on body function and structure.' This kind of processing of information could explain the very rapid response described in the patient presented here.

"In reviewing the cases in which blistering has been produced by hypnotic suggestion, Chertok (1981) states, 'It therefore clearly emerges that these experiments have all been conducted with highly hypnotizable subjects, including a very large proportion of true somnambulists. Inversely, there is not a single known case where a blister has been produced without the subject having been deeply hypnotized beforehand'" (p. 169).

1984

Holmes, David S. (1984). Meditation and somatic arousal evidence. American Psychologist, 39 (1), 1-10.

The conceptual and methodological issues associated with research on the effects of meditation are reviewed. A summary of the research in which the somatic arousal of meditating subjects was compared to the somatic arousal of resting subjects did not reveal any consistent differences between meditating and resting subjects on measures of heart rate, electrodermal activity, respiration rate, systolic blood pressure, diastolic blood pressure, skin temperature, oxygen consumption, EMG activity, blood flow, or various biochemical factors. Similarly, a review of the research on the effects of meditation in controlling arousal in threatening situations did not reveal any consistent differences between meditating and nonmeditating (no-treatment, antimeditation, or relaxation) subjects. The implications of these findings for research and practice are discussed.

LeBaron, Samuel; Zeltzer, Lonnie K. (1984). Research on hypnosis in hemophilia--preliminary success and problems: A brief communication. International Journal of Clinical and Experimental Hypnosis, 32, 290-295.

Although little is known about physiological effects of hypnosis on hemophilia, hypnosis for reduction of pain and/or bleeding in hemophilia has attracted

increasing attention. Literature on this topic is reviewed, and important problems in conducting clinical research on hypnosis for hemophilia are discussed.

**NOTES:**

Reviews literature on physiological effects of hypnosis on hemophilia (for reduction of pain and/or bleeding). Discusses problems in conducting clinical research on same.

**Wain, Harold J.; Amen, Daniel G.; Oetgen, William J. (1984). Hypnotic intervention in cardiac arrhythmias: Advantages, disadvantages, precautions, and theoretical considerations. American Journal of Clinical Hypnosis, 27, 70-75.**

A patient with ventricular tachycardia, which could not be controlled by various drug regimens, was treated using an hypnotic strategy. Among the positive results were a lessening of ectopic beats, an increase in exercise tolerance, a possible break in the arrhythmic pattern, and an increase in the patient's sense of participation in his treatment. Of the disadvantages noted, the most notable was a blocking of the patient's awareness that an arrhythmia was present, which deviated from his previous pattern and may have been facilitated by the dissociative strategy used. Additional well-designed, prospective studies in this area are needed to determine the overall usefulness of hypnosis in cardiac patients.

**1983**

**Borgeat, Francois; Goulet, Jean (1983). Psychophysiological changes following auditory subliminal suggestions for activation and deactivation. Perceptual and Motor Skills, 56, 759-766.**

This study was to measure eventual psychophysiological changes resulting from auditory subliminal activation or deactivation suggestions. 18 subjects were alternately exposed to a control situation and to 25-dB activating and deactivating suggestions masked by a 40-dB white noise. Physiological measures (EMG, heart rate, skin-conductance levels and responses, and skin temperature) were recorded while subjects listened passively to the suggestions, during a stressing task that followed and after that task. Multi-variate analysis of variance showed a significant effect of the activation subliminal suggestions during and following the stressing task. This result is discussed as indicating effects of consciously unrecognized perceptions on psycho- physiological responses.

**1982**

**Friedman, Howard; Taub, Harvey A. (1982). Accessibility: A necessary control for studies of essential hypertension. International Journal of Clinical and Experimental Hypnosis, 30, 4-8.**

A study which was planned to compare the relative effects of relaxation and hypnosis upon essential hypertension also offered the opportunity to replicate some of the findings of a previous investigation. A failure in such replication led to

consideration of the effect of accessibility to the laboratory, a variable not typically controlled. A significant differential effect of easy versus hard access was observed.

Holroyd, Jean; Nuechterlein, Keith; Shapiro, David; Ward, Frederick (1982). Individual differences in hypnotizability and effectiveness of hypnosis or biofeedback. International Journal of Clinical and Experimental Hypnosis, 30 (4), 45-65.

8 high and 8 low hypnotizable Ss used biofeedback and hypnosis to lower blood pressure in one session and forehead EMG activity in another session. Results were analyzed by repeated measures analyses of covariance using baseline physiological level on the dependent variable as the covariate. Electromyographic level was reduced more immediately by biofeedback than by hypnosis. When the task was to lower blood pressure, blood pressure and skin conductance were more effectively reduced by hypnosis than by biofeedback, considering only the first half of each session to eliminate within-session transfer effects. Hypnotizability did not predict overall outcome. Factors which may have prevented demonstrating a clearer relationship between hypnotizability and success using biofeedback or hypnosis are discussed. State and trait anxiety, cognitive strategies used during the tasks, and self-reported hypnotic depth are examined for correlates of successful performance.

Claghorn, James L.; Mathew, Roy J.; Largen, John W.; Meyer, John S. (1981). Directional effects of skin temperature self-regulation on regional cerebral blood flow in normal subjects and migraine patients. American Journal of Psychiatry, 138, 1182-1187.

Vascular headache of the migraine type is associated with vasomotor changes in cerebral arteries. The authors studied whether skin temperature training (biofeedback) reduced the frequency, severity, and duration of these headaches by measuring the regional cerebral blood flow (CBF) in 11 female migraine patients (27-52 years) and 9 female volunteers (22-37 years), using the noninvasive <sup>133</sup>Xe inhalation technique. Half of each group was randomly assigned to a hand-warming or a hand-cooling group. CBF increased in several regions of the left hemisphere to a significant degree only for the migraineurs who were in the hand-warming group. The pattern of vasomotor regulation apparently differed between migraine and normal Ss. The migraineurs' headache symptoms were affected by both warming and cooling, but warming produced more salutary effects.

Case, David B.; Fogel, David H.; Pollack, Albert A. (1980). Intrahypnotic and long-term effects of self-hypnosis on blood pressure in mild hypertension. International Journal of Clinical and Experimental Hypnosis, 28, 27-38.

Self-hypnosis using the method of Spiegel (1974) was evaluated in 15 patients with labile or mild essential hypertension who were equally hypnotizable and adhered to

a regimen of 6-10 daily exercises for a 4-month period. During the hypnotic state, there were consistent rises in both systolic and diastolic pressures in hypnotizable patients, but not in non-hypnotizable controls. Similar but smaller changes were also observed in normotensive subjects. Pressure rose immediately with hypnosis and subsided gradually over 15 minutes. However, the long-term effects of the daily practice of self-hypnosis were variable: ambulatory diastolic pressure fell in 5 patients, was unchanged in 7 patients, and rose in 3 patients. The changes in blood pressure could not be specifically attributed to the daily practice of self-hypnosis; however, all patients experienced improvement in well-being, mood, and behavior patterns during the 4-month period. The study indicates that self-hypnosis can produce changes in behavior and mood which may be beneficial to cardiovascular health, although paradoxically, the act of hypnosis by this technique is pressor. Aside from its therapeutic potential, self-hypnosis may provide useful information about central mechanisms of blood pressure regulation.

Hart, R. (1980). The influence of a taped hypnotic induction treatment procedure on the recovery of surgery patients. International Journal of Clinical and Experimental Hypnosis, 28, 324-331.

A study of 40 open heart surgery patients assigned to 1 of 2 equal size treatment groups sought to evaluate the efficacy and utility of a tape-recorded hypnotic induction procedure that preoperatively prepared patients for surgery. The dependent variables included daily blood pressure measurements and postsurgical outcome data pertaining to postoperative units of blood required, state/trait anxiety, and locus of control dimensions. Results of the study tended to provide some support for the tape-recorded hypnotic induction procedure in lessening state anxiety and in promoting a more self-directed attitude toward surgical recovery.

1980

Puente, Antonio E.; Beiman, Irving (1980). The effects of behavior therapy, self-relaxation, and transcendental meditation on cardiovascular stress response. Journal of Clinical Psychology, 26 (1), 291-295.

#### NOTES

Compared Behavior Therapy (BT), self-relaxation (SR), transcendental meditation (TM), and a waiting-list control group (WL) on measures of cardiovascular and subjective stress response. Male and female respondents (N = 60) to an ad for therapy were evaluated in assessment sessions before and after treatment. The results indicate that BT and SR were more effective than either TM or WL in reducing cardiovascular stress response. These data were interpreted as resulting from therapeutic suggestion and positively reinforced client progress.

1978

Parker, Jerry C.; Gilbert, Gary S.; Thoreson, Richard W. (1978). Reduction of autonomic arousal in alcoholics: A comparison of relaxation and meditation techniques. Journal of Consulting and Clinical Psychology, 46 (5), 879-886.

To investigate and compare the effects of progressive relaxation training and meditation training on autonomic arousal in alcoholics, 30 subjects were selected from a population of alcoholics in a Veterans Administration hospital substance-abuse program. The subjects were randomly assigned to one of the following three experimental conditions: (a) progressive relaxation training group, (b) meditation training group, or (c) quiet rest control group. All groups met for 3 weeks during which state anxiety, blood pressure, heart rate, and spontaneous galvanic skin responses were measured. The measures were designed to assess the treatment effects following the first training session and at the end of the total training period. The results indicate that both progressive relaxation training and meditation training are useful for reducing blood pressure in alcoholics. In addition, significant differences between the groups in the effectiveness of the relaxation procedures were found. Meditation training induced blood pressure decreases at an earlier point in the 3-week training period and affected decreases in systolic blood pressure that progressive relaxation training did not. These results support the idea of considerable specificity of response to relaxation techniques.

Parwatikar, Sadashiv D.; Brown, Marjorie S.; Stern, John A.; Ulett, George A.; Sletten, Ivan S. (1978). Acupuncture, hypnosis and experimental pain - I. Study with volunteers. Acupuncture and Electro-Therapeutic Research: International Journal, **3**, 161-190.

An experiment was designed to evaluate the protective effects of different agents - acupuncture, hypnosis, Morphine, aspirin, Diazepam and placebo - upon experimentally-induced pain in humans. Twenty normal, healthy volunteers were subjected to cold water and tourniquet- induced pain and the protective effects of 35 minutes of hypnotic suggestion, electro- stimulation of both acupuncture points and non-acupuncture points, 10 mg/kg of Morphine, 5 grains of aspirin, 10 mg of Diazepam and a mild sugar placebo were evaluated. Data was collected on subjective evaluation of pain, EKG, EEG, respiration, skin temperature, peripheral vascular activity and EMG. A special study was also done to evaluate the effects of all the above agents on the somatosensory evoked potentials and EEG. The data were further analyzed on the basis of hypnotic susceptibility of the volunteers. The results indicated: 1) Hypnosis, acupuncture at specific sites with electrical stimulation and Morphine Sulphate had about the same reduction in experimental pain. 2) Hypnosis produced different effects from those resulting from acupuncture stimulation on EEG. 3) Acupuncture stimulation in specific loci resulted in a latency increase in the early secondary response on somatosensory evoked potential. 4) Cold water pain was remarkably reduced after true acupuncture point stimulation. 5) Tourniquet (ischemic) pain was reduced by both hypnosis and true acupuncture site stimulation. 6) Skin temperature was significantly reduced on the side of acupuncture points (true) stimulation.

1977

**Fisher, R. (1977). On flashback and hypnotic recall. International Journal of Clinical and Experimental Hypnosis, 217-235.**

**This essay deals with both the intra-individual and inter-individual varieties of arousal state-bound experiences. The former are labelled as "flashbacks" while the latter embrace the great fantasms and repetitive schemes, the ever re-written plots and images of literature, art, and religion.**

**Flashbacks are both arousal-state and stage (i.e., set and setting) bound experiences. Flashback and hypnotic recall differ only in the ways by which they are induced. Induction methods should be distinguished from induced states on the hyperaroused perception-hallucination and hypoaroused perception-meditation continuum.**

**Flashbackers may be characterized by their (a) variability on perceptual-behavioral tasks; (b) tendency to minimize (or reduce) sensory input; (c) high resting heart rates; (d) hypnotizability; and, hence (e) preferential right-cerebral-hemispheric cognition; and (f) a display of EEG-alpha dominance in the resting, waking state.**

**Friedman, Howard; Taub, Harvey A. (1977). The use of hypnosis and biofeedback procedures for essential hypertension. International Journal of Clinical and Experimental Hypnosis, 25, 335-347.**

**In an attempt to evaluate a procedure combining 2 techniques, hypnosis and biofeedback, which might effect significant changes in diastolic blood pressure in essential hypertensives, Ss were placed in 1 of 4 groups: hypnosis only, biofeedback only, hypnosis and biofeedback combined, or measurement only. The first phase -- training sessions and brief follow-ups (1 week and 1 month) -- of the long-term study with 6 monthly follow-up periods, was evaluated. Hypnosis only and biofeedback only procedures were both capable of providing significant lowering of diastolic pressure. However, in intergroup comparisons, the hypnosis only procedure showed the most impressive effect. Unexpectedly, the procedure of combining hypnosis and biofeedback into one technique was as ineffective as the measurement only procedure.**

#### **NOTES**

**In their discussion of the finding that hypnosis + biofeedback did not yield more positive results, the authors state, "it is possible that two opposing sets were established that negated each other: the biofeedback instructions wherein S was enjoined to direct his attention externally and to attempt to change the displayed number which reflected diastolic pressure, versus the more passive, relaxed attitude implied in hypnotic induction. It is interesting to note that Benson et al. (1974b) have similarly suggested that the set involved in biofeedback training may interfere with the elicitation of the 'relaxation response.' Also, Orne [personal communication] has indicated that, although anticipating a synergistic effect as a result of combining hypnotic and biofeedback procedures, some difficulty may lie in requiring Ss to be hypnotized during [emphasis on 'during' in original] the biofeedback training procedure" (p. 344).**

Gatchel, Robert J.; Hatch, John P.; Watson, Paur J.; Smith, Dan; Gaas, Elizabeth (1977). Comparative effectiveness of voluntary heart rate control and muscular relaxation as active coping skills for reducing speech anxiety. Journal of Consulting and Clinical Psychology, 1093-1100.

The present study investigated whether heart rate biofeedback training is as effective as muscular relaxation training in reducing speech anxiety. Also, a combined muscle relaxation/biofeedback treatment group was included in this study. All treatment groups were compared to a false-biofeedback placebo control group. This investigation also assessed whether the degree of autonomic nervous system awareness significantly influences the treatment process. Ten speech-anxious subjects, half of whom scored high on the Autonomic Perception Questionnaire (APQ) and half of whom scored low on the APQ, were assigned to each group. Results indicated that all four groups demonstrated a decrease in self-reported anxiety. Assessment of physiological measures (heart rate and skin conductance) indicated that the three treatment groups were associated with less physiological responding during the posttreatment assessment of anxiety, relative to the false-biofeedback group. Moreover, among the three treatment groups, the combined relaxation/biofeedback group demonstrated the lowest level of responding. The degree of autonomic awareness was not found to be related to therapeutic improvement.

Gatchel, Robert J.; Proctor, Janet D. (1976). Effectiveness of voluntary heart rate control in reducing speech anxiety. Journal of Consulting and Clinical Psychology, 381-389.

The effects of learned control of heart rate deceleration and therapeutic expectancy set in reducing speech anxiety were investigated in a factorial design employing 36 speech-anxious subjects. Heart rate control training and no heart rate control training were each paired with high-therapeutic-expectancy and neutral-expectancy instructions, in order to assess the individual and combined effects of the two factors. Results demonstrated that learning to control heart rate deceleration led to a significant reduction in self-report, physiological (heart rate and skin conductance level), and overt signs of anxiety, relative to the no-heart-rate control condition. High-therapeutic-expectancy instructions also contributed to a reduction in self-reported anxiety. These results demonstrate that learned heart rate control is an effective therapeutic technique for reducing anxiety.

1975

Cowings, Patricia S. (1975, September). Observed differences in learning ability of heart rate self-regulation as a function of hypnotic susceptibility. [Paper] Presented at the 3rd Congress of the International College of Psychosomatic Medicine, Rome.

Three groups of eight men and women were given personality tests and were taught to control their own heart rates. Experimental group I and the control group had

low hypnotic susceptibility (Stanford Hypnotic Susceptibility Scale), and subjects in experimental group II had high hypnotic susceptibility. The experimental groups received autogenic therapy and biofeedback, while the control group was given biofeedback only. Subjects who received autogenic therapy and biofeedback performed better than the control group. Significant differences, however, were found in all psychological test scores between high and low hypnotic susceptibles.

1974

Redmond, Daniel P.; Gaylor, Michael S.; McDonald, Robert H.; Shapiro, Alvin P. (1974). Blood pressure and heart-rate response to verbal instruction and relaxation in hypertension. Psychosomatic Medicine, 36 (4), 285-297.

Recent data have suggested that instructional set and task awareness may play a substantial role in the achievement of directional changes in blood pressure associated with "operant conditioning" techniques. Six hypertensive patients were instructed alternately to raise (UP) and lower (DOWN) their blood pressure by concentrating on changing "heart rate, force of contraction, and blood vessel resistance to flow." Paired 10 min periods were separated by the experimenter's entry and exit. Five of the subjects were taught progressive muscular relaxation (PMR), and the protocol repeated, with PMR induced throughout this session. The immediate cardiovascular response to PMR, induced in both the presence and absence of the experimenter, was studied. Systolic (SBP) and diastolic (DBP) blood pressure and heart rate (HR) were measured every 30 sec in all sessions. Direction of changes in BP and HR for UP and DOWN periods was appropriate and significant in both instruction sessions, and these differences for BP frequently reached significant levels of magnitude. In general, interactions for HR did not reach significant levels. Comparison of the two sessions yielded little difference between them. PMR uniformly lowered BP and HR, but was of significant magnitude only when induction of PMR involved the active participation of the experimenter. Interview data revealed considerable dramatic mental imagery associated with directional shifts in BP. The results indicate that directional instruction may result in appropriate changes in BP and HR of a magnitude comparable to those reported in studies using "external biofeedback." PMR did not alter the response. This study adds to other data which point to the potential for nonspecific or "placebo" effects to be operative in conditioning studies.

**NOTES:**

The authors reviewed literature suggesting that blood pressure changes have been brought about by hypnotic suggestions of attitudes, progressive muscular relaxation, autogenic training (a form of self hypnosis), yogi, transcendental meditation, and hypnotically suggested relaxation.

The instructions to raise and lower blood pressure by concentrating on changing heart rate, force of contraction, and blood vessel resistance to flow were a repetitive monologue with a monotonous emphasis on "rate and force of heart beat and resistance of vessels to flow." Most subjects spontaneously introduced imagery appropriate to the desired change. The authors expressed the opinion that task

awareness (to change the blood pressure) influenced the results, and the changes were accomplished more by associative imagery than by responding to the literal meaning of instructions.

Surman, Owen S.; Hackett, Thomas P.; Silverberg, Elizabeth L.; Behrendt, Douglas M. (1974). Usefulness of psychiatric intervention in patients undergoing cardiac surgery. Archives of General Psychiatry, 30, 830-835.

Twenty patients undergoing cardiac surgery were seen one or more times by a psychiatrist who performed two functions. In a supportive fashion he cleared up any misconceptions the patient had about the forthcoming surgery and he taught him a simple autohypnotic technique. Twenty controls, matched for relevant variables, received routine preoperative care. Contrary to the report of others, a single visit by the psychiatrist did not influence the incidence of postoperative delirium, anxiety, depression, pain, or medication requirements. However, there was a trend for patients receiving a greater number of preoperative visits to have a lower incidence of detected delirium. Age was the only factor in this study that differed significantly between delirious and nondelirious patients.

Aiken, Linda H.; Henrichs, Theodore F. (1971). Systematic relaxation as a nursing intervention technique with open heart surgery patients. Nursing Research, 20, 212-217.

## NOTES

Psychiatric problems frequently occur after open heart surgery, usually from day 2 to day 7 postoperatively. Symptoms include impairment of consciousness, disorientation, sensory disturbances like visual and auditory hallucination, and sometimes delusions and paranoid behavior. Authors defined a postoperative adverse reaction as "when the patient experienced impairment of consciousness with motor restlessness, disordered thinking, sensory disturbances, visual and/or auditory illusions or hallucinations, and paranoid ideation. All of these symptoms do not usually occur together and an additional definition was given for a minor reaction which occurred if only one of the above symptoms was present for 12 hours or less" (p. 214).

The population from which samples were drawn consisted of adult male patients admitted to a university medical center for open heart surgery. The experimental group (N = 15) consisted of all patients admitted from September 1969 through June 1970 (omitting two who were not willing to participate). Controls were 15 adult males admitted for open heart surgery in the prior year.

A relaxation and systematic desensitization technique was used for the experimental group, each patient being given a tape recorder with a 15-minute tape of the exercise "to use whenever he wanted to relax" (p. 214) but at the least four times a day.

On basis of previous research one would expect postoperative adverse reactions of 40% but the Relaxation group had only 8%. (The control group had 27%, but the difference between groups was not significant with Fisher's exact probability test-- $p < .10$ .) Mortality rate was same in both groups.

The results must be interpreted in the context of differences between groups during surgery, which may or may not relate to the intervention. The Relaxation Group was significant lower than Control Group on 4 of 5 surgical risk factors: anesthesia time, cardiopulmonary bypass time, total units of blood, and degree of hypothermia. They were (nonsignificantly) better on duration of hypothermia; and there was no difference on multivalve replacement. This suggests the Relaxation Group were less exposed to these factors to a significant degree.

**Discussion:** The groups were matched on age, sex, preoperative diagnosis, type of surgical procedure, incidence of severe economic problems, family adjustment problems, and history of psychiatric problems (i.e. the groups did not differ). "The major difference between the two groups was in relation to the surgical stress factors studied: degree of hypothermia, amount of time on cardiopulmonary bypass, anesthesia time, and total units of blood received. The experimental group was significantly lower on mean values for all of these stress factors. Without further research it is impossible to conclude that these factors did or did not influence the lower incidence of postoperative reactions found in the experimental group. It should be noted, however, that the decreased surgical stress factors had no apparent effect on reducing mortality in this sample. Also as previously stated, prior research has not been able to demonstrate a direct relationship between these surgical stress factors and the incidence of postoperative reactions" (p. 215).

"The population used in this research ranged from patients with mild symptoms of heart disease to those with severe decompensation and congestive heart failure. It was anticipated prior to beginning the research that some patients would be physically incapable of cooperating due to fatigue and dyspnea; this prove not to be the case" (p. 216).

This intervention is usable by nurses, and "provides an alternative which the professional nurse may prescribe after systematically assessing a patient's needs" (p. 216). "It is a new skill to be learned that is comparable to the skill of giving an injection or learning to recognize arrhythmias. The amount of time required to teach a patient the technique of systematic relaxation is realistically within the scope of any staff nurse's role" (p. 216).

Gray, Arne L.; Bowers, Kenneth S.; Fenz, Walter D. (1970). Heart rate in anticipation of and during a negative visual hallucination. International Journal of Clinical and Experimental Hypnosis, 18 (1), 41-51.

Gave 10 stimulating control and 10 hypnotic undergraduates a suggestion to negatively hallucinate. Heart rate responses recorded prior to and including the hallucination period indicated consistent differences between groups. Hypnotic Ss responded with heart rate acceleration in anticipation of the hallucination, while controls responded with heart rate deceleration during the same period. It is

suggested that these differences reflect differences in the subjective experiences of hypnotic and simulating Ss. (Spanish & German summaries) (PsycINFO Database Record (c) 2003 APA, all rights reserved)

1968

McCord, Hallack (1968). Hypnotic control of nosebleed. American Journal of Clinical Hypnosis, 10, 219.

#### NOTES

Nosebleeds that occurred every two or three days and could not be terminated with the usual clinical interventions were stopped, without symptom substitution, when fairly direct suggestions were added almost "as a sort of after-thought, since the primary purpose of the therapy was to aid in treating the marriage difficulty" (p. 219).

Nuland, William (1968). The use of hypnotherapy in the treatment of the postmyocardial infarction invalid. International Journal of Clinical and Experimental Hypnosis, 16 (3), 139-150.

DEALS WITH THE PSYCHOLOGICAL ASPECTS OF CONVALESCENCE AND REHABILITATION OF PATIENTS FOLLOWING CORONARY INFARCTION. THE FOCUS IS ON THE SITUATIONAL FACTORS WHICH THE PATIENT ENCOUNTERS DURING CONVALESCENCE THAT SERVE TO PROLONG AND REINFORCE THE INVALIDISM. IT IS CONCERNED ESPECIALLY WITH THE VALUE OF HYPNOTHERAPY AS COMPARED WITH OTHER PSYCHOTHERAPEUTIC METHODS IN TREATING THESE CASES. THE ANXIETY AND EMOTIONAL STRESS WHICH CAN BE RELIEVED THROUGH THE USE OF HYPNOSIS IS DIRECTED PRIMARILY TOWARD REDUCING EMOTIONAL TURMOIL WHICH RESULTS FROM THE CORONARY ATTACK WITH THE CONSEQUENT FEAR OF PHYSICAL ACTIVITY AND OF SUDDEN DEATH. SPECIFICALLY, HYPNOSIS IS USED EFFECTIVELY IN REASSURANCE, REEDUCATION, DESENSITIZATION, GUIDANCE, AND OTHER DIRECT SUPPORT TECHNIQUES IN ACCORDANCE WITH THE PATIENT'S SYMPTOMS AND NEEDS. 1965

Barber, Theodore Xenophon (1965). Physiological effects of 'hypnotic suggestions': A critical review of recent research (1960-64). Psychological Bulletin, 201-222.

Recent studies are reviewed which were concerned with the effectiveness of suggestions given under "hypnosis" and "waking" experimental treatments in alleviating allergies, ichthyosis, myopia, and other conditions and in eliciting deafness, blindness, hallucinations, analgesia, cardiac acceleration and deceleration, emotional responses, urine secretion to sham water ingestion, narcotic-like drug

effects, and other phenomena. The review indicates that a wide variety of physiological functions can be influenced by suggestions administered under either hypnosis or waking experimental treatments, and direct and indirect suggestions to show the particular physiological manifestations are crucial variables in producing the effects.

Black, Stephen (1964). Mind and body. London: Kimber.

#### NOTES

Defines psychosomatic disease as one that responds to psychotherapy. Believes only 5% are highly hypnotizable, that hypnosis is learnable in 1/2 hour, that hypnosis is not a useful treatment for psychosomatic disorders because you can't use interpretation [of unconscious]. The 'unconscious' is "... a complex of informational systems derived from such primaevial mechanisms" (p. 133). "Primaevial mind is involved in these mechanisms of genetics and immunology" (p. 133). "There is thus a 'somatic mind' which is unconscious and presumably without any means of verbalization of experience--and a 'cerebral mind' which is conscious" (p. 133). The dividing line is not clear.

Rapport is discussed on pp. 160, 169 as one of the spontaneous characteristics of hypnosis, in the absence of suggestion. The same for posthypnotic suggestion (rapport and amnesia). Spontaneous physiological changes in hypnosis relate to mind-body relationships (p. 169)

Conditioned reflex is discussed on p. 161

"...the subjective evidence indicates that a perceptual change involving any sensory modality can be produced by DSUH" [direct suggestion under hypnosis] p. 178. Suggestion can selectively affect different parts of the body p. 197.

Research: "Hypnosis is not only the most important and practical way of proving the existence of the unconscious--which is still in doubt in some circles--but is in fact the only way in which unconscious mechanisms can be manipulated under repeatable experimental conditions for purposes of investigation" (p. 152).

Mind-body is "amenability to control" Catatonia, which characterizes both animal and human hypnosis, seen in hypnosis, is induced by constriction (i.e. disorientation). The Cartesian concept of mind and body tends to confuse the issue p. 157.

Rapport is discussed (p. 157).

Suggestion (p. 159) "It was this concept of 'suggestion'--which so obviously parallels 'amenability to control' in animals--that eventually established hypnosis in the French schools of psychiatry as a state of increased suggestibility. ... still the standard definition of hypnosis in most medical psychiatric textbooks and in lay dictionaries" (p. 159).

Black (1969) did some biochemical sleuthing to learn how information transmitted by words becomes information encoded somatically, as when psychosomatic allergies flare and recede or disappear. What accounts for suggestion "curing" an allergic skin reaction in one part of the body while another part not included in the suggestion remains reactive? What accounts for the instantaneous skin allergy cure which sometimes occurs with suggestion (in 24 hours)?

Skin sensitivity tests in highly hypnotizable Ss who were also very allergic were inhibited by direct suggestion under hypnosis under highly controlled experimental conditions--and in one subject the effect (inhibition) was relatively permanent--ruling out (he suggests) a neurological mechanism. He did further experiments to examine whether the result was due to an instant neurological mechanism and a long-term endocrinal mechanism.

p. 212 He ruled out peripheral blood flow as the cause of diminished skin sensitivity (there was no change in blood flow with suggestions of heat or cold). Therefore decrease in blood flow couldn't explain in neurovascular terms the 'instant' inhibition of skin sensitivity (allergy) tests. Was it due to systemic--especially adrenal-- changes? He demonstrated increases in plasma cortisol under hypnosis with suggestions of fear. On p. 230 he summarizes the facts he established by skin sensitivity tests, plasma- cortisol studies, and histology - endocrinological.

Black, Stephen; Edholm, O. G.; Fox, R. H.; Kidd, D. J. (1963). The effect of suggestion under hypnosis on the peripheral circulation in man. Clinical Science, 26, 223-230.

#### Summary

The effects on the circulation in the forearm and hand of both direct and indirect suggestion under hypnosis of thermal stimuli have been studied. 2. The induction of hypnosis did not significantly alter the forearm blood flow, but a small reduction in hand blood flow was usually observed. Pulse rate in general slowed slightly as did respiration rate. 3. The effect of body heating on forearm and hand blood flow was not modified by hypnosis. 4. Direct suggestion under hypnosis of body heating or body cooling, with and without body heating, produced only small changes. 5. The changes associated with suggestion were not related to the thermal suggestion. Whatever the suggestion, the usual response was a reduction in hand blood flow and an increase in forearm blood flow. 6. The rise of body temperature with heating was not modified by direct suggestion, under hypnosis, of body cooling. 7. No change in body temperature could be elicited by suggestion. 8. In a few experiments marked changes in forearm blood flow occurred. These appeared to resemble the changes in the circulation produced by emotional stimuli. 9. The smaller changes more frequently observed were also similar to those produced by mild emotional stimuli" (p. 229). [N.B. The Subjects were normal, healthy adults, N = 9, between 21-45 years old; highly hypnotizable, amnesic for trance.]

1960

Crasilneck, Harold B.; Hall, J. A. (1960). Blood pressure and pulse rates in neutral hypnosis. International Journal of Clinical and Experimental Hypnosis, 8 (3), 137-140.

Author's Summary: "Twenty-five Ss were tested for pulse rate and blood pressure in a wakeful resting state and immediately after the induction of neutral hypnosis. No change was found in the measurements by application of the t-test for differences between correlated means. These results strongly suggest that changes in

pulse rate and blood pressure do not occur simply from the induction of hypnosis. The effect of various direct, indirect (emotive), and hallucinatory suggestions remains to be established" (p. 138).

Raginsky, Bernard B. (1959). Temporary cardiac arrest induced under hypnosis. International Journal of Clinical and Experimental Hypnosis, 7 (2), 53-68.

#### NOTES

"An experiment is described in which the symptoms of syncope and temporary complete cardiac arrest were induced under hypnosis in a patient who had been operated on for a so-called Adams-Stokes syndrome and who had, until the time of the experiment, remained free of such symptoms. An attempt is made to correlate contemporary knowledge in explaining this phenomenon.

"It is pointed out that maturity in the biological sciences takes about twice as long to achieve as does maturity in the physical sciences. This holds especially true in the use of hypnosis" (p. 66).

The authors report that in attempting to reinduce a fainting episode, "We were not at all prepared for the complete cardiac arrest which followed the hallucinated episodes" (p. 59).

Duncan, Irma W.; Dressler, Robert L.; Lyon-James, Sara; Sears, Alden B. (1958). The search for an index of hypnosis. Journal of Clinical and Experimental Hypnosis, 6 (2), 95-108.

#### NOTES

"Blood and urine samples were obtained from 18 university students at the beginning and end of two experimental sessions, one with and one without hypnosis.

Some of the subjects relaxed during the sessions; others imagined or hallucinated a traumatic experience.

"Of a variety of measurements made, urinary volumes and 17-ketosteroids, the eosinophil count and psychogalvanometer recordings appear to give useful information about any changes due to the hypnosis. The biochemical changes caused by the experimentally produced emotions seem to depend on the individual and his past experience rather than the hypnosis. The data suggest that if the experience hallucinated is known to the subject, the biochemical changes indicate a relaxed state during the hypnosis. The psycho-galvanometer recordings may indicate an agitated state while the biochemical indices suggest a relaxed state" (pp. 106-107).

Schneck, Jerome M. (1957). Hypnoanalytic observations on the psychopathology of fainting. Journal of Clinical and Experimental Hypnosis, 5 (4), 167-171. (Abstracted in Psychological Abstracts 62: 3 II 67S)

Varieties of fainting have been described as hysterical syncope, vasodepressor syncope, and carotid sinus reactions, among others. Fainting has been linked in general with personality problems, emotional instability, and immaturity. It has been called a mechanism for blocking of ego functions in its role of primitive defense against overwhelming stimuli. The present paper gives in greater detail the specific dynamics in a patient with fainting episodes. A crucial event incorporating major dynamic ingredients was an operative procedure in childhood. The psychological impact of this trauma was revived during a spontaneous hypnotic regression. The personality matrix significant for this patient in relation to the fainting episodes consisted of passive, masochistic submission to a dominant, highly influential mother whose pressure was felt by the patient as pervasive and stifling. Circumstances associated psychologically with this feeling apparently triggered the fainting reactions. As he matured through the years and cast off increasingly this type of maternal influence, the tendency toward fainting reactions diminished" (p. 170).

1956

Bigelow, Newton; Cameron, G. H.; Koroljow, S. A. (1956). Two cases of deep hypnotic sleep investigated by the strain gauge plethysmograph. Journal of Clinical and Experimental Hypnosis, 4 (4), 160-164.

Two subjects, studied by means of a strain gauge plethysmograph, have shown greater changes in the peripheral pulse and the finger volume during deep hypnosis than they did immediately before or after. In the absence of external stimuli, the presence and the degree of such changes reflect the activity of the autonomic nervous system. This result suggests that in hypnosis the inhibiting tendency of the cortex on the autonomic nervous system is reduced or nullified" (p. 164).

## NOTES

"Summary. A young soldier with functional cardiac complaints was treated with hypnosis in a total of 4 interviews. The dynamics were bypassed and the therapeutic suggestions attached to 2 significant events in the patient's childhood, dealing intimately with the oedipal conflict and castration fears. Follow-up studies of 3 weeks duration revealed that significant changes had been produced in the patient's attitudes towards himself and towards his role in the military service" (p. 190).

1953

Schneck, Jerome M. (1953). Hypnoanalytic study of a patient with extrasystoles. Journal of Clinical and Experimental Hypnosis, 1 (4), 11-17. (Abstracted in Psychological Abstracts 6413?)

### Author's Summary -

Psychosomatic studies of heart abnormalities are available in the literature. A few deal with extrasystoles. Fewer still involve hypnosis. Extrasystoles are reported to have been induced hypnotically. Hypnosis has also been used to study other aspects of cardiac functioning. This report deals with some psychological aspects of extrasystoles in a patient treated hypnoanalytically.

In the hypnotic state there appeared to be enhanced recall, less obsessiveness, greater spontaneity, more emotional involvement with material elicited, and improved integration of data made available.

A direct relationship was shown to exist between states of tension and the extrasystoles. Variation in the frequency of their occurrence set in and this was followed by progressive lessening in the symptom as tension decreased.

The symptom was related to the identification by the patient with his father in relation to pulmonary infections. The heart as a vital organ and the early death of the patient's father both assumed considerable psychological significance for the patient and were obsessively elaborated by him. His mother's death following a heart attack resulted in an exacerbation of the symptom and reenforced his concern. Use of the symptom corresponded to his passive inclinations and his conflict over passivity-aggressivity and dependence-independence problems. His failures could be rationalized on the basis of physical malfunctioning and sympathy enlisted thereby. The symptom appeared to be related also to marked guilt about his relationship with his mother and furthered a dependent masochistic relationship with his mother-in-law who dominated his household and (as revealed in other data) was identified in part with the patient's mother. (At this time, incidentally, his mother-in-law, like his mother, was said to be quite ill with hypertension.)

Therapeutic contact with this patient was time-limited. He travelled a considerable distance from another state for each of his appointments. The psychodynamics available are undoubtedly a fraction of many additional elements involved. Removal to another part of the country interrupted treatment but further opportunity for hypnoanalytic work may become available in the future.

CARELTON SKILL TRAINING PROGRAMME

1999

Comey, Gail; Kirsch, Irving (1999). Intentional and spontaneous imagery in hypnosis: The phenomenology of hypnotic responding. International Journal of Clinical and Experimental Hypnosis, 47 (1), 65-85.

Students were given 1 of 2 versions of the Carleton University Responsiveness to Suggestion Scale (CURSS): (a) the original version, which contains instructions to intentionally imagine goal-directed fantasies, and (b) a modified version, in which instructions for suggestion-related imagery were deleted. Participants were asked to report their goal-directed fantasies and to indicate whether these occurred spontaneously or were generated intentionally. They were also asked whether they had tried intentionally to generate the suggested experience and to indicate whether they had believed that the suggested states of affairs were real (e.g., whether they thought a hallucinated cat really existed). The deletion of instructions for goal-related imagery significantly increased responsiveness to CURSS suggestions. Spontaneous goal-directed imagery was significantly correlated with behavioral response, but intentional imagery was not. Most successful responders tried to generate suggested experiences intentionally, indicated that they could have resisted challenge suggestions if they really wanted to, and reported believing in the reality of suggested ideomotor and challenge experiences but not of cognitive suggestions. Voluntary attempts to generate suggested experiences were correlated with subjective responding.

Milling, Leonard S.; Kirsch, Irving; Burgess, Cheryl A. (1999). Brief modification of suggestibility and hypnotic analgesia: Too good to be true?. International Journal of Clinical and Experimental Hypnosis, 47 (2), 91-103.

A 10-minute training procedure, based on the Carleton Skill Training Program, has previously been reported to produce substantial increments in responsiveness to hypnotic suggestion. The authors attempted to replicate this effect and also assessed the impact of the training procedure on hypnotically suggested analgesia. Ninety-eight students who had been preselected for high, medium, and low levels of initial suggestibility were randomly assigned to experimental and control groups. Training failed to increase overall suggestibility scores or to enhance the effects of a suggestion for pain reduction. Suggested pain reduction was more highly correlated with posttreatment suggestibility scores than with pretreatment suggestibility and, in a regression analysis, only posttreatment suggestibility predicted pain reduction uniquely.

1995

Gearan, Paul; Schoenberger, Nancy E.; Kirsch, Irving (1995). Modifying hypnotizability: A new component analysis. International Journal of Clinical and Experimental Hypnosis, 43 (1), 70-89.

The effects of the Carleton Skills Training Program (CSTP) on hypnotizability were compared to those of a modified training program in which instructions for physical

enactment of the response were omitted. After training, subjects in the original CSTP reported an increase in the extent to which they intentionally enacted suggested behaviors. In contrast, subjects in the modified training program reported increased fantasy without voluntary physical enactment. Nevertheless, both training programs increased behavioral and subjective responsiveness to suggestion, and there were no significant differences in response enhancement between the two programs. Across conditions, increases in behavioral and subjective responses to suggestion were correlated with increased use of fantasy. In contrast, increases in enactment were correlated only with compliance. The modified training program is recommended as a means of enhancing suggestibility with less likelihood than the original CSTP of engendering compliance.

**1993**

**Bertrand, Lorne D.; Stam, Henderikus J.; Radtke, Lorraine (1993). The Carleton Skills Training Package for modifying hypnotic susceptibility--a replication and extension: A brief communication. International Journal of Clinical and Experimental Hypnosis, 41, 6-14.**

This study employed the Carleton Skills Training Package (CSTP) to attempt to enhance both objective and subjective components of hypnotic susceptibility. In addition, changes in susceptibility were compared for subjects administered a standard hypnotic induction procedure and for subjects given brief "place yourself in hypnosis" instructions. Results indicated that subjects who were administered the CSTP exhibited significant gains in both objective and subjective susceptibility scores that were maintained at two separate posttests with different scales. No differences were observed between the groups administered the standard induction and those administered the self-induction instructions.

**NOTES:**

The authors do not make much of the latter finding, but I find it to be the more interesting outcome.

"Two experiments (Barber & Calverley, 1969; Stam & Fraser, 1986) found that subjects who sat quietly for 5 minutes following an instruction to "place yourself in hypnosis" attained similar scores when responding to test suggestions as did subjects who were administered a 5-minute hypnotic induction procedure. The CSTP informs subjects that hypnotic induction procedures do not achieve their effects by inducing a trance state and that such procedures function to produce relaxation rather than to enhance responsiveness to suggestion. In addition, the CSTP emphasizes to subjects that responses to suggestions do not 'just happen' but must be actively generated. To the extent that subjects attend to these aspects of the CSTP procedure, they should exhibit equivalent increments on behavioral and subjective indexes of susceptibility regardless of whether they are administered a formal hypnotic induction procedure or simply told to 'place themselves into hypnosis.'" (p. 7).

"That naive subjects can produce equivalent objective, subjective, and involuntariness scores following such instructions highlights the degree to which

hypnotic responses are not dependent on formal induction procedures. The fact that so-called active-alert induction procedures are also equivalent in producing hypnotic responses supports this notion (Banyai & Hilgard, 1976)" (p. 13).

Spanos, Nicholas P.; Flynn, Debora M.; Gabora, Natalie J. (1993). The effects of cognitive skill training on the Stanford Profile Scale: Form I. Contemporary Hypnosis, 10, 29-33.

Low hypnotizable subjects who attained high hypnotizability scores following cognitive skill training (i.e. created highs) were compared with untrained low hypnotizables and with subjects who attained high hypnotizability scores without training (i.e. natural highs) on Form 1 of the Stanford Profile Scale (SPS:I). Created and natural highs did not differ significantly on the SPS:I and equivalent proportions of created and natural highs attained 'virtuoso performance' on the SPS:I. None of the initially low hypnotizables attained high SPS:I scores. Findings indicate that the performance of high-scoring, skill-trained subjects cannot be 'explained away' in terms of post-test hypnotizability scales with limited upper ranges.

1992

Bates, Brad L. (1992). The effect of demands for honesty on the efficacy of the Carleton Skills-Training Program. International Journal of Clinical and Experimental Hypnosis, 40 (2), 88-102.

30 low hypnotizable Ss were administered the Carleton Skills-Training (CST) program. Prior to testing, 15 Ss were administered honesty instructions (Bowers, 1967) in an effort to encourage responses that were consistent with subjective experiences and to dissuade Ss from performing in a manner intended to please E. Posttraining hypnotizability scores for Ss given honesty instructions were consistently smaller than those for 15 Ss who did not receive these instructions, implying that scores for the latter group exaggerate the extent to which hypnotic experiences are altered by the CST program. The pattern of results supports the view that demand characteristics contribute to the efficacy of the CST program, and that improvements in actual hypnotic talent are more limited than Spanos' original work implies.

1991

Bates, Brad L.; Kraft, Patricia M. (1991). The nature of hypnotic performance following administration of the Carleton Skills Training Program. International Journal of Clinical and Experimental Hypnosis, 39, 227-242.

30 low hypnotizability Ss were administered the Carleton Skills Training (CST) program, while 8 were assigned to a practice group. Prior to treatment, an attempt was made to facilitate training by altering the ecological conditions of the laboratory. All Ss were tested immediately after treatment, and trained Ss were retested after 5-7 months. Immediate training gains were large and were

comparable in magnitude to those routinely found at Carleton University. In addition, (a) trained Ss responded comparably whether screened once or twice, (b) practice alone did not enhance hypnotic performance, and (c) natural high hypnotizability Ss obtained significant larger Field Inventory of Hypnotic Depth (Field, 1965) scores than created high hypnotizables. Follow-up scores fell between scores posted at screening and immediately after training. Current findings are interpreted in the context of existing evidence concerning the CST program.

**NOTES: (based on the Discussion) "Results from these two investigations (include Bates et al., 1988) challenge the claim that lasting changes have occurred in the ability of most trained Ss to experience hypnosis. With regard to the present findings, it is reasonable to wonder whether scores would have been even lower had follow-up data been gathered a few months later. In the only other published study to address the problem of maintenance, Spanos, W. P. Cross, Menary, and Smith (1988) found that after at least 9 months, trained Ss outscored low hypnotizability Ss who had never received training. Unfortunately, these investigators do not report comparisons between trained Ss' follow-up scores and either original screening or immediate posttest scores. The authors do report, however, that 20% of trained Ss obtained high scores at follow-up. Given that at least 50%, and as high as 80%, of Ss routinely score in the high range immediately after receiving the CST program at Carleton University, a follow-up figure of 20% implies that with time, the hypnotic performance of most trained Ss began to return to baseline levels.**

**"With regard to the subjective experience of trained Ss.... These results confirm previous findings by Bates & Brigham (1990) which indicated that the hypnotic experiences of CST graduates - even those who are the most responsive to the modification program - may not be comparable in all respects to those of untrained, high hypnotizable individuals" (pp. 237-238).**

**"The present study altered the context in which training occurred by increasing the salience of the laboratory; adding, repainting, carpeting, and redecorating experimental rooms; requiring Es to dress professionally; and temporarily attributing the CST program to Washington State University. When demand characteristics were arranged in this manner, training gains were of the same magnitude as those found at Carleton University and were much larger than those found in all prior replication studies. The apparent importance of contextual factors is underscored by findings reported by Bates et al. (1988), who manipulated demand characteristics in a systematic fashion and observed that Ss' responses to the CST program are moderated by the context in which training occurs. Given the important role that ecological variables have generally played in hypnosis research, it should come as no surprise that factors like these would affect attempts to modify hypnotic performance" (p. 238).**

**Kirkeby, Judith L.; Payne, Paul A.; Hovanitz, Christine; Moser, Steven (1991). Increasing hypnotizability: A comparison of a multimedia form of the Carleton Skills Training Program with a self-administered written form. Contemporary Hypnosis, 8, 161-165.**

Compared a group-administered form of the multimedia Carleton Skills Training Program (CSTP) to a self-administered training program similar in content, but limited to written materials. One hundred and forty-one female subjects were administered one of four conditions: (1) the multimedia CSTP; (2) the self-administering booklet training; (3) a practice-only condition; or (4) a no-practice control condition. Subjects then responded to a shortened form of the Harvard Group Scale of Hypnotic Susceptibility, Form A (HGS:AS). [6 items: arm lowering, arm rigidity, hands together, fly hallucination, eye catalepsy, and amnesia.] Results indicated that objective and subjective hypnotizability measures were higher in both of the training conditions than in the practice-only or control conditions. In comparisons of the two training conditions, the booklet program was judged to be equal in effectiveness to the multi-media group form of the CSTP.

Spanos, Nicholas P.; DuBreuil, Susan C.; Gabora, Natalie J. (1991). Four-month follow-up of skill-training-induced enhancements in hypnotizability. Contemporary Hypnosis, 8, 25-32.

Low hypnotizability subjects were exposed to skill training aimed at enhancing hypnotizability, and post-tested 2 weeks later. Those in a short delay condition were administered a second hypnotizability post-test within 2 weeks of the first, whilst those in a long delay condition were administered the second post-test 16-18 weeks after the first post-test. Skill-trained subjects in the two delay conditions did not differ on the first post-test. Skill-trained subjects in the two delay conditions did not differ significantly on behavioural or subjective indices of hypnotizability at either post-test. However, skill-trained subjects attained significantly higher hypnosis scores on both post-tests than did no-treatment control subjects. Attitudes towards hypnosis were also significantly enhanced by skill training, and these enhancements were maintained across the post-test intervals. Among the skill-trained subjects, post-tested hypnotizability was predicted by subjects' attitudes and by the trainer's ratings of subjects' receptivity and resistance towards the training.

**NOTES:**

Immediately before each hypnotizability test, subjects' attitudes towards hypnosis were assessed with a 14-item questionnaire taken from Spanos, Cross et al. (1987). On this instrument higher scores indicate more positive attitudes" (p. 27).

"Immediately following each skill-training session, the trainer evaluated the subject's receptivity to the training using a nine-item checklist. The items described aspects of the training which experienced trainers in our laboratory have judged to

be indicators of successful modification. The items (e.g. 'Does the subject volunteer that they found the ideas presented interesting/fun?') were scored dichotomously (yes/no), and summed to yield a receptivity to training score for each subject. The trainer also rated the degree to which each subject displayed resistance to the training on a global three-point scale" (p. 27)

The correlation between receptivity towards the skill training procedure and baseline attitudes toward hypnosis was .50.

"Some evidence indicates that untrained subjects (high hypnotizables included) exhibit substantial decrements in responsiveness to suggestions when they are exposed between testings to negative information about hypnosis (Barber & Calverley, 1964; Spanos & McPeake, 1975) or to information that alters their expectations about their responsiveness (Spanos, Gabora, Jarrett & Gwynn, 1989)" (p. 30)

"These findings suggest that the subjects who initially hold the most negative attitudes towards hypnosis are the least receptive to skill-training procedures. After training, these subjects continue to hold relatively negative attitudes towards hypnosis which limit the extent of their hypnotizability gain" (p. 30).

**1990**

**Bates, Brad L.; Brigham, Thomas A. (1990). Modifying hypnotizability with the Carleton skill training program: A partial replication and analysis of components. International Journal of Clinical and Experimental Hypnosis, 38, 183-195.**

3 standard components of the Carleton Skills Training (CST) program - information, modeling, and instructions - were administered in 1 of 3 sequences to 12 low- hypnotizable Ss. Hypnotizability measures were obtained after each component was given, as well as before and after training. Although objective scores showed significant gains from screening to testing, subjective scores did not, suggesting that while training encouraged behavioral compliance, few Ss learned to have the subjective experiences traditionally associated with hypnosis. Results from the component analysis were clear and consistent: whether instructions were presented first, second, or third in the training sequence, no significant changes occurred until this component was provided.

**NOTES:**

Gains shown by CURSS:O scores in the present study are larger than those obtained by Bates et al. (1988), and comparable to those reported by Spanos and his colleagues. Perhaps the attempt by trainers in the current study to develop rapport with Ss enhanced testing scores; this would be consistent with findings by Gfeller et al. (1987) who found that rapport enhances the efficacy of the CST program. Alternatively, administering the components of the CST program separately may have facilitated training.

"Unlike CURSS:O scores, subjective experience measures did not show significant gains . In addition, created highs had significantly lower CURSS:S and FIHD scores than natural highs. These findings contrast with previous work by Spanos and his associates, who consistently find large subjective gains and few if any differences

between created and natural highs (e.g., Gorassini & Spanos, 1986; Spanos et al., 1987b).

"The fact that so much of the CST program is either audiotaped, videotaped, or read from a transcript suggests that important extraprogrammatic variables have not yet been identified by Spanos and his colleagues" (p. 191).

Regarding compliance issues, "Spanos refers to the fact that created and natural highs typically respond comparably on subjective hypnotizability dimensions. Yet, results from the present study would appear to cast doubt on this finding. Moreover, demonstrating that created and natural highs report comparable subjective experiences does not preclude the possibility that the former are merely complying with experimental demands" (p. 192).

" trained Ss consistently obtain lower hypnotizability scores during testing than simulators (Spanos & Flynn, 1989; Spanos et al., 1986). According to Spanos, this indicates that the testing behavior of trained Ss involves more than compliance with experimental demands.

"In actuality, the issue is more complicated than this. ... Since trained Ss are never explicitly told to respond like "excellent hypnotic Ss," the instructions they receive are different from those given simulators. Given different instructions, it is reasonable to expect that compliance will look different for these two groups. In short, Ss given the CST program may be complying, but with experimental demands quite different from those experienced by simulators.

"In summary, the present investigation demonstrates quite clearly that the instructional component is the primary change agent in the CST program. In addition, while objective scores increased substantially in the current study as a result of the training, subjective scores did not, suggesting that behavioral compliance, but not hypnotic ability, was enhanced by the CST program. Although Spanos maintains that recipients of the CST program learn to have the subjective experiences traditionally associated with hypnosis, the available data cannot distinguish between this possibility and the equally plausible hypothesis that trained Ss act as if hypnotized and report "hypnotic" experiences only because they are instructed during training to do so, and not because their hypnotic ability has been enhanced" (pp. 193-194).

1990

Spanos, Nicholas P. (1990). More on compliance and the Carleton Skill Training Program. British Journal of Experimental and Clinical Hypnosis, 7, 165-170.

#### NOTES

In this paper the author counters Bates' (1990) criticisms of the Carlton Skills Training Program, e.g. that the program induces Subject compliance rather than genuine increases in hypnotizability. The author states that the training program is designed to induce conformance rather than simply compliance with suggested demands.

He notes that in order to avoid the twinges of conscience associated with a self-definition of cheating, most Ss fail suggestions to which they are unable to generate the requisite subjective response. (Most Ss fail most of the suggestions on

standardized hypnotizability scales despite the fact that all of these suggestions are easily fakable.)

"The findings of the Spanos et al. (1987) and Cross and Spanos (1988) studies suggest that, given appropriate attitudes and interpretations, subjects who benefit most from skill training are those who possess the cognitive abilities that enable them to vividly create and become absorbed in the imaginary scenarios called for by test suggestions. It is much less clear how these findings could be accounted for in terms of compliance. There is no evidence to indicate that imaginal propensity indexes are strongly related to a general tendency towards compliance and, at any rate, low hypnotizables who undergo skill training are, by definition, subjects who failed to comply with test demands during initial hypnotizability testing.

"In summary, when taken together the available data suggest that compliance cannot account adequately for CSTP-induced gains in hypnotizability. Obviously, this conclusion should not be interpreted as saying that compliance plays no role in training induced hypnotizability gains, or that the role of compliance in this regard should not be thoroughly investigated. As Wagstaff (1981) has repeatedly emphasized, compliance appears to be an integral component of hypnotic responding. Recent evidence from our laboratory (Spanos et al., 1989a) supports Wagstaff's (1981) contention by indicating that untrained high hypnotizables engage in substantial levels of compliance when the 'pass' at least some difficult test suggestions. Given that natural high hypnotizables engage regularly in some compliant responding, it would be rather surprising to find that created highs did not do the same. However, examining this issue empirically requires the application of experimental paradigms that allow compliance to be differentiated from conformance.

Spanos, Nicholas P.; Warnock, Sean; de Groot, Hans P. (1990). Cognitive skill training, confirming sensory stimuli, and responsiveness to suggestions in subjects unselected for hypnotizability. Journal of Research in Personality, 24, 133-144.

Subjects unselected for hypnotizability were administered cognitive skill training which taught them to actively generate hypnotic responses or expectancy enhancing procedures that provided them with sensory stimuli aimed at confirming the false belief that they had successfully experienced suggested effects. Subjects were tested for suggestibility / hypnotizability at the end of their experimental treatment session and again in two follow-up posttests. Skill trained subjects exhibited significantly higher scores than subjects in all other treatments on the behavioral and subjective dimensions of the three suggestibility / hypnotizability tests. Subjects who received confirming stimuli showed higher behavioral scores than no treatment controls only on the behavioral dimension of the first suggestibility test, and no differences from controls on the subjective dimensions of any of theory tests. Theoretical implications are discussed.

Spanos, Nicholas P.; Flynn, Deborah M. (1989). Compliance, imaginal correlates and skill training. [Comment/Discussion] .

## NOTES

The authors defend the Carlton skill training program against accusation that the trained Ss are simply complying in the context of social pressure. They also discuss characteristics of high hypnotizables (absorption and imagery), noting that the majority of lows do not have low absorption/imagery scores (citing de Groh, 1988, and noting the research on context dependency for absorption).

"Despite all of this, it is worth noting that the results of our modification studies are not inconsistent with the hypothesis that high hypnotizability requires imaginative skills that some subjects do not possess in sufficient degrees. For example, two recent studies (Spanos et al., 1987; Cross and Spanos, 1988) found that the extent to which low hypnotizables showed gains following administration of the CSTP was predicted by their pre-tested levels of imagery vividness. Lows with good imagery benefitted substantially more from the CSTP than did lows with poor imagery ability. When it is kept in mind that most low hypnotizables do not score low on measures of imagery/absorption (de Groh, 1988), then the findings that substantial numbers of low hypnotizables can be taught to attain high hypnotizability is not at all inconsistent with the notion that high hypnotizability requires at least moderate levels of imagery/absorption ability" (p. 14).

## 1989

Spanos, Nicholas P.; Flynn, Deborah M. (1989). Simulation, compliance and skill training in the enhancement of hypnotizability. British Journal of Experimental and Clinical Hypnosis, 6, 1-8.

Subjects who underwent cognitive skill training were compared to no treatment controls and to subjects in two simulation treatments on the behavioural and subjective dimensions of two hypnotizability post-tests. Ss in a trained simulation treatment received skill training but were instructed to fake the responses of someone who had been transformed by training into an excellent hypnotic subject. Standard simulators did not receive skill training, but were instructed to fake their responses to the two post-tests. A final group of untrained Ss (i.e. naturals) who attained the same behavioural scores on a hypnotizability index as did post-tested skill-trained Ss, was also compared to the treated groups. Ss in the two simulation treatments performed similarly on all hypnotizability indexes. Simulators outperformed both skill-trained and natural subjects (who failed to differ from one another) on all indexes, and skill-trained and natural subjects, in turn, outperformed the no treatment controls. These findings suggest that sustained faking cannot account adequately for the enhancements in hypnotizability produced by skill training.

Spanos, Nicholas P.; Flynn, Deborah M.; Niles, Judy (1989-90). Rapport and cognitive skill training in the enhancement of hypnotizability. Imagination, Cognition and Personality, 9 (3), 245-262.

The role of interpersonal rapport in facilitating the enhancements in hypnotizability produced by cognitive skill training was examined in two experiments. In Experiment 1 low hypnotizable subjects either received skill training or passively oriented training that was designed to facilitate rapport with the trainer without teaching subjects how to generate the responses called for by test suggestions. Subjects in the two treatments reported equivalently high levels of rapport with their trainer, but only those given skill training attained large gains on two hypnotizability posttests. Subjects given passive training did not differ from untreated controls at posttesting. In Experiment 2 subjects received skill training under conditions designed to either heighten or minimize rapport with the trainer. Those in the high rapport condition showed large hypnotizability gains on both posttests, whereas those in the low rapport condition failed to differ from no treatment controls in the regard. Our findings indicate that high rapport is not sufficient for producing training-induced enhancements in hypnotizability. However, the absence of such rapport may interfere with subjects' learning and applying skills that can enhance hypnotizability

Spanos, Nicholas P.; Lush, Nancy I.; Gwynn, Maxwell I. (1989). Cognitive skill-training enhancement of hypnotizability: Generalization effects and trance logic responding. Journal of Personality and Social Psychology, 56 (5), 795-804.

Compared low-hypnotizable subjects who simulated hypnosis, underwent cognitive skill training, or served as no-treatment controls to subjects who scored as high hypnotizables without training (natural highs) on response to analgesia, age-regression, visual hallucination, selective amnesia, and posthypnotic suggestions. Subjects who attained high hypnotizability following skill training (created highs) did not differ from natural highs on any response index. Natural and created highs scored lower than simulators but higher than controls on the behavioral and subjective aspects of test suggestions. Simulators, however, were significantly less likely than natural highs or skill-trained subjects to exhibit duality responding or incongruous writing during age regression or transparent hallucinating. Results suggest that the hypnotic responses of natural and created highs are mediated by the same cognitive variables and that enhancements in hypnotizability produced by skill training cannot be adequately explained in terms of compliance.

Spanos, Nicholas P.; Cross, Wendi P.; Menary, Evelyn; Smith, Janet (1988). Long term effects of cognitive-skill training for the enhancement of hypnotic susceptibility. British Journal of Experimental and Clinical Hypnosis, 5 (2), 73-78.

Twelve initially low susceptible subjects, who scored in the medium or high susceptibility range on the Carleton University Responsiveness to Suggestion Scale (CURSS) following skill training, were posttested 9 to 30 months later with a group version of the Stanford Hypnotic Susceptibility Scale, Form C. Skill trained subjects scored significantly higher on behavioral and subjective dimensions of the Stanford Hypnotic Susceptibility Scale, Form C than low susceptible untrained control subjects who were posttested after an equivalent interval. Furthermore, the

posttraining CURSS scores of the skill trained subjects were matched to those of subjects who received the same CURSS scores without training. Matched subjects were posttested on the Stanford Hypnotic Susceptibility Scale, Form C after only a brief delay. Skill trained and matched subjects failed to differ significantly on Stanford Hypnotic Susceptibility Scale, Form C susceptibility dimensions, but skill trained subjects showed higher levels of suggested amnesia than matched subjects. These findings support the idea that hypnotic susceptibility is modifiable and that training induced gains in susceptibility can be enduring.

1987

Spanos, Nicholas P.; Robertson, Lynda A.; Menary, Evelyn P.; Brett, Pamela J.; Smith, Janet (1987). Effects of repeated baseline testing on cognitive-skill-training-induced increments in hypnotic susceptibility. Journal of Personality and Social Psychology, 52 (6), 1230-1235.

Subjects who pretested as low in hypnotic susceptibility either received or did not receive a second baseline susceptibility test. Half of the subjects in each baseline test condition were administered cognitive skill training to enhance susceptibility, and half were given no training. Trained subjects exhibited much higher scores than untrained subjects on the objective and subjective dimensions of two different susceptibility posttests. The number of baseline tests given to subjects did not significantly affect posttest responding. These findings support the notion that hypnotic susceptibility can be substantially modified. They argue against the idea that training-induced gains in susceptibility are an artifact of giving subjects only a single- baseline test.

Spanos, Nicholas P.; de Groh, Margaret; de Groot Hans (1987). Skill training for enhancing hypnotic susceptibility and word list amnesia. British Journal of Experimental and Clinical Hypnosis, 4 (1), 15-23.

Subjects who pretested as low on hypnotic susceptibility received either cognitive skills training aimed at inculcating positive attitudes and interpretations concerning hypnotic responding, or no treatment. Trained subjects scored significantly and substantially higher on subjective and behavioral dimensions of susceptibility than controls. A second posttest assessed amnesia for a previously learned word list. Trained subjects showed more word list amnesia than either no treatment controls or subjects who had been matched to the trained subjects in terms of posttest susceptibility. Theoretical implications for theories of hypnotic susceptibility are discussed.

1986

Spanos, Nicholas P.; Robertson, Lynda A.; Menary, Evelyn P.; Brett, Pamela J. (1986). Component analysis of cognitive skill training for the enhancement of hypnotic susceptibility. Journal of Abnormal Psychology, 95, 350-357.

Four treatments to enhance the hypnotic responsiveness of subjects who pretested as low in hypnotic susceptibility were compared. Complete skill training included information aimed at encouraging (a) positive attitudes, (b) the use of imagery strategies, and (c) an interpretation of hypnotic behavior as active responding. Partial training included only components (a) and (b). Both training packages enhanced attitudes toward hypnosis to an equivalent degree. However, complete training was much more effective than either partial training or no treatment at enhancing behavioral and subjective responding on two different posttest scales of hypnotic susceptibility. More than half of the subjects who received complete training, but none of the partial training or control subjects, scored in the high-susceptibility range on both posttests. Subjects explicitly instructed to fake hypnosis and those in the complete skill-training treatment exhibited significantly different patterns of posttest responding. Findings support social psychological perspectives that emphasize the importance of contextual factors in hypnotic responding.

## CASE STUDY

1993

Becker, Philip M. (1993). Chronic insomnia: Outcome of hypnotherapeutic intervention in six cases. American Journal of Clinical Hypnosis, 36, 98-105.

Chronic dyssomnia is highly prevalent and has multiple etiologies. Hypnotherapy has been reported as beneficial for insomnia, but the description of the subject populations has been limited. A group of patients was evaluated at a sleep disorders center for a dyssomnia that occurred on at least 3 nights per week for 6 months or more. Six patients accepted hypnotherapy for their persistent psychophysiological insomnia and other sleep disorder diagnoses. Three patients responded to two sessions of structured hypnotherapy. The three responders remained improved at 16-month follow-up. Factors that seemed to contribute to long-term response in this small group of patients included a report of sleeping at least half of the time while in bed, increased hypnotic susceptibility, no history of major depression, and a lack of secondary gain.

LaGrone, Randy G. (1993). Hypnbehavioral therapy to reduce gag and emesis with a 10-year-old pill swallower. American Journal of Clinical Hypnosis, 36, 132-136.

A 10-year-old child experienced severe nausea and psychogenic vomiting that resulted in refusal to take oral medication in pill form. The youngster was treated with hypnbehavioral therapy consisting of mental imagery, relaxation, direct suggestion, adaptive self-talk, self-monitoring, and self-reinforcement. The child's parents were instructed to reinforce approximations of successful pill swallowing while withdrawing attention for avoidance, whining, gagging, and vomiting. A one-year follow-up revealed successful pill swallowing without significant distress.

## NOTES

Scientists and practitioners are not benefitting from each other's contributions. The central contribution to hypnosis, both basic and applied, is the logic and validity of study designs. The false memory issue is an example. Clinicians supply an answer the public likes, but scientist provide data based on nomothetic (group average) models that are not useful here.

Most of my own work is nomothetic, but it can work together with case study approach. We use a synergistic model: the combined effects of traits, cognitive, social, and affective factors are investigated. Interactions are tricky to detect, but we need a spirit of enquiry that encourages designs sensitive to interactions.

One example is Radke & Spanos' study that used a scale rating whether subject was hypnotized and another indicating degree of absorption-and-hypnotized vs absorption-and-not-hypnotized. Nadon's reanalysis showed a scale by Ss interaction: mediums were different on the 7 point scale but highs were not. (Highs were less manipulated by the scale manipulation).

Jean-Roche Laurence and Nadon replicated the interaction. Then Nadon did a study to test the idea that highs were less affected by scale manipulation because they relied more on subjective experience. They measured Absorption in a different context and hypothesized that the highs here would be less affected on the 7 point scale in the other context; it was validated. There seemed to be a linear absorption by a quadratic hypnotizability interaction.

Another simple example of interaction at work: there are different lines predicting hypnotic ability based on the Absorption scale, representing need for control on the scale. Those low in need for control have a stronger prediction of hypnotizability from Absorption scale. With high need for control, Absorption doesn't predict hypnotizability. This may explain why the correlation isn't stronger between Absorption and hypnotizability.

Nadon investigated how level of relaxation could be affected by an interaction. Measured muscle tension of masseter (?) while listening to music (half of Ss) or focusing on relaxing (50%). In an experiential condition there was a negative correlation between Absorption and muscle tension (highs relaxed more); in an Instrumental condition it was the opposite. So both high and low Absorption people were capable of relaxation, but to get the best relaxation you would have to know their Absorption score.

A second study hypothesized that predispositions for certain kinds of affect (Tellegen's positive affect, like extroversion) and negative effect (like neuroticism). High Absorption extraverts low in neuroticism worked best with music; and [missed words]. This supports Tellegen's hypothesis re the effects of positive and negative affect and Absorption.

Now we can discuss individual characteristics that suggest which relaxation strategy will benefit. The practical implications can be validated by case studies.

Page, Roger A.; Handley, George W. (1993). The use of hypnosis in cocaine addiction. American Journal of Clinical Hypnosis, 36, 120-123.

An unusual case is presented in which hypnosis was successfully used to overcome a \$50-0 (five grams) per day cocaine addiction. The subject was a female in her twenties. Six months into her addiction, she acquired a commercial weight-control tape that she used successfully to stop smoking cigarettes (mentally substituting the word "smoking"), as well as to bring her down from her cocaine high and allow her to fall asleep. After approximately 8 months of addiction, she decided to use the tape in an attempt to overcome the addiction itself. Over the next 4 months, she listened to the tape three times a day, mentally substituting the word "coke." At the end of this period, her addiction was broken, and she has been drug free for the past 9 years. Her withdrawal and recovery were extraordinary because hypnosis was the only intervention, and no support network of any kind was available

1992

Adams, P. C.; Stenn, P. G. (1992). Liver biopsy under hypnosis. Journal of Clinical Gastroenterology, 15, 122-124.

Two patients underwent outpatient percutaneous liver biopsy under hypnosis without complications. One patient had severe anxiety about the procedure because of a previous adverse experience with liver biopsy, and the other had a history of severe allergy to local anesthesia. Both patients had undergone a session of hypnosis at least once prior to the biopsy. One received no local anesthesia, and the other received 1% lidocaine as a local anesthetic. Both patients were completely cooperative during the procedure with the required respiratory maneuvers. Both patients stated that they were aware of the procedure under hypnosis but described no pain and would be most willing to have the procedure done under hypnosis in the future.

Chantler, Lisa J. (1992). The treatment of irritable bowel syndrome using hypnosis. Australian Journal of Clinical and Experimental Hypnosis, 20, 39-47.

ABSTRACT: A single case is reported of the hypnobeavioural treatment of a patient with chronic irritable bowel syndrome. The success of this treatment suggests that it has potential over and above relaxation and other behavioural techniques alone.

Kraft, Tom (1992). Counteracting pain in malignant disease by hypnotic techniques: Five case studies. Contemporary Hypnosis, 9, 123-129.

ABSTRACT: Five cases of patients suffering from cancer are described in which hypnotic visualization techniques were successfully employed to relieve pain and anxiety. This study supports the view that hypnosis can be an effective tool for pain relief in malignant disease, particularly when traditional methods have been exhausted.

Haanen, Huub C.M.; Hoenderdos, Henk T.W.; Van Romunde, Leo K.J.; Hop, Win C.J.; Malle, Constant; Terwiel, Jack P.; Hekster, Gideon B. (1991). Controlled trial of hypnotherapy in the treatment of refractory fibromyalgia. Journal of Rheumatology, 18 (1), 72-75.

In a controlled study, 40 patients with refractory fibromyalgia were randomly allocated to treatment with either hypnotherapy or physical therapy for 12 weeks with followup at 24 weeks. Compared with the patients in the physical therapy group, the patients in the hypnotherapy group showed a significantly better outcome with respect to their pain experience, fatigue on awakening, sleep pattern and global assessment at 12 and 24 weeks, but this was not reflected in an improvement of the total myalgic score measured by a dolorimeter. At baseline most patients in both groups had strong feelings of somatic and psychic discomfort as measured by the Hopkins Symptom Checklist. These feelings showed a significant decrease in patients treated by hypnotherapy compared with physical therapy, but they remained abnormally strong in many cases. We conclude hypnotherapy may be useful in relieving symptoms in patients with refractory fibromyalgia.

#### NOTES

The patients in this study were 38 women and 2 men, ages 30-65, who had had fibromyalgia for an average of 8.5 years (range 1.5 - 40 years). Of these, 25 were on sick leave or incapacitated, and 6 were unemployed. Patients were randomly assigned to hypnotherapy, or to training in muscle relaxation plus massage (designated "physical therapy"). They were withdrawn from analgesics, except for paracetamol (like Tylenol), at the beginning of this program. Hypnotizability was not measured.

Hypnosis treatment consisted of an arm levitation induction, imagery deepening techniques, ego strengthening suggestions, and suggestions for control of muscle pain, relaxation, and improved sleep. Patients received eight one-hour sessions in decreasing frequency over three months; after Session 3 they were given a 30-minute audiotape to assist in daily self hypnosis. Seventeen patients completed hypnotherapy but three were dissatisfied and withdrew after 3 sessions.

Patients did self ratings on (1) duration of morning stiffness, (2) muscle pain, (3) fatigue on awakening, (4) sleep disturbance, and (5) global assessment, the last four using visual analog scales (VAS). Patient assessment at 12 and 24 weeks was the primary outcome measure, since fibromyalgia is diagnosed principally from patient's self described symptoms.

Independent observers did not know to which group the patient belonged. The physician's evaluation included (1) dolorimeter measures of point tenderness (for a Total Myalgic Score, TMS), (2) presence of tender points at 30 points, with 5 control points, (3) overall pain rating with visual analogue scale.

The Hopkins Symptom Checklist (HCL-90) also was used to evaluate outcome.

Using analysis of variance techniques and correcting for initial values, the study found significantly more favorable values in the hypnosis group than in the physical therapy group for muscle pain, fatigue on awakening, sleep disturbance, patient's overall assessment, and HCL total score. However, differences were not significant

for morning stiffness, physician's overall assessment, or T.S. There were no differences between Weeks 12 and 24 for both groups; therefore the mean value for weeks 12 and 24 for each patient were used to calculate percentage change relative to baseline.

The reduction in pain medication used by the hypnosis group was quite remarkable. "Median (range) analgesic drug use at the initiation of the study (mostly paracetamol) was in the hypnotherapy group 3.0 (0-42) tablets/week and in the physical therapy group 4.5 (0-21)/week. At Week 12 this was 1.0 (0-21) tablet/week for the hypnotherapy group and 7.0 (0-34) tablets/week for the physical therapy group. At the end of the study, 10 of 12 patients in hypnotherapy group and 3 of 12 patients in the physical therapy group had reduced their paracetamol use (Fisher exact test:  $p = 0.006$ )" (pp. 73-74).

Although it was observed that the total number of tender points decreased (regardless of treatment group), the Total Myalgic Score assigned by the physician had not changed either at week 12 or at week 24. In fact, even the control points were tender in 44% of the patients; most patients showed some pain response to a control point in one or two sessions of the three. "Only 12 of 40 patients had consistently nontender control points, 4 in hypnotherapy group and 8 in the physical therapy group. ... No relation was found between the initial HCL total score and the changes in the other variables studied" (p. 74).

Figures taken from Table 2, showing percent change as compared to baseline:

Physical Therapy (%)	Hypnotherapy (%)	Morning stiffness (minutes)	0.0	-25.0	
Muscle pain (VAS)	-6.8	-10.2**	Fatigue on awakening (VAS)	-0.3	-16.7**
Sleep disturbance (VAS)	-1.0	-23.1**	Overall assessment patient	-8.4	-33.2**
physician	+5.7	-3.2	T.S. (kg/3 cm <sup>2</sup> )	-11.1	-2.4
HCL total score	-0.9	-13.0**			

In their Discussion, the authors write, "In this controlled therapeutic trial in patients with refractory fibromyalgia hypnotherapy was more successful than physical therapy in improving complaints. The assessment of fatigue on awakening, sleep disturbance, muscle pain, the patient's overall assessment and the total score of the HCL showed a significant decrease in the hypnotherapy group at the end of the hypnotherapy at 12 weeks. This decrease persisted for 3 months after finishing the hypnotherapy. The variables studied in the physical therapy group had not changed significantly at 12 and 24 weeks.

"However, the patients in the hypnotherapy group improved only subjectively. This improvement was not seen via more objective variables (T.S. and number of tender points), in accordance with others [Carette et al., 1986]. This suggests that coping with the disease may be positively influenced by hypnotherapy though the underlying disorder is still present.

"Correction of the sleeping disturbance by hypnotherapy was the most consistent finding and possibly played an important role in the subjective improvement of fibromyalgia" (p. 74).

The authors noted that the HCL yielded scores in the pathological range during the baseline period. "Thus, in our study, patients with long-standing fibromyalgia often showed pathological feelings of discomfort. In the hypnotherapy group the total score of the HCL decreased significantly suggesting that the physical disturbance

may be secondary to long-standing fibromyalgia. It is worth noting that only 3 of the 57 questions on the HCL-90 concern fibromyalgia" (p. 74).

The authors express the opinion that their data do not support a distinction between fibromyalgia and psychogenic rheumatism [Simms, Goldenberg, Felson, & Mason, 1988; Campbell, Clark, & Tindall, 1983] based on pain reported at control points. "Most patients in our study had variable tender control points. The finding of tender control points in fibromyalgia is consistent with others [Wolfe, Smythe, Yunus, et al., 1990; Scudds, Rollman, Harth, & McCain, 1987]. Also we found a positive correlation between the number of tender points and the presence of tender control points. Therefore, it seems more likely that there is a fairly large overlap between fibromyalgia and psychogenic rheumatism (tender all over)" (p. 75).

1991

Madrid, Antonio D.; Barnes, Susan v.d.H. (1991). A hypnotic protocol for eliciting physical changes through suggestions of biochemical responses. American Journal of Clinical Hypnosis, 122-128.

We employed brief hypnotherapy to effect physical changes in patients suffering from medical disorders including allergies, rectal bleeding, systemic lupus, hyperemesis, headache, asthma, and chronic pain. We present, in language appropriate to the individual patient, considerations and suggestions to effect the release of healing biochemicals. Ideomotor signals indicated the patient's awareness of the healing. We hypothesize that the technique triggered novel state-dependent memory, learning, and behavior.

#### NOTES

They hypothesize that the technique they use triggers novel state-dependent memory, learning, and behavior (See for example Rossi, 1987, and Rossi & Cheek, 1988).

Hypnotic Protocol: "1. Tell the patient that he can heal himself by allowing his body to supply its own biochemicals needed to make him well. If a specific biochemical is known, such as cortisone or endorphins, name it. "2. Hypnotize the patient. Resistant or hard to hypnotize patients need not be deeply hypnotized because the patients, using this protocol, will automatically go into trance while accomplishing the next task of accessing and using ideomotor signals (Erickson, 1980; Rossi & Cheek, 1988). "3. Tell the patient that his index finger will automatically and involuntarily twitch and float when his body releases the biochemicals he needs. This ideomotor response (Rossi & Cheek, 1988) is the sole physical response required of the patient. Rossi hypothesizes that the ideomotor response correlates with biochemical changes (Rossi & Cheek, 1988). "4. Next, ask the patient to consider some things (as described below). Present the considerations one after another until one of them triggers the ideomotor response. "5. In some instances, ask the patient to practice on his own. Many patients who have dramatic emotional reactions during or at the completion of the task may not need to practice on their own" (p. 123).

They present several 'considerations' to the patient, one after the other, tailored to the patient's specific case, until his finger twitches or floats, indicating a biochemical response. For example, the following 'considerations' have been used: "1. Psychodynamic: 'Consider that you are not blamed for anything; that you are in fact perfect just the way you are; that you are loved by those you care about.' 'Consider that you can forgive whoever needs forgiving for hurting you.' 'Consider that there are no longer any threats; everything is better; everything is as it used to be.' "2. Autosuggestion: 'Tell your body to heal. It knows what to do; so ask it to do it.' 'Tell your adrenal glands to produce the steroids that your body needs.' 'Allow a glowing light to permeate that injured back, filling it with healing energy.' "3. Incompatible responses: 'Cover yourself with a cool breeze, cooling the injured leg.' 'Imagine your back getting slack and limp and relaxed.' 'Imagine your stomach lining becoming smooth and moving with easy, ocean-like waves.' "4. Emotion calling: 'Consider yourself feeling very happy with everything, for no reason at all.' 'Consider yourself getting angry at someone--your mother, your wife (husband), your boss, your lawyer.' "5. Bargaining: 'Tell yourself that you will heal if you agree to stay away from that job.' 'Tell yourself you will heal by allowing your right arm to begin to hurt when you are over- exerting yourself.' 'Tell yourself that you will heal in exchange for something else, not so serious, to replace this disease and to serve the same function'" (pp. 123-124).

They present seven cases involving, respectively, allergies, rectal bleeding, systemic lupus, hyperemesis of pregnancy, adult onset asthma, chronic pain, and cluster headaches. Two cases were particularly interesting because they represented patients who did not respond initially.

Their procedure involves reframing the state or emotion originally associated with the onset of disease using considerations, and then giving a suggestion that it is within the power of the person, rather than factors outside, to heal the body. First they instruct the patient that the body can heal itself; then they give the list of suggestions for the patient to consider, persisting with different considerations until they get an ideomotor response. Incorporation of the patient's psychodynamic issues appears to be very important.

The authors regard it as unimportant if the patient cannot be hypnotized; "As Cheek (Cheek & LeCron, 1968; Rossi & Cheek, 1988) points out, the patient's inability to be hypnotized may be synonymous with his disease. It is actually beneficial if the patient cannot achieve ideomotor responses at first because both he and the therapist then trust the validity of the response when it does occur after the appropriate

1990

Hoencamp, Erik (1990). Sexual abuse and the abuse of hypnosis in the therapeutic relationship. International Journal of Clinical and Experimental Hypnosis, 38, 283-297.

In the Netherlands, individuals charged with rape may be prosecuted only in instances in which the suspect could have known that the victim was unconscious or in a state of powerlessness. Hypnosis might be looked upon as a method by which an

unscrupulous person could sustain such a state of powerlessness in a victim. As an expert witness, the present author participated in a court case against a lay hypnotist who was accused of abusing 9 women. The methods and strategy used by the lay hypnotist are presented as well as are the diverse reactions of the women involved in the case. Feelings of nonvolition appear to have been a relevant factor in the coercion, especially in women who demonstrated hypnotic phenomena such as arm levitation, catalepsy, etc. The basis for sexual coercion was established only after the interpersonal relationship had been redefined as a therapeutic relationship. Introduction within the pseudotherapeutic relationship of a sexual rationale for the presented complaints helped to provide a framework for actual sexual acts to occur. With certain individual patients, the introduction of hypnosis enhanced the subjective experience of nonvolition and with it the vulnerability for abuse. It may be hypothesized that patients with a tendency for external attribution and high hypnotizability are specifically at risk for this kind of abuse when hypnosis is used in the context of a therapeutic relationship.

Mason, Albert A. (1990, January). A psychoanalyst looks at a hypnotist; or, where the elephant skinned boy took me. [Paper] Presented at the Psychoanalytic Center of California Scientific Meeting.

#### NOTES

The results of working with hypnotism experimentally in the production of anaesthesia for surgery, dentistry and obstetrics; in controlled series of treatments of asthmatics, skin disorders, and allergic manifestations; as well as its clinical use, have convinced me that it is a delusional state akin to mania which depends on the omnipotent denial of mental pain. The mania is stimulated by the hypnotized subject having phantasies of an omnipotent object that it fuses with and shares in the omnipotence. The hypnotist has similar unconscious phantasies about himself. Both subject and hypnotist projectively identify with each others' phantasies, and together produce phenomena like anaesthesia which can be likened to delusional states. In fact, true hallucinations can also be deliberately produced.

"I believe that similar psychotic mechanisms can also occur in life between parents and children and in other relationships, and produce delusional states. These form a continuum from intractable narcissism on the one side, through Christian Science and the denial of evolution in the center, to frank folie a deux and transexualism on the other side. The therapeutic course of these states seems quite dissimilar from that of psychosis arising without the encouragement of external objects."

O'Hanlon, W. H.; Hexum, A. L. (1990). An uncommon casebook: The complete clinical work of Milton H. Erickson, M.D. New York: W. W. Norton & Co.. (Reviewed by Elgan Baker, American Journal of Clinical Hypnosis, 34, 137)

#### NOTES

According to the review by Elgan, cases are organized into sections by the presenting problems of the patients treated and include a wide range of psychopathology. Each case is given an identifying number for ease of cross-

referencing and is presented in a standard form: case summary, presenting problem, age group, modality of treatment, problem duration, treatment length, result of treatment, follow-up (if available), a summary of techniques used, and sources for the case description.

Page, Roger A.; Handley, George W. (1990). Psychogenic and physiological sequelae to hypnosis: Two case reports. American Journal of Clinical Hypnosis, 32 (4), 250-256.

Two cases of hypnotic sequelae occurring in a research context (with a non-clinical college population) are reported. Case 1 was a male who experienced retroactive amnesia following hypnosis: He was unable to recall familiar telephone numbers later that day. This was not a continuation of an earlier confusion or drowsiness (as is often found) since he indicated he was wide awake following hypnosis. Two parallels exist with previous reports: unpleasant childhood experiences with chemical anesthesia and a conflict involving a wish to experience hypnosis but a reluctance to relinquish control. Case 2 was a female who, while in hypnosis, experienced an apparent epileptic seizure that had characteristics of both petit mal and grand mal seizures. Although having a history of epilepsy, she had not had a seizure in 7 years. We suspect that the seizure was psychogenic and may have been triggered by wording used in the hypnotic scale or other similarities. Possible mechanisms are discussed and preventative recommendations are made.

Perry, Campbell (1990). Coercion by hypnosis? Invited discussion of Levitt, Baker, and Fish: Some conditions of compliance and resistance among hypnotic subjects. American Journal of Clinical Hypnosis, 32 (4), 242-243.

## NOTES

A postexperimental inquiry (following Orne, 1959) might have informed the reader of the degree to which operationalization of the coercion in terms of disobedience was successful. Without this additional step, it is difficult to determine whether what was found in the laboratory by these investigators applies to what has been reported in clinical and field settings for almost 200 years" (p. 242).

"In particular, elsewhere, the authors equate coercion with involuntariness and appear to view involition as a euphemism for coercion. While I agree that perceiving involition of one's own behavior may contribute to the commission of unconsenting acts in hypnosis, the two are easily distinguished at the conceptual level. Laboratory subjects ordinarily report much behavior in hypnosis that is experienced involuntarily, without the issue of it being coerced ever being broached" (p. 242).

Author describes cases in which patients claimed they participated in sex with hypnotist against their wills because they were hypnotized. "What may be happening in both of these reports is that the hypnotized subjects found themselves responding involuntarily; from this, they appear to have adduced that they could not resist the hypnotist's suggestion. That is, they were coerced not by hypnosis but by their belief, which was a direct function of the experience of involuntariness, that

they could not resist" (p. 243). "In short, if a hypnotized person equates involuntary behavior with powerlessness, "coercion" may occur in this limited sense. Conceptually, this appears to be a far cry from equating involition with coercion" (p. 243).

1989

Bierman, Steven F. (1989). Hypnosis in the emergency department. American Journal of Emergency Medicine, 7, 238-242.

Five cases are presented wherein hypnosis was used by the emergency physician either as the primary mode of treatment or as an adjuvant to standard medical care. Common hypnotic phenomena (e.g. anesthesia, analgesia), as well as novel effects, are reported. The technique used for trance induction and utilization is briefly outlined, and criteria are set forth for the bedside recognition of hypnotic trance.

Holroyd, Jean; Hill, Alexis (1989). Pushing the limits of recovery: Hypnotherapy with a stroke patient. International Journal of Clinical and Experimental Hypnosis, 37, 189-191.

Hypnotherapy was used to assist recovery of left arm function following stroke in a 66-year-old woman. Treatment protocol is described, and results are discussed in terms of how hypnosis may facilitate voluntary motor movement. Recent literature on cortical changes in hypnosis and motor improvement during hypnosis is discussed in relation to the present results.

#### NOTES:

The patient was 6 months post-stroke and physicians did not expect much additional improvement. She improved despite the fact that she measured as a low hypnotizable on the Stanford Scale, Form C. However, she appeared very absorbed in the hypnotic imagery, and she was highly motivated and exhibited much hope or positive expectation. Also, the author notes that "remarkable improvements in brain functioning have been reported through the use of sophisticated behavioral technology," (p. 124), as in the use of EEG biofeedback to treat untractable seizures (Serman & Lanz, 1981).

In rehabilitation cases, hypnotic dissociation may enhance pain control during the performance of exercises; more vivid hypnotic imagery may facilitate mental rehearsal of movements; attitudes may be reframed using hypnotic suggestion; and focusing attention on bodily sensations may be enhanced with hypnosis. Hypnosis also may improve expectancy, reduce anxiety, increase hope, provide general relaxation (reducing involuntary spasticity), increase cerebral blood flow, or in other ways promote healing.

Research by Pajntar, Roskar, & Vodovnik (1985) has demonstrated improved motor response during hypnosis for patients with hemiparesis. They attributed EMG changes under hypnosis "to a facilitory influx from supraspinal motor centers. They hypothesized that new motor units of paretic muscles were being activated or that there was an increased recruitment of the motor units already

active, and they suggested that relaxation of the spastic antagonist muscle permits the paralyzed muscle to move" (p. 125).

1988

DeBenedittis, Giuseppe; Sironi, Vittorio A. (1988). Arousal effects of electrical deep brain stimulation in hypnosis. International Journal of Clinical and Experimental Hypnosis, 36, 96-106.

In an earlier study, DeBenedittis and Sironi (1986) demonstrated that during depth EEG studies, electrophysiological correlates of hypnotic behavior emphasize the role of the limbic system in mediating the trance experience. In the case of a young man who was affected by medically resistant temporal lobe epilepsy and who was a potential candidate for surgical treatment, diagnostic depth EEG in hypnotic and non-hypnotic conditions offered a unique opportunity to stimulate limbic structures. This permitted an evaluation of the subjective and behavioral responses, as well as of the electrophysiological correlates. During hypnosis, repeated stimulations of the left and the right amygdala produced arousal from the hypnotic state each time, whereas the stimulation of other cerebral structures (e.g., temporal neocortex, Ammon's horn) or pseudostimulations were ineffective on the hypnotic state. These data represent the first experimental, controlled evidence of the amygdala's effects on the arousal from the hypnotic state in man, thus suggesting that hypnotic behavior is mediated, at least in part, by a dynamic balance of antagonizing effects of discrete limbic structures--the amygdala and the hippocampus.

#### NOTES:

The patient was a 30-year-old man who had suffered from medically resistant psychomotor temporal lobe epilepsy since age 7; a diagnostic EEG showed right temporal seizure focus, concomitant with independent, contralateral, temporal spiking abnormalities. Hypnotizability was measured at 6 on the SHSS:C; the patient was given two training sessions in hypnosis, with suggestions for "dissociation, rehearsal and reframing of spontaneous seizure events, desensitization of their negative emotional impact, and amnesia" (p. 99).

Electrodes were implanted in deep cerebral structures (amygdala, Ammon's horn) and corresponding superficial areas of temporal cortex, with confirmation of placement by X-ray. Two weeks later the patient's brain was stimulated on two consecutive days, first in the waking state (Session 1) and then in hypnosis (Session 2). (Antiepileptic medication was discontinued three days before the stimulation sessions.) False (placebo) stimulations were randomly provided along with the true stimulations.

The false (placebo) stimulations did not result in subjective or behavioral changes in either the waking or the hypnosis condition.

In the waking condition, a psychomotor seizure was produced by stimulation of Right amygdala and Left Ammon's horn; stimulation of Left amygdala evoked only the aura patient usually had before a seizure, or a brief lapse of consciousness. Stimulating the temporal neocortex did not evoke seizure activity.

In the hypnosis condition, arousal from hypnosis into the waking condition occurred with stimulation of amygdala (either Right or Left). Stimulation of the temporal neocortex or of the Right Ammon's horn did not arouse the patient. Stimulation of Left Ammon's horn led to abortive seizures, such that it could not be determined whether the hypnotic state had been interrupted. Stimulating the Right amygdala "triggered a psychomotor attack similar to that recorded during the waking stimulation, but with reduced emotional involvement" (p. 100). For the Left Ammon's horn, "waking stimulation always induced clinical seizures with prolonged after-discharge, whereas hypnotic stimulation evoked only abortive seizures, without after-discharge" (p. 100).

In their Discussion, the authors note that animal experimental literature suggests that stimulation of the cortico-medial amygdala facilitates arousal functions, of the baso- lateral amygdala diminishes arousal and produces sleep, and lesions of the amygdala lead to 'amygdala hangover' (Weiskrantz, 1956). "The animal with amygdala destruction appears tame and placid, with reduced social reactivity, insensitive to environmental changes and reluctant to initiate new behavior, unless highly motivated (Isaacson, 1976)" (p. 101-102).

In contrast, the animal research on hippocampus suggests it is involved in inhibitory functions (Isaacson, 1976), and may be the 'internal inhibitor' theorized by Pavlov (1955) to be responsible for animal hypnosis. With lesions, animals are more willing to undertake new behaviors, less inactive, less distractible during goal-oriented behavior (Isaacson, 1976). "Moreover, normal hippocampograms show typical, slow (theta) synchronous activity opposed to the arousal desynchronized activity of the electroencephalogram. During hypnosis, desynchronization of the normal, slow activity of the hippocampal Ammon's horn has been registered as compared with the waking hippocampogram, opposite to the slow synchronous activity of the amygdala" (p. 102).

The authors note that their results are at variance with the finding by Crasilneck et al. (1956) that their patient, during brain surgery for an epileptogenic focus, aroused from hypnosis each time they stimulated the hippocampus. They explain the discrepancy as due to the fact that the hippocampus was not simply stimulated, but in fact there was 'coagulation' of a hippocampal vessel each time. Quoting from Crasilneck et al. "'The patient did not complain of pain during this [brain] excision [in hypnosis] except on one noteworthy occasion, when a blood vessel of the hippocampal region was being coagulated. The patient suddenly awoke from the hypnotic trance ... She was immediately rehypnotized. ... The surgeon then purposefully 'restimulated' the same region of the hippocampus. Once again, the patient abruptly awakened from trance... [p. 1607].'"To the present authors, the description appears misleading and responsible for subsequent misinterpretation of the observation. Because on the first occasion the hypnotic arousal effect followed 'coagulation' of the hippocampal region, it may be assumed that 'restimulation' is a misnomer for repeated coagulation. From this it may be inferred that the arousal effect observed by Crasilneck et al. (1956) could probably be ascribed to a hippocampal microlesion rather than to hippocampal stimulation. This could explain the apparent discrepancy" (p. 104).

Hawkins, Russell; Le Page, Keith (1988). Hypnotic analgesia and reflex inhibition. Australian Journal of Clinical and Experimental Hypnosis, 16, 133-139.

The major change in thinking about models of analgesia over the last decade or so may be seen as a shift away from the earlier emphasis on a one-way afferent transmission sequence. Analgesia was effected, according to the older models, by a simple blocking of afferent impulses at some level (as achieved by local anaesthesia). Recent models suggest that there are at least two CNS analgesia control systems, each operating via an active mechanism for the inhibition of nociception which includes reciprocal afferent impulses able to respond to input from lower centres by sending control signals which modify their output. One CNS analgesia system has now been quite well described. This "opiate" analgesia system has proved to be naloxone reversible and seems to be mediated by reciprocal pathways between brain stem structures and the dorsal horn and trigeminal caudalis. This is not likely to be the system responsible for all cases of hypnotic analgesia, since the common experience of continued awareness of some elements of a normally painful stimulus, in spite of a freedom from pain, implicates a higher level involvement such as input from the prefrontal cortex.

#### NOTES

The authors present a surgery case (of a cystoscopy and urethrotomy performed under hypnotic analgesia, with a highly hypnotizable patient) as an illustration of their position. The patient grimaced when the urethrotome was inserted into the urethra and dilated, but she denied discomfort and did not exhibit a reflex adduction of the thighs that is often observed even under standard general anaesthesia. She had spontaneous amnesia for the entire surgery. Later, under hypnosis, the patient could remember "discomfort and a sharp pain" which lasted for "seconds, if that" (p. 134).

The authors refer to Melzack and Wall's (1965) gate control theory as well as Hilgard's (1973) neodissociation interpretation of pain reduction in hypnosis. They review research by Hardy and Leichnetz (1981) with monkeys, in which they "traced the projections of the periaqueductal gray (PAG) to determine the extent of any possible cortical involvement in the endogenous analgesic system. Their work showed that the prefrontal cortex was the principal source of projections to the PAG" (p. 136). They quote the latter as writing that, "Patients who have had prefrontal lobotomies for relief of chronic pain report that while they still feel the pain they are no longer bothered by it ... the prefrontal cortex by virtue of its projections to the PAG may play a role in modulating nociception at the spinal level" (Hardy & Leichnetz, 1981, p. 99).

"Hardy and Leichnetz have also suggested that there may be more than one analgesic system within the CNS. The first system is a naloxone-reversible mechanism which can be activated by opiates (presumably both endogenous and exogenous) and by acupuncture. Since hypnotic analgesia has shown itself not to be naloxone-reversible (Goldstein & Hilgard, 1975) it may have little to do with the opiate reception analgesia system. Instead the mechanism of hypnotic analgesia may

lie in Hardy and Leichnetz's second system which is sensitive to affective and cognitive influences" (pp. 136-137).

The authors include a review of the work by Mayer and Price (1976) which established the importance of brain stem structures in analgesia, especially for eliciting stimulation-produced analgesia. They cite Mayer and Price as drawing a distinction between "analgesia achieved by incapacitating a component in a pain transmission system or by activating a pain inhibition system" (p. 137). They also report that Mayer and Price conclude that stimulation-produced analgesia does not result from a "functional lesion" in the brain stem, but results from stimulation of a pain-inhibiting mechanism, suggesting the dorsal horn and trigeminal nucleus caudalis may be involved. This would be consistent with the inhibition of spinal reflexes (the adductor reflex) observed in their urethrotomy case, and the spinal reflex to nociception has also been reported by Finer (1974).

"The concomitant inhibition of reflexes in humans during hypnotic analgesia can be interpreted as evidence that nociception is probably not ascending to the cerebral cortex and that therefore the source of analgesia can be localized to the brain stem areas. It may be the case, however, that the locus of effect of hypnotic analgesia is not uniform across cases and may be identified by the overall pattern of subjective reports and physiological responses. Hypnotic analgesia may be experienced in more than one way subjectively and these differences may be attributable to differing underlying physiological mechanisms. On some occasions the relevant body part may be experienced as totally anaesthetised and all sensation (not only painful sensation) may be lost. This experience matches well with a brain stem involvement, which presumably inhibits any further afferent action. On other occasions, however, and more commonly, patients are still aware of a variety of sensations, which might include pressure in the case of childbirth or even cutting in the case of surgery, but these sensations are not described as painful. This is reminiscent of the effect of frontal lobotomy and it is tempting to focus on the frontal lobe as the locus of hypnotic analgesia effects in such instances" (p. 138).

Noll, Robert B. (1988). Hypnotherapy of a child with warts. Journal of Developmental and Behavioral Pediatrics, 9 (2), 89-91.

#### NOTES

Child with 82 warts was treated using hypnosis; suggestions for removal from face only resulted in 8 of 16 facial warts disappearing after one treatment and two weeks. (Child had previous experience with hypnosis for pain and anxiety associated with lumbar punctures and bone marrow aspirates.)

Pettinati, Helen M. (1988). Hypnosis and memory. New York and London: Guilford Press.

#### NOTES

From a review in British Journal of Experimental and Clinical Hypnosis, 7, 175-178, by Vernon H. Gregg]:

Book has 5 sections: 1. method, theory 2. mechanisms of memory enhancement 3. hypnotic and other forms of reversible amnesia 4. clinical uses of hypnosis for increasing accessibility of memories and fantasies 5. Summary

The chapter by Martin Orne et al presents a comprehensive review. Perry, Lawrence, d'Eon and Tallant contribute a lively assessment of age regression procedures in the elicitation of inaccessible memories. They provide a description of procedures, a brief historical review, and discuss problems of confabulation and creation of pseudomemories. Their account is illustrated by clinical and forensic examples and gives an interesting account of belief in reincarnation in terms of source amnesia.

Section 3 has Hollander's chapter on hysteria and memory, which illustrates the concept of reversibility of amnesia with two types of hysterical conditions: one of these types, the dissociative disorders, has the potential for amnesia to be reversed but the other, histrionic personality disorders, is characterized by no reversibility.

In the section on clinical studies of memory enhancement Frankel and Kolb both accept that uncovering repressed memories and fantasies is therapeutically beneficial and that the faithfulness of recovered memories is often not important for therapeutic success. Frankel illustrates the usefulness of hypnosis with several case studies. But he thinks that clinical issues are dealt with too briefly in this book. In her summary chapter Pettinati points to the dearth of systematic research into the effectiveness of hypnosis in clinical settings.

1987

Minichiello, William E. (1987). Treatment of hyperhidrosis of amputation site with hypnosis and suggestions involving classical conditioning. International Journal of Psychosomatics, 7-8.

Hyperhidrosis of an amputation site utilizing hypnosis and/or behavioral strategies has not been reported in the literature. This case report is on the successful use of hypnosis utilizing principles of classical conditioning in the treatment of a patient with hyperhidrosis of an amputated limb with two previous unsuccessful sympathectomies. The patient possessing moderate hypnotic ability as measured by the Stanford Hypnotic Clinical Scale (SHCS), reported a pre-treatment score of 10 on a 0-10 severity and intensity of sweating scale, and a post-treatment score of 0. All gains were maintained at the two-year follow-up.

#### NOTES

The patient was hypnotized while an electric fan was blowing on his stump and prosthesis. Direct suggestions were given according to procedures of thermal biofeedback. The suggestions were: 1. You will notice in days ahead that your stump feels increasingly cooler and drier. 2. You will feel throughout the day as if a cool breeze from a fan is blowing on your stump. 3. Whenever you pay attention to your leg during the day, particularly after the first few hours of the morning, you will associate that leg with a cool dry breeze from a fan blowing on it. 4. You will increasingly develop the power to cool and dry your stump.

The results were that 2 1/2 weeks later patient reported reduced frequency and intensity of sweating and significant healing of the stump ulcers; rating = 2. One month later, patient reported continued progress with almost normal skin color and stump condition; the patient discontinued disability, and returned to work. Patient returned one month later reporting, "It's cured and my physician can't believe it." Rating = 0.

Author concludes that hypnosis should be tried prior to more invasive traditional procedures. In this case two previous sympathectomies failed to correct the condition and a third sympathectomy was being contemplated.

1986

Aronson, David M. (1986). The adolescent as hypnotist: Hypnosis and self-hypnosis with adolescent psychiatric inpatients. American Journal of Clinical Hypnosis, 28 (3), 163-169.

This paper describes the theoretical rationale, pragmatic implementation issues, and procedure for a particular technique of clinical hypnosis which is designed as an adjunctive therapy within a multidisciplinary adolescent inpatient treatment program. A model of combined auto- and heterohypnosis which features collaborative production of audiocassettes is presented. Advantages and indications for this technique are discussed, and a case study is presented. - Journal Abstract

DeBenedittis, Giuseppe; Sironi, Vittorio A. (1986). Depth cerebral electrical activity in man during hypnosis: A brief communication. International Journal of Clinical and Experimental Hypnosis, 34, 63-70.

To the authors' knowledge, hypnosis has never been induced in epileptic patients during a depth EEG study. This neurosurgical diagnostic procedure has been routinely used in medically resistant epileptic patients for the preoperative exact delimitation of the epileptogenic lesion. It offers a unique opportunity to obtain fundamental information on the possible neurophysiological mechanisms implicated in hypnosis. Observations were carried out on 1 patient affected by medically resistant partial seizures with complex symptomatology. A chronic deep electrode study explored rhinencephalic structures as well as specific target areas of the cerebral cortex. Background electrical activity during hypnosis showed a significant decrease of slow waves and an increase of alpha and beta rhythms, with constant increase of amplitude, when compared to activity in the pre- and posthypnosis states. Focal interictal abnormalities were dramatically reduced during hypnosis.

NOTES:

Hypnotizability was assessed with the Barber Suggestibility Scale in order to test for suggestibility without a prior induction of hypnosis. The patient's score was 7 out of 8 possible. Patient was hypnotized with a standard induction procedure (Barber & Calverley, 1963).

Experimental Protocol: 15 minutes resting baseline; 15 minute test of mental imagery (waking suggestions with imagination instructions); hypnosis with progressive relaxation; suggestions for dissociation; suggestions for amnesia;

arousal from hypnosis (the patient was successful with positive hallucinations, catalepsy, total amnesia, and spontaneous analgesia); and posthypnosis awake and alert (5 minutes eyes open, 5 minutes eyes closed, then 15-minute recording of post-treatment waking baseline).

EEG background activity was scored for the number of sec/minute of delta (0-4), theta (4-7), alpha (8-12), and beta (13-30) rhythms, for each 5-min period. Score = percent as related to the 1-minute epoch. Number, amplitude, and diffusion of interictal spikes also were measured but ictal activity was not recorded during the periods considered. Experimenters also measured heart rate, respiratory rate, and mean blood pressure.

ANOVA for 4 conditions (resting, waking suggestion, hypnosis, and posthypnosis) was computed for background and for focal interictal activities, and the t-test used to evaluate significant differences. ANOVA indicated a significant effect across the four experimental conditions for theta and alpha in the temporal anterior cortex, temporal posterior cortex, and frontal convexity cortex. The effect was attributable only to changes in theta and alpha between baseline and hypnosis (theta decreasing, alpha increasing as the patient went into hypnosis). No other significant difference was found. Following arousal from hypnosis, EEG activity was similar to the EEG activity before the induction.

Interictal focal abnormalities were reduced during hypnosis, compared with before hypnosis. The effect was due to changes in the area of Ammon's horn, the amygdala, the posterior temporal cortex, the mesial temporal cortex, and the inferior temporal cortex.

In their Discussion, the authors note that their data supports earlier work indicating that the limbic system is implicated in hypnosis. They cite the publications of Arnold (1959, *International Journal of Clinical and Experimental Hypnosis*) and Crasilneck, McCranie, and Jenkins (1956). The latter authors observed EEG records taken during brain surgery on one patient. Hypnosis terminated every time the hippocampus was stimulated, leading them to suggest that the hippocampus is part of the neural circuit involved in hypnosis.

"If it is assumed that a convulsion can be considered a result of both pathophysiological and emotional events operating in the individual, emotions being the most common precipitating factor in epilepsy, then any amelioration of one will raise the convulsive threshold or lower the seizure level (Goldie, 1979; MacCabe & Habovick, 1963). Although 'voluntary control of the alpha rhythm' was achieved over 40 years ago (Jasper & Shagass, 1941), only since 1969 has such control been used for clinical purposes (Kamiya, 1969). One striking characteristic of the EEG pattern of many epileptics is the absence of a 12 to 14 c/s rhythm normally recorded from the anterior portions of the brain (sensorimotor rhythm) and the presence of a 4 to 7 c/s rhythm at the same location (Olton & Noonberg, 1980). Biofeedback may enable the individual to increase the amount of sensorimotor rhythm and to decrease the amount of 4 to 7 c/s activity. As a consequence, clinically significant decreases in seizure activity have been found after biofeedback training (Serman, 1973, 1977).

"The present data demonstrate that in this female patient hypnosis induced a highly significant reduction of the interictal activity, concomitant with an increase of alpha

and sensorimotor rhythm and a decrease of slow activity, similar to biofeedback but without prior training.

" In conclusion, a depth EEG study in one epileptic patient comparing EEG activity during hypnosis and pre- and posthypnosis suggests the following conclusions: (a) hypnosis may be associated with significant decrease of slow activity and an increase of alpha and relatively high frequency, beta activity; (b) electrophysiological correlates of hypnotic behavior support the possible role of the limbic system in mediating the trance experience; and (c) hypnosis is effective in reducing focal interictal abnormalities in this patient and so it can be considered a promising technique to prevent and/or reduce emotional precipitating factors and the tendency to develop seizure activity" (p. 69).

The article referenced regarding biofeedback training to reduce ictal activity is: Serman, M. B. (1973). Neurophysiologic and clinical studies of sensorimotor EEG biofeedback training: some effects on epilepsy. In L. Birk (Ed.), *Biofeedback: Behavioral medicine.* New York: Grune & Stratton, Pp. 147-165.

Serman, M. B. (1977). Effects of sensorimotor EEG feedback training on sleep and clinical manifestations of epilepsy. In J. Beatty & H. Legewie (Eds.), *Biofeedback: Behavioral medicine.* New York: Plenum, 1977, Pp. 167-200.

1986

Sands, Steven (1986, August). The use of hypnosis in establishing a holding environment to facilitate affect tolerance and integration in impulsive patients. Psychiatry, 49.

This paper is concerned with the use of hypnosis in establishing a facilitating and holding environment in the treatment of impulsive behavior across a range of diagnoses. The reason for this cross-diagnostic viewpoint is to underscore the common sources of such action and the needs to be met in its treatment. Illustrations from work with two patients are presented: One was a hypomanic and bulimic woman who was successful in her profession; the other was an underemployed and sometimes unemployed schizophrenic man. Both were inclined to self-defeating impulsive action---bulimia in the woman, assault in the man.

1985

Morris, Don M.; Nathan, Ronald G.; Goebel, Ronald A.; Blass, Norman H. (1985). Hypnoanesthesia in the morbidly obese. Journal of the American Medical Association, 253 (22), 3292-3294.

The advent of chemical anesthesia relegated hypnosis to an adjunctive role in patients requiring major operations. Anesthesia can be utilized with acceptable risk in the great majority of patients encountered in modern practice. But an occasional patient will present--such as one with morbid obesity--who needs a surgical procedure and who cannot be safely managed by conventional anesthetic techniques. This report describes our experience with such a patient and illustrates some of the advantages and disadvantages of hypnoanesthesia. The greatest disadvantage is that it is unpredictable. Close cooperation between the patient,

hypnotist, anesthesiologist, and surgeon is critical. However, the technique may be utilized to remove very large lesions in selected patients. Hypnoanesthesia is an important alternative for some patients who cannot and should not be managed with conventional anesthetic techniques

1984

Bishay, Emil; Stevens, Grant; Lee, Chingmuh (1984). Hypnotic control of upper gastrointestinal hemorrhage: A case report. American Journal of Clinical Hypnosis, 27, 22-25.

The use of hypnosis for control of bleeding during and after surgical procedures is common practice. It has also been a useful tool for control of bleeding in hemophiliac children, especially during dental procedures, and in traffic accidents. This paper presents the successful treatment with hypnosis of a patient with upper gastrointestinal tract bleeding. After treatment, the patient was discharged from the hospital without the need for surgical intervention.

#### NOTES

The physician explained to the patient that nothing would hurt her and that nobody would do anything against her will, that if she could "relax," then her unconscious mind would help her control her bleeding. [Gives script used in the hypnosis.] Trance terminated after 20 minutes. "One hour later, endoscopy performed under local anesthesia revealed 'non-bleeding gastritis, no ulcers seen.' She had no bleeding following the hypnotherapy" (p. 23).

Brown, Erick L.; Kinsman, Robert A. (1984). Resolving intractable medical problems through psychological intervention: A clinical report. Psychotherapy, 21, 452-455.

Treatment of chronic physical illness is often complicated by psychological factors that maintain and exacerbate the illness. Hypnotic techniques, coupled with insight-oriented psychotherapy comprised an effective strategy for favorably influencing medical outcome. A clinical report illustrates how psychological intervention initiated the resolution of severe medical problems in an asthmatic patient.

Cocores, James A.; Bender, Andrew L.; McBride, Eugene (1984). Multiple personality, seizure disorder, and the electroencephalogram. Journal of Nervous and Mental Disease, 172, 436-438.

Used the EEG to study multiple personality in a 48-yr-old ambidextrous male admitted for alcohol detoxification and individual psychotherapy. Despite conflicting reports in the literature, no changes in the EEG were found that could not be ascribed to the normal changes seen in transitions from various states of alertness. The problems of differentiating multiple personality as a psychiatric entity in itself from those cases arising as a result of chronic partial or partial-complex epilepsy are discussed.

Elkins, Gary R. (1984). Hypnosis in the treatment of myofibrositis and anxiety: A case report. American Journal of Clinical Hypnosis, 27, 26-30.

A 38-year-old woman with chronic myofibrositis pain was treated by the use of hypnosis and psychotherapy. Hypnotherapeutic techniques, including symptom alteration, relaxation, and insight, are described. This regimen resulted in reduction in pain and emotional distress, which was maintained at three months and one year after treatment.

Fogel, Barry S. (1984). The 'sympathetic ear': Case reports of a self-hypnotic approach to chronic pain. American Journal of Clinical Hypnosis, 27 (2), 103-106.

Secondary gain issues may limit the success of hypnotherapeutic approaches to chronic pain. A self-hypnotic suggestion that promotes patients' awareness of the interpersonal aspects of their pain complaints was used in the treatment of two patients with chronic headache. Hypnotic suggestions that help make secondary gains conscious may be a useful addition to hypnotic techniques of pain management.

Gould, Sol S.; Tissler, Doreen M. (1984). The use of hypnosis in the treatment of herpes simplex II. American Journal of Clinical Hypnosis, 26, 171-174.

Hypnosis training was used to treat the painful lesions and emotional symptoms associated with Herpes Simplex II in two females, ages 32 and 26. Three weekly sessions of hypnosis and daily practice sessions were initiated in the first case. During this time, the patient experienced a decline in the subjective level of pain and severity of the lesions, as well as an elevation in mood level. On three-month followup, she reported no pain or skin eruptions and significantly less feelings of stress and anxiety. The second case utilized two sessions of hypnosis and daily practice sessions, and similar results were obtained. A traumatic event caused a relapse in the latter patient, but she was again able to use hypnosis to bring the virus back under control and to experience an elevation in mood level as well. A seven-month follow-up indicated no eruptions and an improvement in self-esteem.

#### NOTES

In the first case the tape included ego-strengthening suggestions (Hartland, 1971); another tape used the patient's fantasy of water and snow skiing. The patient felt that hypnosis helped her acquire a more positive attitude toward herself and relief of guilt and blame, as well as an improved ability to cope with the unpleasant sensations.

In treatment session, ego strengthening suggestions were followed by 2 minutes of quiet for integration of suggestions, then visualization used in cancer therapy (Simonton): suggestions of a strong cell structure, perfect skin, hormonal balance, cleanliness, and a cooling refreshed feeling in the area of the vagina and perineum; imagery of internally controlled friendly white sharks was used to "devour" the

virus; of water and snow skiing, imagery of cool breezes, white refreshing snow, clean fresh water; visualized herself forgiving and releasing her previous boyfriend of guilt, thereby allowing her anger to abate.

For second patient it was similar, plus visualization of being bathed in white lights and traveling through concentric circles radiating peace and protection, being purified as she traveled through the circles until she emerged as flawless as a diamond, reflecting only clarity and light. Both patients scored 4 on Spiegel's Hypnotic Induction Profile (HIP).

Handelsman, Mitchell M. (1984). Self-hypnosis as a facilitator of self-efficacy: A case example. Psychotherapy, 21 (4), 550-553.

This article presents the four-session treatment of Elaine, using self-hypnosis to facilitate the mourning process. It is argued that self-hypnosis-- rather than enhancing imagery-- increases self-efficacy, a person's feeling that he/she can perform behaviors that lead to desired outcomes. Elaine's sense of self-efficacy was increased by allowing her to choose scenes from her life to be explored in the context of the use of imagery. Elaine imagined events surrounding her father's death, and "rewrote history" in an attempt to permit herself the direct expression of emotions.

Margolis, Clorinda G. (1984). Hypnosis and cancer: An overview of the field. [Unpublished manuscript]

NOTES:

This paper apparently was presented either at American Psychological Association or the Society for Clinical and Experimental Hypnosis. The author has two tables summarizing types of cancer associated with pain, and pain syndromes in patients with cancer.

Table 3 is a list of Erickson's procedures for Controlling Pain: --Direct hypnotic suggestion for total abolition of pain --Permissive indirect hypnotic abolition of pain --Amnesia --Hypnotic analgesia --Hypnotic anesthesia --Hypnotic replacement or substitution of sensations --Hypnotic displacement of pain --Hypnotic dissociation Time and body disorientation --Hypnotic reinterpretation of pain experience --Hypnotic time distortion --Hypnotic suggestions effecting a diminution of pain (from Rossi, Ed., Innovative Hypnotherapy, Vol. IV of the Collected Papers of Milton H. Erickson on Hypnosis, 1980

Table 4 is a list of Sacerdote's Procedures for Controlling Pain: --Teleological approach --Reinterpretation of signals --Associating and conditioning --Dissociation --Simile of electric wiring --Development of amnesia --Positive and negative hallucinations --Induction of dreams --Time and space distortion, and elicitation of mystical states --Relaxation techniques --Glove anesthesia and analgesia --Pain management through control of autonomic functions (from Barber & Adrian, Eds., Psychological Approaches to the Management of Pain, 1982)

The author describes cases treated by Erickson (one in which he used 12 hours of training, in one session, reported in Rossi's 1980 edited writings of Milton Erickson, Vol. IV) and by Sacerdote.

Author notes that the Hilgards, in *Hypnosis in the Relief of Pain* (1975), describe the use of hypnosis in treating patients with cancer pain. In all three--Butler (1954), Lea, Ware, and Monroe (1960), and a larger study by Cangello (1961), both success and failure are reported. As the Hilgards point out, about 50% of the patients studied were able to reduce their pain--a percentage the Hilgards remark is rather close to what successful clinicians tend to report.

Nugent, William R.; Carden, Nick A.; Montgomery, Daniel J. (1984). Utilizing the creative unconscious in the treatment of hypodermic phobias and sleep disturbance. *American Journal of Clinical Hypnosis*, 26 (3), 201-205.

An Ericksonian hypnotherapeutic procedure is designed to access and direct creative unconscious processes toward the creation and implementation of satisfactory solutions to recurrent problem behaviors. The use of the procedure is described in 3 cases. Two of the cases involve treatment of severe hypodermic needle phobias. The third case involves use of the procedure in treatment of a somnambulistic sleep disturbance. Possible curative forces tapped by the procedure, suggestions for its continued use, and suggestions for further investigation of the procedure are also discussed.

#### NOTES

The procedure involved: 1. Pretrance discussion of unconscious mental processes 2. Hypnosis, followed by "Now your unconscious mind can do what is necessary, in a manner fully meeting all your needs as a person, to insure that [desired therapeutic outcome], and as soon as your unconscious knows that you will [desired therapeutic outcome] it can signal by [appropriate ideomotor signal]" 3. Post-ratification.

Example: "'Now your unconscious mind can do what is necessary, in a manner fully meeting all your needs as a person, to insure that you remain comfortably awake and alert anytime you receive an injection in the future, and as soon as your unconscious knows you will remain comfortably awake and alert when receiving an injection it can signal by lifting your right hand into the air off the chair.' This suggestion was [their] communicative effort to access and direct unconscious processes to the creation and implementation of altered behavioral responses to injections. Three minutes after the suggestion, B's right hand lifted jerkily into the air. She was then awakened and experienced a complete amnesia for the trance period" (p. 203).

"[They] then carried out a procedure to ratify the therapeutic change. This process presumably further develops expectancy of change, confirms change at the unconscious level, and puts doubt into any conscious beliefs contrary to positive change. This step is standardly carried out as was done with B. [They] had B sit with her hands resting on the arms of the chair. [They] told her they would ask her unconscious mind a question that only it would know the answer to. It could answer 'yes' to the question by lifting her left hand, 'no' by lifting her right hand, and 'I don't know' or 'I don't want to answer' by lifting both hands. Then the question was asked, 'In the future, will B remain comfortably awake and alert anytime she receives an injection or a blood test?' After a few minutes her left hand jerked

momentarily into the air. After some discussion about the ideomotor response and her trance experience they dismissed her with the prescription to 'await the surprising results'" (p. 203).

The authors cite as a source for their work two books: Erickson, Rossi, and Rossi, *Hypnotic Realities*, 1976, pp. 226-230; also Erickson & Rossi, *Hypnotherapy*, 1979.

1981

Baker, Elgan L. (1981). An hypnotherapeutic approach to enhance object relatedness in psychotic patients. *International Journal of Clinical and Experimental Hypnosis*, 29 (2), 136-147.

The present paper develops a conceptual rationale for utilizing hypnosis in the intensive psychotherapy of acutely psychotic patients which emphasizes deficits in object relatedness and associated ego pathology stemming from impaired internalized object representations. From this perspective, specific hypnotherapeutic techniques are suggested to enhance the positive aspects of the emerging transference in psychotherapy and to support the patient's capacity to establish and maintain real connections with the external environment. Special attention is directed toward the hypnotherapeutic management of various aspects of psychotic ambivalence and "primitive splitting" as significant sources of dynamic and structural resistance in work with these patients. Case material is presented to illustrate aspects of this conceptual and technical approach.

Fromm, Erika (1981). How to write a clinical paper: A brief communication. *International Journal of Clinical and Experimental Hypnosis*, 29, 5-9.

The standards for publishing clinical papers are in some ways the same and in some ways different from those applying to experimental articles. The present paper, written by the Clinical Editor of the *International Journal of Clinical and Experimental Hypnosis*, is meant to be a guide to clinicians on how to write publishable papers and to reviewers and readers on how to evaluate them.

NOTES

1:

"An outline could follow this sample:

- a) Statement of problem.
- b) Review of literature -- and not only the literature of the last 5 years.
- c) Clinical material -- number of patients, descriptions of cases.
- d) Description of method of treatment. If it is a new technique, give a verbatim account.
- 3) Results.
- f) Discussion. (Evaluate your own results and, if appropriate, compare them to those in the literature.)
- g) Conclusion.
- h) Tables and Figures (if appropriate).
- i) Footnotes.
- j) List of references.
- k) Abstract" (pp. 6-7).

**"In closing, here is a short reviewers' and editors' guide -- a set of questions editors and referees ask. It might be helpful to be aware of these questions as you write a paper.**

- 1. Is the article appropriate for our journal? Does it deal with hypnosis?**
- 2. Has the hypothesis been made explicit?**
- 3. Has the reason for or the origin of the hypothesis been made clear?**
- 4. Does the paper describe something new or describe the approach to an old field in a new way?**
- 5. Are references missing? Are all the citations correct and necessary? Or, is there padding?**
- 6. Has the author been careful to cite prior reports dealing with the same topic? Prior theories about the same topic?**
- 7. What was the "set" given to subjects? Was there control for experimenter influence and demand characteristics?**
- 8. Were patients led to believe they were receiving treatment or not?**
- 9. How was the diagnosis arrived at? Is it correct? Or, does the material given remain unclear as to the correctness or incorrectness of the diagnosis?**
- 10. Was administration and scoring of tests and evaluation of the results done correctly?**
- 11. If statistics were used, were they used correctly?**
- 12. Are the figures, graphs, and tables used necessary and sufficient? Do they correspond logically to the textual argument of the article?**
- 13. Is the discussion properly confined to the findings or is it digressive? Does it include new post-hoc speculations?**
- 14. Has the author explicitly considered and discussed viable alternative explanations?" (p. 9).**

**Gross, Meir, M. D. (1981). Hypnosis for dissociation -- diagnostic and therapeutic. Journal of the American Society of Psychosomatic Dentistry and Medicine, 28 (2), 49-56**

**NOTES:**

**Dissociative disorders might be at times very difficult to diagnose and treat, especially since they are very similar to epilepsy in general and to temporal lobe epilepsy in particular. Amnesia, fugue, changing personality and depersonalization are part of both disorders. Patients who suffer from dissociative disorders might be diagnosed and treated for epilepsy with anticonvulsive medications without any beneficial results. These patients are labeled as epileptics and have to face the social stigmata associated with being epileptic. The wrong label could even reinforce the sick role and make it become fixed and chronic.**

**Hypnosis was used to diagnose the dissociative disorder by using the hand levitation technique for the differential diagnosis. It was found by the author that patients who suffer from dissociative disorders would get into spontaneous hypnotic trance during the hand levitation. Hypnosis was used also for successful therapy of these patients.**

Seven cases are presented in which the hand levitation technique was used to diagnose the dissociative disorder. They were also treated by hypnotherapy. Their treatment by hypnosis is discussed. The purpose of this paper is to introduce the hand levitation technique for the differential diagnosis of dissociative disorder and to emphasize the effectiveness of hypnotherapy in the treatment of this disorder. Sorting out the cases of dissociative disorders from the epileptics is very important clinically, since it can save many patients from the anguish of having to take anti-convulsants unnecessarily and having to face the social stigmata of being labeled as epileptic.

1979

Kleinhauz, Moris; Dreyfuss, Daniel A.; Beran, Barbara; Goldberg, Tova; Azikri, David (1979). Some after-effects of stage hypnosis: A case study of psychopathological manifestations. International Journal of Clinical and Experimental Hypnosis, 27, 219-226.

Some deleterious effects of stage hypnosis are described through a case report. A middle-aged respected member of a kibbutz who became the subject of an evening's entertainment by a stage hypnotist suffered a posttraumatic neurosis. The stage hypnotist, unaware of her traumatic childhood during World War II when she and her sister were hidden by Gentiles, requested her to regress to that age. This reactivated a former successfully repressed trauma and acted as a precipitating factor to the development of a traumatic neurosis which was left untreated. She was self-referred for adequate psychiatric treatment 11 years later. This treatment successfully restored her to an adequate level of functioning.

1978

Gruenewald, Doris (1978). Analogues of multiple personality in psychosis. International Journal of Clinical and Experimental Hypnosis, 26, 1-8.

A brief discussion of taxonomic and diagnostic problems in the multiple-personality syndrome precedes presentation of theoretical considerations. The disorder is conceptualized as a category sui generis on a continuum from neurosis to psychosis. Attenuated forms are considered as pertaining to the syndrome with supporting case material.

Sanders, Shirley (1978). Creative problem-solving and psychotherapy. International Journal of Clinical and Experimental Hypnosis, 26, 15-21.

The techniques described comprise a creative problem-solving approach to short-term individual psychotherapy which appears effective in conjunction with hypnosis. The techniques include describing and visualizing the client's problem, imagining alternative reactions, dreaming about new solutions, and trying the solutions in real life. The method is illustrated by 2 clinical examples. The discussion focuses on a comparison of the techniques used with individuals versus with small groups, the fostering of regression in the service of the ego, and the redirection of attention from the physically out of control to the recognition of the possibility of

obtaining control. This shift of attention fosters active coping on the part of the client.

1977

Anderson, J. W. (1977). Defensive maneuvers in two incidents involving the Chevreul pendulum: A clinical note. International Journal of Clinical and Experimental Hypnosis, 25, 4-6.

NOTES

"Hypnosis frequently facilitates increased access to the unconscious. In both of these cases, the hypnotized subject gained contact with a thought which otherwise would likely have remained out of awareness. Then the ego quickly resorted to defensive maneuvers in order to deny the thought" (p. 6).

Chertok, Leon; Michaux, D.; Droin, M. C. (1977). Dynamics of hypnotic analgesia: Some new data. Journal of Nervous and Mental Disease, 164, 88-96.

Following two surgical operations under hypnotic anesthesia, it was possible, during subsequent recall under hypnosis, to elicit a representation of the past operative experience. It would seem that under hypnosis there is a persistence of the perception of nociceptive information and of its recognition as such by the subject. From an analysis of these two experiments in recall, it is possible to formulate several hypotheses concerning the psychological processes involved in hypnotic analgesia. In consequence of an affective relationship, in which the hypnotist's word assumes a special importance for the subject, the latter has recourse to two kinds of mechanism: a) internal (assimilation to an analogous sensation, not, however, registered as dangerous-- rationalization); and b) external (total compliance with the interpretations proposed by the hypnotist), which lead to a qualitative transformation of nociceptive information, as also the inhibition of the behavioral manifestations normally associated with a painful stimulus

Novaco, Raymond W. (1977). Stress inoculation: A cognitive therapy for anger and its application to a case of depression. Journal of Consulting and Clinical Psychology, 45 (4), 600-8.

Clinical interventions for anger disorders have been scarcely addressed in both theory and research in psychotherapy. The continued development of a cognitive behavior therapy approach to anger management is presented along with the results of its application to a hospitalized depressive with severe anger problems. The treatment approach follows a procedure called "stress inoculation," which consists of three basic stages: cognitive preparation, skill acquisition and rehearsal, and application practice. The relationship between anger and depression is discussed.

Pelletier, K. R.; Peper, E. (1977). Developing a biofeedback model: Alpha EEG feedback as a means for pain control. International Journal of Clinical and Experimental Hypnosis, 25, 361-371.

3 adept meditators voluntarily inserted steel needles into their bodies while physiological measures (EEG, EMG, GSR, EKG, and respiration) were recorded. Although each adept used a different passive attention technique, none reported pain. During the insertion, 2 of the 3 Ss increased their alpha EEG activity. The role of alpha EEG and its relationship to pain control is discussed.

#### NOTES

The three adepts studied were: (1) RCT, a 34 yr old Ecuadorian who had "demonstrated control over pain by placing bicycle spokes through his body, being suspended from hooks inserted under his shoulder blades, and walking through fire -- all without reported pain or observed damage to his skin;" (2) JSL, a 31 yr old Korean karate expert, who "suspended a 25-pound bucket of water from a sharpened spoke placed through a fold of skin on his forearm;" and (3) JS, a 50-yr old Dutch meditator who had "demonstrated pain and bleeding control" (pp. 363-365). "RCT, JSL, and JS each remarked that pain is principally fear of and attention to pain, and they maintained that anyone can learn to control pain through relaxation and passive attention" (p. 367). Both JS and RCT had increased alpha EEG activity during piercing, whereas JSL showed no increase. The authors suggest that "the karate expert practiced a very focused meditation, during which he mentally saw and felt the ki energy as a point, while RCT and JS employed passive attention and did not attend to the body stimuli. Thus, it is possible for physiological measurements to reflect strategies used in dissociation of pain perception, and that the quality of pain perception is altered if S is at either extreme of focused or unfocused conscious attention" (p. 368). "We hypothesize that, for nonadepts, alpha EEG training without alpha blocking to stimuli could become a distraction technique whereby S again could learn self-control and competence as he becomes more successful in controlling his EEG" (p. 369).

Sachs, Lewis B.; Feuerstein, M.; Vitale, J. H. (1977). Hypnotic self-regulation of chronic pain. American Journal of Clinical Hypnosis, 20, 106-113.

A more diverse conceptualization of pain including the motivational- affective, cognitive-evaluative, as well as sensory components has resulted in a greater emphasis on 'central' factors in pain and the development of comprehensive treatments directed at these various components. This study is one such treatment program. Eight patients with chronic pain (mean duration of 8.8 years) were trained in a hypnotic self- regulation procedure to modify pain. Pre and post measures were collected on a series of indices relevant to the pain experience. The post-treatment evaluation indicated significant reductions in: (1) daily pain intensity, (2) the degree to which pain interfered with major life areas (e.g., sleep and social activity), (3) life dissatisfaction and suffering, (4) personality characteristics relevant to chronic pain and (5) percentage of self-administered pain medication. Despite the lack of a no-treatment comparison and placebo-attention controls, the chronicity of pain and the lack of effectiveness of prior medical interventions suggest that this treatment program is an effective agent in the control of chronic pain.

1976

Gardner, G. G. (1976). Childhood, death, and human dignity: Hypnotherapy for David. International Journal of Clinical and Experimental Hypnosis, 24, 122-139.

Hypnotherapy can be a significant part of the treatment of a dying child. A detailed clinical report illustrates how hypnotherapy was integrated with other treatment modalities to help a terminally ill child and his family cope effectively with problems and enhance their ability to use their own resources for personal growth and mastery throughout the dying process.

NOTES:

Includes report of a mother's hypnosis work with her son for the three hours before he died.

NOTES

1:

NOTES: Author, formerly the UCLA Anesthesiology Department Chairman, uses Herbert Spiegel's approach in hypnotic inductions. His principles of treatment include: 1. Make the patient the therapist. 2. Inform the patient, "I'll teach you everything I can in 3 sessions." 3. Decline to treat patients whom you don't feel comfortable with, and refer them to someone who can help them. 4. Some patients don't want to lose their pain; after 3 sessions with no improvement I ask them to write down (a) all the benefits they're getting from the pain, (b) all the things they're losing. Then I discuss it or confront it. Sometimes I say, "Go home and wait and see if in the future you understand why I can't help you, then call me."

Used in last 4 months at UCLA for: 1. One patient, exquisitely sensitive to medication; used a minute amount of spinal anesthesia. 2. A professor with post operative distended bowel who couldn't tolerate nasal tube. Suggested that the tube would be helpful useful friend, he wouldn't notice it, "you can pull it out yourself when you want but would suggest leaving it in till X-rays say OK to remove it." 3. A physician with neck surgery (cervical disc). Told her there are 2 ways to relieve pain: (1) relax, (2) be distracted. Explained the gate theory of pain control as a kind of disuse atrophy: if a telephone switchboard is busy day after day the signals can't get through, and the same is true with pain signals trying to enter a brain that is kept busy. 4. Burn patients 5. Failed regional anesthesia (e.g. 3 nerve areas of hand). Suggested, "You can spread numbness over the rest of your hand."

He doesn't advocate using hypnosis alone. With chronic cancer patients, he suggests that they carry pain pills in their pocket. Obstetrical patients can have hypnosis plus an epidural or hypnosis plus spinal anesthesia.

Most important use for hypnosis in anesthesia is in one's daily approach to patients.

Cedercrentz, C. (1972). The big mistakes: A note. International Journal of Clinical and Experimental Hypnosis, 20, 15-16.

In his book, A System of Medical Hypnosis, Ainslie Meares writes, "Most books on

hypnosis, from Bernheim to the present time, devote a great deal of space to the description of successful and dramatic cures. These accounts may be of prestige value to the author, and may do something to inform the profession of the potential value of hypnosis in medicine, but these success stories are really of little help to those who would learn the technique of hypnotherapy because the emphasis is always on the success of the treatment rather than on analysis of the psychodynamic mechanisms which brought it about. As in everything else, we learn most from a study of our failures [p. 3]." These comments remain as true today as they were ten years ago. With the notable exception of Meares, few colleagues have been willing to share their errors, allowing us to profit from their experience. Thus, when Dr. Cedercreutz sent along a note describing his experience with one of his patients, I was struck by his generosity, and it seemed most appropriate for all of us to share his experience by way of the Journal. Hopefully, this may encourage other colleagues to share their failures as well as their successes so that all of us may learn to be more effective therapists and better scientists. M.T.O. [Martin Orne]

#### NOTES

The case reported involves a patient who had migraine headache removed with hypnosis, but later developed gastrointestinal symptoms that were operated surgically with absence of positive (physical) pathology noted. Subsequent investigation of the psychological component of the problem with hypnosis revealed an early trauma (seeing a soldier killed with a bayonette) that led to migraine-like pain in the head and vomiting.

Sacerdote, Paul (1972). The nature of the hypnotherapeutic process. American Journal of Clinical Hypnosis, 15 (1), 1-11.

The author presents several clinical cases where hypnosis was successfully utilized. Through detailed description of what takes place during sessions it is shown how various approaches are adapted to the intellectual, cultural, emotional and hypnotic capabilities of the patient and to the progress of therapy. The author analyzes what takes place during and after hypnotic intervention and draws some conclusions about the nature of the hypnotherapeutic process which, he feels, is essentially a convergence of the patient's and therapist's conscious and subconscious expectations and goals. The importance of the therapeutic ego of the doctor is brought into proper focus. One of the clinical cases illustrates how the therapist can convert a therapeutic relationship that may appear sterile or even hostile into a productive one by utilizing the patient's responses, while avoiding stubborn insistence upon expectations of preconceived hypnotic responses. It is suggested that the hypnotherapeutic model may present, in clearer focus, what takes place in other psychotherapeutic exchanges which do not utilize hypnosis.

Crasilneck, Harold B.; Hall, James A. (1970). The use of hypnosis in the rehabilitation of complicated vascular and post-traumatic neurological patients. International Journal of Clinical and Experimental Hypnosis, 18 (3), 152-158.

Hypnotherapy has been found of value in rehabilitation of many patients experiencing difficulty in the usual procedures which follow cerebrovascular or traumatic brain injury. 3 cases are reported to illustrate the approach taken. Of 25 similar cases seen over a 9-year period, 4 were unresponsive to hypnosis. Although an increase in motivation for recovery seemed to be the major change elicited by hypnotherapy, other theoretical possibilities are mentioned. Hypnosis may be a useful way of approaching motivational problems in rehabilitating patients who manifest negativism toward conventional treatment.

Owens, Herbert E. (1970). Hypnosis and psychotherapy in dentistry: Five case histories. International Journal of Clinical and Experimental Hypnosis, 18, 181-193. (Abstracted in Current Contents, 2, 35, 21)

Used hypnosis to facilitate dental psychotherapy in resolving problems specific to the dental situation. Case histories illustrate the use of hypnosis in alleviating dentophobia and in the care and control of allergic responses. Formal induction procedures are not always necessary in achieving the desired result. Through the appropriate use of hypnosis, observable benefits can accrue to some dental patients in their ability to approach the dental situation and receive proper care. THIS REPORT TOUCHES ON THE ROLE OF HYPNOSIS IN FACILITATING THE CONNECTION OF ISOLATED MEMORIES. (SPANISH + FRENCH SUMMARIES) (PsycINFO Database Record (c) 2002 APA, all rights reserved)

1965

Gruenewald, Doris (1965). Hypnotherapy in a case of adult nailbiting. International Journal of Clinical and Experimental Hypnosis, 13 (4), 209-219.

A middle-aged female nailbiter was treated in short-term hypnotherapy. Hypotheses and observations postulated in the literature for the dynamics of the symptom in children and young adults were shown to be valid in this case of more advanced age. Light-to-medium trance proved adequate for exploration and resolution of conflicts of which nailbiting was symptomatic. (PsycINFO Database Record (c) 2002 APA, all rights reserved)

McCord, Hallack (1965). Trance induction under unusual circumstances. International Journal of Clinical and Experimental Hypnosis, 13, 96-102.

In order to obtain a test under naturalistic field conditions of the possible facilitatory or inhibitory effects of ongoing tasks on hypnotizability and the interaction of such effects with S's set either to oppose or not oppose entering hypnosis, a series of Ss were hypnotized either singly or in groups while they were performing a variety of tasks typical of those encountered in office or factory situations. Included were such tasks as typewriting, reading a book, engaging in creative writing, performing the Bennett Hand Tool Dexterity and the Minnesota Rate of Manipulation tests, and performing the Pennsylvania Bi-Manual Worksample. In many cases, it was found that hypnosis could be induced under these conditions. (PsycINFO Database Record (c) 2002 APA, all rights reserved)

Naruse, Gosaku (1965). The hypnotic treatment of stage fright in champion athletes. International Journal of Clinical and Experimental Hypnosis, 13 (2), 63-70.

The use of direct hypnotic suggestion, posthypnotically produced autohypnosis, and self-hypnosis in conjunction with autogenic training and progressive relaxation in the treatment of "stage fright" in athletes is discussed. Illustrative case histories drawn from a sample of athletes participating in the 1960 Olympic Games are presented. (PsycINFO Database Record (c) 2002 APA, all rights reserved)

1962

Moss, C. Scott; Thompson, M. M.; Nolte, J. (1962). An additional study in hysteria: The case of Alice M.. International Journal of Clinical and Experimental Hypnosis, **10**, 54-74. (Abstracted in Index Medicus, 62, 1425)

Detailed account of the psychotherapy of one female hysteric--a treatment failure--is the stimulant for discussion of the genetics and dynamics of this nosology. Hypnosis revealed the experimental basis for the symptoms and associated adjustment difficulties. The dynamics bear a remarkable resemblance to those advanced by Freud, though issue is taken with several psychoanalytic concepts. The discussion deals largely with the phenomenology of the female hysteric. (PsycINFO Database Record (c) 2002 APA, all rights reserved)

Raginsky, Bernard B. (1962). Sensory hypnoplasty with case illustration. International Journal of Clinical and Experimental Hypnosis, **10**, 205-219. (In Index Medicus 63: March, S-543)

Sensory hypnoplasty is a technique in hypnoanalysis in which the hypnotized patient models clay to which various sensory stimuli (e.g., temperature, texture, color, smell) have been added to stimulate basic primitive memories, associations, sensations, and conflicts. This allows the patient to give plastic expression to repressed and suppressed material which is then followed by verbalization of the conflicts. The therapeutic process is reputed to be greatly accelerated. This technique has been used in the successful treatment of diverse pathological conditions. Sacerdote, Paul (1962). The place of hypnosis in the relief of severe protracted pain. American Journal of Clinical Hypnosis, **4**, 150-157.

#### NOTES

Severe chronic pain, such as associated with cancer or severe arthritis has lost any protective quality, and to some degree reflects memories of the pain stored in the central nervous system. There are three kinds of analgesics, those that modify peripheral pain receptors, those than modify central perception, and those that change the patient's reaction to pain. Hypnosis is similar to the third type.

The author reviews literature on hypnosis for severe pain and then discusses his personal experience using hypnosis for pain management. Several authors mention that pain, dysfunction and anxiety can all be present and can be treated effectively using hypnosis. Milton Erickson wrote extensively, indicating that he taught patients how to develop analgesia, anesthesia, negative and positive hallucination, profound amnesia, body disorientation and dissociation, and time distortion. Erickson noted the importance of hypnosis in permitting pain patients to maintain themselves in the warm atmosphere of their family.

Perese (1961) wrote about how to manage pain in malignant disease, based on his experience with 714 cases. Perese wrote, "'As yet, we do not have an ideal analgesic drug that will control the severest pain... cause no anorexia or gastrointestinal symptoms, produce euphoria but no addiction, suppress anxiety and fears without

dampening the mental faculties... cause no toxic symptoms, and induce on tolerance in constant daily use at the highest therapeutic dose for at least 3 months.' (To the reader [Sacerdote], the foregoing describes hypnosis properly employed)" (p. 152). Sacerdote notes that Perese himself did not use hypnosis personally, and that the patients he referred to other physicians did not usually benefit greatly from the hypnosis.

Other investigations by Lea, Ware and Monroe (1960) and Cangello (1961) obtained favorable results using hypnosis. Lea et al. (1960) obtained good results in the control of intractable pain for 12 of 17 unselected patients. They attributed the five poor outcome cases to pre-existing psychiatric problems. Cangello (1961) used hypnosis with 22 advanced cancer patients who were requiring narcotic medication every four hours, with good results: 59% had at least some reduction in narcotic intake. "The duration of effectiveness varied from one week to 4.5 months. However, none of the patients in the so-called failure group who was capable of hypnotic trance eventually required chemical or surgical approach, or developed tolerance to the drug" (p. 152).

"PERSONAL EXPERIENCE. In handling patients with protracted painful illness, the author has attempted to combine minimum quantities of analgesic and tranquilizing medications with deliberate use of placebos, and with application of hypnotic methods. ... not one single method or combination of methods will work equally well in every single case" (p. 152).

"A few excellent subjects will become very adept at using self-hypnosis either automatically or when they find it necessary. The author has found patients who easily tolerate the transfer of the hypnotic rapport from the physician to another physician or to a member of their family. Some patients learn to achieve instant deep trances over the telephone with beneficial results" (p. 153).

"It is worth while in a larger number of patients to combine hypnosis and a systematic use of placebos in such a way that the psychological reaction to pain will be beneficially influenced" (p. 156).

"In no instance has there been adverse developments from the use of hypnosis with these patients, nor was there any development of substitutive psychosomatic symptoms" (p. 156).

Levendula, Dezso (1961). Two case presentations: Treatment of central pain with reconstruction of the body-image -- hypnoanalysis of a travel phobia. International Journal of Clinical and Experimental Hypnosis, 9, 283-289.

## NOTES

Uses analogy of phantom limb (hallucinated pain which is a central pain) with a multiple sclerosis patient who had "excruciating" pain between her thighs despite paralysis from waist down due to multiple sclerosis. She valued her sex life though she couldn't feel sexual response, and felt that she "didn't have any legs" and her husband "had to carry her."

In giving her history the patient noted an increasing numbness and weakness in her legs five years earlier. At that time she also entered menopause and developed

severe vaginitis. She became depressed when she became increasingly unable control her excretory functions. As the pain in the genital region increased, her ability to feel pleasant vaginal sensations diminished. Ultimately the pain was continually present.

The therapist attributed her problem to a faulty body image because she "denied the existence of her legs which were actually physically present, although, she could neither feel, nor see, nor move them" (p. 285). Secondly, it was most necessary for her to hold on to the myth [sic], that her vagina existed, because it made her feel wanted and needed by her husband. She was unconsciously afraid that by giving up her vagina she would lose the most important bond between herself and her husband" (p. 285).

The therapist speculated that "the pain, which was the last sensation perceived before the total sensory loss occurred, was fixated centrally. This "pain-image" served to maintain the pretense, unconsciously of course, that there was still feeling in the vagina even though it was only pain and not pleasure. The pain permitted her to avoid facing reality, just as in the case of an amputee who develops the fantasy of a phantom limb, because he cannot readjust his pre-existing body-image to the acceptance of mutilation" (p. 285). He offered the patient "the rather simple explanation... that because she really did not feel where her lower body ended or began, the pain served her need to know where the body halves were separated. If she could learn to imagine and to accept herself as a full, whole person, the pain probably would leave her. This theory seemed very logical and acceptable to the patient" (p. 285).

"Hypnosis was extensively utilized in the following sessions to regress the patient toward her youth. She went again for long walks with her boyfriend, now her husband. It was fun to re-experience the feeling of walking in her father's apple orchard and stretch up for a red apple. Autohypnosis was taught and [he] told her to exercise "walking" while hypnotized twice daily" (p. 285-286). He also tapped on the soles of her feet repeatedly, until she could localize the vibrations. "She finally learned that she did have legs and also that other sensations besides pain could originate below the waist... Gradually with the acceptance of her "wholeness and tallness" the pain became less and less. She was able to "forget" the pain for a longer period of time. ... Occasionally she does call. She tells [the therapist] that in a stressful situation, such as moving into a new house and not knowing where things are, the pain comes back temporarily, but it is much less and after [they] talk an hour she is relieved" (p. 287). The patient had a total of 20 visits.

The author describes a second case, which is not described in these notes.

**Marcus, Howard W.; Bowers, Margaretta K. (1961). Hypnosis and schizophrenia in the dental situation. A case report. International Journal of Clinical and Experimental Hypnosis, 9, 47-57. (In Index Medicus 61: 1228)**

(Author's Summary) A case is presented of a schizophrenic patient, paranoid type, whose phobic fear of dentistry had resulted in the development of a delusional system: he would get well if his teeth were repaired under hypnosis. In reality, his need of dental care was severe. He had lost three teeth by extraction because of

painful cavities which he could not permit to be treated with conventional methods. He presented deep cavities in his front teeth. The patient was consistently unable to make rapport with several psychiatrists and dental treatment was finally discontinued because of unwillingness to proceed without psychiatric supervision. Alternative methods of handling the situation and its implications are discussed.

Guinazu, S. (1960). *Relajacion de Schultz e ionotoforesis calcica trans cerebral. Acta Hipnologia Latino-Americana, 1, 65-67.* (Abstracted in *American Journal of Clinical Hypnosis, 1962, 5, 75*)

The author recommends the use of autogenic training in conjunction with transcerebral calcium iontoforesis for the treatment of neurotic and psychotic disorders. This combined therapy abbreviates treatment time and leads to greater percentage of recoveries. Four cases, taken from over two hundred, are presented and analyzed.

Lea, Paul A.; Ware, Paul D.; Monroe, Russell R. (1960). *The hypnotic control of intractable pain. American Journal of Clinical Hypnosis, 3, 3-8.*

#### NOTES

Authors located 10 articles dealing with chronic pain and hypnosis. Most reported that it was possible to reduce or control chronic pain during the hypnotic trance but virtually impossible to control it post-hypnotically; particularly for any length of time. Two exceptions were the contributions of Harold Rosen, M.D., who attempted to obtain a psychological lobotomy through hypnosis, and Milton H. Erickson, M.D., who taught his patients positive and negative hallucinations in the areas of touch, deep sensation, and kinesthesia; body disorientations and dissociations; analgesia and anesthesia for both superficial and deep sensations; and time distortions (Erickson, 1959, possibly in *American Journal of Clinical Hypnosis*).

#### SUMMARY.

Twenty unselected patients with chronic intractable pain were referred for treatment by hypnotherapy. Only one did not obtain at least a light hypnotic trance, and two others could not be evaluated [post treatment] for extraneous reasons. Of the remaining 17, three improved sufficiently to be taken off all medications and nine significantly improved in that the character of the pain was changed and less medication was needed. Of the five failures, four had severe complicating psychiatric problems. [Authors note that while one paranoid schizophrenic was a treatment failure, another with that diagnosis was one of their best successes.]

"A somnambulistic trance was not necessary with the technique we used; often as much was accomplished with medium or even light hypnosis" (p. 8). The hypnotists were medical students who had a considerable amount of induction experience but not much treatment experience or doctor-patient relationship experience. The authors noted that responses to post-hypnotic suggestions (e.g. that patients would feel better or not require as much medication) were delayed from several hours to as much as a week.

Their basic technique was to use hypnotic suggestion to alter the character of the chronic pain or to change the patient's attitude towards this pain. This was done by attempting to localize the pain in one pathological area with special emphasis on the fact that the rest of the body was normal or by suggesting that, as the patient learned to relax, the pain would not bother him as much. Only occasionally did they try to remove the pain completely or to control it through the use of self-hypnosis and posthypnotic suggestion. They based their procedure, in part, on the ideas of Wolff and Wolf (1959), who stated that, although the threshold for perception of pain was relatively constant, the reaction to this pain varied between wide limits for a given individual--in fact, for the same individual under different circumstances.

Patients were seen for 4-40 sessions (12 patients for 4-10; only 3 patients for more than 20 sessions). The authors defined results as: Excellent - Character of pain changed and all medication stopped. Good - Character of pain changed, though some medication had to be continued Failure - Character of pain was not changed. (It is important to note that some subjects who experienced only a light trance were nevertheless benefitted.)

The data given in their table are a bit discrepant from the data summarized above, in that the table lists only two who could not be evaluated, and six failures: 3 Excellent 9 Good 6 Failure 2 NA (presumably not evaluated post-therapy)

1959

Platonov, K. I. (1959). The word as a physiological and therapeutic factor: The theory and practice of psychotherapy according to I. P. Pavlov. ( 2nd). Moscow: Foreign Languages Publishing House.

## NOTES

On pp. 75-76 the author discusses conditioning in hypnosis. Most of the theoretical material is in the first part of the book; the rest consists of case studies. He presents the position that the activity of the cortex and subcortex are different during states of waking and suggested sleep.

Note: Much of the Russian research done during "suggested sleep" involves subjects who are hypnotized for a long period of time--sometimes hours. Routinely, in treatment, they would give corrective suggestions and then tell the person to "sleep" and would leave them in the "sleep" for an hour or longer.

"Thus, it appears from the foregoing that the basic peculiarities of the activity of the cerebral cortex manifesting themselves in the state of suggested sleep are as follows: 1. In addition to the division of the cerebral hemispheres into sections of sleep and wakefulness typical of the hypnotic sleep of an animal, there is also a functional dissociation of the two signal systems and within the second signal system. 2. The activity of the second signal system under these conditions is not only confined to the narrow framework of the rapport zone, but is also frequently of a passive nature being directly dependent on the verbal influences of the hypnotist. Outside these influences there is no (or hardly any) activity. 3. A considerable increase in the coupling function with respect to the stimuli of the second signal system is noted at the same time in the rapport zone. This especially favours the formation of new

cortical dynamic structures under the verbal influences of the hypnotist, these structures representing the physiological basis for effectuating the suggested actions and states.

"The foregoing peculiarities manifest themselves in the fact that the entire external second signal activity of the subject is reduced only to direct answers to the questions of the hypnotist with no independent reactions to any influences, including verbal, coming from other people (so-called isolated rapport). This is understandable, since the activity of the second signal system lying outside the rapport zone is inhibited" (pp. 73-74).

"As to the problem of the peculiarities of the conditioned reflex activity during suggested sleep, it will be noted that this problem has not been very extensively studied as yet. Nevertheless, the data of various authors are of indubitable interest, since they have revealed a number of specific peculiarities in the state of the higher nervous activity under these conditions.

"According to these data the conditioned reflex activity in suggested sleep undergoes certain changes. Thus, S. Levin observed in his early studies (1931) that in children under conditions of suggested sleep the motor and secretory conditioned reflexes elaborated earlier in the waking state grew very much weaker and that there was a dissociation both between the motor and secretory conditioned reflexes and between the unconditioned reflexes of salivation and mastication; he also observed the transitional (phasic) states--paradoxical, ultraparadoxical and inhibitory phases, all the way to the onset of complete sleep" (pp. 74-75).

Platonov indicates that conditioned reflexes may disappear during suggested sleep (Povorinsky & Traugott, 1936). Arousal from suggested sleep results in gradual restoration of the reflexes, with speech reactions inhibited first and restored last. Pen & Jigarov (1936) also showed that there is a weakening of conditioned reflexes, with increased latency, in suggested sleep. These authors showed that it is impossible to form new conditioned reflexes in deep states of suggested sleep, and the conditioning is difficult in lighter states.

"Y. Povorinsky's data (1937) indicate that the conditioned reflexes elaborated in the waking state have a longer latent period during suggested sleep and in some subjects they are completely absent. Under these circumstances, the reactions to the verbal influences of the hypnotist are retained even during the deepest suggested sleep. The more complex and ontogenetically later conditioned bonds of the speech-motor analyzer are inhibited first as the subject lapses into a state of suggested sleep and are disinhibited the last as the subject awakens from this state" (p. 75).

"B. Pavlov and Y. Povorinsky observe (1953) that the conditioned bonds reinforced by the words of the hypnotist are formed during suggested sleep faster than in the waking state. In this case, during the somnambulistic phase of suggested sleep verbal reinforcements, as a rule, provoke a stronger and longer reaction with a shorter latent period than a direct first signal stimulus" (p. 76). The conditioning that occurs during suggested sleep does not manifest during waking periods unless suggestions are given during the sleep to react after wakening. The author takes this to be evidence that conditioned reflex activity can be modified by verbal suggestions. During the somnambulistic stage of suggested sleep, subjects are less adept at performing addition. This indicates that inhibition has spread to the second signal

system. However, inhibition of different sensory systems seems to vary from person to person. Krasnogorsky (1951) reported one subject did not react to light, but hearing seemed to be more sensitive than in the waking state.

"All of the above testifies to the considerable changes in the character of cortical activity regularly occurring during suggested sleep and determining, on the whole, the specific nature of higher nervous activity, the systematic study of which should be the object of further research" (p. 77).

1956

McCord, Hallack (1956). Hypnosis as an aid to the teaching of a severely mentally retarded teenage boy. Journal of Clinical and Experimental Hypnosis, 4 (1), 21-23. (Abstracted in Psychological Abstracts 57: 3729)

NOTES

A 16 year old boy with I.Q. measured at 55 was hypnotized for 20 minutes daily for one month. During each session he was given material to learn (multiplication tables, spelling words, reading recognition, and general information -- only one presented during each hypnosis session). "At the end of 90 days, the subject was still retaining almost 100 percent of all material presented except for the multiplication tables which showed about 50 percent loss" (p. 22). "As a result of routinely introduced hypnotic suggestions for well-being, happiness, desire to learn, and assurance of acceptance, Ben's motivation to learn in the classroom situation took a sharp surge upward. (It was for this reason that giving him parallel material in the normal state to be used to measure comparative learning rates promptly became scientifically unsound as a control in this study.)" (p. 22). Although he was not given material to study in between sessions, "it was known that he mentally reviewed the material while working and playing in the school program" (p. 23).

1955

Ament, Phillip (1955). A psychosomatic approach to the use of anesthesia for a hysterical dental patient: A case history. Journal of Clinical and Experimental Hypnosis, 3, 120-123. (Abstracted in Psychological Abstracts 56: 1280)

NOTES

Author describes a case highly resistant both to anesthesia and dentistry. Although very responsive to hypnosis, she continued moaning and moving from side to side (later determined to be her way of preventing dental work even though anesthetized). Ultimately a combination of hypnosis and multiple anesthetics was needed, including nembutal, sodium pentothal, nitrous oxide and novocain. In the author's experience, most other patients require only hypnosis or hypnosis plus novocaine.

Hershman, Seymour (1955). Hypnosis in the treatment of obesity. Journal of Clinical and Experimental Hypnosis, 3 (3), 136-139.

## NOTES

Three case histories are presented for patients treated for obesity using hypnotherapy. The procedure in hypnosis involved: (1) visualizing person on a stage who is unhappy, depressed, followed by a person who is happy, content; (2) discussing diet with indirect suggestions that adherence would lead to the happy, contented feelings and vice versa for non-adherence; (3) giving permissive suggestions regarding behavior change (e.g. "Perhaps it is only certain foods that should be distasteful and not the eating of 'allowed' foods" (p. 137). Patients were seen weekly for 4-6 weeks, then bi-weekly or monthly for several months, and then only occasionally. "The easier acceptance of the therapy in the hypnotic state cannot be too strongly emphasized. ... rapport is established more quickly and easily, and the feeling of participation on the part of the patient convinces him that the therapy will be successful" (p. 139).

Klempner, Edith (1955). The spontaneous self-portrait in hypnoanalysis. Journal of Clinical and Experimental Hypnosis, 3 (1), 28-33. (Abstracted in Psychological Abstracts 55: 8621)

## NOTES

Author presents descriptions patients gave of themselves in hypnoanalysis and compares them with material obtained with Dr. Walter Boernstein's Verbal Self-Portrait Test. On that test, the patient is asked, 'If you were an accomplished artist, how would you paint yourself?' The author concludes, "In summarizing I wanted to show that patients in hypnoanalysis can use the symbolical representation of their body as a means of bringing to the fore psychic traits, conflicts, and unconscious forces motivating them. They can even picture through it the complications of their life histories. In other words, the personality projection as it is revealed in the Spontaneous Self-Portrait here serves as a tool for the recognition and understanding of the neurotic structure" (p. 33).

Erickson, Milton H. (1954). Special techniques of brief hypnotherapy. Journal of Clinical and Experimental Hypnosis, 2, 109-129. (Abstracted in Psychological Abstracts 55: 2508)

## NOTES

Author describes techniques used with patients who aren't able, for internal or environmental reasons, to undertake comprehensive therapy, "Intentionally utilizing neurotic symptomatology to meet the unique needs of the patient" (p. 109). He provides 8 case reports.

Patient 1 was reassured, in hypnosis, that his arm paralysis was due to "inertia syndrome" which he would continue to have, but it wouldn't interfere with his work.

Patient 2, also with arm paralysis had another comparable, non-incapacitating, symptom substituted.

Patients 3 and 4, for whom restrictions on therapy were the limits of time and situational realities, had their symptoms transformed (e.g. by introducing in

hypnosis the obsessional thought or worry that he would NOT have the symptom for which he sought help).

Patients 5 and 6 were helped, through hypnosis, to symptom amelioration. (Patient 5 had an IQ of 65.)

Patient 7 "Therapy was achieved ... by a deliberate correction of immediate emotional responses without rejecting them and the utilization of time to palliate and to force a correction of the problem by the intensity of the emotional reaction to its definition" (p. 121)

Patient 8 "the procedure was the deliberate development, at a near conscious level, of an immediately stronger emotion in a situation compelling an emotional response corrective, in turn, upon the actual problem" (p. 121).

1954

Kline, Milton V. (1954). Psoriasis and hypnotherapy: A case report. Journal of Clinical and Experimental Hypnosis, 2 (4), 318-322.

NOTES

"Summary: A chronic case of psoriasis in a forty-five-year-old woman has been reported upon wherein there has been demonstrated a definitive relationship between emotional factors and the onset of the psoriasis. Despite resolution of the precipitating distress, the psoriasis remained unabated for more than twenty years until successfully treated with hypnotherapy. Some of the theoretical issues related to both the origin and therapeutic rationale have been discussed" (p. 322).

Kupfer, David (1954). Hypnotherapy in a case of functional heart disorder. Journal of Clinical and Experimental Hypnosis, 2 (3), 186-190.

NOTES

Summary.

A young soldier with functional cardiac complaints was treated with hypnosis in a total of 4 interviews. The dynamics were bypassed and the therapeutic suggestions attached to 2 significant events in the patient's childhood, dealing intimately with the oedipal conflict and castration fears. Follow-up studies of 3 weeks duration revealed that significant changes had been produced in the patient's attitudes towards himself and towards his role in the military service" (p. 190).

LeCron, Leslie M. (1954). A hypnotic technique for uncovering unconscious material. Journal of Clinical and Experimental Hypnosis, 2, 76-79. (Abstracted in Psychological Abstracts, 54: 7497)

Summary.

A technique is given whereby unconscious material and information may be learned under hypnosis through automatic movements of the fingers, or of Chevreul's pendulum. The movements are controlled by the unconscious mind of the patient. Questions are asked which can be answered either 'yes' or 'no.' With most people the movements of the pendulum can even be elicited in the waking state. Essentially,

the method is a variation of automatic writing with movements substituted for writing. A brief case history is given wherein knowledge was gained in this way as to the causes for severe menstrual pains" (p. 79).

Rosen, Harold; Erickson, Milton H. (1954). The hypnotic and hypnotherapeutic investigation and determination of symptom-function. Journal of Clinical and Experimental Hypnosis, 2 (3), 201-219. (Abstracted in Psychological Abstracts, 55: 7017)

"Summary.

1. Symptoms and even syndromes may subserve the repetitive enactment of traumatic events; may reproduce, instead, specific life situations; may satisfy repressed erotic and aggressive impulses; or may at one and the same time constitute defenses against, and punishment for, underlying instinctual drives. They may mask underlying schizophrenic reactions, or hold suicidal depressions in check. They may serve these and other functions concurrently, or none, or any specific one or combination of them.

2. With selected patients under hypnosis, symptom-function may be determined rapidly and in a therapeutic setting. Various techniques can be utilized. Attacks may be precipitated and then blocked, either by direct hypnotic suggestion or by regressing the patient to a period pre-dating the onset of his disease, so that substitutive motor or other activity will be precipitated in a form accessible to therapeutic investigation; attacks may be precipitated in slow motion, so that individual components can be therapeutically investigated in detail; dissociated states may be induced; dream acting-out may be suggested; or symptoms may be suggested away while emotions back of symptoms are concurrently intensified, so that, again, underlying dynamic material will immediately become accessible for therapy. Still other techniques may be utilized.

3. If treatment, as well as evaluation, be through these techniques, and if treatment be successful, it may be that the analogy of a log jam will be of value. The jam can usually be broken by pulling out one or two key logs. The rest then start falling into place -- and the whole log jam disappears. This may be what happens, although to a limited extent, during therapy of this type.

4. Various of these techniques have been illustrated throughout this paper. Case histories however, have at times been distorted in order to maintain the anonymity of the patients involved" (pp. 218-219).

Schneck, Jerome M. (1954). An experimental study of hypnotically induced auditory hallucinations. Journal of Clinical and Experimental Hypnosis, 2, 163-170.

Summary. An experimental study of hypnotically induced auditory hallucinations was incorporated into therapeutic contact with a patient at a time when an exploratory phase of treatment process seemed appropriate. The study was divided roughly into ten parts, nine of which involved attempts to induce hallucinations on an auditory level following an initial control procedure involving 'imagined' conversation. Choice of persons to be hallucinated was made at times by the therapist

and at times this was left for spontaneous development by the patient. Some of the episodes involved marked emotional participation by the patient. Others were less intense. 'Imagined' conversations were distinct from hallucinated comments. Her own voice when hallucinated emanated from within herself. Other hallucinated voices had external origins. Some were far away. Her aunt's voice was in the same room. Spatial and temporal elements were divorced from their conventional relationships and distorted in keeping with psychodynamic needs. The patient was able to discuss her experiences and evaluate certain descriptive and dynamic qualities. Certain parts of the total experience served as controls in the evaluation of other parts. The beginning of hallucinatory behavior did not set a pattern for continuous similar activity. Responsive behavior varied from time to time. A hallucinatory episode might be followed by an 'imagined' conversation, although instructions remained the same. Deceased persons were hallucinated on an auditory level. This type of episode with her mother had considerable emotional impact. Her aunt died twenty years ago. Her husband was not hallucinated. Responses involving her daughter showed greater complexity.

"Further studies are in order in connection with the neuropsychological and neurophysiological elements in such hypnotic hallucinatory activity. Such elements as they play a role in visual imagery as described here and in visual hallucinations are also to be examined further. Aside from extensions of the type of investigation presented here, inroads may be made into an understanding of spontaneous hallucinatory activity among psychotic patients through the utilization of hypnotic exploratory methods. This would have to be preceded by more extensive studies of hypnosis in relation to psychotic patients than have been attempted thus far. The procedure discussed here and many potential ramifications makes possible a wide variety of investigations which can be planned for the future" (pp. 169-170).

Schneck, Jerome M. (1954). Hypnotherapy in a case of claustrophobia and its implications for psychotherapy in general. Journal of Clinical and Experimental Hypnosis, 2 (4), 251-260. (Abstracted in Psychological Abstracts, 55: 6064)

#### Summary.

This report presents the hypnotherapy of a patient with claustrophobia. The crucial event responsible for symptom formation occurred in military service when the patient was trapped in a trench by a tank which stopped over the patient before proceeding, and at which time the sides of the trench began to cave in. Subsequent traumatic events served as reinforcement. It is likely that a low threshold for the development of anxiety predisposed this patient to the development of the claustrophobia, although the major trauma sustained was undoubtedly of tremendous impact and a distinct threat to life. Emotional experiences were sealed and free expression was permitted through hypnotic revivification. The dynamics, further elaborated in the report, suggest that similar occurrences not necessarily in military settings may be approached therapeutically in this way. Aside from the reliving technique, recall stimulation through a dream induction approach was employed. Other hypnotic methods were described and further implications for

psychotherapy in general were elaborated. Hypnotherapeutic and hypnoanalytic approaches to phobic reactions have been described at length elsewhere" (p. 260).

Schneck, Jerome M. (1954). The divided personality: A case study aided by hypnosis. International Journal of Clinical and Experimental Hypnosis, 2 (3), 220-232.

#### Summary.

Amnesia as a symptom assumes proportions more complex than would appear on the surface and the role of memory loss with specific reference to hypnotic recovery methods has been presented in several reports. Hypnotherapy would appear to be a preferred technique for resolving the symptom and at times for more extensive investigation of the underlying problems. The case reported now involved an extensive memory loss for past life, including personal identity. This was followed after nearly a year by recall and concurrent amnesia for the intervening time period. The latter amnesia was dispelled by recall at first under hypnosis and then by post-hypnotic extension and elaboration of the nuclear material. The patient's history was outlined and several facts of apparent importance in relation to the memory loss were revealed. The purposive and motivational features were stressed. Therapy was conducted in a medico-disciplinary setting with limitations based on administrative requirements. Military-legal complications of the patient's personality disorder and functioning were outlined. The concept of the divided personality was introduced and related to multiple personality and to another type of behavior which is quite similar to the divided personality except that periods of amnesia are not involved. The divided personality involves major cleavages in the continuity of living with amnesia and the establishment of the individual in a setting where he undergoes extensive, significant operations relating to work, general activities, and even courtship and marriage. Unlike the generally accepted attributes of multiple personality involving considerable overt behavior, affect, and attitude alterations, the divided personality continues to function with his accustomed overt attitudes, interests, affect, and method of relating on an interpersonal level. Descriptively and overtly he is not too different if at all, but he seems to begin life anew in terms of setting and personal contacts. Cases of this type should be studied further with care, whenever possible, for further elicitation [sic] of psychodynamics. Hypnosis as a tool in treatment and investigation should prove helpful and is to be considered important.

#### 1953

Horan, John S. (1953). Hypnosis and recorded suggestions in the treatment of migraine: Case report. Journal of Clinical and Experimental Hypnosis, 1 (4), 7-10. (Abstracted in Psychological Abstracts 54: 6399)

#### NOTES

Author's Discussion: "The case above is presented because of its rather bizarre features. It is notable in that in the hypnotic sessions no attempt was made to explore the dynamics of the patient's resentment or her illness, no insight was given

into psychic mechanisms connected with the migraine. This had been done before, in conventional psychiatric interviewing, without much result. Under hypnosis, the only suggestions given were concerned with direct symptomatic relief of headache, insomnia and anorexia. For the patient's purposes, these were sufficient. Just how the pathological physiological state causing the migraine attacks was altered by direct and recorded suggestion is a mystery to this writer. It may be that hypnotic states can cause a dissociation of the subject from the emotional stress related to the attacks. Or perhaps the strangeness and the mystery of hypnosis was sufficient. It would be absurd to make any claims about the efficacy of hypnosis in migraine patients in general on the basis of this one case. In a disease which causes as much disability and suffering as migraine, however, it is profitable to report any safe means that gives a satisfactory result" (pp. 9-10).

**Kline, Milton V. (1953). Delimited hypnotherapy: The acceptance of resistance in the treatment of a long standing neurodermatitis with a sensory imagery technique. Journal of Clinical and Experimental Hypnosis, 1 (4), 18-22.**

#### **Author's Summary**

A case of experimental hypnotherapy of a chronic neurodermatitis has been presented within which the resistance of the patient was accepted as reasonable. Therapy was structured by the patient's limitations and the results, at least in this one case, justified the procedure. It is suggested that a more global perception of resistance be recognized apart from its unconscious meaning and that cognitive aspects of resistance be evaluated and utilized in treatment planning. The problem of an artifact neurotic reaction in resistance oriented therapy is discussed.

### **CATALEPSY**

**1984**

**Jensen, Peter S. (1984). Case report of conversion catatonia: Indication for hypnosis. American Journal of Psychotherapy, 38 (4), 566-570.**

Describes the successful hypnotic treatment of a 25-yr-old Black male who displayed symptoms of suicidal ideation, insomnia, and feelings of depression alternating with emptiness and boredom that led to an acute catatonic reaction. S met DSM-III criteria for borderline personality disorder. It is contended that since conversion mechanisms may underlie some presentations of catatonia, hypnosis may assist clinicians in the differential diagnosis of acute catatonic conditions.

**1982**

**Reese, William G.; Newton, Joseph E.; Angel, Charles (1982). Induced immobility in nervous and normal pointer dogs. Journal of Nervous and Mental Disease, 170 (10), 605-613.**

Pointer dogs learn complex hunting tasks such as vigorous aim-directed activity in tracking specific birds and sudden rigid immobility "on point" at appropriate distances from the prey. In the presence of a human, dogs of the Arkansas Line of

Nervous Pointers show markedly reduced activity. In close quarters, they usually react to humans by freezing. These responses do not extinguish. The breed demonstrates a strong capacity to inhibit motion. In the present study of 9 normal and 10 nervous dogs, this trait was greatly exaggerated in the nervous Ss. It was found that 10 of 10 nervous Ss, in contrast to kennel mates of a normal line, developed tonic immobility (TI) induced by manual inversion into a sling and stroking. This is the 1st systematic demonstration of TI in mature dogs. The TI was accompanied by reduced telemetered heart rate (HR) compared to baseline. Release from the inverted position was accompanied by marked HR increase. In the absence of humans, both before and after the inversion, all nervous Ss showed little or no movement about the testing area. This was in contrast to the 9 normal Ss of comparable age and sex. The 4 normal Ss that righted themselves soon after the inversion showed reduced HR with the resumed activity. Implications for psychiatry and behavioral biology are discussed. (35 ref).

Whishaw, Ian Q.; Flannigan, K.P.; Schallert, T. (1982). An assessment of the state hypothesis of animal 'hypnosis' through an analysis of neocortical and hippocampal EEG in spontaneously immobile and hypnotized rabbits. Electroencephalography and Clinical Neurophysiology, 54, 365-374.

Hippocampal and neocortical EEG was studied in spontaneously immobile rabbits and in immobilized rabbits, 'animal hypnosis.' Neocortical low voltage fast activity (LVFA) and hippocampal rhythmical slow activity (RSA) occurred spontaneously and were elicited by sensory stimulation, eserine and brain stimulation in normally immobile and hypnotized animals. Atropine sulfate blocked the LVFA and RSA that occurred during spontaneous immobility and hypnosis but not the LVFA and RSA that occurred during movement. RSA was also recorded from both CA1 and dentate gyrus generators of the hippocampus during both types of immobility. The results show that hypnotized rabbits have the same type II (atropine-sensitive) EEG that is found in spontaneously immobile rabbits. The presence of type II EEG during hypnosis and its sustained sensitivity to stimulation is compatible with the view that the EEG activity is not uncoupled from its normal behavioral correlates. Perhaps normal EEG during animal hypnosis allows normal sensorimotor functions. This may permit the possibility of escape from predators at opportune moments once the immobility has served its defensive function.

#### NOTES

State hypotheses of animal hypnosis suggest that "the brain of the hypnotized animal is in a physiological state that is fundamentally different from that of spontaneous immobility ... a state in which active EEG patterns are uncoupled from their usual correlate of movement. For example, Lievens (1960) suggested that hypnosis was a state of 'paroxysmal motor inhibition,' Klemm (1966) suggested that there was a 'functional disconnection' of motor activity and active EEG activity, and Scotti de Carolis et al. (1969) suggested that there was 'some type of interruption' between motor and sensory processes" (p. 365).

In their Discussion, the authors write, "The findings argue that the activated EEG that occurs during animal hypnosis need not be considered a dissociated physiological event since the normal correlate of type II EEG is immobility, regardless of whether the immobility occurs spontaneously, during anesthesia, ... during paradoxical sleep, ... or even following forebrain isolation. Of course, this conclusion does not deny the possibility that there are other physiological or behavioral events that are peculiar to hypnosis and that are dissociated from some of their normal physiological or behavioral correlates. Examples may be electrographic seizure activity that occurs in the absence of movement and the presence of inhibited spinal reflexes. Nor do these results deny that the mechanisms involved in type II EEG have a different relation to motor mechanisms in normal rabbits as compared with hypnotized rabbits. Since type II EEG is normally a correlate of immobility, its relation to movement producing neural systems even in normal animals is unknown.

"Although the function of type II EEG is not known, given its close relation with sensory events, its presence during hypnosis may mean that the animals have the same ability to process sensory information as do normal animals. This would be adaptive. ... But, since type II EEG can occur in states of anesthesia or after forebrain isolation (see above) its presence alone is no guarantee that the hypnotized animal is capable of the full range of responses available to a normal animal" (p. 372).

1981

Wallace, Benjamin; Hoyenga, Katharine Blick (1981). Performance of fine motor coordination activities with an hypnotically anesthetized limb. International Journal of Clinical and Experimental Hypnosis, 29, 54-65.

3 experiments were conducted to determine the effects of induced hypnotic anesthesia in S's dominant arm upon the performance of various motor coordination tasks. Experiment 1 assessed the ability of Ss to tap a pencil within a 20 mm diameter circle while the limb performing the task was or was not anesthetized. Experiment 2 determined the effect of hypnotic anesthesia upon the ability to perform a hand-turn task. Experience 3 considered the effects of hypnotic anesthesia on the ability to draw and duplicate a sine-wave pattern. IN all 3 experiments, hypnotic anesthesia adversely affected task performance. Their results were interpreted as indicating a possible relationship between induced hypnotic anesthesia and mimicked cerebellar dysfunction.

#### NOTES

Although the induction of hypnotic anesthesia in a limb appears to mimic cerebellar dysfunction or damage, the present authors are not implying that this is actually happening. In fact, there are few physiological correlates of hypnosis or hypnotic anesthesia (Evans, 1979; Sarbin & Slagle, 1979) and, to date at least, cerebellar involvement does not appear to be one of them. There appears to be a curious relationship, however, between performance on a motor task as a function of induced hypnotic anesthesia in a limb and as a function of cerebellar damage. This

relationship may simply be coincidental at best but before it can be dismissed as such, further experimentation should take place to study this interesting phenomenon" (p. 61).

**1976**

**Spanos, Nicholas P.; Spillane, Jeanne; McPeake, John (1976). Cognitive strategies and response to suggestion in hypnotic and task-motivated subjects. American Journal of Clinical Hypnosis, 18, 254-262.**

Thirty-two male and 32 female subjects, exposed to an hypnotic induction or task-motivational instruction, were administered either three suggestions which provided a cognitive strategy (i.e., a goal-directed fantasy, GDF) for experiencing suggested effects, or three suggestions that did not provide such a strategy. Subjects provided with GDF strategies were more responsive overtly and subjectively to two out of the three suggestions. Subjects in the No GDF Strategy treatment who spontaneously devised their own goal-directed fantasies were more responsive to suggestions than subjects who failed to devise such a strategy. These results support the contention that goal-directed fantasy helps both hypnotic and non-hypnotic subjects experience suggested effects.

**1975**

**Carli, G. (1975). Some evidence of analgesia during animal hypnosis [Abstract]. Experimental Brain Research, 23, 35**

The purpose of this study was to investigate the response to painful stimuli during animal hypnosis. The experiments were performed on unanesthetized, free-moving rabbits carrying implanted electrodes for recording the EEG and EMG activity and nerve stimulation. Injection of formaline into the dorsal region of the foot produced long lasting EEG desynchronization and motor pain reactions. In some rabbits a procedure of habituation was used to reduce hypnosis duration below 45 sec. Hypnosis was induced by inversion. The following results were obtained: 1) Polysynaptic reflexes elicited [sic] by electrical stimulation of cutaneous and muscle afferents were depressed during hypnosis. 2) Hypnosis transitorily suppressed all the painful manifestations due to formaline injection and was characterized by high [sic] voltage slow wave activity in the EEG, 3) In habituated rabbits, a significant increase in hypnotic duration and EEG synchronization was observed when hypnosis was preceded by formaline injection. Hypnosis duration was not potentiated by painful stimuli when Naloxone (5mg/Kg i.v.) was injected before hypnosis induction. 4) In habituated rabbits a recovery in hypnotic duration coupled to EEG synchronization was obtained, in absence of painful stimuli, following subanalgesic injection of Morphine (1mg/Kg). It has been previously shown that in the rabbit administration of 5-20 mg/Kg of Morphine produces EEG synchronization and strong reduction of pain reactions. It is suggested that, during animal hypnosis in a condition of continuous nociceptive stimulation, the pain response is blocked by a mechanism which exhibit [sic] similar effects of Morphine

both at spinal cord (polysynaptic reflexes) and at cortical levels (EEG synchronization).

1964

Karmanova, I. G. (1964). Fotogennaia katalepsiia [Photogenic catalepsy]. Moscow, USSR: Leningrad Izd. Naule. (Reviewed in American Journal of Clinical Hypnosis 1966, 3, 228)

#### NOTES

The author analyses the phenomenon of photogenic catalepsy from the evolutionary phylogenetic approach, including the phenomenon as demonstrated in the cock, frog, guinea-pig and dog. The following points of view are discussed: the physiological changes, electroencephalography and electromyography in animals, and clinical narcolepsy in man. (Review in AJCH.)

3 student nurses in whom eyelid catalepsy could not be induced during a group hypnotic session were kept for 4 hours in sensory deprivation at the end of which time another attempt at hypnotic induction of eyelid catalepsy was made and again failed. An interview revealed hallucinatory or delusional experiences in 1 and suspicions concerning the implications of the experiment in the other 2 Ss. Sensory restriction does not seem sufficient to overcome all resistances to hypnotic induction. (PsycINFO Database Record (c) 2002 APA, all rights reserved)

#### NOTES:

Found that 3 student nurses, 4 hours in sensory deprivation, did not become more suggestible as measured by eye catalepsy.

1954

Koster, S. (1954). Experimental investigation of the character of hypnosis. Journal of Clinical and Experimental Hypnosis, 2, 42-54.

#### NOTES

In waking, hypnosis, and sleep states 6 subjects were tested for knee-jerk height, key pressing to metronome signal, doing sums, recalling a story, etc. The Summary states:

"1. The height of the knee-jerk of all 6 subjects both in T and in "S" was much lower than in (W), the average height of all knee-jerks computed of the 6 subjects was both in T and in "S" only 39% of the average height in (W).

2. The [arm] catalepsy in T and in "S" continually existed.

3. The subjects in T and in "S" could hear well and perform active movements, though they reacted somewhat more slowly, and less forcibly than in (W) and sometimes only after some provocations.

4. The subjects both in T and in "S" could not only hear well, but could also present more or less complicated psychic impressions, reproducing them later again in "S" and also after the end of the experiment" (p. 50).

The author concluded, "Hypnosis is a sleeping-condition, but a special one. The specific difference consists of the fact that the subject's many impressions, which he would observe in a waking-condition, he does not observe now, and does not react to, aside from impressions coming to him through the hypnotist. It can then be said that there is not an absence but a decrease of the active relation with the outer world. This is exactly the same state as the one during sleepwalking and the writer must repeat after all his investigations, what has already been stated: Essentially there is no difference between the condition of a hypnotized person and that of a sleepwalker" (p. 51).

1953

Guze, Henry (1953). The phylogeny of hypnosis. Journal of Clinical and Experimental Hypnosis, 1 (3), 41-46.

#### NOTES

"The continuity of hypnotic phenomena from infrahuman through human organisms has created an array of problems in interpretation" (p. 41). "Unfortunately, most investigators in animal hypnosis have concerned themselves mainly with states of immobility. Because of this, they have neglected to recognize that hierarchical and group reactions of animals are just as fit in the category of hypnotic behavior" (pp. 41-42). "It is postulated in this paper that hypnosis or hypnotizability is a phylogenetically derived characteristic strongly akin to emotional readiness. It differs in expression from organism to organism within a species and from species to species" (p. 45).

#### CHILDBIRTH

1998

Schauble, Paul G.; Werner, William E. F.; Rai, Surekha H.; Martin, Alice (1998). Childbirth preparation through hypnosis: The hypnoreflexogenous protocol. American Journal of Clinical Hypnosis, 40 (4), 273-283.

A verbatim protocol for the "hypnoreflexogenous" method of preparation for childbirth is presented wherein the patient is taught to enter a hypnotic state and then prepared for labor and delivery. The method provides a "conditioned reflex" effect conducive to a positive outcome for labor and delivery by enhancing the patient's sense of readiness and control. Previous applications of the method demonstrate patients have fewer complications, higher frequency of normal and full-term deliveries, and more positive postpartum adjustment. The benefit and ultimate cost effectiveness of the method are discussed.

1993

Jenkins, M. W.; Pritchard, M. H. (1993). Hypnosis: Practical applications and theoretical considerations in normal labour. British Journal of Obstetrics and Gynecology, 100, 221-226.

This important, well controlled and large N study assessed effects of hypnotherapy on the first and second stages of labor in 126 primigravid women with 300 age-matched controls, and 136 parous women having their second baby with 300 age-matched controls. Only women undergoing spontaneous deliveries were included. Six sessions of hypnosis were used. The mean length of first stage labor in primigravid women was 6.4 hours after hypnosis and 9.3 hours in the control group ( $p < .0001$ ), and the mean length of the second stage was 37 minutes and 50 minutes, respectively ( $p < .001$ ). In the parous women, the corresponding times were 5.3 hours and 6.2 hours ( $p < .01$ ), and 24 and 22 minutes (not significant). The use of analgesic agents was significantly less ( $p < .001$ ) in both hypnotized groups compared with their controls.

1990

Edelmann, R. J. (1990). The treatment of infertility by hypnosis: A note of caution. [Comment/Discussion] .

A case report recently published in this journal by Maden (1989) appeared to suggest that six weekly sessions of hypnosis were responsible for facilitating conception in a woman with unexplained infertility. The present paper argues that Maden's report presented no evidence for this claim and no rationale for why hypnosis might be effective as a treatment for unexplained infertility. Both deserve a far more thoughtful and systematic investigation" (p. 184).

Harmon, Teresa M.; Hynan, Michael T.; Tyre, Timothy E. (1990). Improved obstetric outcomes using hypnotic analgesia and skill mastery combined with childbirth education. Journal of Consulting and Clinical Psychology, 58, 525-530.

Studied the benefits of hypnotic analgesia as an adjunct to childbirth in 60 nulliparous women. Subjects were divided into high- and low-susceptibility groups before receiving six sessions of childbirth education and skill mastery using an ischemic pain task. Half of the subjects in each group received a hypnotic induction at the beginning of each session; the remaining control subjects received relaxation and breathing exercises typically used in childbirth education. Both hypnotic subjects and highly susceptible subjects reported reduced pain. Hypnotically prepared births had shorter Stage 1 labors, less medication, higher Apgar scores, and more frequent spontaneous deliveries than control subjects' births. Highly susceptible, hypnotically treated women had lower depression scores after birth than women in the other three groups. The authors believe that repeated skill mastery facilitated the effectiveness of hypnosis in the study.

McLintock, T. T.; Aitken, H.; Downie, C. F.; Kenny, G. N. (1990). Postoperative analgesic requirements in patients exposed to positive intraoperative suggestions. British Medical Journal, 301 (6755), 788-790.

Sixty-three women undergoing elective abdominal hysterectomy were randomly assigned to a tape of positive suggestions or a blank tape during the operation. Anesthesia was standardized for all of the women. Postoperative analgesia was provided through a patient-controlled analgesia system for the first 24 hours. Pain scores were recorded every 6 hours. The outcome measures were morphine consumption in the first 24 hours and pain scores. Mean morphine requirements were 51.0 mg in women who were played positive suggestions, and 65.7 mg in those played a blank tape ( $p = 0.028$ ). Pain scores were similar in the two groups. It was concluded that intraoperative suggestions seem to have a positive effect in reducing patients' morphine requirements in the early postoperative period.

Tiba, Janos (1990). Clinical, research and organizational aspects of preparation for childbirth and the psychological diminution of pain during labour and delivery. British Journal of Experimental and Clinical Hypnosis, 7 (1), 61-64.

#### NOTES

Studied patients in Hungary and arrived at the following conclusions:

1. Hypnotizability of women coming for hypnosis preparation for birth is higher than non-pregnant women.
2. Primagravidas score higher than women having second child.
3. High hypnotizables have virtually painless delivery "if they are prepared for birth" and can maintain medium depth during birth.
4. Even highly hypnotizable women require sensory imaginative techniques and anaesthesia suggestions to maintain hypnosis throughout the process.
5. "Continuous hypnosis throughout delivery for analgesic reasons is questionable."
6. Benefits of hypnosis include "favourable effect on the course of birth, on reducing pain during birth, on the subjective judgement of birth and on developing positive experiences."
7. Imaginative ability is higher than in a non-pregnant group, and increases with progression of pregnancy.
8. Author developed "a complex psychophysical preparation for birth integrating the imaginative capacity, hypnosis and the preparation of husbands together with their wives has been developed."

The author recommends that followup studies investigate whether hypnotizability and imaginative capacity really increase during pregnancy.

1988

Omer, H.; Darnel, A.; Silberman, N.; Shuval, D.; Palti, T. (1988). The use of hypnotic-relaxation cassettes in a gynecologic-obstetric ward. In Lankton, S. R.; Zeig, J. K. (Ed.), Research, comparisons and medical applications of Ericksonian techniques (pp. 28-36). New York: Brunner-Mazel.

#### NOTES

They did three studies in which they gave women having gynecologic procedures tapes with a Rapid Induction Analgesia hypnosis experience.

**STUDY 1.** Women heard tapes before a painful Fallopian tube procedure (salpingography). The patients reported less pain, tension, anxiety, and fear than control patients. (N.B. Physicians' ratings did not show that difference.)

**STUDY 2.** Women practiced with the tapes at home before labor and delivery. One day after delivery, there was no difference in pain report or experience report between treated and control patients.

**STUDY 3.** Women used the tapes during labor. They reported worse pain and labor experiences than the control patients.

The authors conclude that their research does not support the hypothesis that Rapid Induction Analgesia is useful for acute pain.

**1987**

Venn, Jonathan (1987). Hypnosis and Lamaze method--an exploratory study. International Journal of Clinical and Experimental Hypnosis, 35, 79-82.

Literature on obstetrical hypnosis includes the hypotheses (a) that the ideal form of childbirth preparation would combine hypnosis with didactic education and (b) that Lamaze and natural childbirth methods are essentially the same thing as hypnosis. In the present study, 122 parturient women self-selected into three groups: Lamaze-only, hypnosis-only, and Lamaze-plus-hypnosis. Amount of medication, duration of labor, self- ratings, and nurses' ratings were used as dependent measures of pain and satisfaction. Treatment groups were compared by analysis of variance, and correlation coefficients were obtained between the dependent variables and scores on the SHCS. Neither hypnosis, Lamaze, nor a combination of the 2 emerged as a superior form of treatment. The SHCS scores were moderately correlated ( $r = .55$ ) with self-ratings that Lamaze had lessened pain during delivery. This may suggest a functional similarity between hypnosis and Lamaze, but the present study suffered a number of methodological problems and alternative explanations are discussed.

Omer, Haim; Friedlander, Dov; Palti, Zvi (1986). Hypnotic relaxation in the treatment of premature labor. Psychosomatic Medicine, 48, 351-361.

Hypnotic relaxation was used as an adjunct to pharmacologic treatment with 39 women hospitalized for premature contractions in pregnancy. The control group received medication alone and consisted of 70 women. Treatment was started at the time of hospitalization and lasted for 3 hr on the average. patients were also given cassettes with a hypnotic - relaxation exercise for daily practice. The rate of pregnancy prolongation was significantly higher for the hypnotic - relaxation than for the medication- alone group. Infant weight also showed the advantage of the hypnotic - relaxation treatment. Background variables of the two groups were compared and it was shown that they could not have explained the treatment effect obtained.

Wideman, Margaret V.; Singer, Jerome E. (1984). The role of psychological mechanisms in preparation for childbirth. American Psychologist, 39, 1357-1371.

Psychoprophylactic (Lamaze) preparation for childbirth consists of six to eight classes held during the last trimester of pregnancy. These classes include instruction in the anatomy and physiology of gestation and parturition, respiration techniques, controlled neuromuscular relaxation, visual focusing, and the training of a labor coach. Although the techniques are based upon psychological principles, they have remained largely unstudied by either psychologists or physicians. This article presents a brief history of the development of the training regimen and critically examines the few empirical studies that have been conducted. Because explanations for the efficacy of the preparation, if it exists, are equivocal, literature on the explicit components of the training--that is, information, respiration techniques, conditioned relaxation, cognitive restructuring, and social support--in situations other than child delivery are reviewed and their implications for the Lamaze method discussed. However, because there exist several, more implicit factors that may affect the type of child delivery a prepared woman experiences, the literature concerning social comparison, the effects of commitment and conformity, perceived control, and endorphin secretion are also discussed as they may apply to psychoprophylactic preparation. Problems associated with the study of childbirth preparation are presented, and suggestions for the direction of future research are made.

1982

Werner, William E. F.; Schauble, Paul G.; Knudson, Marshall S. (1982). An argument for the revival of hypnosis in obstetrics. American Journal of Clinical Hypnosis, 24, 149-171.

Available research, clinical reports, and extensive personal experience demonstrate that hypnosis, and especially the hypnoreflexogenous technique, facilitates the mother's comfort in pregnancy, labor, and delivery; is superior to the use of chemicals or other psychophysical methods as the primary aid in childbirth; and results in lasting benefit for the mother, the child, and the family as a whole. Prior to delivery, with the patient in hypnotic trance, a verbal conditioning technique is used that (1) neutralizes the fear of delivery with a positive emotion that exalts maternity as a sublime experience, (2) substitutes the uterine contraction concept for the pain concept, and (3) presumably lowers the excitability of the cortex by psychological sedation. While hypnosis experienced a temporary decrease in popularity due to a number of misconceptions, there has been renewed and promising application of hypnosis to obstetrics and other areas of medicine.

1980

Fuchs, K.; Paldi, E.; Abramovici, H.; Peretz, B. A. (1980). Treatment of hyperemesis gravidarum by hypnosis. International Journal of Clinical and Experimental Hypnosis, 28 (4), 313-323.

Nausea and vomiting are the most common complaints in the first trimester of pregnancy. Hyperemesis gravidarum presents a unique challenge to the obstetrician trained in medical hypnosis. Between the years 1965-1977, 138 women suffering

from extremely severe vomiting in the first trimester of pregnancy were successfully treated by medical hypnosis. 87 patients were treated in groups and 51 received individual therapy. The results with patients in group hypnotherapy were markedly better than those with patients in individual hypnotherapy. With group hypnotherapy, hospitalization was not necessary; treatment [sic] was given to a number of patients simultaneously and the women felt safer and less lonely. The common motivation of the patients consolidated the psychotherapeutic effect. This made treatment easier and more efficient.

1975

Samko, Michael R.; Schoenfeld, Lawrence S. (1975). Hypnotic susceptibility and the Lamaze childbirth experience. American Journal of Obstetrics and Gynecology, 121, 631-6.

This study explored the relationship between childbirth training and hypnotic susceptibility. A multiple linear regression analysis was performed on the various medical and attitudinal variables related to the subjects' Lamaze childbirth experience and these were tested against hypnotic susceptibility. The results of the analysis indicate that hypnotic susceptibility is not significantly related to Lamaze training, nor is it significantly related to the type of childbirth experience that a Lamaze trained woman has.

#### NOTES

Subjects used in this experiment (N = 55) were women who had received Lamaze training within the last two years, and had delivered only one child. The HIP was administered to find a score of hypnotizability and the women were given two questionnaires. The first of the questionnaires sought demographic and medical information, the second was an attitude questionnaire about her childbirth. A third questionnaire was given to the attending physician. "The correlations between hypnotic susceptibility and the physician's rating of how successful he felt the subject's use of the Lamaze technique ( $r = 0.12$ ) and the physician's rating of how helpful he found the mother's use of the Lamaze technique was to delivery ( $r = 0.17$ ) were both nonsignificant" p. 634).

1969

Rock, Nicholas; Shipley, Thomas; Campbell, Colin (1969). Hypnosis with untrained, nonvolunteer patients in labor. International Journal of Clinical and Experimental Hypnosis, 17, 25-36.

20 nonvolunteer, untrained Ss were individually hypnotized during active labor and compared with 18 controls selected by the same criteria and receiving the same obstetrical treatment. Hypnotized Ss required less medication and obtained greater relief of pain than the controls. The time involved in induction of hypnosis was only 20 min., and the total time added by hypnotic procedures was only 45 min. longer than the regular care of the control group. It was concluded that hypnosis can be used easily on nonvolunteer, untrained patients in active labor, even in a noisy

environment, without any serious sequelae. (Spanish & German summaries) (16 ref.) (PsycINFO Database Record (c) 2002 APA, all rights reserved)

**1961**

Cheek, David B. (1961). Value of ideomotor sex-determination technique of LeCron for uncovering subconscious fear in obstetric patients. International Journal of Clinical and Experimental Hypnosis, 9, 249-259.

**Author's Summary**

Unrecognized subconscious fears can be uncovered while using ideomotor questioning with a Chevreul pendulum or with finger signals. The technique described by LeCron for evaluating knowledge regarding the sex of an unborn child is a most helpful way of approaching subconscious fears. The frightened patient refuses to indicate knowledge of the sex of her unborn child. Uncovered fears can be resolved by appealing to conscious-level understanding with adroit questioning" (p. 258).

**1955**

Kline, Milton V.; Guze, Henry (1955). Self-hypnosis in childbirth: A clinical evaluation of a patient conditioning program. Journal of Clinical and Experimental Hypnosis, 3 (3), 142-147.

**NOTES:**

The author reports use of self hypnosis for childbirth by 30 patients. Many required no drugs or greatly reduced drugs. The obstetricians usually had no prior experience with hypnosis and were cautious in providing medication at the earliest sign of discomfort.

"Summary. A two year experimental study of the use of self-hypnosis in childbirth has indicated its general effectiveness for virtually all the patients who received this type of pre-natal preparation. Although problems of selecting patients capable of utilizing this method have not been discussed in detail in this paper, it must be understood that this study depended upon a patient population selected on the basis of specific psychological characteristics which were indicative of both the judiciousness and effectiveness of self-hypnosis for obstetrics.

"Within the limits set by these selective characteristics, which in themselves may be greatly broadened by further study, self-hypnosis as a means of patient participation in childbirth appears to have very great merit. It is a method that lends itself to simple administration and can be extended to many more patients than any other hypnotic approach. It minimizes the need of the obstetrician to utilize time and effort in patient conditioning without sacrificing any of the advantages of hetero-hypnotic techniques. Its use on a larger scale than reported upon here, with more exacting investigative techniques, seems clearly indicated" (pp. 146-147).

Kroger, William S. (1953). Hypnotherapy in obstetrics and gynecology. Journal of Clinical and Experimental Hypnosis, 1 (2), 61-70.

### **Author's Summary**

**A high percentage of gynecologic complaints [sic] are due to psychic factors. Therapeutic efforts, therefore, must be directed primarily toward the psychologic component. Until recently, the principal weapon of the dynamically oriented physician was orthodox psychoanalysis. However, the increased interest for a relatively rapid approach has demonstrated the diagnostic and therapeutic value of hypnoanalysis. This development has been concomitant with the psychoanalyst's [sic] interest in 'brief psychotherapy' and narcosynthesis.**

**"In many functional gynecologic disorders, hypnoanalysis has supplanted the parent therapy even though this form of treatment utilizes the concepts of dynamic psychiatry.**

**"The relevant literature on the use of hypnotherapy in functional obstetrical and gynecological disorders has been reviewed.**

**"Significant areas for research have been pointed out.**

**"This review emphasizes that hypnosis *per se* is only of value in obtaining symptomatic relief. On the other hand, hypnoanalysis elicits the responsible dynamics behind the symptom, and is effective in reaching all aspects of the personality.**

**"Hypnoanalysis will be more applicable in obstetrics and gynecology when there is a wider acceptance of its techniques" (p. 68).**

### **CHILDREN/ADOLESCENTS0**

**One study that shows an increase with hypnotic suggestion has been replicated and is in press.**

**The present study emerges from work using hypnosis with biofeedback. Morgan's work with athletes has suggested the relationship between imagery and physiological activation. This has been observed clinically but not heretofore documented.**

**We are not using formal hypnosis. Each child was asked to think about being in a quiet place, doing exciting activities, baseline, etc. The children exhibited no neurological disorders, cognitive dysfunction, nor were they on medications at time of the study.**

**We confirmed our clinical experience: there was an increase in pulse rate when imagery changed to activity. Skin temperature continued to go up during the period (despite imagery of being active like being on roller coaster). Skin conduction went down during baseline. EDA [electrodermal activities] was higher during active imagery.**

**How do average daily thinking processes impact on autonomic changes over long periods of time? Do these changes affect cardiovascular status?**

**Clinically we observed that some children are more labile in different modalities, and under stress they react more in that system.**

**Brown, Gail W.; Riddell, Rodney; Summers, David; Coffman, Brent (1994, August). Use of hypnosis by practitioners in the school setting. [Paper] Presented at the annual meeting of the American Psychological Association, Los Angeles.**

#### **NOTES**

**Hypnosis is a therapeutic procedure that is appropriate for some school-age clients. Through the use of hypnosis that utilizes metaphors and imagery, children can be empowered to find unique solutions to their problems. Children enjoy the feeling of power and mastery that they have when able to perform hypnotic phenomena. They like to play magic and can be told that a finger or other body part will become numb. Because a major goal of hypnotherapy is to teach a child to be an active participant in his or her own behalf, the focus is on creating solutions and mastering the situation rather than enduring the problems. Four case studies demonstrate the utility of hypnosis in the treatment of phantom pain and nausea, sleep terror disorder, school phobia, and spider phobia. In each case, treatment goals were realized. Because the solutions were self-generated, the behavioral changes maintained over time and situation.**

**Case #1: Hypnosis was used to help alleviate phantom limb pain and nausea during chemotherapy following amputation of the right leg at the knee due to cancer in a thirteen-year-old male. The client had indicated that he loved nature and enjoyed the mountains. The metaphor described a young tree that has just begun to grow small silvery leaves. The spring floods tear the limbs and branches from the stump. The deep roots and stump of the tree are all that remain. The tree is not the same as before the flood. Its roots are stronger, its base more sturdy compared to the branches and limbs. The young tree has withstood the catastrophe of the torrent of waters and is even stronger than before. To counter the nausea and vomiting associated with chemotherapy a switch mechanism metaphor was used. The client was adroit with computers and had no difficulty picturing a switch located in his brain which could "turn off" the nausea from chemotherapy. A room contained all the unpleasant feelings that were being experienced. In this room is a light of a particular color that represents all the unpleasant sensations. Press the key on the computer that controls the switch to turn off the colored light in that room. Suggestions for healing were also given. Your body has known for years how to heal. Visualize the battle between good and bad cells and the victory of the good cells.**

**Case #2: Hypnosis was used to alleviate sleep terror disorder in a ten-year-old female. The onset of the subject's parasomnic symptomatology appeared to coincide with her starting kindergarten and her family's relocation shortly before. The initial treatment consisted of progressive relaxation, deep breathing, and the visual image of her "secret safe place." An induction utilizing a variety of images was presented. Hiking barefoot on a cool moss covered mountain trail, sitting in an alpine meadow on a warm summer afternoon, and flying proved most effective in facilitating trance. The participant was told to "Visualize all your anxiety and tension as hard grey rocks. Pick up these rocks and place them in your pockets. Go to the front porch of your "secret safe place and on the porch is a "magic hefty**

bag." Place your hard grey rocks that contain all your anxiety and tension in the magic bag. Once in the bag, the rocks will no longer weight you down, you will be free of any feelings of stress or tension. Your bed is magic; it is covered with a special glue which will keep you in a reclining position until you are fully rested and ready to awaken."

**Case #3:** Hypnosis was used in the treatment of school phobia in a nine-year-old male. The student experienced intense anxiety whenever separation from the primary caretaker occurred. The teacher stated that this boy experienced frequent absences and crying spells that were only relieved by phone calls to his mother or the presence of his mother next to him in class. In preparation for the intervention, the student was asked to draw a picture of how he felt inside during a panic attack. He drew a fire. He also said that only his mother could put that fire out. This information was utilized in creating a metaphor that described a house in a small town. "The mother had left, and a young boy was left alone. While at home, the boy looked out the window and saw several boys trying to burn a neighbor's yard! Acting quickly, he called the fire department, grabbed the fire extinguisher and unraveled the garden hose. He was able to extinguish the fire. The neighbors and friends were very happy and praised the boy's performance. When his mother heard the good news, she quickly returned home and held a celebration in his honor." Following the metaphor, hypnotherapy continued with suggestions about fire extinguishers that the subject could use to put out emotional fires.

**Case #4:** Hypnosis was used in the treatment of spider phobia. Diagnosis of phobia was made in this eleven-year-old female when the fear or avoidance behavior was distressing. The child's strained facial expressions occurred even at the thought of seeing what she described as "a creepy, crawly creature with 8 legs." Preparatory to her first induction the participant was read the story of Charlotte's Web (White, 1980) to facilitate the imagery for future hypnotic work. In the following session systematic desensitization was accomplished using characters from the story of Charlotte's Web. During the third session the subject was age regressed to the first time she remembered seeing a spider. She recalled playing in the woods outside her family home on an island and seeing a large web stretched between two trees with a very large spider in the center of its web. She was then asked to remain at that place to look closely at that spider as it was most likely Charlotte or one of Charlotte's family. Upon closer investigation she saw not only Charlotte but "teeny-tiny babies." The event was reconstructed as a happy experience. The imagery provided by Charlotte's Web permitted the subject to fantasize her previous frightful experience and reframe spiders as cute little "teeny-tiny" babies with admirable human qualities.

1994

Eisen, Marlene (1994, August). Children and adolescents in hypnotherapy in the clinical setting. [Paper] Presented at the annual meeting of the American Psychological Association, Los Angeles.

NOTES

Sanders & Sostis are publishing a book on Hypnosis with Children (Norton Press). Elliotson used Mesmeric passes for dentistry with children. Eisen thinks that the classic age-related curve for hypnotizability is wrong. She notes that some very young children respond to soothing inductions, whereas children 6-11 want to please so much that they engage in simulation. Furthermore the aged respond well to hypnotic inductions as long as you don't ask for arm levitation.

Considering Piaget's developmental theory, what works is related to developmental stages.

Before age 2-3 are sensorimotor operations (stroking, rocking, colored pinwheel, mobile, floating balloon).

Ages 2 1/2 to 5 or 6, preoperational stage (anthropomorphic thought - enables use of puppets; children think aloud in monologues, with no attempt to be communicative, so techniques that are nonverbal but engage child in focused activity are good (e.g. watching the fish in tank, talking about what the fish might be doing, what they would like to do); or telling stories. Physiological suggestions are useful (to feel like a raggedy doll). Using a transitional object that they have at home. Or an imaginary companion can come along, be invested with powers to protect the child.

Ages 6-12 Operational thought stage. Moving to higher levels of abstraction, becoming masters of world. Good for inductions are heroic stories of power; or magic rituals (give them magic fingers, that can do wonderful things (stop pain, not fall down). Magic buttons are good.

Adolescents can use, in addition to what we use with adults, anything involving experimentation. They play hypnotic games (e.g. light as a feather, stiff as a board). It is important to know where patients are developmentally, not simply the chronological age.

Visual techniques: imagine your favorite place. Can suggest "there's an animal here in your lap. What does it feel like?" etc. Or cloud gazing; or think of TV show, movie-- "you can be the star of the show. Tell me what you do. And then?" Flying blanket, big bird, merrie go round, little car in amusement park, are all useful images. Ideomotor suggestions are useful (magnets).

Food images are good, because they are soothing--"filled with good feelings," like jelly beans. Sliding down big ice cream mountain.

Story time imagery is useful: "I'm going to tell you a story. You can close your eyes to imagine all the people."

Freyd, Jennifer J. (1994). Betrayal-trauma: Traumatic amnesia as an adaptive response to childhood abuse. Ethics and Behavior, 4.

Betrayal-trauma theory suggests that psychogenic amnesia is an adaptive response to childhood abuse. When a parent or other powerful figure violates a fundamental ethic of human relationships, victims may need to remain unaware of the trauma not to reduce suffering but rather to promote survival. Amnesia enables the child to maintain an attachment with a figure vital to survival, development, and thriving. Analysis of evolutionary pressures, mental modules, social cognitions, and developmental needs suggests that the degree to which the most fundamental human

ethics are violated can influence the nature, form, processes, and responses to trauma.

#### NOTES

A logical extension of this research direction, based on a strategy that has been very effective in cognitive neuroscience, would be to look for neuroanatomical underpinnings of the cognitive mechanisms implicated in dissociation. ... For instance, the ability to dissociate current experience may depend partly on representational structures that support spontaneous perceptual transformations of incoming events. One possible perceptual transformation that is amenable to scientific investigation, would be the creation of spatial representations in which the mental 'observer' is spatially distinct from the real body of that observer. Such a representation would fit patient descriptions of 'leaving their body' during a traumatic episode and viewing the scene as if from afar. Additionally one could investigate the role of mental recoding and restructuring during memory 'recovery' and psychotherapy" (pp. 19-20).

1994

Krippner, Stanley (1994, August). Improvement of academic skills for children and adolescents with hypnosis. [Paper] Presented at the annual meeting of the American Psychological Association, Los Angeles.

#### NOTES

Literature and research in this area are sparse, though there is clinical evidence that hypnosis is useful. My definition of hypnosis is a procedure facilitating a variety of structured goals or procedures in which a suggestion or motivation is enhanced by a mechanical device, another person, or oneself.

There are 3 areas of application in academics:

study habits

test taking

strengthening academic motivation

The hypnotist should know the specifics of academic achievement, because specific suggestions (e.g. "Imagine you are at desk focusing well for 20 minutes,") are better. Emphasis on the positive is better than negative. Use the words "imagination," "concentration," or "imagining pictures," rather than "hypnosis." I try to determine what they expect, based in part on what words they use.

In elementary school I focus on attitude and self esteem. I have them imagine reading a story, then how well they feel; that when they notice mistakes they won't be bothered because everyone makes mistakes.

For high school, I help them develop good habits for time motivation (e.g. suggestions to "make an outline to follow while you study"). At college level, I introduce self hypnosis. I make frequent use of mental imagery, at all levels--especially imagery rehearsal, in which the person is engaged in a particular activity. In the NSF report on accelerated learning techniques (a project sponsored by the Army), Lozonov's "suggestopedia" techniques were studied. This review indicated it might enhance training effectiveness and reduce training time.

I have observed the suggestopedia classes in Bulgaria and Hungary. Classes had a relaxed comfortable learning environment. Rather than individual learning, it was group learning. It included preliminary exercises, new material, and a review of what was learned. The first stage used 2/3 of the time. Then suggestions were given by the teacher to promote learning. The presentation phase took one third of the time. The method encourages students to make mental images of the material. In foreign language classes, people take on new roles.

Malinoski, Peter; Aronoff, Jodi; Lynn, Steven J.; Moretsky, Michael (1994, August). Hypnosis and early memories. [Paper] Presented at the annual meeting of the American Psychological Association, Los Angeles.

## NOTES

We studied autobiographical memory in the college population, as manifested in the therapy situation, as a way of investigating an individual difference variable. Most people do not have recall before age 3 or 4 (and probably infantile amnesia begins before age 2).

Administered Autobiographical Memory Scale (AMS), and later in context of a hypnosis scale. 247 students were in phase 1, conducted as two separate experiments so that Ss wouldn't link the AMS to measures used in the second study.

First study was presented as a study of personal memories. Asked Ss to distinguish first five birthdays, circumstances around loss of first tooth, first day of high school. Also, they were asked about their earliest memory events, rated according to 3 scales (detail, vividness, accuracy of recall). Authors summed Ss' responses on these 3 ratings for the 8 item scale.

Part II. Administered various scales: Life Experiences, Fantasy Proneness, Wilson & Barber's scale, Imagery Control Scale, Global Psychopathology, 25 item scale of physical and sexual abuse, Brier's list of symptoms of abuse, and DES (Dissociative Experiences Scale). Imbedded were 12 items to test carelessness in responding (e.g. "I have never said Hello to anyone who wore eyeglasses.")

## RESULTS.

Phase 1. Two people indicated they had memories dating to before their first birthday; an additional 5% of Ss gave memories between 12-24 months. This would probably be impossible. Another 14.4% described events between 24-36 months; 37.4% said their earliest memory was at age 3. Mean age for earliest memory was 3.4 years (which agrees with other surveys.) Only 1 subject stated his earliest memory was as late as the tenth year of life.

High intercorrelation was obtained, ranging .79 to .89, between ratings on any of the memory event ratings (as detailed, vivid, or accurate). There was a negative correlation of these ratings with age of recall. Ss who report more detail, vividness, and competence, were also likely to report earlier first memories.

Authors divided Ss into three groups based on age of first memory: 12 with first memory earlier than first year; those whose first memory was between 1-7 years; and those with a later first memory. The earlier memory group were more fantasy prone; and rated their memories as more reliable, vivid. This suggests there are persons who report memories that are covered by infantile amnesia, report them

with greater detail, and are more fantasy prone than those who report memory events beginning later in life. This is consistent with Wilson & Barber's finding that fantasy prone people have vivid recall of early childhood events.

None of the memory reports correlated with psychopathology or dissociation. Dissociation (DES) was correlated with abuse indicators, however. Compared top and lowest 10% and middle range on DES on their memory scores and found no relationship. There was no support for the idea that report of early life events in dissociative people is compromised. Failure to recall early memories shouldn't suggest that people are dissociative (which some therapists tend to do).

All three memory measures were associated with Harvard Scale scores. The AMS was administered at the same time as the Harvard. Objective responding on the Harvard correlated with detail, vividness, and accuracy of recall. Also, involuntariness of response correlated with all 3 measures of the AMS. Finally, subjective involvement correlated with all three measures of AMS. At least when hypnosis is measured first, and explicit connection is suggested, there is a connection. Further research is needed to see if the relationship holds when measured in independent contexts. This may explain why High Hypnotizables are more prone to pseudo memories and leading questions. They may come to confuse them with historical reality.

The results suggest caution for early memory reports. They may be vulnerable to confusing fantasy and reality, as well as to biasing effects.

Banerjee, Sanjay; Srivastav, Anita; Palan, Bhupendra M. (1993). Hypnosis and self-hypnosis in the management of nocturnal enuresis: A comparative study with imipramine therapy. American Journal of Clinical Hypnosis, 36, 113-119.

Various therapeutic modalities have been used for treating enuresis due to the lack of a single identifiable cause. We carried out a comparative study of imipramine and direct hypnotic suggestions with imagery used for the management of functional nocturnal enuresis. Enuretic children, ranging in age from 5 to 16 years, underwent 3 months of therapy with imipramine (N = 25) or hypnosis (N = 25). After termination of the active treatment, the hypnosis group continued practicing self-hypnosis daily during the follow-up period of another 6 months. Of the patients treated with imipramine, 76% had a positive response (all dry beds); for patients treated with hypnotic strategies, 72% responded positively. At the 9-month follow-up, 68% of patients in the hypnosis group maintained a positive response, whereas only 24% of the imipramine group did. Hypnosis and self-hypnosis strategies were found to be less effective in younger children (5-7 years old) compared to imipramine treatment. The treatment response was not related to the hypnotic responsivity of the patient in either group.

Sivec, Harry; Lynn, Steven Jay (1993, October). Hypnosis and early memories. [Paper] Presented at the annual meeting of the Society for Clinical and Experimental Hypnosis, Arlington Heights, IL.

NOTES

The investigators hypnotized people and asked that they recall their earliest memories. Gorham & Hafner tested highs and lows in 2 sessions, one with a hypnotic induction. Ss in hypnosis reported more themes, whether high hypnotizables or not. Ss might have held back in non hypnosis condition however.

Hypothesized that early memories would have affect-laden materials.

20 Ss in hypnosis group, 20 Ss in relaxation condition, all highs (scored minimum of 9 of 12 on the Harvard Scale). Ss were told they were randomly selected from a pool and that it was a study of personality. Ss were administered a number of questionnaires and tests.

The two groups received either a Stanford Form C Scale induction or a relaxation procedure.

We used the procedure of Bloom [spelling?] for recall of two memories, and to probe the earliest memory. Also to recall two recent memories. Counterbalanced for order of presentation.

Positive affect, negative affect, affect intensity, and primary process were rated; 12 themes were rated. ANOVA was used.

Earliest memory at 3.8 yrs. Next earliest is 7.5 for hypnosis and 5.2 for relaxation groups. 4.3 is earliest for hypnosis group; there may be a basement effect. Negative affect varied by condition and by order of administration and recency of memory assessed. When early memories were elicited first, no differences were found in groups; when elicited second, negative affect was greater for [missed words]. Affect was more abundant and intense in the hypnosis group, but only when recent memories were elicited before early memories and only in the [missed words].

Early recollections were slightly more primary process (bizarre) than later, which should alert clinicians.

Themes didn't differ between groups. Early memories involved more trauma than later memories. Negative affect correlated with psychopathology measures for earliest memory but not later memory.

Used posthypnotic experiences scales. There is a decrease in unpleasant experiences, suggesting the benefit of catharsis when recalling early memories.

## 1992

Barrett, Deidre (1992). Fantasizers and dissociaters: Data on two distinct subgroups of deep trance subjects. Psychological Reports, 71, 1011-1014

The study delineated two subgroups of highly hypnotizable subjects. The first subgroup (fantasizers) entered trance rapidly, scored high on absorption (mean of 34 on the 37-item Absorption Scale), and described hypnosis as much like their rich, vivid, and very realistic waking fantasy life. None of the fantasizers experienced unsuggested amnesia, and 5/19 failed to produce suggested amnesia. Only 2/19 fantasizers described hypnosis as very different from their other experiences. The earliest memories of fantasizers were all identified as occurring before age 3, and before age 2 for 11 of 19. The second subgroup (dissociaters) took time to achieve a deep trance (unlike Wilson and Barber's fantasy-prone subjects, but they did achieve as deep a trance as fantasizers), experienced hypnosis as different from any prior experiences, and were more likely to exhibit amnesia for both hypnotic

experience and waking fantasies. None of the dissociators described their waking imagery as entirely realistic, and the earliest memories in this group were all over the age of 3 (mean age - 5). Of the 15 dissociators, 7 scored below the norm on the Absorption Scale (Mean - 26).

Claridge, Karen (1992). Reconstructing memories of abuse: A theory-based approach. *Psychotherapy*, 29, 243-252.

The recovery of traumatic memories is an important part of therapy with survivors of abuse. This article describes a conceptual framework for memory reconstruction based on Horowitz' (1986) theory of stress response syndromes. The client's history of intrusive symptoms provides a way to anticipate the nature of the trauma, even when no memory of it exists. Ongoing intrusive symptoms are used to retrieve memory fragments, and their emotional impact is used to build the client's emotional tolerance. Emphasis is placed on preparing for memories by identifying what the client will need when the memories return, building coping skills, and beginning to restructure cognitions at the "what if" stage of remembering. Case material is used to illustrate.

Hall, Howard R. (1992, October). Voluntary immunomodulation in adolescents: A cyberphysiologic approach. [Paper] Presented at the annual meeting of the Society for Clinical and Experimental Hypnosis, Arlington, VA.

#### NOTES

He is working with a normal population studying neutrophils.

Gave Ss 30 minutes of an imagery exercise to increase neutrophil adherence when compared with controls; e.g., imagery could be ping pong balls in the blood stream, clumping together with honey.

Phase 1: blood sample; strategy or rest; blood sample  
practice for 1 week at home

blood sample; strategy; blood sample Hypothesis 2 Healthy adolescents who practice cyberphysiologic (imagery) strategies for 2 weeks will increase neutrophil adherence compared with controls.

Phase 2:

2 week training in cyberphysiologic technique

Session 1 and Session 2 same as in first study. (Thus, these Ss had practiced the technique already.)

Results were analyzed with ANOVA. Only one factor was significant: neutrophil adherence, the one they were studying.

The experimental group with no prior training showed less adherence than controls, as did the trained group in session 1; but the trained group in session 2 showed a large increase over session 1.

Does this reflect relaxation or an active cognitive process? The group that showed the most change did not show relaxation effect of lowered pulse and finger temperature, though the other two groups lowered pulse rate some. Therefore, it is not relaxation.

There was no association of hypnotizability to the increase in neutrophils, using the Penn State Group Hypnotizability Scale, which correlates with the Stanford Scale. In future the author will look at whether Ss can increase and decrease neutrophil adherence.

1991

Chu, James A.; Dill, Diana L. (1991). Dissociation, borderline personality disorder, and childhood trauma. American Journal of Psychiatry, 148 (6), 812.

Comments on the article by S. N. Ogata et al (see PA, vol 78:4681) on the high prevalence of childhood physical and sexual abuse in inpatients with borderline personality disorder. It is suggested that dissociative symptoms in borderline patients may simply be a less severe form of intrapsychic fragmentation than multiple personalities.

Cornell, William F.; Olio, Karen A. (1991). Integrating affect in treatment with adult survivors of physical and sexual abuse. American Journal of Orthopsychiatry, 61 (1), 59-69.

Presents a theoretical and technical model for affectively centered treatment of adults abused as children, focusing on the function of denial and dissociation as central defense mechanisms. The concept is introduced of working at an "affective edge." At this experiential point, a client can maintain both cognitive understanding and emotional and bodily awareness without triggering denial and dissociation. This approach fosters careful monitoring of the client's functioning both during and between therapeutic sessions. The proposed therapeutic approach uses noninvasive touch and body-centered techniques. Focus is on integrating affect and on the importance of the therapeutic relationship.

Sanders, Barbara; Giolas, Marina H. (1991). Dissociation and childhood trauma in psychologically disturbed adolescents. American Journal of Psychiatry, 148, 50-54. Tested the hypothesis that dissociation in adolescence is positively correlated with stress or abuse experienced earlier by assessing the relationship between degree of dissociation and degree of reported childhood stress, abuse, or trauma in 47 13- 17 year old disturbed adolescents. Subjects had been institutionalized for periods of 1-13 weeks. Subjects completed a Dissociative Experiences Scale (DES) and a child abuse and trauma questionnaire. Scores on the DES correlated significantly with self-reported physical abuse or punishment, sexual abuse, psychological abuse, neglect, and negative home atmosphere but not with abuse ratings made from hospital records. Findings support the view that dissociation represents a reaction to early negative experience and places multiple personality disorder at the extreme end of a continuum of dissociative sequelae of childhood trauma.

Rhue, Judith W.; Lynn, Steven Jay; Henry, Stephanie; Buhk, Kerry; Boyd, Patti (1990-91). Child abuse, imagination and hypnotizability. Imagination, Cognition and Personality, 10, 53-63.

Research was designed to provide a rigorous test of J. R. Hilgard's hypothesis that hypnotizability is related to a history of physical punishment and to imaginative involvements. College students who reported a history of physical abuse (N = 21) and sexual abuse (N = 23) were compared with control subjects who either lost a parent by way of death or divorce (N = 20) or who were from intact homes (N = 35), under test conditions that minimized the possibility that context effects would prejudice the findings. No support was found for the hypothesis that increased hypnotizability was associated with a history of physical or sexual abuse: All of the groups are indistinguishable on measures of objective and subjective response to hypnosis. However, consistent with Hilgard's hypothesis, physically and sexually abused subjects were found to be more fantasy-prone than subjects in both nonabused control conditions.

Bogenberger, Robert; Allen, Steven (1988, November). Relationship between Rorschach responses and hypnotic responsiveness. [Lecture] Presented at the annual meeting of the Society for Clinical and Experimental Hypnosis, Asheville, NC.

**NOTES:**

The Rorschach is stable in adults, in terms of introversive vs. extroversive direction. Investigated four dependent variables: (1) distortions (e.g. "I felt the walls closing in."), (2) Loss of Distance (e.g. "I thought of abortions and infanticide."), (3) abstract/conceptual, (4) irrelevant imagery (e.g. "I thought of the book Watership Down.")

Highs gave responses more often in these groups. The combination of these four and some others discriminated Highs hypnotized from Highs not hypnotized and from Lows in both hypnotized and not hypnotized conditions.

Chu, James A. (1988). Ten traps for therapists in the treatment of trauma survivors. Dissociation, 1, 24-32.

**ABSTRACT:** Patients who have survived trauma, particularly those who have experienced early childhood abuse, stand out in the clinical experience of many therapists as being among the most difficult patients to treat. These patients have particular patterns of relatedness, along with intense neediness and dependency which make them superb testers of the abilities of their therapists. They often push therapists to examine the rationales and limits of their therapeutic abilities, and frequently force therapists to examine their own personal issues and ethical beliefs. A conceptual framework for understanding treatment traps is presented, along with 10 traps which these patients present, consciously and unconsciously, in the course of treatment. Included are traps around trust, distance, boundaries, limits, responsibility, control, denial, projection, idealization, and motivation.

1988

Kuttner, Leora (1988). Favorite stories: A hypnotic pain-reduction technique for children in acute pain. American Journal of Clinical Hypnosis, 30, 289-295.

For young children (aged 3 to 6-11) with leukemia, a hypnotic trance consisting of a child's favorite story was found to be statistically more effective than behavioral distraction and standard medical practice in alleviating distress, pain, and anxiety during painful bone marrow aspirations. Measured by a behavioral checklist and judgment ratings by physician, parent, nurse, and observers, the favorite-story hypnotic technique had immediate therapeutic impact on these young patients, and the reduction in distress, pain, and anxiety was sustained on subsequent medical procedures. Self-report measures, however, were nonsignificant.

LeBaron, Samuel; Zeltzer, Lonnie K. (1988). Imaginative involvement and hypnotizability in childhood. International Journal of Clinical and Experimental Hypnosis, 36, 284-295.

2 pilot studies assessed the relationship between hypnotizability in children and extent of involvement in fantasy-related activities during early childhood. The Stanford Hypnotic Clinical Scale for Children and a structured interview questionnaire regarding fantasy activities based on previous work by Singer (1973) were given to 30 medical patients aged 6-18 years in the first study and to 37 healthy children aged 6-12 years from a school population in the second study. In both studies, hypnotizability correlated moderately (.42 and .39, respectively) with extent of involvement in fantasy-related activities. Results support Hilgard's (1979) findings that hypnotizability is related in part to the development of imaginative involvement in childhood.

Noll, Robert B. (1988). Hypnotherapy of a child with warts. Journal of Developmental and Behavioral Pediatrics, 9 (2), 89-91.

#### NOTES

Child with 82 warts was treated using hypnosis; suggestions for removal from face only resulted in 8 of 16 facial warts disappearing after one treatment and two weeks. (Child had previous experience with hypnosis for pain and anxiety associated with lumbar punctures and bone marrow aspirates.)

1987

Jay, Susan (1987, October). Hypnotic susceptibility and response to psychological intervention for distress related to painful procedures in leukemic children. [Paper] Presented at the annual meeting of the Society for Clinical and Experimental Hypnosis, Los Angeles.

#### NOTES

Presented children with a cognitive behavioral intervention package that involved five elements 1. Filmed Modeling (child modeling and talking about it with good coping skills) 2. Positive Reinforcement - trophy 'for doing the best you can,' to change aversive situation to a positive situation 3. Breathing Exercises - 'puff yourself up like a tire' 4. Emotive Imagery/Distracton - super hero image

(Superman), or being in a favorite place 5. Behavioral Rehearsal - dollplay, reviewing the procedure with medical equipment.

For Numbers 4 and 5 the therapist would actively guide the procedures; numbers 3, 4 & 5 are hypnotic elements.

Valium had lowered children's distress prior to procedures but not during the procedures. This study involved Valium plus cognitive behavior therapy.

25 Subjects ages 6-12, were measured for hypnotizability

2 groups: (1) Cognitive Behavior Therapy + Valium given just before intervention started, after film ended; (2) Cognitive Behavior Therapy alone.

Dependent Measures: 1. Observation Scale of Behavioral Distress coded every 15 seconds. 2. Faces Scale for Fear (self report) before procedure

Faces Scale for Pain (self report) after procedure 3. Blood pressure

RESULTS. No Significant Differences were found between the two groups (CBT vs CBT + Valium). Pre-Post Analyses: Post intervention scores were significant lower than Pretest on [missed notes]

Jay, Susan M.; Elliott, Charles H.; Katz, Ernest; Siegel, Stuart E. (1987). Cognitive-behavioral and pharmacologic interventions for children's' distress during painful medical procedures. Journal of Consulting and Clinical Psychology, 55, 860-865.

This study evaluated the efficacy of a cognitive-behavioral intervention package and a low-risk pharmacologic intervention (oral Valium), as compared with a minimal treatment-attention control condition, in reducing children's distress during bone marrow aspirations. The subjects were 56 leukemia patients who ranged in age from 3 years to 13 years. The three intervention conditions were delivered in a randomized sequence within a repeated-measures counterbalanced design. Dependent outcome measures included observed behavioral distress scores, self-reported pain scores, pulse rate, and blood pressure scores. Repeated-measures analyses of variance indicated that children in the cognitive-behavior therapy condition had significantly lower behavioral distress, lower pain ratings, and lower pulse rates than when they were in the attention- control condition. When children were in the Valium condition, they exhibited no significant differences from the attention control condition except that they had lower diastolic blood pressure scores.

#### NOTES

Lonnie Zelzer, M.D., in a UCLA Hypnosis Seminar lecture in 1992, stated that in pre-treatment with Valium the patients did worse during the procedure, vs no pretreatment with Valium, because the medicated patients didn't have clarity of attention during the cognitive behavioral learning.

Katz, Ernest R.; Kellerman, Jonathan; Ellenberg, Leah (1987). Hypnosis in the reduction of acute pain and distress in children with cancer. Journal of Pediatric Psychology, 12, 379-394.

Hypnosis has been used as a behavioral approach to help children tolerate aversive medical procedures more effectively, but empirical longitudinal research evaluating the outcome of such interventions has been limited. In the present study, 36 children with acute lymphoblastic leukemia between the ages of 6 and 12 years of age undergoing repeated bone marrow aspirations (BMAs) were randomized to hypnosis or play comparison groups. Subjects were selected on their behavioral performance on baseline procedures and received interventions prior to their next three BMA procedures. Major results indicated an improvement in self-reported distress over baseline with both interventions, with no differences between them. Girls exhibited more distress behavior than boys on three of four dependent measures used. Suggestions of an interaction effect between sex and treatment group were noted. The role of rapport between patient and therapist in therapeutic outcome was also evaluated. Results are discussed in terms of potential individual differences in responding to stress and intervention that warrant further research.

1986

Aronson, David M. (1986). The adolescent as hypnotist: Hypnosis and self-hypnosis with adolescent psychiatric inpatients. American Journal of Clinical Hypnosis, 28 (3), 163-169.

This paper describes the theoretical rationale, pragmatic implementation issues, and procedure for a particular technique of clinical hypnosis which is designed as an adjunctive therapy within a multidisciplinary adolescent inpatient treatment program. A model of combined auto- and heterohypnosis which features collaborative production of audiocassettes is presented. Advantages and indications for this technique are discussed, and a case study is presented. - Journal Abstract

Olness, Karen N. (1986, March). Hypnotherapy in children: New approach to solving common pediatric problems. Postgraduate Medicine, 79 (4), 95-105.

Hypnotherapy, once thought of as magical and mysterious, is rapidly becoming accepted as an appropriate form of treatment for a wide range of disorders. Some primary care physicians are beginning to discover the value of hypnotherapy in controlling chronic disease and pain, in changing negative behavior, and in facilitating self-regulation of autonomic responses. Dr. Olness explores such use of hypnotherapy in children, the age-group that most readily acquires self-hypnosis skills and in which this technique has had dramatic results.

1985

Olness, Karen N.; Conroy, Mary Margaret (1985). A pilot study of voluntary control of transcutaneous PO<sub>2</sub> by children: A brief communication. International Journal of Clinical and Experimental Hypnosis, 33, 1-5.

This pilot study took place to determine whether or not children could voluntarily change tissue oxygen as measured by a transcutaneous oxygen monitor. It tested 2 hypotheses: (a) children can voluntarily change tissue oxygen as reflected by a

transcutaneous oxygen monitor and (b) children, experienced in use of self-hypnosis exercises, will be able to change tissue oxygen to a greater degree than children unfamiliar with such exercises. 11 children between the ages of 7 and 17 year were studied. 8 children were previously experienced in the use of self-hypnosis; 3 were not. A Novamatrix transcutaneous O<sub>2</sub>/CO<sub>2</sub> monitoring system provided a constant read-out of PO<sub>1</sub>, PCO<sub>1</sub> and local perfusion. After stabilization, children were asked to attempt increases of oxygen. 9 children increased tissue oxygen significantly. Of those, 8 children had previous self-hypnosis training. 1 had not. Only 2 children with no previous self-hypnosis training were unable to change oxygen values. This pilot study upholds both hypotheses; however, it does not conclude that self-hypnosis mediated the changes noted or that self-hypnosis would be essential to success in voluntary control of tissue oxygen.

1984

Hogan, Marjorie; MacDonald, John; Olness, Karen (1984). Voluntary control of auditory evoked responses by children with and without hypnosis. American Journal of Clinical Hypnosis, 27 (2), 91-94.

Reports ability of children to voluntarily change brainstem auditory evoked responses (BAER). Fifteen children were studied. Both control and hypnosis groups showed changes in interwave latencies after verbal suggestions when compared to a normal control group. These findings suggest that children may be able to modify peripheral auditory input into the brainstem through simple suggestion alone. Children in the formal hypnosis group did have more specific control for the task suggested. However, it is possible that children in the control group moved into an altered state of consciousness after listening to a taped story, reading a book, or spontaneously. They may have attained the observed changes in BAER while in a hypnosis-like state. This study encourages additional research in self-regulatory skills of autonomic processes in children.

Kohen, D.; Olness, K.; Colwell, S.; Heimel, A. (1984). The use of relaxation-mental imagery (self-hypnosis) in the management of 505 pediatric behavioral encounters. Journal of Developmental and Behavioral Pediatrics, 5, 21-25.

This report assessed outcomes of hypnotherapeutic interventions for 505 children and adolescents seen by four pediatricians over a period of one year and followed from four months to two years. Presenting problems included enuresis, acute pain, chronic pain, asthma, habit disorders, obesity, encopresis, and anxiety. Using strict criteria for determination of problem resolution (e.g., all beds dry) and recognizing that some conditions were intrinsically chronic, the authors found that 51% of these children and adolescents achieved complete resolution of the presenting problem; an additional 32% achieved significant improvement, 9% showed initial or some improvement; and 7% demonstrated no apparent change or improvement. Children as young as three years of age effectively applied self-hypnosis techniques. In general, facility in self-hypnosis increased with age. There was an inverse

correlation ( $p$  less than 0.001) between clinical success and number of visits, suggesting that prediction of responsivity is possible after four visits or less.

#### NOTES

Discusses the treatment of 505 pediatric patients with a variety of problems(enuresis, pain, obesity, anxiety reactions, habit problems, encopresis, headache, fear of pelvic examinations).

Nash, Michael R.; Lynn, Steven Jay; Givens, Deborah L. (1984). Adult hypnotic susceptibility, childhood punishment, and child abuse: A brief communication. International Journal of Clinical and Experimental Hypnosis, 32, 6-11.

Earlier empirical and theoretical work has suggested that there is a relationship between higher hypnotic susceptibility and severity of childhood punishment. Experiment 1 surveyed the parents of 14 extremely high and 11 extremely low susceptible Ss concerning punishment. Low susceptible Ss were found to be more frequently punished than highs; no significant differences were found on the severity measure. Experiment 2 assessed the hypnotizability of 16 adult Ss who reported being physically abused before the age of 10 and compared these scores to those of 300 adult Ss who had not reported being abused. The mean hypnotizability of abused Ss was greater than that of controls, and the distribution of their scores appeared bimodal. Limitations of both experiments are discussed and suggestions are made for future investigations.

Smith, Mark Scott; Kamitsuka, Michael (1984). Self-hypnosis misinterpreted as CNS deterioration in an adolescent with leukemia and Vincristine toxicity. American Journal of Clinical Hypnosis, 26 (4), 280-282.

A thirteen year-old girl with leukemia was taught self-hypnosis techniques for symptom control. She was hospitalized with probable vincristine toxicity and a superimposed hyperventilation syndrome. Her spontaneous use of the self-hypnosis technique was misinterpreted as central nervous system deterioration until her apparently comatose state resolved with suggestions from the therapist.

#### 1982

Hilgard, Josephine R.; LeBaron, Samuel (1982). Relief of anxiety and pain in children and adolescents with cancer: Quantitative measures and clinical observations. International Journal of Clinical and Experimental Hypnosis, 30, 417-442.

Children and adolescents with cancer, chiefly forms of leukemia, aged 6 to 19 years, underwent medical treatments which required repeated bone marrow aspirations, normally a painful and anxiety-provoking experience. Data were obtained in baseline bone marrow observations on 63 patients, who were then offered the opportunity to volunteer for hypnotic help in pain control. Of the 24 patients who accepted hypnosis, 9 were highly hypnotizable. 10 of the 19 reduced self-reported

pain substantially by the first hypnotic treatment (the prompt pain reducers) and 5 more reduced self-reported pain by the second treatment (the delayed pain reducers) while none of the 5 less hypnotizable patients accomplished this. The latter benefitted by reducing anxiety. Short case reports illustrate the variety of experiences.

Analysis of baseline observations before any therapeutic intervention revealed age and sex differences. The difference between self-reported and observed pain was not statistically significant for patients under age 10 but was significant for the patients age 10 and older ( $p < .001$ ). There were minor but significant sex differences both in observed pain ( $p < .01$ ) and in self-reported pain ( $p < .05$ ), with the females reporting more pain.

LeBaron, Samuel; Zeltzer, Lonnie (1982, October). The effectiveness of behavioral intervention for reducing chemotherapy related nausea and vomiting in children with cancer. [Paper] Presented at the annual meeting of the Society for Clinical and Experimental Hypnosis, Indianapolis, IN.

Eight children (nine to seventeen years, Mean age 12.1) with cancer received behavioral intervention for chemotherapy related nausea and vomiting. Within three to five days after the administration of each course of chemotherapy, patients rated (1-10 scale; 1 = none, 10 = all the time or maximal amount) their nausea and vomiting and the extent to which chemotherapy bothered them and disrupted their daily routine. After a pre-intervention assessment of 2.5 courses of chemotherapy, patients received intervention (Mean = 2.6 courses). Significant reductions following intervention (Wilcoxon matched- pairs signed ranks test) were found in nausea ( $Z = 2.37$ ,  $p < .02$ ), vomiting ( $Z = 2.52$ ,  $p < .01$ ), bother ( $Z = 2.24$ ,  $p < .02$ ), and disruption of activities ( $Z = 2.38$ ,  $p < .02$ ). This preliminary study indicates that chemotherapy side effects can be reduced through behavioral intervention.

1981

Gardner, G. G. (1981). Teaching self-hypnosis to children. International Journal of Clinical and Experimental Hypnosis, 29, 300-312.

Hypnotherapy with children increasingly includes teaching self-hypnosis in order that young patients may make the fullest possible use of their hypnotic talent. This paper discusses indications and contraindications, reviews issues of patient resistance and parental involvement, and describes in detail Gardner's 3-step method of teaching self-hypnosis to children.

NOTES

1:

Table 1 lists the problems treated by self-hypnosis in children aged 3-20 years as: anxiety, asthma, bleeding disorders (hemophilia), body cast immobilization, burns and burn therapy, depression, drug abuse, enuresis, functional megacolon, hair-pulling, helpless feelings, insomnia, learning difficulties, muscle spasm, nausea, pain, poor self-esteem, psychogenic seizures, stuttering, tension. The author lists references discussing the use of self hypnosis with each of these problem areas.

1978

Porter, J. W. (1978). Suggestions and success imagery for study problems. International Journal of Clinical and Experimental Hypnosis, 26, 63-75.

A procedure is presented for dealing with study problems in cases where patients come with an expectancy of help through hypnosis. Specific suggestions directly related to the study difficulty are given. "Success imagery" is outlined for use under hypnosis and by the student himself in his daily life. Two self-management techniques associated with the relaxation induced by exhalation are given further strength by being made posthypnotic suggestions. A direct posthypnotic suggestion for "concentration and recall" is combined with contingency management to effect more efficient performance when the decision is made to study. Four sessions are shown by clinical experience to be generally adequate to allow a transition from therapy to self-management of the problem aided by the student's own use of self-hypnosis. A general outline of how this is achieved for the first three sessions incorporates both Wolberg's (19656) suggestions to remove barriers preventing progress and Stanton's (1977) Rational-Emotive Therapy suggestions to strengthen the person's belief in himself.

1977

Lazar, Billie S. (1977). Hypnotic imagery as a tool in working with a cerebral palsied child. International Journal of Clinical and Experimental Hypnosis, 25 (2), 78-87.

Hypnotic imagery was used with a moderately severe athetoid cerebral palsied 12-year-old boy who was mildly retarded and a poor hypnotic subject. Techniques included imagery, observation of the self, revivification of relaxing experiences, proprioceptive feedback about the athetoid movements, and dealing with feelings and motivation. Athetoid movements were reduced, results extended beyond the treatment situation, and improvement was made in practical skills.

Call, Justin D. (1976). Children, parents, and hypnosis: A discussion. International Journal of Clinical and Experimental Hypnosis, 24, 149-155.

Ease of hypnotic induction in children depends on the setting, expectancies and nature of the relationship between the child, parent, and hypnotist. The capacity to center attention seems to be reflected in an increased alpha base rate. The capacity to suspend reality testing and to become subject to the authority of the hypnotist has its counterpart in the child's relationship with idealized authoritarian parents. Hypnotic induction utilizes the child's readiness for regressive object relations in which union of self and idealized parent imago is reactivated leading to high degrees of both suggestibility and feelings of omnipotence in the child. It is hypothesized that the child shares reality testing with the hypnotist as the infant did earlier with the all-powerful parent.

The fact that children can easily be hypnotized by the experienced hypnotist tells us nothing about indication for, dangers of, or potential success of treatment. Brief

symptomatic improvement of single symptoms means little and proves nothing. Success of hypnotic treatment with children depends on appropriate articulation of hypnotic procedures with total need-systems of child and family.

1976

Cooper, Leslie M.; London, Perry (1976). Children's hypnotic susceptibility, personality, and EEG patterns. International Journal of Clinical and Experimental Hypnosis, 24, 140-148.

19 boys and 16 girls, aged 7 to 16, were given the EEG and then the Children's Hypnotic Susceptibility Scale, while a parent watched. About 1 week later, after some separate tests and interviews, each child was given a puzzle to solve in the parent's presence, while Es recorded offers and requests for help. Hypnotic susceptibility was positively correlated with the alpha duration with eyes open, but not with eyes closed. Both susceptibility and alpha duration tended to be negatively correlated with age. Highly susceptible children tended to wait longer than low susceptibles before asking parents for help with the puzzle, and their parents tended to be more strict, anxious, and impatient than did the parents of low susceptible children.

Gardner, G. Gail (1976). Attitudes of child health professionals toward hypnosis: Implications for training. International Journal of Clinical and Experimental Hypnosis, 24, 63-73.

A survey of child health professionals -- pediatricians, pediatric nurses, child psychologists, and child psychiatrists -- revealed that they have generally positive attitudes toward hypnosis but little knowledge of its specific advantages or applications. Recommendations are made for designing training opportunities in hypnosis which might enhance the probability that the professional will actually use hypnosis or refer a child elsewhere for hypnotherapy.

Gardner, G. G. (1976). Childhood, death, and human dignity: Hypnotherapy for David. International Journal of Clinical and Experimental Hypnosis, 24, 122-139.

Hypnotherapy can be a significant part of the treatment of a dying child. A detailed clinical report illustrates how hypnotherapy was integrated with other treatment modalities to help a terminally ill child and his family cope effectively with problems and enhance their ability to use their own resources for personal growth and mastery throughout the dying process.

NOTES:

Includes report of a mother's hypnosis work with her son for the three hours before he died.

Illovsy, J.; Fredman, N. (1976). Group suggestion in learning disabilities of primary grade children. International Journal of Clinical and Experimental Hypnosis, 24, 87-97

**This study reports the effects of tape-recorded hypnotic suggestions given to 48 hyperactive children between the ages of 6 and 8 from 3 public schools. The children had short attention spans, low frustration and tolerance [sic], and poor learning motivation. They were taught by the same method in class and received remedial instruction as in the previous year. In order to participate in this study, the children were brought from their regular classrooms every morning to listen in groups of 9, 10, or 19 -- according to the available accommodation in the school -- to suggestions of relaxation, to ideas of coping with emotional problems, and to suggestions of modifying attitudes towards learning. The corrective reading teachers conducted these 15-minute sessions. After the session was over, the children were returned to their respective classes. At the beginning and at the end of the school year, the classroom teachers evaluated the children's behavior in class and their attitudes toward learning. The addition of the modified hypnotic technique enabled 45 of 48 children to function better in school. The improvement ranged from decreased hyperactivity to better than average performance in class. Significant correlations were found between percent of relaxation with increased attention span ( $r = .40$ ) and number of sessions attended with increased self-confidence ( $r = .46$ ).**

**Laguaite, J. K. (1976). The use of hypnosis with children with deviant voices. International Journal of Clinical and Experimental Hypnosis, 24, 98-104.**

**Hypnosis was used with 18 children aged 4 years, 7 months to 10 years, 1 month, with a mean age of 6 years, 8 months. All children had deviant voices -- 7 had vocal nodules, 4 had hypertrophy of the vocal bands, 5 had normal larynges, and 2 could not be visualized adequately. All but 1 of the children responded by entering some degree of trance state. The younger children responded better when eye closure was not suggested. Post-therapy judgments of voice quality and laryngeal examinations showed that only 2 had shown no improvement. The 2 were the least responsive to hypnosis. Factors thought to be important in influencing the children's responses are discussed.**

**Lawlor, E. D. (1976). Hypnotic intervention with 'school phobic' children. International Journal of Clinical and Experimental Hypnosis, 24, 74-86.**

**Case studies are used to illustrate the use of hypnosis in working with children who exhibit symptoms of "school phobia." Responses obtained during and after hypnosis are utilized to uncover underlying conflicts and fears.**

**The literature (Ansbacher, 1956; Friedman, 1959; Johnson, 1957; Johnson, Falstein, Szurek, & Svendsen, 1941; Kessler, 1966; Waldfogel & Gardner, 1961) confirms the findings that a child through his symptoms has fears which he is unable to bring to consciousness and talk about. Typical are fears of abandonment by parents; fears of disaster befalling parents, especially the mother; fears based on destructive wishes toward siblings due to severe rivalry for the mother's love and attention; fears that exhibiting angry feelings will be punished by the parents; and fears of annihilation and starvation.**

Hypnosis has aided in restoring these children to a school environment more quickly than more traditional methods. One case is reported with excerpts from a session. The perceptions uncovered through the use of hypnosis can be utilized with children in various school settings.

7-12 yr. olds received 2 role-playing tests in 1 session and London's Children's Hypnotic Susceptibility Scale (CHSS) 1 wk. later. Performances were compared to a previous sample of 42 children who had received the same tests in reverse order of administration. Means of the role test were essentially the same in both samples. 1 of the role tests, Dramatic Acting, was unrelated to hypnotic susceptibility in both samples; the other, Hypnotic Simulation, was uncorrelated with overall susceptibility in the present sample, unlike the previous one, but seemed to have inhibited 1 aspect (Subjective Involvement scores) of performance on the CHSS. Order of administration of the simulation test and CHSS also differentially affected some Overt Behavior item scores; CHSS functioned as a rehearsal for the subsequent simulation performance of low-susceptibles, and the simulation test had the same function for the CHSS performances of high-susceptibles. 1969

Nowlis, D. P. (1969). The child-rearing antecedents of hypnotic susceptibility and of naturally occurring hypnotic-like experience. International Journal of Clinical and Experimental Hypnosis, 17, 109-120.

Data pertaining to early and mid-childhood socialization experiences available from a sample of children and their mothers as studied earlier by R. R. Sears, E. E. Maccoby, H. Levin, and others were related to hypnotizability scores and scores of susceptibility to naturally occurring hypnotic-like experiences for a part of the same sample when the children reached late adolescence. As hypothesized by J. R. Hilgard and E. R. Hilgard (see 37:3) after retrospective interviewing with college-age hypnotic Ss, the present study, using a longitudinal method of investigation, indicated some relationship between firm parental discipline in childhood and subsequent susceptibility to hypnosis and hypnotic-like experiences in adolescence. Correlations, however, were low and the overall yield of significant data was judged to be meager. This was particularly true of hypnotizability scores in relation to the other variables available for analysis. Long, T. E. (1968). Some early-life stimulus correlates of hypnotizability. International Journal of Clinical and Experimental Hypnosis, 16, 61-67.

34 MALE COLLEGE SS WERE PLACED INTO 3 HYPNOTIZABILITY GROUPINGS WITH THE USE OF THE PASCAL TECHNIQUE OF HYPNOSIS. THE PASCAL-JENKINS BEHAVIORAL SCALES WERE USED TO INVESTIGATE STIMULUS SITUATIONS PRESENTED BY MOTHER AND

FATHER DURING THE 1ST 10 YR. OF SS' LIVES. THE SPECIFICALLY DEFINED BEHAVIORAL VARIABLES OF ACTIVITIES WITH S AND DISPLAYS OF AFFECTION FOR THE FATHER STIMULUS CATEGORY AND THE VARIABLE VERBAL PUNISHMENT FOR MOTHER SIGNIFICANTLY DIFFERENTIATED THE HIGH HYPNOTIZABLE SS FROM THE COMBINED MIDDLE-LOW HYPNOTIZABLE SS. THE OTHER PHYSICAL CONTACT VARIABLES, WHICH INVOLVE INTIMATE CONTACT BETWEEN S AND THE PARENT, SHOWED CONSISTENT TRENDS IN THE SAME DIRECTION. THUS, EARLY LIFE FAMILY EXPERIENCES OF A MORE POSITIVE AND LESS DEVIANT NATURE SEEM TO BE ASSOCIATED WITH HIGHER SUSCEPTIBILITY TO HYPNOSIS. (SPANISH + GERMAN ABSTRACTS) (PsycINFO Database Record (c) 2002 APA, all rights reserved)

1966

Cooper, Leslie M.; London, Perry (1966). Sex and hypnotic susceptibility in children. International Journal of Clinical and Experimental Hypnosis, 14, 55-60.

Sex differences in hypnotic susceptibility were investigated in a sample of 240 children. The Children's Hypnotic Susceptibility Scale was administered to 10 boys and 10 girls at each age level for 5-16 yr. There were no differences between the means of the boys and girls at any age for the 3 scores yielded by the measure. The percentage passing each item at each age for each sex was also computed. Of the resulting 264 comparisons only 1 (Item 10, Eye Catalepsy) was found to be significantly different at 1 age level (7 yr. of age) and was attributed to chance. It was concluded that there were no sex differences for the various items at the ages tested. (PsycINFO Database Record (c) 2002 APA, all rights reserved)

Moore, R. K.; Cooper, L. M. (1966). Item difficulty in childhood hypnotic susceptibility scales as a function of item wording, repetition, and age. International Journal of Clinical and Experimental Hypnosis, 14, 316-323.

THE CHILDREN'S HYPNOTIC SUSCEPTIBILITY SCALE (CHSS) AND A REVISED VERSION FOR CHILDREN OF THE STANFORD HYPNOTIC SUSCEPTIBILITY SCALE, FORM B (REV. SHSS:B) WERE ADMINISTERED TO 26 CHILDREN, AGES 8-16 YR., TO WHOM THE CHSS HAD BEEN ADMINISTERED 3 YR. EARLIER. COMPARISON OF THE RESULTS OF THE 2 ADMINISTRATIONS OF CHSS SHOWED NO SIGNIFICANT DIFFERENCES IN MEANS OR STANDARD DEVIATIONS. THE RELIABILITY WAS .72 ( $P = .001$ ) WHEN 3 ATYPICAL SS WERE ELIMINATED. THE ITEM DIFFICULTIES OF EYE CLOSURE AND ARM IMMOBILIZATION DIFFERED ( $P = .05$ ) OVER THE 2 ADMINISTRATIONS, BOTH BEING MORE DIFFICULT AT THE EARLIER TESTING. IT IS SUGGESTED THAT THESE CHANGES WERE A RESULT OF BOTH PRACTICE AND AGE EFFECTS. THE COMPARISON OF THE 2 DIFFERENT SCALES USED AT THE LATER TESTING ALSO SHOWED NO SIGNIFICANT DIFFERENCES IN MEAN SCORES OR STANDARD DEVIATIONS. THE CORRELATION BETWEEN

THE 2 SCALES WAS .77 (P = .01). 3 ITEMS, EYE CLOSURE, ARM IMMOBILIZATION, AND AMNESIA, SHOWED SIGNIFICANT DIFFERENCES (P = .05) IN THE PERCENT PASSING THE ITEM, THE 1ST BEING LESS DIFFICULT ON THE REV. SHSS:B, AND THE LATTER 2 BEING MORE DIFFICULT. CONTENT AND PROCEDURAL DIFFERENCES ARE SUGGESTED TO EXPLAIN THESE DIFFERENCES IN ITEM DIFFICULTIES. 1965

Bernstein, Norman R. (1965). Observations on the use of hypnosis with burned children on a pediatric ward. International Journal of Clinical and Experimental Hypnosis, 13 (1), 1-10.

Several cases are described and observations made about the interplay of forces between staff, patient, and therapist, as well as the expectations of the patients to assess how these factors influenced the use of hypnosis. Hypnosis appears to be a particularly useful means for reaching isolated and depressed children with burns and for improving the morale of the staff team working with these children. The results may be along specific lines in terms of pain tolerance and improved eating, or in general improvement of cooperativeness and mood on the part of the child. 1962

Kolouch, Fred T. (1962). Role of suggestion in surgical convalescence. Archives of Surgery, 85, 144-155.

#### NOTES

The author is a surgeon who has offered hypnosis to many patients in his practice. His inductions were usually rapid (30 seconds to 10 minutes), stressing optimistic expectations. The procedure is described as follows: "Suggestion is then utilized in a purposeful manner to communicate a reality image of the entire surgical procedure to the patient. A frank but optimistic discussion of morbidity and mortality is made. An estimate of the pain to be experienced is offered with the emphasis that this can be controlled in part and it will be temporary. The patients are told that they may use opiates or sedatives if they feel a need for chemical pain relief. Any subconscious fears of surgery are investigated using ideomotor questioning. These are ventilated by the patient and put in the proper perspective in relationship to the realities of the forthcoming surgical procedure. If the patient is capable, he is taught glove anesthesia of the hand and given a posthypnotic suggestion for the transference of this to his operative site. He is asked to visualize himself at the conclusion of his convalescence, free of his pathology, alive and well and rehabilitated to normal productivity. It is emphasized to him that by judicious application of his subconscious thoughts to relaxation, pain control, normal respiratory, gastrointestinal, and urinary functions, he may rapidly accomplish his own preconceived notion of his convalescence.

**"He is given a posthypnotic suggestion that he will never respond to hypnosis without his consent. ...**

**"A posthypnotic suggestion is given to establish a simple signal as a trance inducer for future hypnosis or to enable him to use autohypnosis.**

**"The patient who is to have a general anesthetic is given the suggestion that while asleep he will not listen to any conversation in the operating room except that which is directed toward him by name.**

**"In the patients undergoing minor outpatient surgery, hypnosis is frequently induced in the operating room during the scrub time.**

**"Patients undergoing general or regional anesthesia are frequently placed in a trance before the anesthetic period. ...**

**"During the surgery care is taken to keep discussion at a level unrelated to the surgical procedure. ...**

**"At the conclusion, consistent with an honest appraisal of the situation, optimistic, purposeful suggestions are offered the patient while he is still asleep or in hypnosis" (p. 305.**

**The author evaluated the outcome for 100 surgical patients who had received this procedure, using subjective measures (confidence, well-being, freedom from fear and anxiety) and two objective measures (needs for postoperative pain-relieving drugs, and postoperative hospitalization). Seventy-five patients aged 6-80 had 81 different procedures (breast biopsies, tenorrhaphies, orchiopexies, herniorrhaphies, thyroidectomies, a radical neck dissection, radical mastectomies, cholecystectomies, gastrectomies, rectal surgery, etc.); the remaining 25 patients had minor outpatient procedures under local or hypnoanesthesia.**

**The author compared the dosage of medications needed by patients he judged to have benefitted from hypnosis and those who didn't benefit. He did the same analysis for length of stay. Based on his own observations, he judged that 75% of the hospitalized patients and nearly all of the OPD patients benefitted and experienced a simplified convalescence. Laparotomy patients required more medications than the other patients.**

**The author compared the hospitalized patients who received hypnotic suggestion to a similar group who were not subjected to such suggestion, on needs for opiates and postoperative hospitalization. There was a reduction in drug needs in most categories of cases, but equal needs in the biliary cases. Patients subjected to thyroidectomy or herniorrhaphy left the hospital sooner if they had been given hypnosis, but the patients undergoing biliary and gastric surgery still required the usual hospital care.**

**Herniorrhaphy patients benefitted in terms of catheterization: only was catheterized in the hypnosis group compared to 7 in the nonhypnosis group. The author attributed this outcome to a combination of suggestion and local anesthesia. Postoperative complications were rare in the patients utilizing hypnosis.**

**The economic advantages of suggestion are illustrated in a comparison of the costs of hospitalization of the series of patients undergoing herniorrhaphy and thyroidectomy with and without hypnosis: average cost of thyroidectomy with hypnosis used effectively (\$196) and without hypnosis (\$311); of herniorrhaphies with hypnosis used effectively (\$125) and without hypnosis (\$181). N.B. These costs**

are presumably from the time period of approximately 1959-60, inasmuch as the paper was read at the Annual Session of the Western Surgical Association on December 1, 1961.

"Probably the most pleasure for the surgeon results from the observation of the responses of children to suggestion in hypnosis. A degree of cooperation and freedom from fear is exhibited that is nearly unbelievable. With hypnosis in children one may utilize local anesthesia in situations which previously required general anesthetics" (p. 310).

1961

Klopp, Kirk K. (1961). Production of local anesthesia using waking suggestion with the child patient. International Journal of Clinical and Experimental Hypnosis, 9, 59-62.

#### NOTES

Author describes the use of waking suggestion with children, as opposed to hypnosis. The technique "is simply the presentation of an idea which is sold to the child with such emphasis that when it is communicated to him, he accepts it with conviction. As children reason for the most part paralogically, the absence of logical grounds for the acceptance of the idea is arrived at easier than with the more mature mind of the adult" (p. 59).

1956

McCord, Hallack (1956). Hypnosis as an aid to the teaching of a severely mentally retarded teenage boy. Journal of Clinical and Experimental Hypnosis, 4 (1), 21-23. (Abstracted in Psychological Abstracts 57: 3729)

#### NOTES

A 16 year old boy with I.Q. measured at 55 was hypnotized for 20 minutes daily for one month. During each session he was given material to learn (multiplication tables, spelling words, reading recognition, and general information -- only one presented during each hypnosis session). "At the end of 90 days, the subject was still retaining almost 100 percent of all material presented except for the multiplication tables which showed about 50 percent loss" (p. 22). "As a result of routinely introduced hypnotic suggestions for well-being, happiness, desire to learn, and assurance of acceptance, Ben's motivation to learn in the classroom situation took a sharp surge upward. (It was for this reason that giving him parallel material in the normal state to be used to measure comparative learning rates promptly became scientifically unsound as a control in this study.)" (p. 22). Although he was not given material to study in between sessions, "it was known that he mentally reviewed the material while working and playing in the school program" (p. 23).

### COGNITION

1994

Freeman, R.; Barabasz, A.; Barabasz, M. (1994, October). EEG topographic differences between dissociation and distraction during cold pressor pain in high and low hypnotizables. [Paper] Presented at the annual meeting of the Society for Clinical and Experimental Hypnosis, San Francisco.

**NOTES:**

Hilgard once said we should study what is going on inside the skull when we study hypnotic behavior. Theta EEG was studied, in 3.5 and 5.5-7.5 band widths, based on Crawford's research (no differences between high and low hypnotizables in low range but significant differences in waking state, eyes closed condition).

Also employed new type of distraction procedure. Previously used as comparison conditions things like imagine a pleasant scene, do whatever you can do to reduce pain, or imagine an instructor giving a lecture. Barabasz theorized that highs, given the opportunity, may spontaneously get involved in imagery; so distraction used in some experiments may actually become hypnosis. Here, distraction involved using a storage box, with plexiglass covering front, and 3 lights--subjects were to recall sequence of light changes that occurred during 60 sec when arm was in the cold water.

Cold pressor pain. 3 immersions with simultaneous pain reporting and EEG monitoring. --Waking State --Light array distraction --Hypnotic induction and suggested analgesia (Distraction and hypnosis with analgesia were presented in a balanced design)

Pain Ratings ranged from 0 = no pain, 10 = level would very much like to remove arm from water (rating could exceed 10 however). After removing arm, subjects were to report the maximum amount of pain that they had felt. Pain Scores were obtained at 30 seconds and 60 seconds after immersion in the cold water.

Also got qualitative data. During recovery period after each arm immersion, Subjects were asked what if anything they had done to reduce the pain felt.

30 second pain scores: Waking 7.60 vs 7.50 Distraction 8.60 vs 6.80 Hypnotic analgesia 7.80 vs 4.10 (Significantly different).

60 second pain scores: Showed same trend

There was no difference whatsoever for the lows.

Results for the 2 EEG sites: P3 left hemisphere parietal in waking and hypnotic analgesia, high theta, had significantly different activity O1 left hemisphere in waking and hypnotic analgesia, was significantly different between highs and lows (same as above).

Results for two theta ranges: Low theta range, T4 temporal right hemisphere, for lows in waking and [missed words] condition--hard to interpret this finding.

**RESULTS.** Highs demonstrated pain reduction in hypnotic analgesia compared to waking and distraction conditions and compared to lows. Lows had no differences in any condition.

Enhanced EEG theta in left parietal area differentiated highs and lows. This suggests that highs generate enhanced disattention that may be controlled by these areas.

P3 area regulates the integration and association of somatic perceptions. The O1 area controls processing of visual imagery. Perhaps high hypnotizables have more

ability to alter afferent sensory information through focused attentional processes. Also, the ability to alter the suffering portion of pain experience may involve visual imagery activity.

State and trait differences are apparent.

The low theta range may be more closely related to slower delta range 0-3.5 that is associated with sleep and drowsiness. High theta = low arousal and attention capacity. That's why theta seems associated with wide range of behaviors that appear contradictory

The qualitative data shows highs reported they spontaneously preferred strategies that were more than distraction (associating colors with warmth, thinking of warm water) and the most frequent responses of lows were "nothing" or "told myself it would be over soon."

Highs in analgesia condition used no specific strategy: 8/10 reported the arm simply felt more numb.

1993

Atkinson, Richard P. (1993, October). Shifts in Muller-Lyer Illusion difference thresholds: Are high hypnotizables more sensitive than lows in hypnosis?. [Paper] Presented at the annual meeting of the Society for Clinical and Experimental Hypnosis, Arlington Heights, IL.

NOTES

Refers to Wallace (1979) finding that hypnotizability correlates with afterimage persistence. Atkinson showed highs perform better than lows in perceptual tasks in hypnosis only. Also studies indicate highs are more susceptible to illusions. Our study showed difference in threshold and point of subjective equality for highs and lows.

32 undergraduates had Harvard and Group Stanford Form C, were 9-12 or 0-3 on both scales. Counterbalanced conditions of waking and hypnosis. Used computer monitor to compare length of lines. Waking condition Ss had to close eyes for 15 minutes before the trials, same length of time as for hypnosis condition.

Significant interaction between hypnotizability and sessions was observed: highs had significantly decreased difference thresholds in hypnosis compared to waking, and significantly decreased difference thresholds compared to lows in hypnosis. Thus they had greater sensitivity than lows.

The point of subjective equality ANOVA did not yield significant effects.

Highs show higher sensitivity to illusion in hypnosis than in waking, and more than the lows.

## NOTES

Author is developing Ernest Hartman's Mental Boundaries Questionnaire. Hartman does research on chronic nightmare sufferers. He says they have thin mental boundaries, defined in various ways. Art students have thin boundaries, Navy officers thick boundaries. The questionnaire has 145 items, less 7 that are scored zero.

Item Groups: Sleep/wake/dream Unusual experiences (e.g., déjà vu) Thoughts, feelings, moods Child, Adolescent, Adulthood feelings Sensitivity Neat, exact, precise Edges, lines, clothing (flexible space) = Personal score

Opinions about children about organizations about people, nations, groups, about beauty, truth = World total

Sumbound (personal + world total) Hypnotizability should relate to Personal score more than World total.

Also used: 2. Field's Inventory 3. Kirsch's Inner subjective experiences (of the Harvard Scale) 4. Tellegen's Absorption Scale 5. Harvard Hypnotizability Scale

Gave the measures in different contexts from the hypnotizability measures. The Absorption scale (different subscales) correlated best with the Hartman's scale, but subjective scales also correlated with "Personal Score."

The lack of significant correlation between Harvard and Thinness of Boundaries questionnaires may be due to differences in voluntariness experience on the Harvard. Or Woody and others suggest hypnotic response may be due to compliance in some samples. Barrett had found a correlation of .19 with hypnotizability; and Robert Kunzendorf found a similar correlation.

1993

Dabic-Jeftic, Mirjana; Barnes, Graham (1993). Event-related potentials (P300) during cognitive processing in hypnotic and non-hypnotic conditions. Psychiatria Danubina, 5 (1-2), 47-61.

In this study authors investigated to find out if there were any specific changes of event related potentials in subjects before hypnosis, entering hypnosis, in deep hypnosis and leaving hypnosis, and to compare mental activities of subjects such as capability of correctly calculating and remembering the exact number of unexpected stimuli delivered by stimulator with their verbal or nonverbal reports

during any of the conditions investigated. The methodology was of testing the cognitive evoked potentials elicited by auditory stimuli, using the oddball paradigm. Obtained results show that the most constant values of shortest latency and highest amplitudes of the cognitive waves, especially P300 were found during deep hypnosis. All five subjects in the investigation answered with the exact number of delivered target stimuli only after deep hypnosis. Conversely, in all other conditions their answers were approximate to the correct number of delivered target stimuli. (Author abstract.)

**NOTES:**

In this experiment, 5 adult volunteers were told to attend to one of two tones delivered through headphones. The tones were randomly delivered but one occurred 85% of the time (the 'frequent, non-target tone') and the other occurred 15% of the time (the 'rare, target tone'). The subjects were to notice, remember, and count the target tone. Measures were taken during five periods: pre-hypnosis, entering hypnosis, deep hypnosis, leaving hypnosis, and post-hypnosis.

Some subjects had extensive hypnosis experience prior to the experiment; others had little.

The EEG P300 wave was sensitive to condition. Latency of P300 was significantly shorter in deep hypnosis compared with other periods. Higher amplitude of P300 also occurred during deep hypnosis compared with other periods. (Notes taken from secondary reference, Ericksonian Newsletter.)

Elter-Nodvin, Sabette; Lynch, Gregory; Nash, Michael R. (1993, October). Is primary process mentation a feature of hypnotic responding?. [Paper] Presented at the annual meeting of the Society for Clinical and Experimental Hypnosis, Arlington Heights, IL.

**NOTES**

1:

**NOTES:** It is difficult to measure primary process; usually measures from Rorschach are used. Recently Steven Lynn and Ken Bowers have done interesting work.

From literary criticism, we took the newer method of lexical pattern analysis--like a fingerprint (e.g. of Shakespeare's language). Wanted to determine whether there are differences between High and Low hypnotizables; or a difference in waking and hypnotic state. Martindale has a measure based on a lexical dictionary.

In Martindale's method, you take a long verbal sample, transcribe it into computer text file (response to TAT cards, and 3 tasks like--"Imagine you are ascending a spiral staircase and see someone at the top; describe what you see"); then do word count.

Farvolden, Peter; Bowers, Kenneth S.; Woody, Erik Z. (1993, October). Hypnotic amnesia: Avoiding the 'Intentional Loop'. [Paper] Presented at the annual meeting of the Society for Clinical and Experimental Hypnosis, Arlington Heights, IL.

**NOTES**

The social cognitive view is that Ss actively try to forget and fool themselves, making an attributional error. Davidson & Bowers say (in neo-dissociation theory) the information is temporarily unconscious--like forgetting a friend's name at a cocktail party. Executive initiative, effort, and control are bypassed.

We used heart rate as indicator of cognitive effort. For highs there should be little increase in heart rate. 20 lows and 20 highs who passed amnesia item on Waterloo-C were used. Post-experimentally we asked them what they were doing following the suggestion of amnesia, and had judges evaluate the degree of effort.

Gruzelier, John; Warren, Kristen (1993). Neuropsychological evidence of reductions on left frontal tests with hypnosis. Psychological Medicine, 23, 93-101.

Individuals with high and low susceptibility to hypnosis were compared in a baseline condition and after instructions of hypnosis on tests of anterior left and right hemispheric functions of word fluency to letter categories, word fluency to semantic categories, design fluency and bilateral finger tapping dexterity. With hypnosis high susceptibles showed a reduction in word generation to letter categories, no significant change in word generation to semantic categories, an improvement in design fluency, and bilateral reductions in finger tapping dexterity. Low susceptibles showed the opposite changes except for the improvement in design fluency. These results, together with correlational results, were interpreted as evidence of central inhibitory processes, particularly of the left hemisphere, in response to instructions of hypnosis in high susceptibles.

#### NOTES

The authors discussion of their study includes the following statements. "The main result of the study was the differential influence of instructions of hypnosis on high and low susceptibles for word fluency to letter designated categories, as distinct from semantic categories, and design fluency" (p. 98).

"The absence of effects of hypnosis on word generation to semantic categories (left fronto-temporoparietal) versus letter categories (left frontal) has a bearing on evoked potential evidence (Gruzelier et al. 1987). Bilateral comparisons at temporal lobe and central locations showed that high susceptibles were characterized by asymmetric changes in evoked potential amplitude (N116 component) with hypnosis. Activity at the central electrodes was compatible with a left-to-right hemispheric shift of function, but this was not the case at the temporal electrodes. Instead of an inhibition of left temporal activity with hypnosis activation was maintained. Maintenance of activity in the left temporal lobe follows consideration of the fact that hypnosis requires sustained attention to the voice of the hypnotist, which is predominantly a left temporal function" (p. 99).

"The absence of differences in the pre-hypnotic condition between high and low susceptibles indicates that hemisphericity per se may not be a factor that characterizes susceptibility. The fact that lateral differences were found in some experiments (e.g. Gruzelier et al. 1984; Gruzelier & Brow, 1985) but not others (e.g. Cikurel & Gruzelier, 1990; McCormack & Gruzelier, 1993) may indicate that such

effects, when apparent, were secondary to another factor such as cognitive flexibility as conceptualized by Crawford (1989)" (p. 99).

Laidlaw, Tannis M. (1993). Hypnosis and attention deficits after closed head injury. International Journal of Clinical and Experimental Hypnosis, 31, 97-111.

In a controlled study of patients attending a concussion clinic because of ongoing postconcussion symptoms, attention deficits were recorded in the head-injured group for the aspects of alertness, assessed by the Continuous Performance Test (CPT), and processing capacity, assessed by a version of the Paced Auditory Serial Addition Test (PASAT). Selective attention was intact. Hypnotizability was assessed by the Harvard Group Scale of Hypnotic Susceptibility, Form A (HGSHS:A), with normal means and standard deviations found in both the concussed and control groups. There was a significant correlation, however, between HGSHS:A scores and PASAT scores in the concussed group only. The results of this preliminary study suggest that slower processing capacity after a closed head injury may predict higher hypnotizability and that hypnosis could be an appropriate rehabilitation technique for these patients who present with postconcussion symptoms.

1992

Greenwald, Anthony G. (1992). New Look 3: Unconscious cognition reclaimed. American Psychologist, 47, 766-779.

Recent research has established several empirical results that are widely agreed to merit description in terms of unconscious cognition. These findings come from experiments that use indirect tests for immediate or long-term residues of barely perceptible, perceptible-but-unattended, or attended-but-forgotten events. Importantly, these well-established phenomena--insofar as they occur without initially involving focal attention--are limited to relatively minor cognitive feats. Unconscious cognition is now solidly established in empirical research, but it appears to be intellectually much simpler than the sophisticated agency portrayed in psychoanalytic theory. The strengthened position of unconscious cognitive phenomena can be related to their fit with the developing neural network (connectionist) theoretical framework in psychology.

Hilgard, Ernest R. (1992). Dissociation and theories of hypnosis. In Fromm, Erika; Nash, Michael R. (Ed.), Contemporary hypnosis research (pp. 69-101). New York: Guilford Press.

## NOTES

[These Notes were made from a prepublication copy and the pagination for quotes added later.]

The author reviews the history of dissociation theory, the hidden observer, and the credible-skeptical arguments regarding hypnosis. He briefly summarizes alternative theories about hypnosis, and asserts that we can turn aside from debate by examining the common topic studied, the "domain of hypnosis" or what happens

when hypnotist, with consent of subject, attempts to induce hypnosis through conventional procedures: production of hallucinations, contractions, paralyses, age regression, analgesia, posthypnotic amnesia, etc. Even if one disagrees about the nature of these phenomena or the appropriate explanatory concepts, one can agree on the area to be investigated.

The author notes that one never sees these behaviors in the same situation, in any other context. They are distinguishable from other phenomena like meditation, highway hypnosis, responses to a persuasive leader, and even some waking suggestions by several delimiting factors:

1. Hypnosis is not simply a response to suggestion, because that kind of response occurs in other situations. Suggestions can be divided into personal and impersonal (Hull, 1933); and suggestibility can be divided into primary and secondary (Eysenck & Furneaux, 1945). Primary suggestibility includes responses to waking suggestion (e.g. postural sway) that correlate with hypnotizability; secondary suggestibility involves responses to waking suggestion that do not correlate with primary suggestibility. Hypnotizability does not correlate with social suggestibility (i.e. gullibility or conformity) (Burns & Hammer, 1970; Moore, 1964); nor does it correlate with placebo response (McGlashan, Evans, & Orne, 1979).

2. Test-retest correlations are approximately  $+0.70$  between scores on hypnotizability scales with and without formal inductions. Thus, responses to the type of suggestion on hypnotizability scales--even when in the waking context--belong within the domain of hypnosis. The individual differences in responsivity to items on hypnotizability scales persist over time (Piccione, Hilgard, & Zimbardo, 1989:  $r = .64$  for 10 years test- retest,  $.82$  for 15 years, and  $.71$  for 25 years, on Stanford Form A); and this persistence is observed in twin studies as well (Morgan, 1973; Morgan, Hilgard, & Davert, 1970).

3. Additional evidence of coherence of the domain comes from reports of hypnotized Subjects about their phenomenological experience.

Hilgard's discussion of the executive and monitoring functions within hypnosis place his theory within the area of cognitive psychology. He presents a theory of a central regulating mechanism, with a hierarchy of subsystems that may be activated (and once activated may continue with some autonomy). When autonomous action occurs, the conscious representation of the control system may recede. Furthermore, the hypnotist's suggestions may alter the relationships within the hierarchy of subsystems and may also influence the executive functions. He gives as a common example, when a bilingual person talks in one language, the other language is temporarily inhibited.

There are a number of concepts or positions in the history of psychology that relate to Hilgard's theory of hierarchical control with executive and subsystems:

1. 'Cognitive structure' (Edward Tolman, 1932; 1938; Kurt Lewin, 1935). There may be communication problems between cognitive structures.
2. 'Habit family hierarchy' (Clark Hull, 1934). Habits are organized in a preferential system, so that if one is blocked the next is activated.
3. 'Cell assemblies' (Hebb, 1949; 1975), which are a physiological counterpart of the 'hidden observer' phenomenon.
4. 'Roles' (Sarbin & Coe, 1972) may be considered cognitive substructures.

5. 'Cognitive networks' (Blum, Geiwitz, & Stewart, 1967) serve similar functions.
6. 'Images' and 'plans' (Miller, Galanter, & Pribram, 1960) provide for control of thought and action and have some kind of hierarchy.
7. 'Subordinate ego-structures' (Gill & Brenman, 1959) with a dominant ego; or the ego-apparatuses in a 'conflict-free ego sphere' (Hartmann, 1958).

In hypnosis, central executive functions may be shared between hypnotist and Subject. Hilgard gives extensive examples of varying degrees of split in the executive control system.

"It can be argued that, except for relinquishing control over the subsystems that are specifically dissociated from control by suggestion, and the readiness for relinquishing control, the central executive functions have not been much modified in hypnosis. In superficial hypnosis, these mild dissociations can occur through waking suggestions, with little alteration of the general state of consciousness. When varied suggestions to a talented hypnotic subject have cumulative effects, as in suggestions of relaxation and detachment from the environment, the more general features of the hypnotic state begin to appear. A more massive dissociation, so far as the executive is concerned, may be the consequence of the summing up of many specific subsystems for which control has been relinquished. Such an interpretation permits hypnosis as a state to be a relative matter, the specific dissociations being identifiable, but the general state being a matter of how many specific dissociations are operative and how pervasive they are. Only when they are sufficiently pervasive is it appropriate to speak of a change of state" (p. 96).

Hilgard also discusses the monitoring function extensively, relating it to trance logic and contrasting it with the waking state. Less of the usual monitor is retained when the hypnotic involvement is greater, as in deep hypnosis, or when the subject becomes more deeply engrossed in an activated system that has been aroused. He also relates the monitoring function to the Hidden Observer phenomenon.

Kihlstrom, John F.; Barnhardt, Terrence M.; Tataryn, Douglas J. (1992). The psychological unconscious. American Psychologist, 47, 788-791.

In response to Greenwald's article on contemporary research on unconscious mental processes, the authors address three issues: (a) the independence of much recent research and theory from psychodynamic formulations; (b) the broad sweep of the psychological unconscious, including implicit perception, memory, thought, learning, and emotion; and (c) the possibility that the analytic power of unconscious processing may depend both on the manner in which mental contents are rendered unconscious and the manner in which they are to be processed.

Lewicki, Pawel; Hill, Thomas; Czyzewska, Maria (1992). Nonconscious acquisition of information. American Psychologist, 47, 796-801.

The authors review and summarize evidence for the process of acquisition of information outside of conscious awareness (covariations, nonconscious indirect and interactive inferences, self-perpetuation of procedural knowledge). Data indicate that as compared with consciously controlled cognition, the nonconscious

information - acquisition processes are not only much faster but are also structurally more sophisticated, in that they are capable of efficient processing of multidimensional and interactive relations between variables. Those mechanisms of non-conscious acquisition of information provide a major channel for the development of procedural knowledge that is indispensable for such important aspects of cognitive functioning as encoding and interpretation of stimuli and the triggering of emotional reactions.

**Loftus, Elizabeth F.; Klinger, Mark R. (1992). Is the unconscious smart or dumb?. American Psychologist, 47, 761-765.**

How sophisticated is unconscious cognition? This is one of the most fundamental questions about the unconscious that has been posed by research psychologists over the past century. Anthony Greenwald takes a contemporary look at this classical problem and concludes that unconscious cognition is severely limited in its analytic capability. In response, other leading scholars agree that the reality of unconscious processes is no longer questionable. Although there is some disagreement about just how sophisticated these processes are, the consensus is that exciting times are ahead for both research and theory concerning the mental processes involved in unconscious cognition.

**Hasher, L.; Stoltzfus, E. R.; Zacks, R. T.; Rypma, B. (1991). Age and inhibition. Journal of Experimental Psychology: Learning, Memory, and Cognition, 17 (1), 163-169.**

Two experiments assess adult age differences in the extent of inhibition or negative priming generated in a selective-attention task. Younger adults consistently demonstrated negative priming effects; they were slower to name a letter on a current trial that had served as a distractor on the previous trial relative to one that had not occurred on the previous trial. Whether or not inhibition dissipated when the response to stimulus interval was lengthened from 500 ms in Experiment 1 to 1,200 ms in Experiment 2 depended upon whether young subjects were aware of the patterns across trial types. Older adults did not show inhibition at either interval. The age effects are interpreted within the Hasher-Zacks (1988) framework, which proposes inhibition as a central mechanism determining the contents of working memory and consequently influencing a wide array of cognitive functions.

**1990**

**Bartis, Scott P.; Zamansky, Harold S. (1990). Cognitive strategies in hypnosis: Toward resolving the hypnotic conflict. International Journal of Clinical and Experimental Hypnosis, 38, 168-182.**

Two experiments were carried out to assess the relative contributions of dissociation and absorption as cognitive strategies employed by high and low hypnotizability Ss in responding successfully to hypnotic suggestions. Of special interest was the manner in which Ss deal with conflicting information typically inherent in hypnotic

suggestions. In the first experiment, Ss rated their attentional focus and the involuntariness of their experience after responding to a number of hypnotic suggestions administered in the usual manner. In the second experiment, the level of conflict was varied by instructing some Ss to imagine a circumstance that was congruent and other Ss to imagine a circumstance that was incongruent with the suggested behavioral response. The results of the 2 experiments were consistent in suggesting that, depending upon the nature of the hypnotic suggestion, high hypnotizability Ss are able to employ dissociation or absorption in order to respond successfully. Low hypnotizability Ss, on the other hand, seem to be relatively ineffective dissociators. When the structure of the hypnotic suggestion precludes the use of absorption, the performance of low hypnotizables deteriorates.

Burgess, Cheryl A.; Du Breuil, Susan C.; Jones, Bill; Spanos, Nicholas P. (1990-91). Compliance and the modification of hypnotizability. Imagination, Cognition and Personality, 10 (4), 293-304.

This study compared compliance-induced reporting bias in subjects who attained high hypnotizability scores following skill training and subjects who obtained equivalent scores without benefit of skill training (naturals). Low hypnotizables in one condition were administered the Carleton Skills Training Package and later posttested for hypnotizability. Control subjects were posttested without benefit of skill training. As in previous studies, skill-trained subjects attained substantially higher posttest hypnotizability scores than controls. In a final session, skill trained subjects, untrained naturals matched against the skill trained subjects on hypnotizability scores, and low hypnotizable controls were tested in a suggested deafness paradigm designed to assess compliant responding. Skill-trained subjects and matched naturals reported significantly greater suggested deafness than did the controls. However, only theory matched naturals exhibited significant levels of compliance-induced reporting bias. These findings indicate that skill-trained subjects exhibit no more compliant responding than do natural high hypnotizables.

1990

Fellows, Brian J. (1990). Current theories of hypnosis: A critical overview. British Journal of Experimental and Clinical Hypnosis, 7, 81-92.

The present state of theory in hypnosis is reviewed and observations are made concerning future prospects. The state- non-state issue continues to dominate theoretical debate, although no satisfactory reply has yet been made to T. X. Barber's criticisms of the 'hypnotic trance' concept. The impact of social-psychological theory has been considerable and the results of Spanos's hypnotic training programme could have significant implications for our understanding of hypnosis. Future theorizing should see a move towards a more integrated sociocognitive approach. Neodissociation theory has generally not fulfilled its early promise and is encumbered with the 'hidden observer' concept. The role of imaginative processes continues to be a dominant theme in hypnosis theory, although the relatively small correlation between imaginative and hypnotic abilities

remains a problem. The links between hypnosis, sleep and relaxation deserve further research, although, as theories of hypnosis, their scope seems limited. Suggestibility and role enactment theories have shown few signs of development in recent years. Theoretical problems over the interpretation of hypnosis need to be more widely recognized and the use of question-begging terminology curtailed. One advantage of the imagination hypothesis is that it provides a bridge, or a point of convergence, between state and non-state approaches (Spanos & Barber, 1974). It also handles certain hypnotic phenomena very well. For example, the known facts of age regression can be readily interpreted, together with the oddities of age progression and past life regression, as imaginative reconstructions (Barber, 1979). However, other phenomena, such as amnesia and analgesia, are less easily explained.

**Freeman, William B., Jr.; Kessler, Marc; Vigne, Jeffery (1990). Random number generation, absorption, and hypnotizability: A brief communication. International Journal of Clinical and Experimental Hypnosis, 38, 10-16.**

Graham and Evans (1977) found that a measure of random number generation (RNG) was related to hypnotizability. In 2 studies, the relationship between hypnotizability and Graham and Evans' RNG (1977) index was examined. In Study 1 Evans' (1981) measures of controlled and automatic absorption were also evaluated. In Study 1 no relationship was found between the measures of absorption or RNG and hypnotizability. Since Study 1 was carried out primarily to evaluate methods for modifying hypnotizability, Study 2 was designed to evaluate RNG measure directly. Study 2 found no consistent relationship between RNG and hypnotizability, or between RNG and measures of the experience of hypnotic depth and nonvolition.

**Gil, Karen M.; Williams, David A.; Keefe, Francis J.; Beckham, Jean C. (1990). The relationship of negative thoughts to pain and psychological distress. Behavior Therapy, 21 (3), 349-362.**

Examined the degree to which negative thoughts during flare-ups of pain are related to pain and psychological distress in 3 pain populations: sickle cell disease, rheumatoid arthritis, and chronic pain. 185 adults completed the Inventory of Negative Thoughts in Response to Pain (INTRP), a pain rating scale, the SCL-90 (revised), and a coping strategies questionnaire. Factor analysis of the INTRP revealed 3 factors: Negative Self-Statements, Negative Social Cognitions, and Self-Blame. High scorers on Negative Self-Statement and Negative Social Cognitions reported more severe pain and psychological distress. Ss with chronic daily pain had more frequent negative thoughts during flare-ups than those having intermittent pain secondary to sickle cell disease or rheumatoid arthritis. The INTRP appears to have adequate internal consistency and construct validity

Heyneman, Nicholas E. (1990). The role of imagery in hypnosis: An information processing approach. International Journal of Clinical and Experimental Hypnosis, 38 (1), 39-59.

Imagery is widely agreed to be an important component of hypnosis. The theoretical framework from which to conceptualize the role of imagery in hypnosis, however, has remained controversial. A model is presented which attempts to reconceptualize hypnotic imaginal processing in terms of current theory and research in cognitive psychology and psychophysiology. This model draws from a propositional approach to imagery (e.g. Pylyshyn, 1973), particularly as adapted by Lang's (1979) bioinformational theory. It is argued that the hypnotic image is fundamentally more complex than simple iconic mental representation, containing instead both stimulus and response components. It is proposed that the critical properties of the hypnotic image are not the stimulus components or propositions which give rise to the experience of the image but instead are response propositions which are associated with overt behavior. Processing of these response propositions is conceptualized as a negative feedback system between the brain and effector site. Some preliminary sources of support as well as implications and research suggested by this model are discussed.

#### NOTES

The author notes that the brain does not store a kind of "photograph," but rather stores "meanings" (Anderson, 1978); and that images actually represent response processes, as observable in physiological concomitants (Lang, 1977).

The hypnotic suggestion that a Subject's arm is being pulled up into the air by a large helium balloon is represented by two separate propositions: "There is a helium balloon tied to your arm" (a stimulus proposition) and "Your arm is moving up into the air" (a response proposition). According to Peter Lang (1979), an image is not a mental stimulus to which a response is made, but is in itself an active response process, accompanied by physiological activity. Verbal instructions to a Subject determine whether they will access stimulus propositions or response propositions. "Lang et al. (1980) found that only those Ss given response training coupled with response proposition scripts showed significant physiological arousal. These Ss were presumably better able to access and process that portion of the propositional network which controls visceral and motoric responding" (p. 46).

This author proposes that cognitive processing of a hypnotic image involves (internal) responding, and that 'responsive propositions' provide the basis for understanding the function of imagery in hypnosis, and are more important to hypnotic imagery than stimulus propositions. "In other words, the experience of a visual image and thus the vividness or controllability of that image is not critical for hypnosis. What is important to note is that the hypnotic behavior is not a response to a visual image but is instead a function of the processing of the image itself (cf. Lang, 1979)" (pp. 47-48).

In explaining how an image might facilitate amplification of a subtle response (such as in arm levitation), the author suggests that physiological and external feedback systems are involved--principally a neural feedback loop between brain and target

organ (in this case, arm muscles). "Efferent signals, which are activated by processing response propositions, initiate the overt behavior while afferent signals feed back to the brain and modulate further input to the effector system. The process progressively reduces the mismatch between the image instructions and behavior until the hypnotic task is completed" (p. 48). The feedback loop "provides information on the discrepancy between desired behavior and actual behavior:  $e = B_d - B_a$ , where  $e$  = error,  $B_d$  = desired behavior, and  $B_a$  = actual behavior (Arbib, 1972). The error signal generated by this discrepancy modifies the efferent output so as to eventually approximate  $e = 0$ " (p. 49). The author notes that this complex process of physiological feedback may be "augmented by external feedback such as modified verbal instructions or vocal intonations of the hypnotist and self-observation by S" (p. 49).

The author's model is summarized as: "1. The context, setting, and expectations implied by being hypnotized as well as the wording of the hypnotic suggestions provides S with: (a) explicit or implicit instructions to use imagery, (b) repetitious wording which may increase the probability of fully accessing the relevant propositions, and (c) instructions that task completion is expected. This may function to increase the probability that the deep structure of the response propositions will be processed. 2. The hypnotic suggestion proper is composed of stimulus and response propositions embedded within a propositional network. 3. Stimulus propositions give rise to the phenomenological characteristics or the percept-like experience of the image but may be unimportant in determining hypnotic behavior. 4. Processing of the response propositions includes an active response. This response process is facilitated by S's expectation to become actively involved in the imagined scene. Response propositions are the critical features of hypnotic imagery. 5. During hypnosis, the propositional network may be systematically modified by physiological or external feedback regarding the relative progress of the behavior toward task completion. This processing of response propositions is conceptualized as a negative feedback system. Efferent signals are delivered to the appropriate effector site while afferent signals feed back to the brain in order to modify further neural input, functioning to reduce the error between image and behavior. While the initial feedback is probably physiological, additional feedback may be obtained from the hypnotist's instructions and S's self-observations. 6. If stimulus propositions are simultaneously accessed, S experiences an image" (p. 51).

Kihlstrom, John F.; McConkey, K. M. (1990). William James and hypnosis: A centennial reflection. Psychological Science, 1, 174-178.

For William James, hypnosis was both an experimental technique for creating divisions of consciousness, and a laboratory model of naturally occurring disorders of awareness. James' treatment of consciousness in hypnosis presages contemporary interests in dissociation and implicit cognition, and underscores the role of the self in conscious mental life. At the same time, James recognized the complexity of hypnosis as an interpersonal process. In the end, James' views suggest how a

rapprochement between the cognitive and social approaches to hypnosis might be achieved.

Kunzendorf, Robert G.; Jesses, Michael; Dupille, Leonard; Butler, William (1990-91). Subliminal activation of intrapsychic conflicts: Subconscious realms of mind vs subconscious processes of mentation. Imagination, Cognition and Personality, 10, 117-128.

#### NOTES

Cognitive-state monitoring theory asserts that people perceive subliminal stimulation without self-consciously monitoring its external innervation (as opposed to central innervation). Thus monitoring theory predicts that subconsciously perceived discord, in the absence of any 'external location' cues, should be misinterpreted as centrally generated discord and should disrupt self-generated behavior. Consistent with this prediction, mathematical problem-solving in the current experiment was disrupted after mathematically competitive males repeatedly heard the subliminal message IT'S WRONG TO CRUSH DADDY stereophonically localized in the middle of their heads--but not after they repeatedly heard this subliminal 'Oedipal' message binaurally localized on one side of their heads. A subliminal message binaurally localized on one side of the self should not interfere with problem-solving behavior \_because, even though the message's external innervation is not self-consciously 'monitored,' its external location is inferable from subconscious cues.\_

Monitoring theory asserts that subliminal [perceptions] of 'unmonitored' messages are unaccompanied by any self-consciousness that one is perceiving them (rather than imaging them), and that subliminal or 'unmonitored' messages of distress are mistaken for self-generated distress.

Disruption by the 'internal' subliminal word WRONG seems to us consistent with the fact that disruption was limited to mathematically competent males.

Indeed, 'repression' itself is a mode of processing fearful information: a mode in which subjects suspend their self-awareness that they are perceiving fearful stimulation, as research by Kunzendorf and McLaughlin has demonstrated. This selective suspension of monitoring provides immediate relief from fearful stimuli, Freudian or otherwise, but it does so at the risk of turning self-conscious fear into subconscious anxiety (into consciously lingering fear without a self consciously perceived source). No subconscious realm full of lurking fears is implicated in this 'unmonitored' mode of self-protection. All that is implicated is an unconscious storehouse of potentially fearful memories--potentially fearful but sensationless memories, which can be 'suppressed' from conscious sensory representation or 'constructed' into conscious memory images or 'subconsciously represented' as unself-consciously imaged sensations.

Martin, Maryanne (1990). On the induction of mood. Clinical Psychology Review, 10, 669-697.

#### NOTES

Increasing interest in the relation between emotion and cognition has led to the development of a range of laboratory methods for inducing temporary mood states. Sixteen such techniques are reviewed and compared on a range of factors including success rate, the possibility of demand effects, the intensity of the induced mood, and the range of different moods that can be induced. Three different cognitive models (self- schema theory, semantic network theory, and fragmentation theory) which have been successfully used to describe long-term mood states, such as clinical depression, are elaborated to describe the process of temporary mood induction. Finally, the use of mood induction is contrasted with alternative methods (such as the study of patients suffering from depression) for investigating emotion.

**1989**

Blum, Gerald S. (1989). A computer model for unconscious spread of anxiety-linked inhibition in cognitive networks. Behavioral Science, 34, 16-45.

Unconscious inhibitory processes, triggered by a potential anxiety reaction, are reviewed in the context of an emerging rapprochement between psychodynamic and cognitive approaches in experimental psychology. Conditions underlying spread of inhibitory action to other cognitive networks are first explored in three tachistoscopic experiments utilizing words posthypnotically tied to a potential anxiety, pleasure, or neutral reaction. Response times of subjects, instructed to ignore those words while naming pictures or solving anagrams as quickly as possible, reveal a highly differentiated pattern of circumstances governing likelihood of inhibitory spread from anxiety-linked words to target stimuli. Next a computer model is constructed to simulate cognitive processes from onset of display to eventual response, and the model is then tested for its fit to the empirical data. Finally, an illustrative study shows that a subset of computer- generated predictions for spread of inhibitory action is verifiable experimentally.

Edelson, Jeffrey; Fitzpatrick, Jody L. (1989). A comparison of cognitive-behavioral and hypnotic treatments of chronic pain. Journal of Clinical Psychology, 45, 316-323.

27 male chronic pain patients were assigned to 1 of 3 treatment groups: hypnosis, cognitive-behavioral, and attention control. Hypnosis and cognitive-behavioral treatments were identical, with the exception of the hypnotic induction. Scores on the McGill Pain Questionnaire (MPQ) and a measure of the overt motor behavior element of chronic pain were collected at pretreatment, posttreatment, and follow-up intervals. Analyses showed significant increases in activity and decreases in pain intensity for the cognitive-behavioral treatment. Changes for the hypnosis treatment were noted only on the MPQ. Changes for both groups were sustained on the 1-mo follow-up. Findings generally support the superiority of the cognitive-behavioral treatment on behavior measures and its equivalence to hypnosis on subjective measures.

**1989**

Jupp, J. J.; Collins, J. K.; Walker, W. L. (1989). Relationships between behavioural responsiveness to hypnotic suggestions and estimates of hypnotic depth following 11 sequential instances of hypnosis. Australian Journal of Clinical and Experimental Hypnosis, 17, 93-98

Behavioral responsiveness to suggestions was assessed in an initial hypnosis session, and hypnotic depth was assessed in this session, followed by 10 weekly standardized hypnotic experiences. Correlations were calculated between behavioral responsiveness, initial and subsequent depth estimates, and between successive trance depth estimates. Levels of trance depth estimates were found to increase through weeks 1 to 11. Significant positive correlations were found between behavioral responsiveness scores and trance depth estimates to the fourth week but not beyond. Significant positive relations were found between successive estimates of trance depth except for the correlation between estimates for the fourth and fifth weeks. These results are discussed in terms of the estimates of trance depth being attributions from self-observations of behavioral responsiveness to hypnotic suggestions.

Matheson, George; Shu, Karen L.; Bart, Catherine (1989). A validation study of a short-form hypnotic-experience questionnaire and its relationship to hypnotizability. American Journal of Clinical Hypnosis, 32, 17-26.

#### NOTES

Investigated the validity of a 16-item scale inquiring about hypnotic experience, drawn from the Hypnotic Experience Questionnaire developed by Kelly (1985) to measure components of hypnotic experience. We administered the HEQ-S and the Harvard Group Scale of Hypnotic Susceptibility: Form A (HGSHS:A) to 198 students. Factor analysis of the scale produced three stable principal components accounting for 70% of the data variance: Dissociation/Altered State (DAS), Rapport (RAP), and Relaxation (REL). Subscales representing these three factors and a composite measure, "General Depth," were constructed. Subscale correlations with HGSHS:A scores were highest for the DAS subscale (.69) and lowest for REL (.41). Applications of the HEQ-S in clinical and research use are considered.

Using the phenomenological studies and theories of J. R. Hilgard (1979) and Shor (1962), Kelly (1985) constructed the Hypnotic Experience Questionnaire (HEQ), a 47- item scale designed to demonstrate the existence of five factors of the hypnotic experience. These factors included dissociation/altered state, relaxation, rapport, visual imagery, and a negatively correlated factor of cognitive rumination measuring the amount of anxious self-reflective, and interfering thought. A composite scale, General Depth, was also derived to provide a summary measure of the subjective quality of the hypnotic experience. The HEQ was developed as a research instrument.

The HEQ-S was administered immediately after Ss completed the Harvard response record. Items were responded to on a 5-point Likert scale ranging from one (No, none or not at all) to 5 (Yes, a great deal, or almost completely).

de Groh, Margaret (1989). Correlates of hypnotic susceptibility. In Spanos, Nicholas P.; Chaves, John F. (Ed.), Hypnosis: The cognitive-behavioral perspective (pp. 32-63). Buffalo, NY: Prometheus Books.

#### NOTES

The author describes a non-linear relationship between imagery and hypnotizability and between absorption and hypnotizability. People good at imagery may be high or low on hypnotizability scales; the same is true for people high on absorption trait. However, people low on those traits generally are low on measured hypnotizability.

Cross, W. P.; Spanos, Nicholas P. (1988-89). The effects of imagery vividness and receptivity on skill training induced enhancements in hypnotic susceptibility. Imagination, Cognition and Personality, 8, 89-103.

#### NOTES

This article is cited by Spanos & Flynn (1989) as indicating that high hypnotizability requires imaginative skills that some people do not possess in sufficient degrees.

#### 1988

De Pascalis, Vilfredo; Silveri, Alessandra; Palumbo, Giovanni (1988). EEG asymmetry during covert mental activity and its relationship with hypnotizability. International Journal of Clinical and Experimental Hypnosis, 36, 38-52.

Parietal-occipital EEG was recorded bilaterally while 20 high and 20 low hypnotizable Ss performed, in the eyes-closed condition, 2 covert right-hemisphere tasks (visual long-term memory and fantasy) and 2 covert left-hemisphere tasks (multiplication and verbal long-term memory). Ss were not, however, hypnotized during any aspect of the psychophysiological testing. After each task, Ss rated orally their degree of involvement in the tasks. The integrated amplitude alpha, the alpha density, and the alpha ratio as a measure of hemispheric asymmetry, were evaluated. Finally, the proportion of relatively greater right activation periods during right-hemisphere tasks minus the analogous proportion during left-hemisphere tasks was used as index of hemispheric specificity. The high hypnotizable Ss showed significantly higher alpha amplitude than the low hypnotizables; the alpha amplitude was correlated with hypnotizability, while the alpha density was not. The alpha amplitude of the right hemisphere during right-hemisphere tasks was significantly lower than the same amplitude during left-hemisphere tasks, while no significant differences related to task-type were detected in the left hemisphere. The pattern of task-effect on alpha ratio scores was the same as that on alpha amplitudes. Verbal and multiplication ratings were related to the alpha ratio, imaginative- visual memory ratings were not. No differences in hemispheric specificity between high and low hypnotizable Ss were found to exist, and no relationship between hypnotizability and hemispheric specificity was observed.

## NOTES

The authors review the literature on differences between the two hemispheres' involvement during hemisphere-specialized tasks. The ratio between left- and right-hemisphere alpha amplitudes has been shown to be a reliable measure of hemisphere lateralization as a function of task demands (Amochaev & Salamy, 1979).

They also review the literature on EEG asymmetry and hypnotizability. Most investigations used tasks with a problem solving component, whereas this study used "a covert numeric task and other covert self-generated tasks in which the range of cognitive activities resembled natural thinking" (p. 40).

Purposes of this research were "to investigate whether (a) the amount of alpha in EEG is correlated with hypnotizability, (b) high hypnotizable Ss would reveal higher hemispheric specificities during covert mental tasks than low hypnotizable Ss, and (c) verbal-numeric tasks involve more left-hemisphere activation and imaginative-visual tasks more right-hemisphere activation" (p. 40).

The subjects were 40 women (from an original pool of 71), aged 19-23, with no previous experience using hypnosis. To minimize the possible effects of expectation, hypnosis was not mentioned in the invitation to participate in research. All subjects were tested first with the Harvard Group Scale of Hypnotic Susceptibility, then with the Stanford Scale of Hypnotic Susceptibility (SHSS:C). The SHSS:C was used to select 20 high hypnotizables (defined as having a score 1 standard deviation above the group mean of 6.51) and 20 low hypnotizables (with scores 1 standard deviation below the group mean). The mean score for highs was 10.05 (S.D. = .88) and mean score for lows was 2.75 (S.D. = 1.49).

Although subjects were selected on the basis of their measured hypnotizability, hypnosis was not used during the investigation's psychophysiological testing. However, they were required to relax and keep eyes closed during trials on the tasks. After each trial, the subjects rated their involvement in the task.

Tasks used for this research were: 1. Visual long-term memory. Ss were asked to recall from memory pictures, places, faces, or visual scenes that were in a movie, but not scenes with a negative content. 2. Fantasy. Ss were requested to fantasize about something new that they like (nothing from past experience, and nothing sexual). 3. Multiplication. Ss were asked to multiply 2 serially, as,  $2 \times 2 = 4$ ,  $\times 2 = 8$ , etc., and to do it verbally without visual representation. 4. Verbal long-term memory. Ss were requested to think of some poem, speech, or other verbal material that they could recall from memory, and to repeat it mentally, to themselves.

Results can be summarized as follows.

Hypnotizability correlated .38 and .35 with right alpha amplitude and left alpha amplitude during baseline (statistically significant).

There was a significant association between alpha density and hypnotizability, when the group was divided at the median on density. (Alpha density = the time periods in which the alpha was present over the 6-second epochs accumulated during each 1-minute period which preceded the tasks). This association may be seen in the Table that follows:

SHSS:C Alpha Density Low High

+ 6 13

- 14 7

Chi Square = 3.61,  $p < .05$

There was a significant interaction between type of task (verbal-numeric, imaginative-visual memory) and hemisphere, which was attributable to changes in alpha amplitudes in right hemisphere, according to tasks. "Alpha amplitude of the right hemisphere during right-hemisphere tasks was significantly lower than during left-hemisphere tasks, while no significant differences were detected in the left hemisphere as a result of the differences between left- and right-hemisphere tasks" (p. 44)

Alpha ratio =  $(\text{Right-hemisphere alpha} - \text{Left-hemisphere alpha}) / (\text{Right-hemisphere alpha} + \text{Left-hemisphere alpha})$  exhibited the same pattern as for alpha amplitudes. The ANOVA 2 (high/low)  $\times$  2 (right tasks/left tasks) repeated measures on alpha ratio revealed a significant main effect for tasks, and a significant interaction between right-left tasks and hypnotizability. "During right-hemisphere tasks there were no significant differences ( $p < .5$ ) [sic] in alpha ratio between high and low hypnotizable groups, while during the multiplication task, the low hypnotizable Ss evidenced a higher mean alpha ratio ( $p < .05$ ) than the high hypnotizable group (.08 & .04, respectively); identical ratios were found during verbal tasks" (p. 45).

Task involvement was expected to be positively related with left-hemisphere tasks, but negatively related to right-hemisphere tasks (i.e. greater subjective involvement in the task would be associated with more negative alpha ratios, showing a bias towards right-hemisphere activation. "Verbal ratings were substantially related to alpha ratios ( $\rho = 0.82$ ;  $p < .01$ ), and multiplication ratings moderately related to alpha ratios ( $\rho = 0.31$ ;  $p < .05$ ); visual memory and fantasy ratings were not related to alpha ratios ( $r = -.04$  &  $r = -.18$ , respectively)" (p. 45).

Hemispheric specificity was defined as the proportion of greater relative right-hemisphere activation periods during right-hemisphere tasks minus the analogous proportion during left-hemisphere tasks. The authors did an analysis to "verify whether the task rating moderates the hemispheric specificity (i.e., the level of subjective involvement in a task is related to the level of hemispheric lateralization, while S is carrying it out)" (p. 46). They concluded that hypnotizability (SHSS:C) is not significantly related to Ss' hemispheric specificity.

In the discussion, the authors present a Table summarizing the results of similar investigations. They mention that the alpha-hypnotizability relationship may depend on which alpha variable is taken into account, or whether eyes-open/closed is varied. They conclude that the different methodological procedures render any comparison of results across studies very difficult.

They note that there was a significant correlation between alpha amplitude and hypnotizability even though Ss did not know in advance that hypnosis would be part of the experiment (the hypothesis proposed by Dumas, 1977, to account for this type of correlation). "One possible explanation of these data might lie in a different level of arousal in the high and low hypnotizable Ss: the high hypnotizable Ss might have been simply more relaxed than the lows.

"Nevertheless, his explanation must be taken with caution. The study of Paskewitz and M. T. Orne (1973), in fact, pointed out that in dark-adapted Ss, the relaxation condition does not produce increases of alpha activity. In a further study, contrary to previous reports, M. T. Orne and Paskewitz (1974) also found that a reduction in alpha activity is not a necessary consequence of apprehension or heightened arousal. Thus, it is not yet clear whether a decrease in anxiety tends to cause an increase in alpha density and vice versa" (p. 48).

1988

Dywan, Jane (1988). The imagery factor in hypnotic hypermnesia. International Journal of Clinical and Experimental Hypnosis, 36, 312-326.

Week-long repeated recall attempts were used as baseline against which to assess the effects of hypnosis on the recall of pictures. Hypnosis increased errors for all Ss but especially for high hypnotizables. In Experiment 1, dividing Ss on the basis of imagery ability had the same effect on recall as dividing them on the basis of hypnotic ability. In Experiment 2, imagery ability was found to interact with hypnosis in mediating the level of error during waking trials. Results do not support the claim that hypnosis enhances recall, but they do suggest that further study is needed to clarify the role that imagery ability plays in recall patterns over time.

#### NOTES

Author reviews research indicating that introduction of confident errors is a reliable finding in hypnosis-memory research, and notes that the role of imagery ability has not as yet been examined even though imagery is viewed as important to memory functioning. She also reviews the imagery- hypnotizability correlation literature.

EXPERIMENT 1 involved 54 Ss screened by Harvard Scale and SHSS:C, divided into highs (7-12) and lows (1-6) by SHSS:C. Stimuli were 60 black and white line drawings. There were 3 baseline trials in the lab; Ss were then given 6 envelopes, each containing a 60 blank item recall sheet, and asked to complete one each day and return it via campus mail. (When unable to recall more items, they were asked to draw a line under the last item recalled and then use "educated guesses." ) After a week of repeated recalls, Ss in the hypnosis condition were told they would be able to 'see' the slides appear before them; in the task motivating condition Ss were informed about such things as context dependent recall, the importance of focused attention, and the importance of good recall for forensic investigations.

Results were analyzed for increase in recall over the cumulative number of correct items recalled. Neither hypnotizability nor visual imagery ability influenced the cumulative baseline measures. High hypnotizable Ss produced a small but significantly greater increase in new, correct information during hypnosis than other Ss, but also made 3 times as many errors.

Dividing Ss by imagery score produced similar results. That is, people with very good imaging ability reacted in the same manner as the highly hypnotizable Ss: in hypnosis they increased the number of items they were willing to call a memory but also increased the number of errors.

**EXPERIMENT 2** differed from Experiment 1 in that Ss were selected for hypnotic ability and imagery ability so that both would be adequately represented. (The high hypnotizable - low visual imagery group is a group that hasn't been represented much in earlier research, and the author notes that those Ss are rather difficult to locate. ) The task motivation condition was not used, based on results of Experiment 1. Ss who were low on hypnotizability and imagery ability served as the controls.

Ss were told that they could be either in a hypnosis condition or a control condition but actually all Ss received a hypnotic induction. (This is like the London- Fuhrer, 1961, research design, which goes on the assumption that low hypnotizables do not enter into hypnosis even though they are exposed to an induction. Thus, hypnotic effects are not assumed for lows in the hypnotic condition and they become "controls.")

Results of correct and error recall over the baseline week were analyzed. There was no difference in correct recall as a function of hypnotic ability or visual imagery ability. However, there was a main effect for visual imagery ability and for hypnotizability, and a significant interaction between trials, for cumulative errors over the baseline week.

Effects of hypnosis were weaker than in Experiment 1 but followed same pattern. Those Ss most likely to have been hypnotized (highs) produced slightly more correct information than lows, and showed a greater increase in errors than lows. However high and low visualizers did not differ in response to hypnosis for correct information or for errors.

Since there was an interaction between hypnotic ability and visual imagery ability for error rate during waking trials, the author tested for the interaction during hypnosis. Using a 2 x 2 ANOVA with new errors as the dependent measure; no interaction was found. Hypnotic ability was therefore responsible for determining Ss' responses in the hypnosis condition. Author attributes the effect to being hypnotized rather than to individual differences in hypnotizability or to context effects.

**DISCUSSION** includes the author's delineation of differences between the two experiments that might explain differences in results. The increase in errors that was observed may be due to increased fluency in producing items under hypnosis (Sheehan & Tilden, 1984, 1986) or to a shift in reporting criterion (e.g., M. T. Orne, Soskis, Dinges, & E. C. Orne, 1984).

"Both high and low hypnotizable Ss produced more memories in the task-motivating condition, and low hypnotizables are not totally immune from the effect in the hypnotic context. What the report-criterion hypothesis does not explain is the reason why the memory reports of high hypnotizable Ss are differentially affected by task demands (e.g., task-motivating instructions versus hypnosis in Experiment 1) nor why hypnotized Ss so often seem surprised by the ease with which information seems to be 'recalled' during hypnosis . An alternative hypothesis is that being hypnotized results in a shift to a more imagistic style of information processing. The enhanced vividness of items generated during the retrieval process may convince Ss that these items must have been part of the original stimulus presentation (Dywan, 1985).

"Whatever the mechanisms might be, it is clear that the hypnotic effect is the result of an interaction between contextual factors and pre-existing characteristics of the individual. Moreover, these same mechanisms would likely be at work when hypnosis is actually used in the forensic situation, where the pressure to retrieve information could be more acute than what can be mustered in the experimental context. This should cause some concern because the differential increase in errors did not occur only for the relatively small proportion of Ss who were very high in hypnotic ability. The 'high' hypnotizable group in these experiments consisted of Ss of moderate to high levels of hypnotic ability and so the results can be generalized to at least one-half the population" (p. 323).

"In summary, it would seem that any pressure for Ss to increase their recall--whether it be repeated trials, task-motivating instructions, or hypnotic suggestion--results in higher levels of output and lower levels of accuracy. Repeated recall attempts lead to increases in recall and in errors. Some Ss (viz., those with high levels of hypnotic ability and low levels of imagery ability) are particularly prone to producing false-positive responses over the course of repeated recall attempts. When Ss are pressed to recall more information, they all try to do so by increasing their output and this increased output is usually accompanied by an increase in error. When hypnosis is introduced, however, those Ss who are hypnotizable show a differential increase in output. The amount of new correct information retrieved by hypnotized Ss is small and not a highly reliable phenomenon. The increase in errors that occurs in the recall of hypnotized individuals, however, is a substantial and highly reliable effect. Irrespective of how many errors were made as a function of repeated recall attempts, hypnosis can be counted on to increase errors over and above the increases in errors that occur when Ss are not hypnotized. Further work is needed to identify the mechanisms involved in the hypnotic distortion of recall. The role that imagery ability might have in the context of waking and hypnotic recall has not been resolved and this also presents an interesting problem for future study" (pp. 323-324).

Fine, C. G. (1988). Thoughts on the cognitive perceptual substrates of multiple personality disorder. Dissociation, 1, 5-10.

Although MPD [multiple personality disorder] patients typically present to treatment with affective symptoms, trauma-related information is originally encoded in the patients' perceptions and mediated by their cognitions. This paper describes the dysfunctional assumptive and perceptual categories that form the building blocks of MPD patients' distorted experiences. Perceptual shifting techniques and cognitive reframing will consequently be the recommended interventions prior to therapeutic abreactive work.

Gabel, Stewart (1988). The right hemisphere in imagery, hypnosis, rapid eye movement sleep, and dreaming: Empirical studies and tentative conclusions. Journal of Nervous and Mental Disease, 176, 323-331.

Reviews studies that have addressed the issue of whether there is an increased

activation or efficiency of right-hemispheric processes during imagery, hypnosis, REM sleep, and dreaming. Evidence strongly supports the notion of increased right-hemispheric activation in simple imaginal or visual states during usual consciousness. There are also studies supporting this view of REM sleep, dreaming, and hypnotic phenomena. It is concluded, however, that the lack of adequate studies, contradictory or negative findings, and moderating variables (e.g., task difficulty, cognitive style) make it difficult to draw definitive conclusions concerning right-hemispheric processes.

Gorassini, Donald R.; Hooper, Cynthia L.; Kitching, Kathleen J. (1988). The active participation of highly susceptible hypnotic subjects in generating their hypnotic experiences. Imagination, Cognition and Personality, 7 (3), 215-226.

Hypnotized individuals have traditionally been considered to be detached from the control of their own suggested behavior. We tested this and the alternative notion that hypnotized subjects attempt to self-generate the experiences (i.e., mainly of involuntariness) as well as produce the behaviors thought to be prototypical of high hypnotic ability. In an experimental investigation, highly susceptible hypnotic subjects were found to engage in the kind of imaginative activity that would be expected of individuals who were attempting deliberately to generate their experiences of involuntariness; they engaged as actively in imagery-generation as did subjects who were specifically instructed to imagine during suggested responding, and they experienced as much involuntariness as subjects in whom suggested movements were produced by an external physical force. The implications of these findings for the neodissociation and social psychological theories of hypnotic responding are discussed.

1987

Friedman, Howard; Taub, Harvey A.; Sturr, Joseph F.; Monty, Richard A. (1987). Visual information processing speed in hypnotized and nonhypnotized subjects. Journal of General Psychology, 114 (4), 363-372.

Using a backward-masking paradigm with a bias-free and ceiling-free psychophysical task, we tested hypnotized and control subjects for speed of visual information processing. Approximately half of each group received visual imagery suggestions in an attempt to influence attention. Imagery produced no significant differential effect. Although an absence of a hypnotizability-performance relationship was in keeping with findings of a previous study, those subjects in the present study who performed under hypnosis were, as a group, significantly superior to the other subjects in speed of information processing.

Geiselman, R. Edward; Machlovitz, Helen (1987). Hypnosis memory recall: Implications for forensic use. American Journal of Forensic Psychology, 1, 37-47.

NOTES

Examines 38 major published experiments (1930-1985) on hypnosis memory recall. Concludes that differences in experimental methodology significantly predict the success versus failure of hypnosis aided recall and remarks that, "Even if forensic hypnosis aids in the solution of only a small percentage of cases, it is still a valuable tool from the perspective of law enforcement." As Tarasoff has balanced the right of the victim to enjoy protection from violence with the patient-litigant's right to confidentiality, so too does the increased acceptance of hypnotically induced testimony go toward redressing in part the uneven balance between the slender compensations afforded the innocent victim of violent crime and the multiple constitutional protections and indemnities enjoyed by criminal perpetrators in our judicial system.

Gfeller, Jeffrey D.; Lynn, Steven Jay; Pribble, W. Eric (1987). Enhancing hypnotic susceptibility: Interpersonal and rapport factors. Journal of Personality and Social Psychology, 52 (3), 586-595.

This research supported the hypothesis that hypnosis can be thought of as a set of potentially modifiable social-cognitive skills and attitudes. A low-interpersonal-training treatment devised by Gorassini and Spanos (1986) was compared with a treatment designed to modify not only cognitive factors but also to augment rapport with the trainer and diminish resistance to responding (high-interpersonal training). Fifty percent of the initially un hypnotizable subjects in the high-interpersonal condition tested as being highly susceptible to hypnosis (high susceptibles) at posttest on the Harvard Group Scale of Hypnotic Susceptibility (Shor & Orne, 1962); 25% of the un hypnotizable subjects in the low-interpersonal condition responded comparably. Eighty-three percent of the medium- susceptibility (medium susceptibles) subjects tested as being highly susceptible at posttest in both conditions. Practice-alone control subjects' performance was stable across testings. The study was the first to demonstrate that treatment gains generalize to a battery of novel, demanding, suggestions (generalization index) that have been found to differentiate highly susceptible subjects from un hypnotizable simulating subjects. The importance of rapport was evidenced by the finding that rapport ratings paralleled group differences in hypnotic responding and that rapport correlated substantially with susceptibility scores at posttest and with the generalization index. Whereas initial hypnotizability scores correlated significantly with retest susceptibility scores, initial hypnotizability failed to correlate significantly with the generalization index.

#### NOTES

On p. 593 one could get the impression that S's feelings of rapport may result from success in the hypnotic experience.

1987

Jacobs, Sharon B.; Salzberg, Herman C. (1987). The effects of posthypnotic performance-enhancing instructions on cognitive-motor performance. International Journal of Clinical and Experimental Hypnosis, 35, 41-50.

The effects of performance-enhancing instructions on a cognitive-motor task (typing) was assessed using 3 groups: hypnosis and control groups with performance-enhancing instructions, and a control group without instructions. Unlike previous hypnosis research, the performance-enhancing instructions were given after substantial learning had occurred. Results indicated that posthypnotic performance-enhancing instructions, or performance-enhancing instructions alone, did not have a facilitative effect on performance. The results also suggested potential negative performance effects following hypnotic induction, depending on Ss' initial typing ability. The implications of these findings are discussed.

#### NOTES

The research investigated whether hypnotic suggestions could influence various factors thought to inhibit peak performance by increasing confidence, increasing motivation, and decreasing performance anxiety. 84 undergraduates of varying levels of typing ability were recruited, not mentioning in advance that the research involved hypnosis (in order to avoid selection bias). The experimental materials included a modified version of the Apple Typing Tutor program, which measures words per minute (WPM), key strokes missed (KM), and net words per minute (NWPM, which was obtained by subtracting 2 (KM) from WPM). These measures were obtained for the average of every 9 paragraphs.

Subjects received nine practice sessions and then were assigned to Experimental or Control group based on NWPM and sex. The hypnosis group received the Stanford Hypnotic Susceptibility Scale, Form C, minus suggestions for drowsiness, sleepiness, or posthypnotic amnesia. Additional suggestions for performance enhancement were introduced. The control group watched a film. The average of every nine paragraphs was used.

The analyses of variance for dependent measures revealed no significant effects except for one interaction effect that actually was in the unexpected or wrong direction. That effect appeared to be spurious as it was due to extreme errors produced by one subject.

"Only speed of typing (WPM) changed from pre to posttreatment, and this effect interacted with ability level. Post hoc analyses (Scheffe) indicated that beginner typists became less proficient, intermediate typists did not change, and advanced typists became more proficient" (p. 46).

Hypnotizability on SHSS:C did not correlate with change on NWPM.

A 3 x 3 x 2 ANOVA indicated a significant change over time on KM. "Although no change occurred from pretreatment to posttreatment, there was a decrease in errors at follow-up. There was also a significant Group x Level x Time interaction for KM ( $F = 2.57, p < .05$ ). This was accounted for by post hoc analyses showing that hypnotized beginner Ss changed over time, while control beginner Ss did not. Hypnotized Ss made significantly more errors following hypnosis than at pretreatment or follow-up" (p. 46).

"There was a significant main effect for time on NWPM. ... The Ss' overall typing performance decreased from pretreatment to posttreatment, but increased at

follow-up. Only the advanced Ss demonstrated significant improvement between pretreatment and follow-up.

"There was also a significant interaction between time and ability level on WPM. ... beginner Ss typed significantly slower at posttreatment than at pretreatment or follow-up" (p. 47).

In their Discussion, the authors note that the outcomes of their investigation are consonant with results obtained by other investigators studying hypnosis effects on skills (Arnold, 1971; Edmonston & Marks, 1967). In contrast, earlier studies on reaction time demonstrated that either motivational instructions and/or alert hypnotic inductions improved performance (e.g. Ham & Edmonston, 1971; Rader, 1972). They raise the question whether Ss' relaxation following hypnosis may have slowed response time and canceled the effects of motivating instructions.

"When looking at all groups combined, Ss did not improve between pretreatment and posttreatment. At follow-up, however, Ss showed significant improvement on two out of the three measures. This suggests that learning had occurred, but that temporary inhibitory factors such as S restlessness and indifference observed by Es may have affected performance at posttreatment. The length of the task (90 minutes in one sitting) may have been responsible for the fatigue and boredom that seemed to set in. It is probable that the performance-enhancing instructions were not potent enough to counteract these effects. At follow-up (which took much less time) fatigue and boredom were apparently absent, hence typing improved. In addition, other factors may have affected performance (e.g., anxiety, lack of motivation). The data indicate that Ss of different ability levels responded differently over time.

"The results of the present study cast doubt on the utility of hypnosis in improving performance on a cognitive-motor task. Although there are many anecdotal reports of hypnosis improving performance, research studies indicate that hypnosis, with motivational instructions, is effective only in improving reaction time and not more complex measures of performance. This apparent inconsistency may be explained by considering the level of motivation of participants. It is likely that a person requesting hypnosis to help improve performance is more motivated than experimental Ss" (p. 48).

Kihlstrom, John F. (1987). The cognitive unconscious. Science, 237, 1445-1452.

Contemporary research in cognitive psychology reveals the impact of nonconscious mental structures and processes on the individual's conscious experience, thought, and action. Research on perceptual-cognitive and motoric skills indicates that they are automatized through experience, and thus rendered unconscious. In addition, research on subliminal perception, implicit memory, and hypnosis indicates that events can affect mental functions even though they cannot be consciously perceived or remembered. These findings suggest a tripartite division of the cognitive unconscious into truly unconscious mental processes operating on knowledge structures that may themselves be preconscious or subconscious

Subjects low and medium in hypnotic susceptibility were administered cognitive strategy and instructional set information and also practiced responding to test

suggestions in order to enhance susceptibility. Those in one modification treatment received this information both from the experimenter and by observing a videotaped female model who responded successfully to suggestions and reported on the cognitive strategies she used to do so. Those in a second modification treatment received the information and practice but were not exposed to the model. Low and medium susceptibles in a third condition (practice alone) received a hypnotic induction procedure and practice suggestions but neither modification information nor modeling. No-treatment controls performed a filler task. All subjects were posttested on two different susceptibility scales. Information plus modeling produced significantly greater increments on all objective and subjective indices of susceptibility on both posttests than did practice- alone or control treatments. Susceptibility increments in the information without model treatment always fell between those of the model and practice-alone treatments. In the modeling treatment, over half of the initial low susceptibles and over two thirds of the initial medium susceptibles scored as high susceptibles on both posttests. These findings provide strong support for a social-cognitive skill formulation of hypnotic susceptibility.

Laurence, Jean-Roch; Nadon, Robert (1986). Reports of hypnotic depth: Are they more than mere words?. International Journal of Clinical and Experimental Hypnosis, 34, 215-233.

The empirical work relating hypnotizability, the hypnotic situation, and the reports of hypnotic depth is reviewed and evaluated. Asking Ss to assess their hypnotic depth is a complex task involving the interaction of experiential, cognitive, and contextual variables. Accordingly, future experimental work should take into account this multidimensionality; phenomenological, situational, cognitive, and motivational factors implicated in verbal reports should be explored in terms of their respective relationships with both hypnotizability and self-ratings of hypnotic depth. More sophistication in the experimental inquiries of hypnotic depth is required in order to further our understanding of the cognitive and affective structures underlying the hypnotic experience.

#### NOTES

In past years, hypnotic susceptibility and hypnotic depth were regarded as the same thing, and depth was inferred from responses to test suggestions on hypnotizability scales (e.g. Davis & Husband, 1931; LeCron, 1953).

There has been little investigation of the relationship between Subjects' subjective experiences and reported "depth." Research suggests that "hypnotic depth reports are usually significantly higher for Ss who have undergone a hypnotic treatment than for those who have received task-motivation (Ham & Spanos, 1974; Spanos & Barber, 1968; Spanos, Stam, D'Eon, Pawlak, & Radtke-Bodorik, 1980); imagination-control; or relaxation-control instructions (Connors & Sheehan, 1978; Gilbert & Barber, 1972; Spanos & Barber, 1968; Spanos, Radtke-Bodorik, & Stam, 1980, Experiment 2)" (pp. 217-218). Others have found that changes in inward experiencing (e.g. feelings of unreality, a sense of disappearance of body parts) could

not be attributed simply to sitting quietly with the eyes closed (Barber & Calverley, 1979). [A footnote on p. 218 indicates some studies didn't find this difference between a hypnosis group and a task-motivation control group.]

When Ss are asked to estimate subjective depth after having experienced hypnotizability test items, they are likely to infer depth from whether or not they passed the items (and indeed, early scales promoted that assumption). Reports of subjective depth taken before rather than after the test items still correlate with overall hypnotizability score, though not to as high a degree (E. R. Hilgard & Tart, 1966; Tart, 1970). Although usually depth estimates correlate with hypnotizability in the .50 to .75 range (Perry & Laurence, 1980), the correlations were obtained in the hypnotic context, and Ss may use their own behaviors as one determinant of their estimated depth.

From another line of study it is observed that Ss' subjective depth may be at variance with behavioral performance on hypnosis scales (Bowers, 1981). High hypnotizables judge their own depth from their performance on cognitive items (e.g. amnesia, hallucinations) while mediums and lows judge their own performance based on their responses to motor items and challenge items (Kihlstrom, 1981). In one experiment on amnesia, it appeared that Ss did not judge their own depth by how well they did on the amnesia task (Spanos, Stam, D'Eon, Pawlak, and Radtke-Bodorik, 1980). "M. T. Orne (1966, 1980) has emphasized that although it is necessary to operationalize S's responses to hypnotic suggestions, behavioral concomitants are only valid if they accurately reflect subjective alterations in an individual's experience" (p. 221).

"The social-psychological approach (see Barber, 1969; Radtke & Spanos, 1981, 1982; Spanos, 1982; Wagstaff, 1981) rejects the notion of hypnotic depth as an indicator of a unique state. These authors argue that the reports of having been hypnotized reflect attributions made by Ss when confronted with a hypnotic context. ... Bem (1972) and Kelley (1972) have emphasized the idea that the more ambiguous an experience is, the more a person is likely to base his or her judgment primarily on available external information" (p. 222). In this case, defining the situation as involving "hypnosis" is one of the most potent predictors of Ss' reports of subjective experience (Spanos, Radtke-Bodorik, and Stam, 1980). Other variables that influence subjective depth estimates are the wording of the hypnotizability scale, expectancy, and information provided directly or indirectly. On the other hand, McCord (1961) found that his patients had widely disparate expectations for how they thought they would feel when hypnotized, so expectancy as a predictor would not necessarily determine specific experience.

Direct experimental work on predicting response to hypnosis test items from expectancies (Council, Kirsch, Vickery, & Carlson, 1983; Kirsch, Council, & Vickery, 1984) suggests that expectations may predict test response when people are given a cognitive skill type of induction, but not when given a 'typical trance' type of induction. Also, another study from that laboratory (Council & Kirsch, 1983) established that only when expectancies are assessed after an induction (but before the test items) do they effectively predict hypnotic behaviors. The present authors express the view that these results are difficult to account for on the basis of social

psychology theories that weight heavily the role of expectancy in generating hypnotic response.

When Ss are permitted to use several different descriptors for their experience (being hypnotized, experiencing the effects, being absorbed, and responding to the suggestions), most Ss rated their own experiences as nonhypnotic (Radtke & Spanos, 1982). This was particularly true for medium hypnotizable Ss. Thus, unidimensional scales purporting to measure "depth" actually force Ss to interpret their multi-aspect experience in terms of the investigator's frame of reference, in this case "hypnotic depth." Nevertheless, the highly hypnotizable Ss were the least likely to be swayed from their self description of being "deep" when offered alternative ways of describing their experience. This is concordant with results reported earlier by Barber et al. (1968).

"The attribution literature may provide clues as to why most highly hypnotizability Ss retain their high ratings of experienced depth when confronted with situational manipulations. Self-perception theory strictly applies when Ss' experiences are ambiguous, forcing them to fall back on contextual factors to make self-appraisals. The relationship between expectancies, absorption, effect of scale wording, and hypnotizability scores suggest, however, that high hypnotizable Ss do not rely heavily on contextual factors when assessing their levels of hypnotic depth. Most of these Ss maintain their reports of altered experiences, even when situational determinants are changed (Harackiewicz, 1979; Kihlstrom, 1984; Lepper, Greene, & Nisbett, 1973). Thus, the hypnotizability by depth scale interaction found by Radtke and Spanos (1981) may suggest that experiences reported by high hypnotizable S are not inherently ambiguous. Accordingly, self-perception theory may not apply to them" (pp.226-227).

In their Discussion, the authors state, "Several studies have attempted to relate personal, real-life events to the experience of hypnosis. A number of studies (e.g., As, 1963; Field, 1965; Shor et al., 1962; Wilson & Barber, 1982) have shown that absorption, tolerance of unusual experiences, automaticity, compulsion, and trust are related to the capacity to be hypnotized. Other studies (Bowers & Brenneman, 1981; Tellegen & Atkinson, 1974; Van Nuys, 1973) have shown that certain variants of attention are also related to hypnotizability. Extensive work by J. R. Hilgard (1970, 1979) has shown that patterns of personal development relate to hypnotizability in adult life. It appears then that hypnotizable individuals bring a host of experiences and abilities with them to the hypnotic context. It makes intuitive sense which is supported by the available empirical data, that a complex interaction among these experiences and abilities, the hypnotic context, and hypnotic responsiveness is implicated in Ss' assessments of their hypnotic depth. Studies are needed in which all of these potential determinants of hypnotic depth reports are taken into account. Only then will a clearer picture of their respective importance emerge" (p. 228).

1986

Lynn, Steven Jay; Rhue, Judith W. (1986). The fantasy-prone person: Hypnosis, imagination, and creativity. Journal of Personality and Social Psychology, 51, 404-408.

Experimenters selected subjects who ranged along the continuum of fantasy proneness and assessed hypnotizability, absorption, vividness of mental imagery (QMI; Sheehan, 1967), response to waking suggestion (Creative Imagination Scale), creativity, and social desirability (Crowne & Marlowe). Fantasy-proneness was evaluated with the Inventory of Childhood Memories and Imaginings (Wilson & Barber, 1981). Strong support was secured for J. R. Hilgard's construct of imaginative involvement and Wilson and Barber's contention that fantasy prone persons can be distinguished from others in terms of fantasy and related cognitive processes. Fantasizers were found to outscore subjects in both comparison groups on all of the measures of fantasy, imagination, and creativity, with social desirability used as a covariate. Low fantasy-prone subjects were no less creative or less responsive to hypnosis than their medium fantasy-prone counterparts.

Madigan, R. J.; Bollenbach, A. K. (1986). The effects of induced mood on irrational thoughts and views of the world. Cognitive Therapy and Research, 10 (5), 547-562.

Sixty college students participated in an experiment concerning the influence of somatic mood induction statements on measurements of irrationality as defined by Ellis. Subjects were randomly assigned to depression, elation, and neutral mood induction groups. There were significant differences between groups on mood and irrationality. Results are discussed in terms of the Ellis and Beck cognitive models of depression, the Isen cognitive loop model, and the relationship between irrationality and depression. This study added irrational thinking as defined by Ellis to the growing list of cognitions that have been manipulated by mood, and it supports a body of findings that demonstrate the reciprocal influence of cognition and mood in depression. The study also has implications for the Beck and Ellis hypothesis that cognitions are the dominant causes of depression.

Markus, Hazel; Nurius, Paula (1986). Possible selves. American Psychologist, 41 (9), 954-969.

The concept of possible selves is introduced to complement current conceptions of self-knowledge. Possible selves represent individuals' ideas of what they might become, what they would like to become, and what they are afraid of becoming, and thus provide a conceptual link between cognition and motivation. Possible selves are the cognitive components of hopes, fears, goals, and threats, and they give the specific self-relevant form, meaning, organization, and direction to these dynamics. Possible selves are important, first, because they function as incentives for future behavior (i.e., they are selves to be approached or avoided) and second, because they provide an evaluative and interpretive context for the current view of self. A discussion of the nature and function of possible selves is followed by an exploration of their role in addressing several persistent problems, including the stability and malleability of the self, the unity of the self, self-distortion, and the relationship between the self-concept and behavior

1985

Acosta, Enrique; Crawford, Helen J. (1985). Iconic memory and hypnotizability: Processing speed, skill or strategy differences?. International Journal of Clinical and Experimental Hypnosis, 33, 236-245.

The purported relationship between hypnotizability and speed of information transfer from iconic to short-term memory was studied in a comparison of 12 low and 12 high hypnotizable Ss. As in Ingram, Saccuzzo, McNeill, and McDonald (1979), high hypnotizable Ss showed less interference from a visual mask in the report of a briefly presented item than did low hypnotizable Ss when the mask delays were predictable. When the delay of the mask could not be anticipated, however, differences between high and low hypnotizable Ss disappeared. It is suggested that differences in information processing related to hypnotizability may be due to differences in strategy, skills, or other factors, rather than underlying information processing speed.

#### NOTES

Hypnosis may require concentrative or selective attention, which usually is measured by self-report (e.g. Absorption) or by experimental measures. Several investigations indicate that high hypnotizable people are better than low hypnotizables at focusing on a task and ignoring extraneous information (Brown, Crawford, Smith, Leu, & Brock, 1983; Graham & Evans, 1977; Karlin, 1979; Miller, 1975; Wallace, 1979; Wallace, Garrett, & Anstadt, 1974; Wallace, Knight, & Garrett, 1976). One way to study attentional processes is through the effect of presenting a mask (e.g. \$\$\$\$) shortly after presenting a stimulus (e.g. ABCDE). Ingram (1979) found that highs had faster information processing, but that might be due to anticipation bias associated with the method of limits employed. This study uses both an ascending method of limits, like Ingram, and a condition in which the mask delays were presented randomly within another block of trials.

#### RESULTS

"While the present study replicated Ingram et al.'s (1979) findings when an ascending method of limits was used (the same used by Ingram et al.) differences were not found in processing when ISIs were presented randomly. Thus, these results suggest that high and low hypnotizable Ss do not differ in their information transmission rates, but rather they may differ in other aspects which mediate performance in this task" (pp. 241- 242).

"Several lines of evidence point towards strategy or skill differences between high and low hypnotizable Ss as a possible explanation for the present findings. First, it was found that when Ss could anticipate the mask delay (the ascending condition), high hypnotizable Ss outperformed the low hypnotizables. When this anticipation was controlled, as in the random condition, the two groups did not differ when the data were scored by serial position. When the data were scored by a free recall scheme, there was a nonsignificant trend for high hypnotizable Ss to score higher than did the low hypnotizables. This trend suggests that high hypnotizable Ss may be more willing to guess, and to guess more accurately than low hypnotizables, when they have partial information about a letter, and/or they may have greater skill in

perceiving incomplete information. The latter suggestion finds indirect support from Crawford (1981) who reported that high hypnotizable Ss can process fragmented stimuli (Gestalt Closure tests, see Thurstone & Jeffrey, 1966), significantly better than can low hypnotizables. High imagers have been shown also to perform significantly better than low imagers in Gestalt Closure tasks (Ernest, 1980). At a speculative level, given that recent research has suggested that iconic memory may be a right hemisphere phenomenon (e.g. Cohen, 1976, but also see DiLollo, 1981), and high hypnotizable Ss outperform low hypnotizables on certain right hemisphere tasks (e.g. Crawford, 1981), it may be asked if the trends found with the free recall scoring scheme in the present study might be a reflection of differential right hemisphere processing. Such a hypothesis could be investigated in future research by comparing the performance of high and low hypnotizable Ss, as possibly moderated by visuo-spatial ability, for stimuli presented to the left versus the right visual hemifield (Ernest, 1983).

"A second set of evidence in favor of strategy differences was found in Saccuzzo et al. (1982) which was published after the data for the present experiment were collected. In the Saccuzzo et al. (1982) paper, which was an extension and replication of Ingram et al. (1979), the same mask delay was used throughout a 10-trial block. The order of the blocks (i.e., the mask delays) was random. Thus, while S did not know which mask delay was used in the first trial of a block, the remaining 9 trials were the same and could be anticipated. During the first session, high hypnotizable Ss outperformed the low hypnotizables, but these differences disappeared on the second testing session. These results suggest that practice may have affected performance, rather than any underlying information processing speed differences" (pp. 242-243).

Kerry Buhk; Rhue, Judith; Henry, Stephanie; Lynn, Steven Jay (1985, November). Fantasy proneness: Are their word associations richer?. [Paper] Presented at the annual meeting of the Society for Clinical and Experimental Hypnosis, Asheville, NC.

## NOTES

Experimenters screened 7000 students to get 6 samples of fantasy prone Ss (top 2.4% on Wilson and Barber's ICMI). They found less association between fantasy proneness and hypnotizability than did Wilson and Barber.

They had fantasizers hallucinate a second cup next to a first styrofoam cup. Results were that 87% of High fantasizers, < 50% Medium fantasizers, < 25% Low fantasizers could do it, but they didn't describe seeing the hallucinated cup "as real as real" as Wilson and Barber said they did.

Experimenters were concerned about context effects (expectancy) because the Creativity and Fantasy Proneness tests were run proximal in time, so they separated in time the administration of Fantasy Prone and Creativity tests and also looked at word associations.

23 High and 20 Low fantasy prone students selected by ICMI, which was administered to Subjects 18 mos before the creativity study. At the time of the creativity study, Ss were informed they were randomly picked. There were two 90' sessions, counterbalanced.

Sessions: 1. Hallucinate image of R.A. and of styrofoam cup. Other tests were administered for intelligence and personality: Shipley-Hartford, MMPI, Crowne-Marlowe, etc. 2. Creativity tests (Revised Art Scale, Hilgard's Alternate Uses; story production which was scored on detail, imagery and fantasy and on imagery nouns.) Results of this study which was independent of context (i.e. the tests being correlated were administered independently of each other, separated by time). 1. Fantasizers were more creative than low fantasizers on both Creativity Scales. 2. Fantasizers show more divergent thinking on Hilgard Alternate Uses test, but relationship between fantasy proneness and creativity were not strong,  $r = .30$ . 3. Fantasizers and non fantasizers did not differ on the story measures! This diverges from Wilson and Barber's results. Fantasizers may have more vivid images, but storytelling does not capture that.

1985

Geiselman, R. Edward; Fisher, Ronald P.; MacKinnon, David P.; Holland, Heidi L. (1985). Eyewitness memory enhancement in the police interview: Cognitive retrieval mnemonics versus hypnosis. Journal of Applied Psychology, 70, 401-412.

Compared effectiveness of three interview procedures for optimizing eyewitness memory performance: (a) the 'cognitive interview' based on memory-retrieval mnemonics from current memory theory, (b) the presently controversial hypnosis interview, and (c) the standard (control) police interview. Both the cognitive and hypnosis procedures elicited a significantly greater number of correct items of information from the Ss than did the standard interview. This result, which held even for the most critical facts from the films, was most pronounced for crime scenarios in which the density of events was high. The number of incorrect items of information generated did not differ across the three interview conditions. The observed memory enhancement was interpreted in terms of the memory-guidance techniques common to both the cognitive and hypnosis interviews. Neither differential questioning, time nor heightened subject or interviewer motivation could explain the results

Kelly, Paul James (1985, November). The relationship between hypnotic ability and hypnotic experience (Dissertation). Dissertation Abstracts International, 46 (5), 1690-B.

This study investigated the relationship between four types of hypnotic experience and hypnotic ability. The types of experiences were: dissociation, the experience of involuntariness, altered state effects, such as perceptual alterations and diminished reality sense rapport, transference-like involvement with the hypnotist, and relaxation. A 47-item scale, the Hypnotic Experience Questionnaire was developed to measure types of hypnotic experience. It was given to 484 subjects and then to a subsample of 272 students. When the scale was factored, four stable factors emerged: Nonconscious /Trance, Rapport, Relaxation, and Cognitive Rumination. A Group Profile Scale was also developed to measure students and when it was factor analyzed four factors were extracted: Hallucinations and Fantasies, Amnesias and

**Post-Hypnotic Compulsions, Motor Inhibition, and Direct Motor Suggestion.** "Two statistical approaches were used to investigate the connections between hypnotic ability and hypnotic experience . Canonical analysis was used to identify the main relationships between hypnotic ability and hypnotic experience and factor analysis was used to explore the relationship among measures of hypnotizability and hypnotic experience. Two canonical variates from the canonical analysis were significant. The first variate was characterized by a dissociative-imaginative involvement process, and the second variate tapped a rapport-social compliance process. "When 25 variables, representing components of hypnotic ability and hypnotic experience, were factored, five factors were extracted. Imaginative Involvement, Ideomotor Response, Rapport, Cognitive Inhibition, and Relaxation. The results of the factor analysis suggested that dissociative experience and altered state experience are related to hypnotic ability but rapport and relaxation are not. "The results of study, taken as a whole, suggest that relaxation and rapport may happen in the hypnotic situation, but neither experience is related to the condition of being hypnotized in any essential way. The results suggest that the hypnotic condition is characterized by dissociative experience, altered state experience, and by successful performance on hypnotic ability tasks. From a theoretical point of view, the results strongly supported Hilgard's theory, partially supported Shor's theory, and failed to support Edmonston's theory" (p. 1690).

**1984**

**Bakker, Dirk J. (1984). The brain as a dependent variable. Journal of Clinical Neuropsychology, 6, 1-16.**

The mainstream of neuropsychological research and practice has been devoted to the impact of the brain as an independent variable on behavior as a dependent variable. Evidence is currently available to make clear that the order of causation may be reversed: Behavioral changes can have a durable impact on the brain. The results of extensive research indicate that a large number of neuroanatomical, neurophysiological, neurochemical, and neuropsychological parameters of the animal brain can be modified through environmental manipulation, sensory experience, and systematic training. Some evidence is available to show that psychological stimulation has certain effects on the physiology of the human brain. For instance, hemisphere-specific stimulation through the presentation of words flashed in a visual hemifield appears to modify the electrophysiological activity of the contralateral hemisphere in dyslexic children and to affect their subsequent reading performance. Neuropsychology may profit from paying more attention to the ecology of the human brain.

#### **NOTES**

An 18th Century anatomist in Italy, Malacarne, demonstrated increased cerebellar folds in the brains of trained (vs. untrained) dogs and birds. His approach to neuroanatomy was not continued because psychology has been more concerned with innate traits of the individual, and because of philosophical rationalism (citing

Walsh, 1981). Until very recently, scientists have viewed the brain as "structurally insensitive to environmental experience" (p. 3).

Now we have evidence that animal brains are modifiable by experience, in gross morphology, fine (synapse) morphology, and neurochemicals. "Rich environments [for rats] ... produce heavier and thicker cerebral cortices and callosal connections (Walsh, 1981), larger cortex/subcortex weight ratios, larger cell bodies and nuclei (Walsh, 1981), and higher metabolic activity as suggested by increased RNA/DNA ratios (Rosenzweig, Bennett, & Diamond, 1972)" (p. 4). Enrichment leads to more extensive dendritic fields (occipital and temporal cortex, some hippocampal regions); this implies that each neuron has more synapses. Researchers have found large Purkinje-cell bodies and many dendrites in richly educated monkeys.

"Some evidence is available to show that 'preventive' and 'therapeutic' environments positively affect behavioral performances of brain-lesioned animals. However, knowledge about the brain mechanisms which underly these effects is, as yet, lacking" (p. 6). Rats that were handled during the first 21 days of life exhibited different brain lateralization from rats that were not (Denenberg, cited by Marx, 1983). Those stimulated early stored memories mainly in the right hemisphere.

The author also reviews evidence that human brains are psychologically modifiable. Children with astigmatism generate weakened cortical response to visual stimulation (Freeman & Thibos, 1973), because they experience difficulty in processing some visual-spatial patterns. People who have visual-field defects due to brain damage can improve in vision when forced to make eye movements toward lighted targets flashed in the blind areas (Zihl, 1981).

Bakker theorizes that hemispheric control of reading shifts from right to left during the learning-to-read process of normal readers; at least some aspects of reading are successively mediated by the right hemisphere at age 6 and by the left hemisphere at age 8, according to electrophysiological data in a longitudinal study (Licht, Bakker, Kok, & Bouma, 1983). He thinks P-type dyslexia results from continuing to rely on right- hemispheric strategies, leading to slow reading with fragmentation errors and repetitions. L-type dyslexia results from prematurely adopting a left-hemispheric strategy, i.e. at the very beginning of the learning process, making child insensitive to the perceptual features of script with consequent substantive errors such as omissions and additions. Thus, P- type dyslexics presumably show functional overdevelopment of the right hemisphere and L-types of the left hemisphere. Treatment would involve specific stimulation of the hemisphere that they are ignoring.

He presents data suggesting that "some electrophysiological parameters of the cerebral hemispheres can be modified in dyslexic children through hemisphere-specific stimulation and loading, and that these modifications may induce better reading" (p. 12).

Kelly, Paul James (1984, December). The relationship between hypnotic ability and hypnotic experience. Newsletter of Division 30, Psychological Hypnosis, of the American Psychological Association, 5.

This study investigated the relationship between four types of hypnotic experience and hypnotic ability. The types of experience were: dissociation, the experience of involuntariness; altered state effects, such as perceptual alterations and diminished reality sense; rapport, transference-like involvement with the hypnotist; and relaxation. A sample of 230 students was given the HGSHS:A, a group version of the SHSS:C, and the Hypnotic Experience Questionnaire (Kelly, 1984), a 47-item multidimensional scale of hypnotic experience. Items were taken from these tests to form 11 hypnotic ability variables (Positive Hallucinations, Dreams and Regressions, Post- Hypnotic Compulsions, Amnesia (HGSHS:A), Amnesia (SHSS:C), Arm Rigidity, Arm Immobilization, Other Motor Inhibitions, Head Falling, Moving Hands Together, and Hand Lowering). Fourteen hypnotic experience variables were also formed (Generalized Dissociative Effects, Dissociative Inhibition, Trance, Unawareness, Transference-like Involvement, Trust, Friendliness, Physical Relaxation, Mental Relaxation, Imagery Presence, Imagery Vividness, Imagery Detail, Self Consciousness, and Analytic Thoughts). The 25 variables were intercorrelated and factored with principal axis factoring. Five factors with eigenvalues greater than 1 were extracted and rotated to varimax criteria. These factors, which accounted for 54.4 percent of the variance, were called: Imaginative Involvement, Ideomotor Response, Rapport, Cognitive Inhibition, and Relaxation. Hypnotic ability variables loaded significantly on three of the factors (Imaginative Involvement, Ideomotor Response, and Cognitive Inhibition) and these three factors also tapped some aspect of altered state experience and/or dissociative experience. It was concluded therefore that dissociative experience and altered state experience are related to hypnotic ability. The remaining two factors, Rapport and Relaxation, showed significant loadings only for rapport variables and relaxation variables, respectively. Neither of these two factors were related to any of the traditional measures of hypnotic ability or to the experience of dissociative effects or altered state effects. The results of this study suggest that rapport and relaxation may happen in the hypnotic situation but neither experience is related to the condition of being hypnotized in any essential way. The hypnotic condition is characterized by dissociative experience, altered state experience, and by successful performance on hypnotic ability tasks. The results also raise questions about Edmonston's (1981) theory that relaxation is the essence of hypnotic responsiveness. The finding that the experience of relaxation is unrelated to hypnotic ability is more congruent with Hilgard's (1977) view that relaxation is a nonhypnotic process.

#### NOTES

This is an abstract of an unpublished Ph.D. dissertation, University of Waterloo, 1984. It won the American Psychological Association Division 30 award for Best Student Paper at the 1984 APA Convention.

Lynn, Steven Jay; Nash, Michael R.; Rhue, Judith W., Frauman, David C.; Sweeney, Carol A. (1984). Nonvolition, expectancies, and hypnotic rapport. Journal of Abnormal Psychology, 93 (3), 295-303.

Prior to hypnosis, subjects were informed either that hypnotizable subjects can resist motoric suggestions or that such control does not characterize good hypnotic subjects. During hypnosis, susceptible and simulating subjects received countering suggestions involving inhibiting suggestion-related movements. Susceptible subjects' responses were found to be sensitive to prehypnotic normative information. There was a corresponding tendency for reports of involuntariness to be sensitive to the expectancy manipulation. Furthermore, subjects were able to feel deeply hypnotized and to rate themselves as good subjects yet concomitantly experience themselves as in control over their actions when normative information supported this attribution. Reports of suggestion-related sensations but not imaginative involvement were associated with movements in response to countersuggestion. Simulators were unable to fake susceptibles' reports of sensations and involuntariness. However, for all subjects, movements paralleled expectancies about appropriate response, supporting the hypothesis that involuntary experiences are sensitive to the broad expectational context and are mediated by active cognitive processes. Also, rapport with the hypnotist was found to be a factor. Susceptible subjects with highly positive rapport resolved hypnotic conflict, in part, by achieving a compromise between meeting normative expectations and complying with the hypnotist's counterdemand.

1983

Council, James R.; Kirsch, Irving; Vickery, Anne R.; Carlson, Dawn (1983). 'Trance' versus 'skill' hypnotic inductions: The effects of credibility, expectancy, and experimenter modeling. Journal of Consulting and Clinical Psychology, 31 (3), 432-440.

A hypnotic induction procedure based on social learning principles (skill induction) was compared with a traditional eye-fixation/relaxation trance induction, a highly credible placebo induction, and a no-induction base-rate control. The trance induction surpassed the skill induction only on the Field Inventory, a measure of hypnotic depth that contains items corresponding to suggestions contained in the trance induction. Experimenter modeling was not found to enhance the effectiveness of the skill induction. Skill and trance inductions elicited slightly higher behavioral scores on the Stanford Hypnotic Susceptibility Scale: Form C than did the placebo induction. However, this difference was not obtained on other measures of hypnotic responsibility and depth. Significant correlations were found between expectancy, absorption, and responsiveness on all dependent measures. Multiple regression analyses indicated that the relationship between absorption and responsivity was mediated by expectancy. The results are interpreted as supporting the hypotheses that hypnotic responses are elicited by the expectancy for their occurrence and that induction procedures are a means of increasing subjects' expectancies for hypnotic responses.

#### NOTES

Trance induction resulted in a higher score on subjective experiences (cognitive & perceptual distortions) but not higher suggestibility scores than cognitive-

behavioral skill induction. 2) Trance and cognitive-behavioral inductions got slightly higher scores in suggestibility than placebo biofeedback induction. 3) All inductions did better than a "no induction" control group on subjective and behavioral indices of hypnosis.

One of the goals of this research was to examine the contribution of experimenter modeling to the behavioral skill induction that "trains the subject in hypnosis skills and requires the subject's conscious cooperation in learning cognitive strategies that will enhance hypnotic responsivity" (p. 432). Another goal was to assess the contribution of "a subject's expectancies for the occurrence of behaviors perceived as being involuntary" (p. 433). A third goal was to determine whether congruence between a subject's beliefs about hypnosis and the rationale for a particular induction would increase expectancy. Two different skill inductions were employed (one with, one without a model). Subjects were asked to predict their performance, based on a description of the induction that they would receive. The contributions of credibility and expectancy were assessed using a highly credible placebo (pseudo biofeedback of EEG theta rhythm).

The investigation used only subjects who had never experienced hypnosis.

Independent variables included Rotter's (1966) Internal-External Locus of Control Scale, Rotter's (1967) Interpersonal Trust Scale, and Tellegen's Absorption Scale (Tellegen & Atkinson, 1974). Mediating variables included a measure of induction credibility based on Borkovec and Nau (1972), and a 20-item inventory measuring expectancies for hypnotic performance. Dependent variables included 20 standard hypnotic suggestions taken from the Stanford Hypnotic Susceptibility Scale, Form C; the Creative Imagination Scale; ratings of the 'realness' or experienced intensity of each suggestion; and the Field Inventory of Hypnotic Depth (Field, 1965).

The authors conclusion reads as follows: "The results of this study may be summarized as follows: (a) Traditional trance hypnotic inductions and cognitive-behavioral skill inductions were shown to be equally effective in eliciting experiential and behavioral responses to hypnotic suggestions, although trance subjects reported a somewhat greater alteration in conscious experience. (b) Experimenter modeling was not found to be an effective component of the skill induction package. (c) Subjects' expectancies for hypnotic responses, reported prior to hypnotic induction, bore a very strong relationship to hypnotic responsivity. (d) A highly credible placebo induction resulted in levels of expectancy and hypnotic responsivity generally comparable to those produced by trance and skill hypnotic inductions. (e) Absorption was significantly correlated with expectancy, but was not found to be significantly related to responsiveness once variance due to expectancy was taken into account. Thus the relationship between absorption and hypnotic responsiveness appears to be mediated by expectancies.

"In sum, these results suggest that various hypnotic inductions elicit expectancies for responding to hypnotic suggestions and that these expectancies are sufficient to elicit hypnotic responses. Further studies are needed to determine the nature of the relationship between absorption and hypnotic response expectancies" (p. 439).

Dillon, F. Richard; Spanos, Nicholas P. (1983). Proactive interference and the functional ablation hypothesis: More disconfirmatory data. International Journal of Clinical and Experimental Hypnosis, 31, 47-56.

According to the functional ablation hypothesis, memories for which amnesia has been hypnotically suggested do not interact with other information in memory. This hypothesis was tested in 2 interrelated experiments. In Experiment 1, Ss high and low in hypnotic susceptibility were administered a hypnotic induction procedure and tested on a Brown-Peterson (e.g., Wickens & Gittis, 1974) memory task designed to induce proactive interference (PI). Ss were exposed to 10 blocks of successive 3-word lists. Within each block, all words were strongly related, and, therefore, lists presented early in a block interfered with the retention of lists presented later (PI "buildup"). Following the "buildup" of PI, Ss were administered either a cue to be amnesic for the previous words of a block or a cue to relax. Contrary to the functional ablation hypothesis, the amnesia suggestion did not produce a "release" from PI in high susceptible hypnotic Ss. In other words, the amnesia suggestion did not prevent previously learned material from interfering with newly presented material. Experiment 2 demonstrated that the amnesia cues employed in the Brown-Peterson task produced a reversible recall deficit even though they failed to produce PI "release." These findings are consistent with the results of studies of the functional ablation hypothesis using the retroactive interference paradigms.

1982

Crawford, Helen J. (1982). Cognitive processing during hypnosis; much unfinished business. Research Communications in Psychology, Psychiatry and Behavior, 7, 169-179.

Studies of cognitive processing during hypnosis per se are reviewed suggesting that hypnotically responsive individuals not only experience subjective changes during hypnosis that are seen as often being discontinuous from their normal consciousness but also may exhibit measurable cognitive changes. Evidence (ego functioning changes, enhanced creativity, enhanced imagery processing, etc.) is presented to support the hypothesis that hypnosis may involve a shift in cognitive functioning away from a verbal, detail-oriented strategy towards a more imaginal, non-analytic, holistic- oriented strategy. Limitations of present research and potentially valuable research areas are discussed.

#### NOTES

The author reviews evidence for cognitive changes during hypnosis--evident especially in high hypnotizables but also to some degree in moderate hypnotizables. She concludes that there may be changes in ego functioning, imagery functioning, creativity, and strategy preferences and that high hypnotizables are more flexible in cognitive processing . "The question remains whether or not there are accompanying objectively measurable cognitive changes during hypnosis" (p. 170).

**"In normal waking consciousness, the hypnotically responsive individual is typically found to be more involved in nonhypnotic imaginative activities and experiences (Hilgard, 1979; Tellegen & Atkinson, 1974), more able to image things (for review, see Sheehan, 1979) and daydream vividly and positively (Crawford, 1982), more able to perceive gestalt closure figures (Crawford, 1981), more able to divert attentional process (e.g., Karlin, 1979), and more creative on certain tasks (e.g., P. Bowers, 1979). Experiential reports indicate that it is these very cognitive processes, amongst others, which are perceived to be enhanced or changed during the hypnotic state" (p. 170).**

**"Levin and Harrison (1976) found that hypnosis ego changes occurred most in those individuals who also demonstrated good capacity for adaptive regression in the waking state" (p. 171).**

**"Dave (1979) compared hypnotically induced dreams with rational-cognitive treatment as to their effects on creative problem solving of the problems or projects. 'Conditional support' was given to the significantly stronger effect form the hypnotically induced dreams" (p. 172).**

**There are many investigations of the effect of hypnosis on imagery, with a number of methodological problems. "Self-reports can be criticized on the grounds that they are easily subject to demand characteristics, subject expectations, and social desirability influences. Coe et al. (1980) found order of condition influenced their findings, while Crawford (1979) found that imagery rating scales suffered from a low ceiling effect among high imagers" (pp. 172-173).**

**"Surprisingly, while the field of cognitive psychology has devoted extensive attention to the study of the enhancing effects of imagery upon memory, few of their paradigms have been applied to the study of hypnotic processing of information. Germaine to the field of hypnosis are three operational approaches to the investigation of imagery: (a) the manipulation of the availability of imagery as a coding device, such as varying the degree to which stimuli may evoke imagery, (b) the manipulation of the processing strategy in cognitive performance, such as asking subjects to use imagery in the mediation of stimuli information, and (c) the comparing of information processing strategies and performance in subjects who are low and high in imagery ability (Paivio, 1971)" (p. 173).**

**"Several studies (Nomura, Crawford, & Slater, 1981; Walker, Garrett, & Wallace, 1976; Wallace, 1978) found that a very few high hypnotizables can successfully produce eidetic imagery, using nonfakable stereograms, during hypnosis even though they cannot during waking. Spanos, Ansari, & Stam (1979) were unable to replicate these findings. It was only self-reported childhood eidetikers who exhibited eidetic imagery during hypnosis, and then only a few. This research suggests that hypnosis permits certain individuals to access the "lost" ability to image eidetically, possibly through a shift in cognitive strategies" (p. 174).**

**"An underlying emphasis of this paper is the need for hypnotic investigators to integrate findings from cognitive psychology into their research, as well as apply the many new approaches to understanding brain functioning which are now being developed, in their search for a better understanding of what occurs during hypnosis" (p. 176).**

**1980**

**Ericsson, K. Anders; Simon, Herbert A. (1980). Verbal reports as data. Psychological Review, 87 (3), 215-251.**

**NOTES**

**Proposes that verbal reports are data and that accounting for them, as well as for other kinds of data, requires explication of the mechanisms by which the reports are generated, and the ways in which they are sensitive to experimental factors (instructions, tasks, etc.). Within the theoretical framework of human information processing, different types of processes underlying verbalization are discussed, and a model is presented of how ss, in response to an instruction to think aloud, verbalize information that they are attending to in short-term memory (STM). Verbalizing information is shown to affect cognitive processes only if the instructions require verbalization of information that would not otherwise be attended to. From an analysis of what would be in STM at the time of report, the model predicts what could be reliably reported. The inaccurate reports found by other research are shown to result from requesting information that was never directly heeded, thus forcing Ss to infer rather than remember their mental processes. (112 ref)**

**1979**

**Karlin, Robert A. (1979). Hypnotizability and attention. Journal of Abnormal Psychology, 88 (1), 92-95.**

**An attentional explanation of cognitive hypnotic phenomena (e.g., hallucinations and amnesia) based on the ability to shift the pertinence of stored information was developed. It was hypothesized that individuals who were successful at a difficult attentional task would also succeed on cognitive hypnotic items. The Harvard Group Scale of Hypnotic Susceptibility, Form A was used to assess hypnotizability. To measure pertinence-shift ability, two tape recordings made by the same person were played through a single sound source. One tape was designated the target tape. Amount remembered and perceived task ease were summed to form an additive score of task success. Subjects above the median on the task were assigned to the good pertinence shift group (GP); those below the median were assigned to the poor pertinence shift group (PP). As predicted, GP subjects passed significantly more cognitive hypnotic items than did PP subjects ( $p < .05$ ). When task difficulty and compliance were controlled for, the results remained significant ( $p < .05$ ). These results were replicated in a second study.**

**A brief version of this paper was presented at the Annual Meeting of the Society for Clinical and Experimental Hypnosis, Asheville, North Carolina, October, 1978**

**1978**

**Kihlstrom, John F. (1978). Context and cognition in posthypnotic amnesia. International Journal of Clinical and Experimental Hypnosis, 26, 246-267**

Coe's (1978) contextualist analysis of posthypnotic amnesia appears to be predicated on the mistaken assumption that the amnesic S actually remembers the critical material. This position leads Coe to place inappropriate emphasis on the social context in which amnesia takes place and to focus on the social-psychological processes that might lead Ss to say that they do not remember something, be believed by others, and even believe themselves. An alternative view is outlined which affirms the surface similarities between posthypnotic amnesia and other failures of memory. From this vantage point, the investigator seeks to understand the cognitive processes that produce subjectively compelling disruptions of memory retrieval, whether found in association with hypnosis or in other circumstances.

1976

Coe, William C.; Basden, B.; Basden, D.; Graham, C. (1976). Posthypnotic amnesia: Suggestions of an active process in dissociative phenomena. Journal of Abnormal Psychology, 85, 455-458.

A retroactive inhibition design was used to examine the process of posthypnotic amnesia. The results supported the notion that "forgotten" material is as available to amnesic subjects at some level as it is to nonamnesic subjects. Further, so-called forgetting appears to be the result of an active process, that is, something the subject does. Implications for understanding dissociative phenomena in general are discussed.

Krippner, Stanley; Bindler, P. R. (1974). Hypnosis and attention: A review. American Journal of Clinical Hypnosis, 16 (3), 166-177.

Two seemingly contradictory formulations in hypnosis literature are reviewed: that hypnotic induction can produce a condition of diffuse attention, and that hypnotic induction can produce a condition of selective attention. It is concluded that either condition can be produced, depending on the set, level of arousal, individual differences, type of task to be performed, type of instructions, etc. It is also suggested that diffuse attention and selective attention be kept conceptually distinct since the terms may reflect a series of related processes rather than a dichotomy. (Authors' abstract.)

Kihlstrom, J. F.; Edmonston, W. E., Jr. (1971). Alterations in consciousness in neutral hypnosis: Distortions in semantic space. American Journal of Clinical Hypnosis, 13, 243-248.

30 highly hypnotizable Ss were equally divided into three groups, equated for age, sex and hypnotic susceptibility. A semantic differential scale was administered to each S in waking, individual sessions. An oral form of the same scale was administered during: (a) hypnosis (E), (b) waking -- post hypnosis (C1), and (c) waking -- no hypnosis (C2). All groups showed significant change between administrations of the scale; E showed more change than C1, and the latter more

than C2. Ratings of "My Self" changed toward the negative pole in the evaluative factor. Results were interpreted as indicating a distortion in semantic space and an alteration in ego-state occurring spontaneously with hypnosis.

Fromm, Erika; Oberlander, Mark I.; Gruenewald, Doris (1970). Perceptual and cognitive processes in different states of consciousness: The waking state and hypnosis. Journal of Projective Techniques and Personality Assessment, 34, 375-387.

Hypnosis was assumed to influence perceptual and cognitive functioning in the direction of increased primary process ideation and adaptive regression. The Rorschach test was administered to 32 Ss in the waking state and under hypnosis in counterbalanced order. Hypnosis was induced by a standardized procedure. Ss received identical instructions for the Rorschach in both conditions. Protocols were scored according to Holt's system for manifestations and control of primary process. Hypnotic Rorschachs showed an increase in primary process manifestations, but no changes in defensive and coping functioning, and no overall changes in the Adaptive Regression Score. However, the nature of the data was found to be influenced by Ss' sex and level of adjustment.

#### NOTES

The authors used High hypnotizables (SHSS>9) in this investigation.

1969

Hunt, Sonja M. (1969). The speech of the subject under hypnosis. International Journal of Clinical and Experimental Hypnosis, 17, 209-216.

Attempts to objectify changes taking place in the speech of 12 undergraduates under hypnosis as compared with their waking speech. A series of open-ended questions was asked in the waking and hypnotized states and the responses compared. Results indicate that the latency of response may be longer, the rate of speech slower, and the number of words in the response fewer under hypnosis. The rate of speech of E, however, also differed significantly between Ss in waking and hypnotized conditions. It was therefore not possible to attribute the speech changes only to the hypnotized state. They could have arisen from E's differential verbal treatment of hypnotized and waking Ss. The need for future research and its nature are discussed. (Spanish & German summaries) (PsycINFO Database Record (c) 2002 APA, all rights reserved)

Barber, Theodore Xenophon (1957). Hypnosis as perceptual-cognitive restructuring: I. Analysis of concepts. Journal of Clinical and Experimental Hypnosis, 5 (4), 147-166.

NOTES

Summary

1. 'Trance' involves a selective and relative inattention to internal and external stimulation.
2. Hypnosis involves one type of 'trance' behavior but hypnosis differs from other types of 'trance' in that it is an interpersonal relationship in which one person, the operator, restructures the 'perceptions' and conceptions of the other person, the subject.
3. The operator can restructure the thoughts and 'perceptions' of the 'good' hypnotic subject because (a) the subject is relatively detached and inattentive to his self and his surroundings and (b) the subject is 'set' -- he is ready and willing -- to accept the operator's words as true statements and to 'literally think as the operator wants him to think.'
4. 'Perceptual-cognitive restructuring' and not 'suggestion' is the essential element in hypnosis.

5. We can begin to understand hypnosis and the phenomena of hypnosis by one general principle: the hypnotic subject behaves differently because he 'perceives' and conceives differently. The behavior of the hypnotic subject is in strict accordance with his altered conceptions of his self and his surroundings" (p. 162).

1953

Beigel, Hugo B. (1953). Hypnosis as an instrument in psychological experimentation. Journal of Clinical and Experimental Hypnosis, 1, 13-17. (Abstracted in Psychological Abstracts, 53: 6385)

**Author's Summary -** In this paper various areas of psychological research were pointed out in which experimentation with hypnotized subjects has been or could be employed to advantage. It is held that there are several problems which offer no point of attack unless hypnosis is used and several others which, in view of their complexity, cannot be effectually approached by the classic method of experimentation. Specifically mentioned were the areas of thinking, learning, perception, apperception, imagination, and emotion, in which the hypnotic experiment proves valuable when either amnesia for preceding experiences, isolation from concomitant influences, or the introduction of an as-if situation is necessary. While it is undeniable that some of the experiments cited need improvement if their results are to be considered reliable -- a remediable shortcoming they share with most first experiments -- it is also evident that the use of hypnosis in experiments offers an approach to some areas that have thus far been inaccessible. Needless to say, hypnosis should not be used when similar results can be as readily obtained by the customary experimental method, but as Gidro-Frank and Bull (10) state, our scant knowledge of the nature of the hypnotic state should not bar it from use as a scientific tool. Still the only one available technique to solve a problem. It must be added, however, that the experimenter must be thoroughly familiar with the technique but also to their physical and mental health.

Israeli, Nathan (1953). Experimental study of projection in time: I. Outlook upon the remote future--extending through the quintillionth year. Journal of Clinical and Experimental Hypnosis, 1 (2), 49-60.

**Author's Summary -** This report on research now under progress is concerned with time projection and with hypnotic imagination and dreams of projection into varying remote future periods extending to the very distant quintillionth year. The work proceeded in stages including (a) orientation to the general procedure, (b) hypnotic future autobiographic material (age progression), (c) going successively from one future period to another from the end of the 21st century through the quintillionth year -- devoting usually one experimental session to any future period. This paper reports on the self-ratings for hypnosis depth reached by the subjects, their description of life, things, and events, in connection with each projection into a future period, and their visual or nonvisual imagery.

1. Self-ratings for hypnosis depth show with one insignificant exceptional instance that all subjects were always at least at the trance-level or in a deeper hypnotic

stage. Individual differences in level reached were indicated with a general trend towards more profound trance in later sessions. The deeper levels on the scale used were not described by the experimenter. Each subject gave those levels his own interpretation in setting up his own scale.

2. The time projections are to be explained in terms of changing space-time framework, social topographic reorientation, recentering, and non-conventional time centering.

3. Hypnotic suggestion to imagine and dream about being suddenly transported and projected into a specified future period is followed by rapid recentering as the subjects follow out the suggestions.

4. Although no specific instructions or sets of suggestions were included about the nature of their anticipations, the description of life, things, and events of any future period was on a predominant impersonal level, with the personal aspects in the background. Nonetheless, the suggestion of transportation and projection into a future period leads to various changes in one's present-situation perceptions, imagery, space-time framework, and system of concepts and beliefs. With a change in time reference, the description of life, things, and events is adjusted to the era or epoch specified. This involves description of technological, biological, psychological, and anthropological changes. The extinction of mankind is anticipated in the very remote future by some subjects. The earth and the moon are expected to disappear by collision or otherwise.

5. Individual analysis shows that the descriptions of the different future periods approximately fit into patterns and are not discontinuous. An individual subject's descriptions beginning with the first future period and taking in all the other periods show constructive or catastrophic trends or cyclical variation between both extremes. Descriptions of life, things, and events of each future period in the main change in a constructive or in a catastrophic direction. They are continuous but with certain discontinuities and incoherence.

6. A geocentric orientation and a heliocentric preoccupation are invariant and predominant. The subjects are unable to abandon their basic planetary orientation or schemata.

7. Colored imagery includes mainly the primary colors. They comprise both expanse colors and surface colors. Auditory imagery is quite frequent. There are also references to olfactory, tactile, and kinesthetic imagery. Thermic imagery becomes increasingly prominent in the more remote future periods when the sun's heat is described as more intense. Imagery changes with the outlook patterns and appears to have personal, structural, and social determinants. One subject's imagery was macropic

## COMMUNICATION

Spanos NP. De Groh M. Structure of communication and reports of involuntariness by hypnotic and nonhypnotic subjects. *Perceptual & Motor Skills* 1983;57(3 Pt 2):1179-86

We hypothesized that phrasing a communication to move the arm as either a suggestion, a directive, or an instruction would differentially affect subjects' interpretations of the movement. 45 hypnotic and 45 nonhypnotic subjects who responded positively to a suggestion tended to describe the movement as involuntary both on open-ended questionnaires and later on an explicit involuntariness scale. Subjects given a directive to move the arm, or an instruction to reach for a pencil, rarely described their experience as involuntary on the open-ended questionnaires but sometimes rated it as involuntary on the scale. The ratings of involuntariness by subjects given suggestions seem likely to reflect interpretations made concurrently with the movement suggested. However, such ratings by subjects given directives or instructions are likely to reflect retrospective interpretations cued by the instrument used to assess subjects' experiences.

1998

Vandenberg, Brian (1998). Infant communication and the development of hypnotic responsivity. International Journal of Clinical and Experimental Hypnosis, 46 (4), 334-350.

The research on the development of hypnotic responsivity indicates that it emerges, ex nihilo, sometime after the age of 3. The measures used to assess hypnotic responsivity rely on complex verbal instructions, thus precluding investigation of infancy. Recent research on infancy, however, suggests that the ontogenesis of hypnotic responsivity is likely to be found in fundamental human capacities that emerge in the first weeks and months of life. The aims of the article are threefold: (a) to demonstrate that infants possess capacities on the nonverbal plane of communication that are analogous to those required for hypnosis; (b) to identify situations in infancy that are analogous to the hypnotic context; and (c) to examine dispositional and relational attributes in infancy that may account for later individual differences in hypnotic responsivity.

Erickson, James C. (1994, October). The metaphors of pain and therapy. [Paper] Presented at the annual meeting of the Society for Clinical and Experimental Hypnosis, San Francisco.

NOTES:

Metaphors of Pain may be: 1. Anatomically or physiologically descriptive. 2. Extremely common, especially in chronic pain syndromes. 3. Unrecognized by many therapists. 4. Often pithy, succinct phrases (like puns). "Pain in the neck, pain in the butt" may reflect symbolic meaning of the pain, which if attended to may benefit the patient.

Head and neck pain metaphors include such things as "a headache, a pain in the neck, grit your teeth, and grin and bear it" (related to bruxism and TMJ syndrome). Also pertains to post-rhinoplasty pain in the nose.

Back pains: upper thoracic pain "a load on my shoulders" like Atlas carrying the world. Or "a cross to bear" which implies uncomplaining, but bearing a heavy burden. Low back pain - a "weak spine," or "spineless." With laminectomy, a "yellow streak up the back."

Dermatitis: Pruritis or dermatitis when "something gets under the skin."

Chest pains when "sick at heart."

Nagging, nasty situation is a "thorn in my side."

"A stab in the back" when wronged by society or a person. "Pain in the ass" may be a spouse or a situation. [Other material provided by the speaker is not reported here.]

1993

Dabic-Jeftic, Mirjana; Barnes, Graham (1993). Event-related potentials (P300) during cognitive processing in hypnotic and non-hypnotic conditions. Psychiatria Danubina, 5 (1-2), 47-61.

In this study authors investigated to find out if there were any specific changes of event related potentials in subjects before hypnosis, entering hypnosis, in deep hypnosis and leaving hypnosis, and to compare mental activities of subjects such as capability of correctly calculating and remembering the exact number of unexpected stimuli delivered by stimulator with their verbal or nonverbal reports during any of the conditions investigated. The methodology was of testing the cognitive evoked potentials elicited by auditive stimuli, using the oddball paradigm. Obtained results show that the most constant values of shortest latency and highest amplitudes of the cognitive waves, especially P300 were found during deep hypnosis. All five subjects in the investigation answered with the exact number of delivered target stimuli only after deep hypnosis. Conversely, in all other conditions their answers were approximate to the correct number of delivered target stimuli. (Author abstract.)

NOTES:

In this experiment, 5 adult volunteers were told to attend to one of two tones delivered through headphones. The tones were randomly delivered but one occurred 85% of the time (the 'frequent, non-target tone') and the other occurred 15% of the time (the 'rare, target tone'). The subjects were to notice, remember, and count the target tone. Measures were taken during five periods: pre-hypnosis, entering hypnosis, deep hypnosis, leaving hypnosis, and post-hypnosis.

Some subjects had extensive hypnosis experience prior to the experiment; others had little.

The EEG P300 wave was sensitive to condition. Latency of P300 was significantly shorter in deep hypnosis compared with other periods. Higher amplitude of P300 also occurred during deep hypnosis compared with other periods. (Notes taken from secondary reference, Ericksonian Newsletter.)

Kraft, Tom (1993). Using hypnosis with cancer patients: Six case studies. Contemporary Hypnosis, 10, 43-48.

Hypnosis can be used in a number of different ways for helping patients suffering from cancer. As well as pain relief, hypnosis may be used to correct insomnia that does not respond to sleeping tablets; for the reduction in skin irritation and dyspnoea when these are due to organic causes, and for treatment-related over-eating. Some patients will use hypnosis in a symbolic way. When this occurs, just as in dream interpretation, it is important to ask the patient for associations, so that these symbols can be understood. Hypnosis can be an extremely useful addition to the medical armamentarium, and should be employed as an adjunct to standard forms of cancer treatment. This paper reports six case studies in which hypnosis was used to help cancer patients.

1992

Isenberg, S. A.; Lehrer, P. M.; Hochran, S. (1992). The effects of suggestions and emotional arousal on pulmonary functions in asthma: A review and a hypothesis regarding verbal mediation. Psychosomatic Medicine, 54, 192-216.

This paper reviews the empirical literature on the relation between asthma, suggestion, and emotion, and proposes the hypothesis that these effects are mediated parasympathetically. The literature indicates that, among asthmatics, suggestion can produce both bronchoconstriction and bronchodilation, and that stress can produce bronchoconstriction. The proportion of asthmatic subjects showing bronchoconstriction to both suggestion and stress averages 35%-40% across studies, but, because of methodological considerations, might be conservatively estimated as closer to 20%. The effect is smaller for suggestion of bronchodilation, and is very short-lived among nonasthmatics. No clear connection has been found between these responses and such subject variables as age, gender, asthma severity, atopy, or method of pulmonary assessment, although some nonsignificant tendencies appear. Most studies in this literature used small n's and did not systematically examine various somatic, environmental, and demographic factors that could influence results. A hypothesis is presented regarding vagal mediation of psychological effects on the airways, as well as possible alternative mechanisms, and recommendations for future research to evaluate these hypotheses.

Schacter, Daniel L. (1992). Understanding implicit memory. American Psychologist, 47 (4), 559-569.

Dissociations between implicit and explicit memory have attracted considerable attention in recent memory research. A central issue concerns whether such dissociations require the postulation of separate memory systems or are best understood in terms of different processes operating within a single system. This article presents a cognitive neuroscience approach to implicit memory in general and the systems-processes debate in particular, which draws on evidence from research with brain-damaged patients, neuroimaging techniques, and nonhuman primates. The article illustrates how a cognitive neuroscience orientation can help to supply a basis for postulating memory systems, can provide useful constraints for

processing views, and can encourage the use of research strategies that the author refers to as cross-domain hypothesis testing and cross-domain hypothesis generation, respectively. The cognitive neuroscience orientation suggests a complementary role for multiple systems and processing approaches.

**NOTES:**

Implicit memory is an unintentional, nonconscious form of retention that can be contrasted with explicit memory, which involves conscious recollection of previous experiences" (p. 559). The author provides examples of memory dissociations, some of them from neuropathology and some from experimental psychology.

Different brain systems may account for some of the dissociations. For example, there are "studies of patients who show relatively intact access to perceptual-structural knowledge of words or objects, despite severely impaired access to semantic knowledge of the same items. ... Similarly, studies of lexical processing using positron emission tomography (PET) indicate that visual word form information and semantic information are handled by separate brain regions. ... These kinds of observations suggest the existence of a perceptual representation system (PRS)" (p. 561). .

"Marsolek et al. (1992) drew on independent evidence from cognitive neuroscience concerning the characteristics of the hemispheres to argue that a left hemisphere subsystem computes abstract word form representations that do not preserve specific features of particular inputs, whereas a right-hemisphere subsystem computes perceptually specific word form representations (in the present terminology, both could be viewed as PRS subsystems)" (p. 562)..

"Our approach to auditory implicit memory was guided by neuropsychological studies of patients who exhibit dissociations between access to form and semantic information in the auditory domain that are similar to those discussed earlier in the visual domain. ... More specifically, patients with so-called word meaning deafness are unable to understand spoken words (e.g. Ellis & Young, 1988). However, they can repeat spoken words quite well and show some ability to write words to dictation, thus suggesting that they can gain access to stored auditory word form representations. ... Rather more frequently encountered are patients with transcortical sensory aphasia (e.g. Kertesz, Sheppard, & MacKenzie, 1982), who exhibit spared abilities to repeat spoken words and write them to dictation, together with impaired comprehension. In these patients, however, the comprehension deficit is also observed in other modalities, thus indicating damage to the semantic system itself.

"These dissociations point toward the existence of a PRS subsystem that handles information about auditory word forms separately from semantic information (cf. Ellis & Young, 1988)" (p. 565)..

"Various investigators have argued that auditory processing differs in the two hemispheres: The left hemisphere relies on categorical or abstract auditory information and operates primarily on phonemes, whereas the right hemisphere relies more on 'acoustic gestalts' and operates primarily on prosodic features of speech, including voice information... In addition, studies of normal subjects using dichotic listening techniques have shown a left-ear (i.e., right-hemisphere)

advantage for certain types of voice information, in contrast to the usual right-ear advantage for speech" (p. 566).

1991

Brown, Peter (1991). The hypnotic brain: Hypnotherapy and social communication. New Haven, CT: Yale University Press.

**NOTES:**

Notes are taken from a review of this book: Diamond, Michael (1993). Book review. *Bulletin of the Menninger Clinic*, 57 (Winter), 120-121.

Brown "posits that because the fundamental matrix of the human brain is metaphoric, hypnosis results from skillful matching of metaphorical communication with the brain's biological, rhythmic alterations. The most significant feature of trance experience is thereby located in the hypnotist-subject interaction" (p. 120).

"The middle section [of the book is comprised largely of] literature reviews in support of Rossi's (1986) ultradian rhythm theory of hypnosis and Lakoff and Johnson's (Johnson, 1987; Lakoff & Johnson, 1980) experientialist theory of conceptual thought" (p. 120). The final section includes "research evidence on medical uses of hypnosis, a theory of dissociation and multiple personality disorders, and an uncritical discussion of Milton Erickson's naturalistic hypnotherapeutic approach ... [and also] a brief discussion of the social-cultural functions of possession states among the Mayotte culture" (p. 120).

Rhue, Judith W.; Lynn, Steven Jay (1991). Storytelling, hypnosis and the treatment of sexually abused children. International Journal of Clinical and Experimental Hypnosis, 39 (4), 198-214.

The present article describes an assessment and therapy program for sexually abused children using hypnotherapeutic techniques which center on storytelling. Storytelling presents the therapist with an opportunity to use comforting suggestions, symbolism, and metaphor to provide the emotional distance necessary to deal with the trauma of abuse. Hypnotherapy proceeds in a stepwise fashion from the building of a sense of safety and security; to imaginative sharing; to the introduction of reality events; to the final step of addressing complex emotional issues of loss, trust, love, and guilt brought about by the abuse.

Spiegel, David (1991, August). New directions in traumatic stress research. [Paper] Presented at the annual meeting of the American Psychological Association, San Francisco.

**NOTES**

Trauma is the experience of being made into an object of someone else's rage. It is a sudden discontinuity in experience: our physical and mental state can be changed radically. The experience of loss of control is what is most horrifying, more than fear of death. Guilt, (blaming oneself) helps deny the loss of control. People who

experience trauma distance from the information but the cortex maintains the traumatic memories.

Author reviewed literature on effective interventions with trauma victims. 1. Harbor & Pennebaker: Contrast how earthquake victims can talk about it but rape victims often are isolated. The importance of having someone listen raises the question of usefulness of only writing about the trauma. 2. Greenberg: Studied 103 trauma cases; employed a clever methodology, using 2 control groups (but it is difficult for the imaginary control group to be free of associating to their own traumas). I believe the health findings, but it troubles me that there were intrusions (thoughts); the control group utilization [of health services?] went up. 3. Kilpatrick: It is important not to blame the victim for being traumatized. But there may be some people who for sociological or other reasons do not get out of dangerous situations. 4. Terri Orbach: There is a process of "going public" about the trauma, like in Alcoholics Anonymous disclosures. Trauma victims create an account and they go to someone else to tell about it.

Summary of what seems important about treatment: There are three means of working with trauma, with thinking, writing, and talking. If you just think but don't talk, assault rate goes up (Pennebaker); and if you don't talk with someone else you feel worse physically. In simply writing about the trauma, there may be an increase of mental intrusions, or avoidance. What seems to be beneficial is not just making sense to oneself about the experience cognitively, but the traumatized person must get feedback from another individual that they are not transformed as a person.

Ovens, H.; Talbot, Y.; Harris, F.; Newman, B. (1990). Hypnosis training enhances communication skills. Medical Teacher, 12 (3-4), 357-361

NOTES:

Found in a controlled study that family medicine residents who went through an introductory hypnosis workshop made more comments on their patients' nonverbal behavior, helping to reveal a patient's hidden agenda.

1988

Kirmayer, Laurence J. (1988). Word magic and the rhetoric of common sense: Erickson's metaphors for mind. International Journal of Clinical and Experimental Hypnosis, 36 (3), 157-172.

Milton Erickson did not produce a systematic theory of psychotherapy. His talent was as a storyteller, inventing metaphors and more extended healing fictions for his patients. A great many of Erickson's cases did not involve hypnosis in any conventional sense of the term. He used a wide range of persuasive rhetorical forms to encourage behavioral change in his patients. Nevertheless, taken together his work represents a significant shift in paradigm from prevailing schools of psychotherapy. Erickson captured the power of word magic in the language of common sense. This coupling of magical power with folk psychology accounts for much of his current popularity. Attempts to experimentally test his techniques are

likely to be unsuccessful because these techniques were unique inventions tailored to the individual idiosyncrasies of patient and context. Although regularities in his work can be found, Erickson's most important contributions are not techniques but changes in the values or ethos under which psychotherapy is conducted.

## NOTES

This paper focuses Erickson's implicit models of mind and the values they carry. "It is here that Erickson made his most significant contribution to the general practice of psychotherapy . Erickson avoided systematization. His writing is unusually anecdotal, even for psychotherapy (Erickson, 1980; Vol IV, passim). Erickson's writing format consists of 'thin' case descriptions, freely recycled in parable or homiletic form to serve his immediate rhetorical purpose. ... For Erickson, flexibility and eclecticism were not signs of a lack of coherence but a spirited rejection of rigid dogma that needlessly limited therapeutic possibilities" (pp. 158-59).

Erickson used language of the common man rather than a technical vocabulary, even when speaking of 'hypnosis' or 'trance' or 'the unconscious.' He called his approach 'naturalistic' and viewed hypnotic phenomena as an extension of normal experience and behavior. His common sense descriptions of events and techniques are easily understood in general terms. "Erickson took magic and dressed it in the familiar clothes of common sense. Some of his less critical followers, however, seem intent on taking common sense and dressing it in the cloak of magic" (p. 163).

Erickson used metaphors as a way of actively involving the patient in conceptual, affective, and sensory qualities of experiences, i.e. as a "tool for thought" (p. 164).

In attempting to understand Erickson's psychotherapy, one must note his "elastic use of the word 'hypnosis.' Sometimes Erickson uses the term narrowly with a focus on the elicitation of trance or dissociative phenomena, but more often he uses it broadly to mean any state of absorption" (p. 165). For him, this was "\_a state of special awareness characterized by a receptiveness to ideas\_" [Erickson, 1985, p. 223, emphasis in original]. By this he does not mean exclusively the classic suggestion effect where motor acts are experienced as involuntary (Evans, 1967). ... The hypnotic subject exhibits a "\_special willingness to examine ideas for their inherent values\_" [p. 224, emphasis in original]. ... For Erickson, any move in the direction of increased absorption is an instance of hypnosis. Dissociation accounts for a great deal but not all of hypnotic behavior" (p. 165). That is why he used the word hypnosis to describe heightened attention that might occur when someone is surprised. But in fact, his published cases include many other kinds of interventions, such as reframing, symptom prescription, etc.--forms of influence and persuasion used by many therapists who do not consider themselves working with hypnosis.

Erickson also emphasized that hypnosis enables one to work with 'the unconscious.' "Ordinarily, we view our consciousness as the causal agent of doing while our unconscious is the place where things just 'happen to us.' Erickson reversed this attribution, emphasizing the unconscious as the agent of active control working for the benefit of the patient while consciousness adopts the attitude of 'wait and see.' This leads consciousness into reverie--the state where images and events move of their own accord, animated by emotion, before the 'passive audience' of consciousness" (p. 167). So Erickson viewed hypnosis as liberating the unconscious.

There was healing potential in helping the ego to relinquish "rigid control over the creative and benevolent processes of the unconscious" (p. 168). From this theoretical position, the patient and therapist are seen as allies and psychotherapy is a collaboration; there is no need for the Freudian concepts of resistance and defense. "Erickson's metaphors for hypnotherapy link it with normal processes of learning and imagining. His image of the unconscious as a storehouse of creative potential supports a non-pathologized view of man amid all his troubles and craziness. In contrast to psychiatry's current preoccupation with nosology, and the emphasis of psychoanalysis on the dimensions of human frailty, Erickson adopted a non-pathologizing attitude. He did not deny his patient's difficulties but neither was he excessively fascinated by them. He recognized that healing depends not on cataloguing deficiency but on fully mobilizing the person's intelligence, imagination, and integrity. This message of therapeutic optimism was balanced by his own example of the benefits and limitations of hypnotherapeutic practice" (p. 170).

Kuttner, Leora (1988). Favorite stories: A hypnotic pain-reduction technique for children in acute pain. American Journal of Clinical Hypnosis, 30, 289-295.

For young children (aged 3 to 6-11) with leukemia, a hypnotic trance consisting of a child's favorite story was found to be statistically more effective than behavioral distraction and standard medical practice in alleviating distress, pain, and anxiety during painful bone marrow aspirations. Measured by a behavioral checklist and judgment ratings by physician, parent, nurse, and observers, the favorite-story hypnotic technique had immediate therapeutic impact on these young patients, and the reduction in distress, pain, and anxiety was sustained on subsequent medical procedures. Self-report measures, however, were nonsignificant.

Spanos, Nicholas P.; Cross, Wendi P.; Lepage, Mark; Coristine, Marjorie (1986). Glossolalia as learned behavior: An experimental demonstration. Journal of Abnormal Psychology, 95, 21-23.

60 Ss listened to a 60-s sample of glossolalia (defined to them as pseudolanguage) and then attempted to produce glossolalia on a 30-s baseline trial. Afterward, half of the Ss received two training sessions that included audio- and videotaped samples of glossolalia interspersed with opportunities to practice glossolalia. Also, live modeling of glossolalia, direct instruction, and encouragement were provided by an experimenter. Both the trained subjects and untreated controls attempted to produce glossolalia on a 30-s posttest trial. About 20% of subjects exhibited fluent glossolalia on the baseline trial, and training significantly enhanced fluency. Seventy percent of trained subjects spoke fluent glossolalia on the posttest. Our findings are more consistent with social learning than with altered state conceptions of glossolalia.

Coe, William C.; Scharcoff, J. A. (1985). An empirical evaluation of the neurolinguistic programming model. International Journal of Clinical and Experimental Hypnosis, 33 (4), 310-318.

The neurolinguistic programming hypothesis that most people have a preferred way of dealing with the world -- a primary representational system -- was tested. 50 Ss were evaluated for sensory modality preference in 3 ways: (a) they chose among written descriptions using either visual, auditory, or kinesthetic wording (preference); (b) their eye movements were recorded during an interview; and (c) their verbal responses were scored for sensory predicates. The results did not support neurolinguistic programming theory in that preference of 1 modality on 1 measure did not relate to the same modality on the other measures as would be expected if primary representational systems were characteristic of the sample. Other studies have shown mixed results. The conclusion seems warranted that a good deal more empirical support is needed before the positive therapeutic claims of neurolinguistic programming proponents can be taken seriously.

Spanos, Nicholas P.; de Groh, Margaret; Weekes, John R. (1984). Involuntariness and attributions: A reply to Zamansky and Bartis. [Comment/Discussion] .

#### NOTES

The authors take the position "that hypnotic subjects (like almost everyone else) retain control over their behaviour (Spanos, 1982). These subjects sometimes define (i.e., interpret) their responses as involuntary, because this interpretation is sometimes fostered and legitimated by contextual demands. However, interpretations of involuntariness do not mean that purposeful, goal-directed actions have been somehow transformed into automatic, nonvoluntary happenings" (p. 54).

1982

Chertok, Leon (1982). The unconscious and hypnosis. International Journal of Clinical and Experimental Hypnosis, 30 (2), 95-107.

This paper reviews Soviet approaches to the unconscious and to hypnotic phenomena, before examining psychoanalytic theories of hypnosis which are generally based on transference. The author believes the existing theories are inadequate, arguing that there is a psychophysiological dimension to hypnosis; but what unconscious processes does this conceal? Psychoanalysis opened one road to the unconscious, but affect, nonverbal communication, and psychophysiological process are still uncharted territories towards which hypnosis may yet prove to be another royal road.

#### NOTES

The author concludes, "hypnosis and the unconscious ... are closely linked. Historically, experiments on posthypnotic suggestion were in fact the starting point for the discovery of the unconscious. Posthypnotic suggestion is in effect one of the most irrefutable proofs that psychical contents can influence behavior, albeit eluding the subject's consciousness.

"In this paper, the present author provides a description of Soviet researchers' conceptions of the unconscious, and of the point of view from which they approach

hypnotic phenomena. Psychoanalytic theories of hypnosis are then presented, which are essentially based on transference. It is shown why this notion seems to the present author powerless to account for the specific nature of the hypnotic relationship. There is, in effect, a psychophysiological dimension to hypnosis. It lies at the crossroads between the instrumental and the relational dimension. But nothing is known about what unconscious processes hide at the psychophysiological level. Psychoanalysis has brought to light the laws governing the functioning of unconscious representations. But the realm of the affect, the nonverbal communication, and bodily processes still remain beyond our knowledge. This is a hidden side of the unconscious, in relation to which hypnosis may serve as another 'royal road'" (pp. 104-105).

Hong, G. K.; Skiba, A. H.; Yepes, E.; O'Brien, R. M. (1982). Effects of ethnicity of hypnotist and subject on hypnotic susceptibility. International Journal of Clinical and Experimental Hypnosis, 30 (1), 23-31.

The effect of ethnic similarity of hypnotist and hypnotic S on hypnotic susceptibility was examined in a 2-part study. The first part of the study compared the performance of Anglo versus Chinese hypnotists on Anglo versus Chinese Ss. In the second half of the study, Anglo and Hispanic Ss and hypnotists were compared using the same Anglo hypnotist-S control group. In total, 112 volunteers were administered the Stanford Hypnotic Susceptibility Scale, Form A, of A. M. Weitzenhoffer and Hilgard (1959), with 16 Ss (8 males and 8 females) in each condition. A 2 x 2 ANOVA was performed on the data for each part of the study. Ethnic similarity of hypnotist and S was found not to enhance hypnotic susceptibility. The implications of these results are discussed in relation to the assumed superiority of homoethnicity in psychotherapy

Dosamantes-Alperson, Erma (1981). Experiencing in movement psychotherapy. American Journal of Dance Therapy, 4, 33-44.

Experiencing is a process variable in psychotherapy which deals with the manner with which individuals use their internal, ongoing bodily-felt flow of experience to gain self-awareness and to communicate about themselves. A consistent finding across research process studies in psychotherapy is that successful clients start, continue, and end therapy at higher experiencing levels than do less successful clients. The implication of this finding for all therapists, irrespective of their theoretical framework, is that they need to help their clients process the content they raise in therapy at a high level of experiencing throughout the course of therapy. This paper discusses and demonstrates several body movement based procedures that enhance clients' experiencing level while working within the context of experiential movement psychotherapy, a form of psychotherapy which emphasizes the acquisition of personal meanings by clients from any of the following three experiential and expressive modalities: body movement, kinetic imagery, or verbal communication.

Ericsson, K. Anders; Simon, Herbert A. (1980). Verbal reports as data. Psychological Review, 87 (3), 215-251.

**NOTES:**

Proposes that verbal reports are data and that accounting for them, as well as for other kinds of data, requires explication of the mechanisms by which the reports are generated, and the ways in which they are sensitive to experimental factors (instructions, tasks, etc.). Within the theoretical framework of human information processing, different types of processes underlying verbalization are discussed, and a model is presented of how ss, in response to an instruction to think aloud, verbalize information that they are attending to in short-term memory (STM). Verbalizing information is shown to affect cognitive processes only if the instructions require verbalization of information that would not otherwise be attended to. From an analysis of what would be in STM at the time of report, the model predicts what could be reliably reported. The inaccurate reports found by other research are shown to result from requesting information that was never directly heeded, thus forcing Ss to infer rather than remember their mental processes. Zeig, Jeffrey K. (1980). Symptom prescription and Ericksonian principles of hypnosis and psychotherapy. American Journal of Clinical Hypnosis, 23, 16-22.

The technique of symptom prescription is used by therapists with diverse theoretical backgrounds. Using three historical case examples, the use of symptom prescription is explored from the perspective of three principles of hypnosis and psychotherapy espoused by Milton H. Erickson: (1) meeting the patient within his frame of reference, (2) using the patient's own behavior and understandings to make small therapeutic modifications, and (3) eliciting the cure from the patient in a manner that allows the opportunity for patient-initiated change.

1978

Schumann, John H.; Holroyd, Jean; Campbell, Russell N.; Ward, Frederick A. (1978). Improvement of pronunciation under hypnosis: A preliminary study. Language Learning, 28, 143-148.

This paper reports an experiment which was designed to determine whether foreign language pronunciation could be improved through hypnosis. Twenty subjects were first given the Harvard Group Scale of Hypnotizability to familiarize them with the state of hypnosis. In the second session each subject was individually tested on his/her ability to pronounce Thai words under three conditions: Baseline, Hypnosis, and Post- Hypnosis. For each experimental condition the subjects heard and repeated the stimulus items on one of three lists of 15 Thai words. The subjects' responses were later evaluated by a native Thai linguist. The results indicate that deeply hypnotized subjects (as defined by self-reported depth) performed significantly better than less well hypnotized subjects.

#### **NOTES:**

**Guiora (1972) suggested that pronunciation of a foreign language is more difficult than vocabulary, syntax, and grammar skills because it requires modifying a basic method of self-identification, the way one sounds. He introduced a concept of language ego, analogous to body ego" (p. 143). During hypnosis subjects were evaluated for subjective estimate of hypnotic depth by asking them to "visualize themselves on a stairway in which the top (zero) represented their normal waking state and the bottom (ten) a very very deep relaxed state of hypnosis, and to report the number of the step on which they stood" (p. 146). Thus, "it was not assumed that administration of an induction assured a hypnotized subject, nor was it assumed that subjects rated highly hypnotizable were in a deep trance at the time Thai words were being spoken" (p. 146).**

**Buckner, Linda G.; Coe, William C. (1977). Imaginative skill, wording of suggestions and hypnotic-susceptibility. International Journal of Clinical and Experimental Hypnosis, 25, 27-36.**

**3 groups of 20 s based on preselected imaginative capacity were administered either a hypnotic susceptibility scale containing item wording that suggested a goal-directed fantasy or one that did not. Preselected imaginative ability did not predict hypnotic susceptibility or the production of goal-directed fantasies during hypnosis. However, Ss who received the hypnotic scale containing item wording that suggested goal-directed fantasies reported more goal-directed fantasies than Ss who received the other scale. Limitations of the study are discussed and the causal role of goal-directed fantasy in hypnotic responsiveness is questioned.**

#### **1974**

Weitzenhoffer, Andre M. (1974). When is an 'instruction' an 'instruction?'. International Journal of Clinical and Experimental Hypnosis, 22 (3), 258-269.

In the course of validating with 100 undergraduate Ss the concept of a "classical suggestion-effect" (i.e., the existence of a class of nonvoluntary behaviors elicited by communications intended to serve as traditional "suggestions"), evidence was incidentally obtained showing that many "instructions" given to presumably hypnotized Ss also function like "suggestions." In these circumstances it is not possible to state a priori that a verbal communication will function as an "instruction" rather than as a "suggestion." Such a statement can be made with certainty only a posteriori, on the basis of the nature of the resulting behavior. The implications of this finding for research and for the clinical uses of hypnotic suggestion are discussed. NOTES

2:

This document reports on a U.S. Army research project using hypnosis to collect high fidelity samples of the voice under "combat stress" conditions in the laboratory. Using hypnotic regression, combat veterans "re-experienced" their own, actual high stress combat situations. Besides subjective reports of stress levels by subjects, physiological stress measures were obtained from polygraph recordings of heart, respiration and GSR activity. The voice samples were later analyzed by spectrographic techniques to determine which factors remain invariant to identify and authenticate the speaker in a military communications situation. Hypnotic techniques were shown to be useful in establishing controlled emotional states for laboratory research purposes. (Richard Bloom)

Kihlstrom, J. F.; Edmonston, W. E., Jr. (1971). Alterations in consciousness in neutral hypnosis: Distortions in semantic space. American Journal of Clinical Hypnosis, 13, 243-248.

30 highly hypnotizable Ss were equally divided into three groups, equated for age, sex and hypnotic susceptibility. A semantic differential scale was administered to each S in waking, individual sessions. An oral form of the same scale was administered during: (a) hypnosis (E), (b) waking -- post hypnosis (C1), and (c) waking -- no hypnosis (C2). All groups showed significant change between

administrations of the scale; E showed more change than C1, and the latter more than C2. Ratings of "My Self" changed toward the negative pole in the evaluative factor. Results were interpreted as indicating a distortion in semantic space and an alteration in ego-state occurring spontaneously with hypnosis.

#### NOTES

The review of this book by Leo Wollman (*American Journal of Clinical Hypnosis*, 1965, vol. 8, pp. 146-147) states, "Many interesting theories about hypnosis are aired in this book. The opinions Pavlov propounded many years ago, about cortical inhibition are assiduously asserted, yet some statements made bear investigation. The mere sight of the experimenter in B. N. Birman's experiments with dogs put the dog into a hypnotic state. The appearance in the room of other people, who had not participated in the experiments, had no sleep inducing effect. For the experimental animal, therefore, the experimenter himself had been transformed into a conditioned hypnogenous stimulus. Similarly, in group hypnotherapy, the entrance of the physician-hypnotist into the room often effects a hypnotic state in some of the subjects. The doctor has become the stimulus for the conditioned response, that of hypnotic trance state induction.

" An interesting and perhaps little known fact elicited from Chapter III (Hypnotism and Suggestion) is the high percentage (12%) of those replies to questionnaires during the First International Congress on Experimental Psychology held in Paris in 1899, which indicated that 3,000 respondents had hallucinations while in a normal state of health. The majority were visual; auditory and tactile hallucinations were less frequent" (pp. 146-147).

Sears, Alden B.; Talcott, Martha M. (1958). Hypnotic induction by use of non-meaningful languages: A pilot study. Journal of Clinical and Experimental Hypnosis, 6 (3), 136-138.

**NOTES**

In order to explore the question of whether hypnosis is due to suggestion, rhythm, monotony, etc. a spiral disk focus induction was delivered to 46 college students in 3 different languages (Bohemian, Japanese, and Spanish) by female native speakers. The students were asked to rate which part was "most relaxing." Language sequence was counterbalanced.

Fourteen students went into light trance; in a later induction they were found to be hypnotizable -- 13 to a medium trance level (higher number than would be expected based on results with students who had not listened to the tapes). However the authors did not know which aspect of the preparatory 3-language period to which to attribute the better response.

**1955**

Weitzenhoffer, Andre M. (1955). The influence of hypnosis on the learning process. Some theoretical considerations: II. Recall of meaningful material. Journal of Clinical and Experimental Hypnosis, 3 (3), 148-165.

**Summary.**

1. Past investigations of recall in hypnosis have been reviewed. The results appear to indicate that hypnosis favors the recall of 'meaningful' material over that of nonsense material above and beyond the difference in recall known to exist in the waking state for the recall of these two kinds of material. The results also suggest that the hypnotic increment is a monotonic increasing function of the 'degree of meaningfulness.'

2. Various important issues inherent in the problem under discussion have been examined. It is concluded that further gains in knowledge in this area demand the development of an adequate theory of 'meaning,' the recognition of the multidimensionality of 'meaning,' and the designing and constructing of satisfactory scales of 'meaning.'

3. A model was derived from Osgood's Mediation Hypothesis and Hull's theory of learning. This model accounts for the effects of 'meaningfulness' upon learning and recall in the waking state. According to it, a stimulus has 'meaning' to the extent that certain kinds of implicit cue-producing responses are attached to it. When such a stimulus becomes associated with an overt response in a learning situation, each implicit response takes on the function of a stimulus and as such becomes associated with the overt response. The net effect is a stimulus compounding situation in which the net reaction potential increases with the number of implicit responses involved, hence with the degree of 'meaningfulness' of the stimulus. From this the well-known greater recall associated with 'meaningful' material follows. With increase in 'meaningfulness' there is, however, also an increase in interference due to stimulus generalization. Application of the principle of the hypnotic stimulus shift developed in a previous paper allows one to account for the reported effects of hypnosis upon recall.

4. In final conclusions the value of hypnosis as a tool for deciding between alternate theories, and as a guide in theory construction and in the designing of experiments is emphasized in the light of the material of this paper" (p. 164).

#### COMPLIANCE

1998

Perugini, Eve Marie; Kirsch, Irving; Allen, Sarah T.; Coldwell, Eleanor; Meredith, Janelle M.; Montgomery, Guy H.; Sheehan, Julia (1998). Surreptitious observation of responses to hypnotically suggested hallucinations: A test of the compliance hypothesis. International Journal of Clinical and Experimental Hypnosis, 46 (2), 191-203.

Suggestions for arm levitation and for visual, auditory, tactile, and taste hallucinations were administered twice via audiotape to a group of high suggestible students and low suggestible simulators. During one of the administrations, participants were led to believe they were alone, but their behavior was surreptitiously recorded on videotape and observed on a video monitor. During the other administration, they were observed openly by an experimenter who had not been informed about group assignment. When unaware that they were being observed, simulators were significantly less responsive to suggestion and engaged in substantially more role-inappropriate behavior. In contrast, the responsiveness of nonsimulating students was not affected by the presence of an experimenter, and they exhibited little role-inappropriate behavior even when alone. These data indicate that the responses of suggestible individuals reflect internally generated changes in experience and are not due to simple intentional compliance (i.e., faking).

1997

Ruehle, Beth L.; Zamansky, Harold S. (1997). The experience of effortlessness in hypnosis: Perceived or real. International Journal of Clinical and Experimental Hypnosis, 45 (2), 144-157.

Hypnotized individuals who successfully respond to a suggestion typically report

that the response requires little or no cognitive effort. It is important, however, to distinguish between whether this effect occurs in actual effort or is only perceived. In addition, the authors distinguish between cognitive effort expended to initiate a response and that required to maintain it. The authors examine the different predictions of four theories-compliance theory, sociocognitive theory (Lynn & Rhue, 1991), Hilgard's (1986) neodissociation theory, and Bowers's (1992) theory of dissociated control-regarding both of these distinctions. Experimental evidence bearing on the various predictions is examined. Additionally, the authors propose a number of design modifications that may help sort out the variables contributing to the effortlessness of the hypnotic response. -- Journal Abstract

Reed, Steven B.; Kirsch, Irving; Wickless, Cynthia; Moffitt, Kathie H.; Taren, Paul (1996). Reporting biases in hypnosis: Suggestion or compliance?. Journal of Abnormal Psychology, 105 (1), 142-145.

The tendency of highly hypnotizable participants to bias their retrospective perceptual reports in response to instructional demands was reexamined with the addition of low-hypnotizable control participants instructed to simulate hypnosis. Mean scores of high-hypnotizable participants and simulators did not differ, but the responses of simulators to the demand instruction was less variable than those of high-hypnotizable participants, and the shape of the response distribution was different. Unlike simulators, some high-hypnotizable participants who had reported changes in perception that were consistent with a hypnotic suggestion subsequently reported changes opposite to those suggested by a demand instruction. These data were interpreted as suggesting that the responses of high-hypnotizable participants to both the demand instruction and the preceding hypnotic suggestion were not entirely due to compliance.

1995

Gearan, Paul; Schoenberger, Nancy E.; Kirsch, Irving (1995). Modifying hypnotizability: A new component analysis. International Journal of Clinical and Experimental Hypnosis, 43 (1), 70-89.

The effects of the Carleton Skills Training Program (CSTP) on hypnotizability were compared to those of a modified training program in which instructions for physical enactment of the response were omitted. After training, subjects in the original CSTP reported an increase in the extent to which they intentionally enacted suggested behaviors. In contrast, subjects in the modified training program reported increased fantasy without voluntary physical enactment. Nevertheless, both training programs increased behavioral and subjective responsiveness to suggestion, and there were no significant differences in response enhancement between the two programs. Across conditions, increases in behavioral and subjective responses to suggestion were correlated with increased use of fantasy. In contrast, increases in enactment were correlated only with compliance. The modified training

program is recommended as a means of enhancing suggestibility with less likelihood than the original CSTP of engendering compliance.

Malinoski, Peter; Martin, Daniel F.; Aronoff, Jodi; Lynn, Steven Jay; Gedeon, Scott (1995, November). Hypnotizability, individual differences, and interpersonal pressure to report early childhood memories. [Paper] Presented at the annual meeting of the Society for Clinical and Experimental Hypnosis, San Antonio, TX.

#### NOTES

Infantile amnesia is attributed to developmental issues before 24 months. This study indicates non-hypnotic influences can shape early memories that cross the amnesia barrier.

227 Ss completed Harvard Scale and personality measures in Session 1. In Session 2 182 completed a suggestibility scale. In Session 3 they were selected, as if independent of earlier sessions - 143 [may have misheard number] Ss.

Interviewers told the selected Ss that they were experiencing something like psychotherapy, and they were asked to recall their earliest memory (independent of photos, what people had told them, etc.) Then Experimenters probed for earlier memories; that continued until Ss denied any more memories after 2 consecutive probes. Then Ss were asked to close their eyes and get in touch with more memories. Then they were told most Ss can remember more, including sometimes their second birthday party. After 1 minute, Ss were asked about memories of their second birthday. Then they were asked to focus on even earlier memories, implying it was expected and receiving complements for reporting earlier memories. Finally, Ss completed a post-study questionnaire.

Memory report was a verbal description of an event, person, or object. Initial memory mean age was 3.7; it correlated with Openness to Experience Scale and with Fantasy Proneness. Mean age of the last earliest memory report before the close eyes instruction was 3.2 years. After receiving visualization instructions, 59% reported a memory of their second birthday. Compliance correlated .33 with this. Subjective response, nonvoluntariness, and [missed words] also correlated.

Compliance scores correlated .28 with at least one memory at or before age 24 months. Yielding to leading questions correlated also with memory for an event at or before 24 months.

Clarity of memories decreased between conditions of initial memory, earliest query, birthday, and earliest memory. Mean confidence rating on 5 point scale for second birthday memory was 3.3; mean confidence rating for earliest memory was 3.6. Mean accuracy rating was 4.0, and 94% said their memory reports were accurate to at least a moderate degree.

The post study questionnaire, totally anonymous, indicated Ss did not feel much pressure to recall (2.9 on scale of 1-5). Only 9.8% indicated they felt a lot of pressure. Subjects also usually denied that they made up memories to satisfy the experimenter. On average, the reports of memory under visualization conditions occurred two years earlier than their first reported memories.

Zamansky, Harold S.; Ruehle, Beth L. (1995). Making hypnosis happen: The involuntariness of the hypnotic experience. International Journal of Clinical and Experimental Hypnosis, 43 (4), 386-398.

The authors tested the hypothesis that hypnotized individuals do not truly experience their responses to suggestions as occurring involuntarily, but instead absorb themselves in imagery that is congruent with the suggestions while avoiding critical thoughts, or even simply comply with suggestions without genuinely experiencing their responses as nonvolitional. Participants were instructed to engage in thoughts and imagery that conflicted with the suggestions given, were urged to pay attention to their behavior, and were questioned regarding the perceived involuntariness of their responses. Simultaneously, electrodermal skin conductance responses provided a measure of the truthfulness of their reports. It was found that responses to all hypnotic suggestions were reported as being involuntary, in spite of the conflicting imagery and increased saliency, and that these reports were truthful. These findings provide disconfirming evidence for the sociocognitive theories of hypnosis.

Balthazard, Claude G. (1993). The hypnosis scales at their centenary: Some fundamental issues still unresolved. International Journal of Clinical and Experimental Hypnosis, 41, 47-73.

Current approaches to the measurement of hypnotic performance can be traced back to the 19th century. In part because of these early origins and in part because of the nature of hypnotic phenomena, the hypnosis scales are unique psychometric instruments. The classic hypnosis scales are based on the notion of a "performance ladder"; items are scored on a pass/fail basis and can be arranged in increasing order of difficulty. Some of the implications on [sic]this "performance ladder" approach are reviewed. The evidence for two-mechanism models of hypnotic performance is reviewed. It is argued that this kind of formulation is at least as plausible as one that argues that the hypnosis scales measure "one thing" or "mostly one thing." If it were the case that the hypnosis scales were tapping two different and distinct processes, the label "hypnotic susceptibility" could not be unambiguously applied to scores on the hypnosis scales. The hypnosis scales would appear well-suited to the investigation of underlying mechanisms, yet no consistent picture of the mechanisms underlying hypnotic performance on the scales has emerged thus far. No resolution is presented, but some of the reasons why such a resolution is so elusive are discussed. The future of hypnosis scales is discussed with respect to multidimensional assessment and alternatives to the "work sample" approach.

#### NOTES

Author discusses the hypnotizability scales' history and psychometric properties, suggesting that they cannot have construct validity if more than one construct is involved. He states that many of the alternative formulations "posit structurally similar two- mechanism models, where the relative contributions of one and the other mechanism changes gradually with the difficulty of the hypnotic performance-

-that is, one mechanism is more important for easy items and the other more important in the difficult range. This kind of formulation has been advanced by a number of authors .... Although these formulations are structurally similar, the nature of the mechanisms has been variously conceptualized: nonability and ability components (Shor, Orne & O'Connell, 1962), primary suggestibility and somnambulism (Weitzenhoffer, 1962), minor and major dissociations (Hilgard, 1977), compliance and true hypnosis (Tellegen, 1978-1979), and cooperativeness and expectation at one end and absorption at the other (Spanos, Mah, Pawlak, D'Eon, & Ritchie, 1980). ... In a formulation such as Hilgard's (1977), where both mechanisms are dissociative, it may be that it makes some sense to understand both mechanisms as aspects of the same complex construct. In other formulations... it would appear more cogent to speak of two constructs. Spanos et al. (1980) found that 'cooperativeness and expectation may be particularly important in responding to ideomotor and challenge suggestions, while the ability to convincingly treat imaginings as real (i.e., absorption) becomes increasingly important for more difficult 'cognitive' items" (p. 21). Balthazard & Woody (1992) presented evidence that the more difficult items on hypnotizability scales are related to absorption more than the easier items.

Balthazard & Woody (1989) investigated the proposition that hypnotizability scores are distributed bimodally, and concluded that statistical problems clouded the issue. Furthermore, most analyses previously have been of surface structure, which does not relate directly to the underlying mechanisms of hypnosis, and current psychometric methods cannot address the mechanisms that underlie surface relations. "There are two aspects of hypnotic processes ... that obscure underlying mechanism: synergisms and overdetermination. Synergisms occur when mechanisms potentiate each other in such a way that a combination of processes becomes more than the sum of its parts. Overdetermination occurs when co-occurring mechanisms do not potentiate each other, such that any one of the mechanisms would have been sufficient to produce the observed effect" (p. 63-64).

The author suggests there are two options at present: Corrective Scoring (like the Curss.OI, an objective-involuntary score which, although unreliable on test-retest, appears it could be more a measure of "pure" hypnotizability) and not using the typical "work sample" approach. Balthazard and Woody (1992) suggested the Absorption Scale may provide a better measure of "hypnotizability" than the standard hypnosis scales because absorption scores are more strongly related to difficult hypnotic performances.

1992

Balthazard, Claude G.; Woody, Erik Z. (1992). The spectral analysis of hypnotic performance with respect to 'Absorption'. International Journal of Clinical and Experimental Hypnosis, 40, 21-43.

In factor analyses of the hypnosis scales, the essential result is that the items form a continuous, 2-dimensional fan-shaped pattern. This continuum is referred to as the "spectrum of hypnotic performance." "Spectral analysis" is introduced as an exploratory procedure which makes use of this notion of continuum or spectrum.

Spectral analysis consists of a graphical display of the level of latent correlation between a variable and individual hypnotic performances when the latter are arranged according to their position in the spectrum. The spectral analysis of hypnotic performance with respect to absorption is illustrated using data from a sample of 160 Ss. The results indicate that absorption is more strongly related to difficult hypnotic performances than to easy ones. In particular, illustrative item characteristic curves are presented to show that although easy hypnotic performances do not require the processes tapped by individual differences in absorption, a certain level of absorption is necessary to pass difficult hypnotic items. In addition, a high level of absorption may be sufficient in and of itself for difficult hypnotic performances. These results are discussed in light of some speculations by Shor, M. T. Orne, and O'Connell (1962) and Tellegen (1978/1979) concerning the differential contribution of ability components to performance on difficult hypnotic suggestions. The results are also related to a variety of work in social psychological models of hypnotic performance.

**NOTES:**

Spectral analysis "consists of a graphical display of the level of latent correlation between a variable and individual hypnotic performances when these hypnotic performances are arranged according to their position in the spectrum---which is indexed by item difficulty" (p. 25). Difficulty (the proportion of Ss that pass a given item) is on the X-axis; the degree of latent correlation is on the Y-axis. "It is necessary to differentiate between the manifest and the latent relationship of a variable to a dichotomously scored hypnotic performance. The manifest relationship is given by the point biserial correlation and the latent relationship is given by the biserial correlation. ... By inspecting the overall pattern of these biserial correlations as a function of item difficulty, it is possible to overcome the difficulty-content confound, because the biserial correlations are not affected by item difficulty" (p. 25).

"Throughout the easy and middle ranges [of item difficulty], the biserial correlation of hypnotic performance with absorption remains slightly above .2, then it rises sharply in the difficult range--beginning roughly where only one in four Ss can pass the item--to a value slightly above .5 " (p. 27). "In essence, the proportion of Ss that pass a particular hypnosis suggestion given a particular score on the absorption scale is being plotted" (p. 30).

In their discussion, the authors relate their position to that of other theorists. Shor, Orne, & O'Connell (1962) proposed that both ability and nonability components contributed to hypnosis, with ability being the primary determinant of hypnotic performance at deeper levels. Shor et al. found a correlation between depth ratings and a questionnaire that tapped 'hypnotic-like experiences' to be .45; the correlation was .84 when computed for only the Ss who became deeply hypnotized, but only .17 for Ss who were only lightly or medium-level hypnotized. They concluded that their questionnaire predicted hypnotizability only for the "deeper region" of hypnosis.

Tellegen (1978/1979) proposed a two-factor model, one factor being genuine responsiveness and the other being compliance . He suggested that various hypnosis test items draw on the two factors in differing degrees. Tellegen's genuine

responsiveness factor would be similar to Shor et al.'s ability components, and Tellegen's compliance factor would be similar to Shor et al.'s non-ability components. (The Shor model goes farther than Tellegen in positing a gradual shift in the relative contributions of the two components as one moves from easy to difficult items, and this gradualness is part of the authors' spectrum model.)

The two-factor model is different from the general factor (plus special factors) model suggested by E. R. Hilgard (1965); Hilgard's general factor would probably correspond better to the Tellegen genuine responsiveness factor and the Shor et al. ability component than to the compliance factor or nonability component, which probably would correspond more to the easier items on hypnotizability scales.

Spanos et al. (1980) suggested that cooperativeness and expectation might be more important with ideomotor and challenge suggestions, and ability to treat imaginings as real (i.e. absorption) more important for more difficult cognitive items. Sarbin (1984) developed a typology with two types of individuals--those who respond to the hypnosis context by "joining the game" and knowingly create an illusion that their response is involuntary (the compliance kind of response), and those who convince themselves and others that their response is involuntary (the genuine responsiveness factor kind of response).

[Speaking of the context effects observed but not replicated 100% of the time, on the correlation between absorption and hypnotizability.] "It is possible that context effects may depend on the difficulty of the hypnotic suggestions and the latent abilities of the sample used. For relatively good hypnotic Ss performing relatively difficult suggestions, the correlation of absorption with hypnotizability may be stable across different contexts; however, for less able Ss performing relatively easy suggestions, the correlation, depending more on the 'non-ability' component, may be quite responsive to context manipulations. It might also be mentioned parenthetically that details of the instructions used to introduce the particular hypnosis scale employed may differentially pull for one kind of component or the other" (p. 39).

**Bowers, Kenneth S. (1992). Imagination and dissociation in hypnotic responding. International Journal of Clinical and Experimental Hypnosis, 40 (4), 253-275.**

A neodissociative model of mind is better equipped than a social-psychological model to deal with the complexities of hypnosis, and of human behavior generally. It recognizes, as Coe's (1992) model does not, that behavior can be more automatically activated than strategically enacted. In particular, Coe's emphasis on human behavior as purposeful and goal directed does not distinguish between goal-directed behavior that serves a purpose, and goal-directed behavior that is performed on purpose. It is this distinction that permits goal-directed behavior to be dissociated from a person's conscious plans and intentions. In addition to offering a critique of Coe's "limited process" view of hypnosis, 4 main points are made in the interest of developing a slightly modified, neodissociation view of hypnosis. First, it is argued that goal-directed fantasies are more limited in their ability to mediate hypnotic responding than is commonly appreciated; as well, they do not seem to account for the nonvolitional quality of hypnotic responding. Second, it is argued that hypnotic

ability is not unidimensional, with compliance and social influence more apt to account for the low than for the high hypnotizable's responsiveness to suggestion. Third, compared to low hypnotizables, the hypnotic responsiveness of high hypnotizables seems more likely to result from dissociated control. In other words, for high hypnotizables, hypnotic suggestions may often directly activate subsystems of cognitive control. Consequently, the need for executive initiative and effort to produce hypnotically suggested behavior is minimized, and such responses are therefore experienced as nonvolitional. Fourth and finally, while goal-directed fantasies typically accompany hypnotically suggested responses, they are in many cases more a marker of dissociated control than a mediator of suggested effects.

Nadon, Robert; Dywan, Jane; Adams, Barbara (1992, October). The social psychology of depth reports: Skirting the important data. [Paper] Presented at the annual meeting of the Society for Clinical and Experimental Hypnosis, Arlington, ones who are affected by scale manipulations.

#### NOTES

Radke & Spanos used a new 7-point scale that permitted Ss to say they passed an item but were not hypnotized, and only 25% (instead of 88% on usual 4-point scale) said that they were hypnotized.

Do we delude ourselves in thinking reports of hypnotic depth just reflect scale wording, or is something genuine being measured? Radke & Spanos found that breaking down Ss into low, medium, and high hypnotizable groups, the mediums are the ones who are affected by scale manipulations.

Ofshe, Richard J. (1992). Inadvertent hypnosis during interrogation: False confession due to dissociative state; mis-identified multiple personality and the satanic cult hypothesis. International Journal of Clinical and Experimental Hypnosis, 40, 125-156.

Induction of a dissociative state followed by suggestion during interrogation caused a suspect to develop pseudo-memories of raping his daughters and of participation in a baby-murdering Satanic cult. The pseudo-memories coupled with influence from authority figures convinced him of his guilt for 6 months. During this time, the suspect, the witnesses, and all the evidence in the case were studied. No evidence supported an inference of guilt and substantial evidence supported the conclusion that no crime had been committed. An experiment demonstrated the suspect's extreme suggestibility. The conclusion reached was that the cult did not exist and the suspect's confessions were coerced- internalized confessions. During the investigation, 2 psychologists diagnosed the suspect as suffering from a dissociative disorder similar to multiple personality. Both psychologists were predisposed to find Satanic cult activity. Each concluded that the disorder was due to "programming" by the non-existent Satanic cult.

Spanos, Nicholas P.; Burgess, C. A.; Cross, P. A.; MacLeod, G. (1992). Hypnosis, reporting bias, and suggested negative hallucinations. Journal of Abnormal Psychology, 101, 192-199.

Examined the role of reporting bias in hypnotic negative hallucinations by using a paradigm in which reporting bias was assessed independently of perceptual change. In Experiment 1, highly hypnotizable subjects reported significant loudness reductions when tested for hypnotic deafness. Later, however, these subjects biased their reported loudness reductions in the absence of perceptual change, and their reporting bias scores were almost as large as their hypnotic deafness reports. Subjects also biased their ratings of strategy use. In Experiment 2, ratings of blindness given in response to a hypnotic negative visual hallucination suggestion were significantly correlated with reporting bias scores obtained in this paradigm. Although hypnotic blindness and hypnotic deafness correlated significantly, the partial correlation between these variables was nonsignificant when reporting bias scores were statistically controlled. Results are used to support a skeptical view of hypnotic response as being based on compliance.

Wagstaff, Graham F. (1991). The role of compliance in hypnotic and nonhypnotic analgesia. Contemporary Hypnosis, 8, 176-180.

NOTES

This is a review of the paper by Spanos, Perlini, Patrick, Bell, & Gwynn (1990), The role of compliance in hypnotic and nonhypnotic analgesia, *Journal of Research in Personality*, 24, 433-453.

The author interprets the Spanos et al. results to indicate that high hypnotizables are more compliant or conforming when a measure of compliance is taken close to the hypnosis situation, and that hypnotic analgesia demonstrated in laboratory studies is largely the result of compliance (and Highs are most likely to exhibit compliance here as well). He suggests that compliance is not rare and frequently contributes to hypnotic response (especially among highly hypnotizable people), and would 'explain' such phenomena as hypnotic hallucinations (both positive and negative), automatic writing, and hypnotic amnesia and analgesia. Highly hypnotizable people seem to reinterpret their experiences in line with what is expected of them, then they come to believe in their own reinterpretations.

He emphasizes that "there is no necessary contradiction between the operation of compliance and the efficacy of techniques employing suggestion in some therapeutic situations especially when patients present with symptoms that are social in origin. In clinical contexts, not only might compliance motivate patients to obey instructions, and modify deviant behaviours, it could also operate as a useful social device to modify undesirable behaviours, by enabling the patient to 'save face' ... Also, for some subjects at least, some degree of compliance may be necessary to experience certain effects genuinely; for example, reports from some subjects in our laboratory at Liverpool suggest that it may be necessary to voluntarily initiate suggested 'involuntary' movement, before the movement can subsequently be interpreted as involuntary (see also Cardena & Spiegel, 1991, p. 104 [Cardena, E. &

Spiegel, D. Suggestibility, absorption, and dissociation, In J. F. Schumaker (Ed.), *Human Suggestibility: Advances in Theory, Research and Application*. New York: Routledge] (p. 179).

Bates, Brad L. (1990). Compliance and the Carleton Skill Training Program. *British Journal of Experimental and Clinical Hypnosis*, 7, 159-164.

#### NOTES

He presents examples of how the Carleton training program for increasing hypnotizability encourages compliance, which suggests that the results are not truly an increase in suggestibility or hypnotizability.

Burgess, Cheryl A.; Du Breuil, Susan C.; Jones, Bill; Spanos, Nicholas P. (1990-91). Compliance and the modification of hypnotizability. *Imagination, Cognition and Personality*, 10 (4), 293-304.

This study compared compliance-induced reporting bias in subjects who attained high hypnotizability scores following skill training and subjects who obtained equivalent scores without benefit of skill training (naturals). Low hypnotizables in one condition were administered the Carleton Skills Training Package and later posttested for hypnotizability. Control subjects were posttested without benefit of skill training. As in previous studies, skill-trained subjects attained substantially higher posttest hypnotizability scores than controls. In a final session, skill trained subjects, untrained naturals matched against the skill trained subjects on hypnotizability scores, and low hypnotizable controls were tested in a suggested deafness paradigm designed to assess compliant responding. Skill-trained subjects and matched naturals reported significantly greater suggested deafness than did the controls. However, only theory matched naturals exhibited significant levels of compliance-induced reporting bias. These findings indicate that skill-trained subjects exhibit no more compliant responding than do natural high hypnotizables

Levitt, Eugene E.; Baker, Elgan L., Jr.; Fish, Ronald C. (1990). Some conditions of compliance and resistance among hypnotic subjects. *American Journal of Clinical Hypnosis*, 32 (4), 225-236.

Five experimental approaches to the resolution of the century-old Bernheim/Janet dispute and the issue of involuntariness or coercion (the classical suggestion effect) are presented. Four experiments are reported that follow one of the approaches: attempts to induce hypnotic subjects to resist suggestions made in trance. The design is one in which a "resistance instructor" proposes a reward for the resisting subject. Tentative inferences from the results are that the classical suggestion effect is found with a small number of subjects; for a larger number of subjects there is no classical suggestion effect, and for many subjects the outcome is equivocal. Relational factors in the hypnotic dyad influence responsiveness in the subject, the effect being least for those whose susceptibility is high.

## NOTES

**Study I.** Used a \$5 bribe, two suggestions, and Ss resisted average of 1.2 suggestions. 9 Ss resisted both, 5 resisted neither, and 6 (30% of Ss) resisted one test suggestion. Resistance appeared to be related to impression of the resistance instructor, suggesting that "neither the monetary bribe nor hypnotic responsiveness was as important to the resistance/compliance dimension as relational factors" (p. 228).

**Study II.** Used only one suggestion, obtained quantitative ratings of the two instructors, and offered \$10 to resist one suggestion. 19/40 Ss (48%) resisted. The authors wondered whether the difference in impressions of hypnotist and resistance instructor might be due to very limited contact with the latter.

**Study III.** Ss were greeted by the resistance instructor, who accompanied Ss to the experimental room, discussed the information under 'Establishing Rapport Prior to the Initial Induction' in the SHSS:A and a condensed version of the introduction to the Eye Closure item (10 minutes). Then he left, the hypnotist entered and administered the same 9-item SHSS:A that had been employed in Studies I and II. The resistance instructor then entered and offered \$10 if the S could successfully resist the hypnotist's suggestion on the second try [of an item just passed successfully]. The hypnotist re-entered, repeated SHSS:A instructions for the selected item, brought S out of hypnosis, and then a different experimenter did a structured interview--to give impressions of the hypnotist and the resistance instructor on an Adjective Rating Form (ARF), to estimate depth of their trance on 0-8 scale before and after contact by the resistance instructor. Then S was paid if he/she had resisted. The resisters obtained a mean on the SHSS:A of 4.8 compared to 7.9 for the nonresisters, significant t-test for the difference ( $p < .01$ ).

**Table 1 A Comparison of Interview Ratings of Hypnotists and Resistance Instructors in Two Studies**

Hypnotist\* Resistance Instructors\*\* Study N Pos Neutral Neg Pos Neutral Neg II 39 69% 31% 0% 5% 72% 23% III 30 63% 20% 17% 43% 27% 30%

\* Chi square (2) = 7.71,  $p < .05$  \*\* Chi square (2) = 24.3,  $p < .001$  [N.B. Figures were rounded to nearest whole number by JH.]

The correlation between hypnotizability on the SHSS and Resistance may be found in Table 2, along with the percentage of nonresisters in each of the four studies.

**Table 2**

\* Not significant

In Table 1 it may be seen that perceptions of the hypnotist and the resistance instructor changed from Study II to Study III. "In summary, the manipulation of time spent in the second experiment increased the proportion of resisters and dramatically improved the impression of the resistance instructor. Nevertheless, the evidence suggests that the hypnotist continued to be perceived positively and, according to our best measure, was still perceived more positively than the resistance instructor" (p. 232).

Because they suspected that the impressions of the experimenters might be confounded by hypnotic susceptibility, and \$10 might not be enough reward for

behavior shaping, the experimenters designed Study IV. Study IV used 12 high hypnotizables (scoring 11 or 12 on Harvard Scale; with a group mean of 8.8 on a 9-item version of the SHSS:A). The same procedure as in Study II was carried out, except that four experimenters other than the authors were the hypnotists and resistance instructors; each experimenter worked with three subjects. The incentive was \$100 to resist.

The results of this procedure were that six Subjects resisted and six complied; each group scored 8.8 on the SHSS:A 9-item scale; resisters had 5.7 mean and nonresisters 5.1 mean depth (nonsignificant).

Resisters and compliers were exactly alike in their perceptions of the hypnotist, but appeared different in perception of the resistance instructor (and the N was too small to test statistically).

**Table 3**

**Rated Impression of Hypnotist (%)**

	IV	41	54	48	50
		65	57		

\*Lower score is more favorable.

**Summary of the Four Studies:**

The data in Tables 2-5 reflect a critical finding. "There was a sharp drop in the number of Ss who did not resist, or it may be clearer to put it as a sharp increase in the number of resisters. The change is nearly 40%.

"However, when only responsive subjects were used as in Study IV, the percentage of nonresisters is much the same as it was in Study II" (p. 233). The authors conclude that "relational factors are more important in hypnotic behavior among less responsive subjects" (p. 233).

"The data contrasting resisters and nonresisters are somewhat confusing. There were more positive and negative impressions among subjects who resisted and more neutral impressions and no negative impressions among the nonresisters," (pp. 233-234) though the number of cases involved is quite small. Using the ratings, the nonresisters had a more favorable impression of the hypnotist than did the resisters, which is in accord with the interviewers' ratings.

"A striking finding is that nonresister Ss in Study IV had a less favorable impression of both hypnotist and resistance instructor ... a clear reversal from Study III for the hypnotist, not quite so clear for the resistance instructor" (p.234).

Levitt, Baker, & Fish draw the following inferences: "1. Hypnotic influence is truly coercive for a very small number of what Register & Kihlstrom (1986) have called the 'hypnotic virtuoso,' the most responsive individuals; for them, the classical suggestion effect is a reality; 2. Hypnotic influence, though perhaps not truly coercive, is manifestly strong for a somewhat larger group of highly responsive

individuals; the classical suggestion effect may exist for them; 3. For many individuals who behave in accordance with hypnotic suggestions, the classical suggestion effect does not exist; 4. Relational factors in the hypnotic dyad influence hypnotic responsiveness. The influence is strongest among individuals of low-to-moderate hypnotic responsiveness; 5. The more positive the impression of the hypnotist, the greater will be his influence on the hypnotized individual; 6. A subject's impression of a hypnotist will tend to be favorable even though the sole interaction between the two is the induction of the trance; 7. Preliminary efforts to build rapport with the subject will tend to improve the already positive impression created by the hypnotist" (pp. 234-235).

Some conditions of compliance and resistance among hypnotic subjects: A rejoinder to invited discussion of Levitt, Baker, and Fish: Some conditions of compliance and resistance among hypnotic subjects. American Journal of Clinical Hypnosis, 32 (4), 246-249.

#### NOTES

We cannot see how Lynn can allege that in three of the studies there was no relationship between resistance-nonresistance and perception of the hypnotist. The appropriate correlation coefficients are reported in Studies II and III.

"Coe's point about the confounding of incentive and susceptibility might be valid if we had no prior knowledge of the relationship between resistance and susceptibility. But we already knew that the most susceptible Ss were likely to be the nonresisters. In Study IV, we abandoned susceptibility as an independent variable and made it a sample descriptor. ... [However] we resonate to Coe's suggestion of simulators" (p. 247).

"In our first three studies, we reported no relationship between occupation and resistance, an admittedly crude but unobtrusive approach to the question of whether the most financially needy subjects were the resisters. We usually compared the students in the sample with the employed subjects. We did not report this lack of relationship in Study IV in which only three subjects were students. Two resisted, one did not.

We must accept responsibility for provoking Coe's question about the credibility of the financial incentive in Study IV, by poor reporting. In a postexperimental inquiry, one subject (a resister) was mildly suspicious of the offer. All other Ss found the resistance instructor credible" (pp. 247-248).

"Our own more recent research suggests that offering undergraduate students additional points toward the final class grade can yield more resisters than the money incentive in Study IV (Levitt, Baker, Hacker, Klion, Krause, Lytle, & Vanderwater- Piercy, 1990 in press)" (p. 248).

"We have suggested that the hypnotic phenomenon is apparently experienced differently among subjects, and the critical factors are thus also likely to vary from subject to subject. We would be quite willing to accept Bernheim's estimate that 17% are incapable of resisting hypnotic suggestions, as cited by Weitzenhoffer. We agree with Spiegel that the issue of the coercive potential of hypnosis is 'not really

settled by mean differences across groups.' Measures of central tendency are apt to obscure the minority of Ss who may experience coercion in experiments with designs different from ours" (p. 248).

Compliance and resistance in the hypnotic state: the effect of a social or an academic countermotivation. In R. van Dyck, P. Spinhoven, . J. W. van der Does, Y. R. van Rood, & W. De Moor (Eds.), *Hypnosis: Current theory, research, and practice.* Amsterdam: Free University Press.]

Lynn, Steven Jay (1990). Is hypnotic influence coercive? Invited discussion of Levitt, Baker, and Fish: Some conditions of compliance and resistance among hypnotic subjects. *American Journal of Clinical Hypnosis*, 32 (4), 239-241.

#### NOTES

Unlike Levitt, Baker, & Fish (1990), Lynn, Rhue, & Weekes (Psychological Review, 1990 in press) concluded that nonvoluntary behaviors in hypnosis are similar to other spontaneous social behaviors (like conversational response to social stimuli). "Hypnotized subjects, like nonhypnotized subjects, act in terms of their aims, according to their point of view, and in relation to their interpretation of appropriate behavior and feelings" (p. 239).

"Research shows that hypnotizable subjects resist and even oppose suggestions as a function of their expectancies and perceptions about appropriate hypnotic behavior (Lynn, Nash, Rhue, Frauman, & Sweeney, 1984; Lynn, Snodgrass, Rhue, & Hardaway, 1987; Lynn, Weekes, Snodgrass, Abrams, Weiss, & Rhue, 1986; Spanos, Cobb, & Gorassini, 1985). In one study (Spanos et al., 1985), when subjects were informed that deeply hypnotized subjects were capable of becoming involved in suggestions and simultaneously resisting them, subjects resisted 95% of the suggestions. When subjects were told that deeply hypnotized subjects were incapable of resisting suggestions, they passed the majority of suggestions. Thus, knowledge about what constitutes appropriate hypnotic role behavior is a reliable determinant of resistance, apparently more reliable than the monetary lures used by Levitt et al." (P. 240).

These studies by Levitt et al. only used behavioral measures of resistance and hypnotizability, and Ss' perceptions of the resistance instructor and hypnotist. "The ratings of global perceptions are, however, no substitute for measures of subjects' perception of the *\_relationship\_*. ... The failure to measure important variables relevant to the central dimensions of concern--coercion, compliance, involuntariness, and relational factors--precludes meaningful interpretation of the nonresisters' motivation and behavior" (p. 240).

As Orne (1959) has suggested, we should not attribute behavior in the hypnosis context to something unique to hypnosis (such as coercive influence), because other kinds of social context also constrain behavior, e.g. psychotherapy and psychology experiments, with coercive features. Therefore, it seems important in the future to compare the responses of hypnotized subjects with those of subjects in waking-

imagination and hypnosis-simulating conditions. In addition to looking at their behavior, it is important to examine their own perceptions of their actions, given the complexity of the social situation entailed in hypnosis.

"Finally, there are statistical grounds to be wary of the authors' conclusions. They assert that 'relational factors in the hypnotic dyad influence hypnotic responsiveness,' yet in three of the studies (I, II, and IV), subjects' ratings of the hypnotist failed to discriminate whether they resisted or responded to the suggestion" (p. 241). Even where Study III was compared with Study II, the difference in the percentage of Ss who resisted failed to reach statistical significance. "In fact, across all studies, differences in overall resistance rates were not documented by statistical tests--despite procedural variations and differing monetary incentives. So contrary to authors' assertion, relational factors \_in the hypnotic dyad\_ generally had little bearing on resistance behavior. If anything, ratings of the resistance instructor had greater weight" (p. 241).

Spanos, Nicholas P. (1990). More on compliance and the Carleton Skill Training Program. British Journal of Experimental and Clinical Hypnosis, 7, 165-170.

#### NOTES

In this paper the author counters Bates' (1990) criticisms of the Carlton Skills Training Program, e.g. that the program induces Subject compliance rather than genuine increases in hypnotizability. The author states that the training program is designed to induce conformance rather than simply compliance with suggested demands.

He notes that in order to avoid the twinges of conscience associated with a self-definition of cheating, most Ss fail suggestions to which they are unable to generate the requisite subjective response. (Most Ss fail most of the suggestions on standardized hypnotizability scales despite the fact that all of these suggestions are easily fokable.)

"The findings of the Spanos et al. (1987) and Cross and Spanos (1988) studies suggest that, given appropriate attitudes and interpretations, subjects who benefit most from skill training are those who possess the cognitive abilities that enable them to vividly create and become absorbed in the imaginary scenarios called for by test suggestions. It is much less clear how these findings could be accounted for in terms of compliance. There is no evidence to indicate that imaginal propensity indexes are strongly related to a general tendency towards compliance and, at any rate, low hypnotizables who undergo skill training are, by definition, subjects who failed to comply with test demands during initial hypnotizability testing.

"In summary, when taken together the available data suggest that compliance cannot account adequately for CSTP-induced gains in hypnotizability. Obviously, this conclusion should not be interpreted as saying that compliance plays no role in training induced hypnotizability gains, or that the role of compliance in this regard should not be thoroughly investigated. As Wagstaff (1981) has repeatedly emphasized, compliance appears to be an integral component of hypnotic responding. Recent evidence from our laboratory (Spanos et al., 1989a) supports Wagstaff's (1981) contention by indicating that untrained high hypnotizables engage

in substantial levels of compliance when the 'pass' at least some difficult test suggestions. Given that natural high hypnotizables engage regularly in some compliant responding, it would be rather surprising to find that created highs did not do the same. However, examining this issue empirically requires the application of experimental paradigms that allow compliance to be differentiated from conformance.

Spiegel, David (1990). Theoretical and empirical resistance to hypnotic compliance. Invited discussion of Levitt, Baker, and Fish: Some conditions of compliance and resistance among hypnotic subjects. American Journal of Clinical Hypnosis, 32 (4), 243-245.

#### NOTES

Does hypnosis bypass the will, facilitate coercion? The hardest thing for trauma victims to do is to admit helplessness. Furthermore, it is interesting that these same dissociative phenomena seem to be elicited by traumatic experience, the stark imposition of involuntariness (Stutman & Bliss, 1985; Spiegel, Hunt, & Dondershine, 1988). What, then, are we to make of experiments that purport to show that hypnotizable and hypnotized individuals comply with hypnotic instructions irrationally? At some level this challenges our comfortable belief that we always act in our enlightened self-interest, unaffected by unwanted influence. If that can happen even once, our pride of self-ownership is reduced.

Taken as a whole, the studies show that high hypnotizables comply with hypnotic instructions, even in the face of resistance instructions, whereas low hypnotizables are less likely to, especially when conditions foster a relatively less negative view of the resistance instructor. As the authors note, subjects always viewed the hypnotist more positively than the resistance instructor, which in itself suggests the nonrational influence intrinsic to hypnosis. Free will is not abrogated, it is simply not exercised. The Ss are fundamentally choosing whether or not to comply. Half of the highs in Study IV resisted the hypnotic instruction. However, hypnotized individuals tend to narrow the focus of attention, thereby reducing their ability to consider alternatives such as the resistance instruction.

William James (1890) believed that all ideas were invitations to action. Why, then, do we not act on every idea we have, he pondered on a snowy morning while lying in bed. He observed that he would try to get himself to arise by picturing himself doing so. "Why, then, am I still in bed?" He realized that he was editing the primary idea, reflecting on how cold it was, how long it would take to light a fire, and how much time he had until his classes. In a state characterized by a narrowing of the focus of attention, we are less likely to edit the primary idea, and therefore more likely to act. In the experiments presented, the resistance instructor attempts to act as an external editor on the primary hypnotic instruction. Those capable of focusing attention sufficiently disattend to the editing and comply. These studies show that, thankfully, hypnosis is less than automatic submission to instruction but, interestingly, more than simple conscious response to new information.

Weitzenhoffer, Andre M. (1990). Are induced automatism necessarily coercive? Invited discussion of Levitt, Baker, and Fish: Some conditions of compliance and resistance among hypnotic subjects. American Journal of Clinical Hypnosis, 32 (4), 245-246.

## NOTES

For the sake of maintaining historical accuracy, I would like first to remark that the ability of hypnotized Ss to resist suggestions was probably never a central issue in the Nancy-Salpetriere controversy. The main quarrel was about other fundamental matters (Crocq, 1900; Barrucand, 1967). It also needs to be said that Pierre Janet should not be seen as representing the Salpetriere in the above controversy. Very little of his extensive writings reflect the ideas of Charcot with whom he was associated for only 4 years (1889- 1893) (Barrucand, 1967; Ellenberger, 1970). Lastly, let it be noted that the association of automatism with hypnotic behavior antedates Bernheim. Despine wrote about it at length as early as 1868, and Charcot (1882) clearly stated before Bernheim that automatic responses to suggestions were characteristic of induced somnambulism. This was at least one view they shared.

Referring to the material quoted from my 1978 paper, the authors assert Bernheim's definition of automatism implies a subject responding to a suggestion qua suggestion is "unable to resist" it. But all the definition says is that the will does not directly enter into the production of automatism. It does not say the will cannot effectively intrude at some point or other. This definition, quoted out of context, was part of a more extensive discussion of what the nature of an automatism was for Bernheim. The discussion also went into details regarding the conditions under which Bernheim understood automatism can occur and hold sway. In this greater context, Bernheim (1888a, 1888b) viewed the occurrence of automatism as normally subject to control by the ego processes responsible for volitional activities. He saw the degree to which a person's behavior can be controlled by automatism initiated by suggestions to be a function of the extent to which certain ego processes become inactive, ineffective, or cooperatively permit the automatism to occur. Bernheim recognized that both cognitive and relational factors played an important part in the latter case. Bernheim (1888a, 1888b) also stated that data he had collected showed subjects could resist suggestions to varying degrees, with only 17%, who made up the class of somnambules, being totally incapable of resisting" (pp. 245-246).

"Stating the matter more concretely, I doubt many people would speak of an individual having been 'coerced' into producing a knee-jerk reflex under appropriate stimulation. Should the situation be any different in the case of other reflexes and, more particularly, the reflex ideodynamic action presumed to underlay suggested acts (Weitzenhoffer 1978, 1989)? I do not think so. It seems to me that what the authors have really and directly examined in their article is the extent to which the classical suggestion effect can be countered by conscious, voluntary control" (p. 246).

Baker, Elgan L.; Levitt, Eugene E. (1989). The hypnotic relationship: An investigation of compliance and resistance. International Journal of Clinical and Experimental Hypnosis, 37, 145-153.

The purpose of this investigation was to assess the ability of hypnotic Ss to voluntarily resist a neutral suggestion when a monetary reward was offered for resistance. 19 of 40 Ss (47.5%) successfully resisted after money was offered by the "resistance instructor." The correlation between resistance/compliance and hypnotizability was  $-.44$  (high hypnotizables were more likely to comply). Ss' impressions of the hypnotist tended to be positive; impressions of the resistance instructor tended to be neutral. There was a tendency for nonresistors to have a more positive view of the hypnotist but it is not as marked as was found in an earlier study (Levitt & Baker, 1983).

#### NOTES

Twelve (75%) of the high hypnotizables did not resist; two (16.7%) of the low hypnotizable Ss did not resist.

In their discussion, they state that "these data support the conclusion that hypnotizability or talent accounts for a significant portion of the variance in determining compliance with suggestions during trance. ... [Further], this research may be conceptualized as examining the contributions of a trait variable (hypnotizability) as compared with a variety of situational or state variables (motivation, social perception, environmental contingencies) in determining compliance and suggestibility. Inherent in this model of research is the assumption that many observed hypnotic phenomena (such as suggestibility) are interactive in nature, representing the outcome of the interplay between trait and state variables and between historically determined and contemporary forces. Such a perspective is consistent with the emerging view of trance behavior and experience and validly parallels the phenomenology of experimental and clinical hypnosis which describe both consistency and variability in hypnotic responsiveness for a specific subject or patient across varying conditions and time" (p. 151).

"This study also serves to clarify the important role of positive social perception and a positive sense of alliance with the hypnotist as a correlate of compliance with suggestion. It is clear that Ss who complied despite inducements to resist reported a more positive perception of the hypnotist and a more gratifying sense of relatedness with him than did their counterparts who resisted in response to financial inducement. These data do not indicate whether the positive perceptions contributed to compliance, as transference theories of trance involvement would predict, or whether they were consolidated after the fact due to other variables such as management of potential cognitive dissonance. It does seem reasonable to conclude, however, that the relationship is influential in the process of suggestibility and compliance" (p. 151).

1989

Holroyd, Jean; Maguen, Ezra (1989). And so to sleep: Hypnotherapy for lagophthalmos. American Journal of Clinical Hypnosis.

We used hypnosis to facilitate eye closure during sleep for a 44-year-old woman whose nocturnal lagophthalmos prevented use of a contact lens following cataract surgery and could have resulted in severe corneal damage. On three separate occasions the symptoms remitted following a very brief course of treatment. We discuss the results in terms of alternate theories of hypnotic performance.

#### NOTES

The Discussion section notes, "There was an excellent correlation between the onset of hypnotherapy and the cessation of the recurrent corneal erosion secondary to nocturnal lagophthalmos. Healing of corneal erosion, disappearance of the superficial punctate keratopathy, and alleviation of ocular foreign body sensation occurred promptly following hypnotherapy (with two separate therapists)" (pp. 267-268).

The authors present the view that "heightened suggestibility, more vivid imagery, and more specific influence of thoughts upon organ systems probably came into play (Brown & Fromm, 1986; Holroyd, 1987). Social influence explanations (role taking, expectancy, compliance) seem less relevant as explanations. This highly motivated patient had not been able to keep her eyes closed during sleep despite her conscious efforts, her "good-patient" role, her positive expectations about the benefits of standard treatments, and respectful incorporation of the assistance provided by her ophthalmologist" (p. 268).

Jupp, J. J.; Collins, J. K.; Walker, W. L. (1989). Relationships between behavioural responsiveness to hypnotic suggestions and estimates of hypnotic depth following 11 sequential instances of hypnosis. Australian Journal of Clinical and Experimental Hypnosis, 17, 93-98.

Behavioral responsiveness to suggestions was assessed in an initial hypnosis session, and hypnotic depth was assessed in this session, followed by 10 weekly standardized hypnotic experiences. Correlations were calculated between behavioral responsiveness, initial and subsequent depth estimates, and between successive trance depth estimates. Levels of trance depth estimates were found to increase through weeks 1 to 11. Significant positive correlations were found between behavioral responsiveness scores and trance depth estimates to the fourth week but not beyond. Significant positive relations were found between successive estimates of trance depth except for the correlation between estimates for the fourth and fifth weeks. These results are discussed in terms of the estimates of trance depth being attributions from self-observations of behavioral responsiveness to hypnotic suggestions.

Nash, Michael R.; Spinler, Dwayne (1989). Hypnosis and transference: A measure of archaic involvement. International Journal of Clinical and Experimental Hypnosis, 37, 129-144.

20 Likert-type items were derived directly from Shor's theoretical propositions concerning the occurrence of transference-like experiences among hypnotic Ss. In 3 separate experiments, this 20-item Archaic Involvement Measure (AIM) was administered to 452 Ss following termination of both group and individually administered hypnosis procedures. Results suggest that: (a) AIM is internally consistent, and is significantly correlated with hypnotizability; (b) among high hypnotizable Ss, AIM scores assess an important aspect of hypnotic experience which is relatively unrelated to behavioral response to hypnotic suggestions; (c) there is no change in AIM scores associated with the sex of the hypnotist or S; and (d) there are 3 clusters of AIM items; perceived power of the hypnotist, positive emotional bond to the hypnotist, and fear of negative appraisal. Possible validation and clinical research applications of AIM are presented, along with a plea for further empirical examination of the relational dimensions of hypnosis.

**NOTES:**

Relates these findings to 'countering' (Sheehan, P., *Countering preconceptions about hypnosis: An objective index of involvement with the hypnotist. Journal of Abnormal Psychology, 1971, 78, 299-322*). "Countering is the tendency of some highly hypnotizable Subjects to comply with the intent of the hypnotist, even when there are strong nonhypnotic influences (e.g., social influences, expectations derived from previous lectures, perceptual constraints) to perform otherwise. ... Sheehan and Dolby (1979) found that hypnotic Subjects' dreams about the hypnotist were different than nonhypnotic Subjects' dreams, by being more positive and more often containing themes of protection, care, and authority. Interestingly, these themes were especially evident in the dreams of hypnotic Subjects who countered" (p. 130). The several experiments in this study investigate reliability, concurrent validity, and factor structure of the AIM. In their discussion, Nash and Spinler make the following points. As is the case with hypnotizability, AIM scores may have a bimodal distribution, at least when administered in the same context as a hypnosis measure. It is possible that these two modes define qualitatively different kinds of involvement with the hypnotist. "For high hypnotizable Ss, behavioral response to hypnotic suggestions appeared unrelated to the extent of archaic involvement with the hypnotist across both Experiments 2 and 3. Considering only the overall correlation between AIM and hypnotic responsiveness, one might argue that both scales measure general behavioral compliance and conformity, and that this explains their degree of association. It may indeed be correct to associate AIM scores with an overall conformity to respond, but only among low hypnotizable Subjects. For high hypnotizable Subjects, behavioral compliance (task performance) was not associated with AIM scores. Just as Sheehan's (1971, 1980) 'countering' studies suggest, among high hypnotizable Ss there appears to be no clear-cut relationship between the ability to perform hypnotic tasks and the special, motivated commitment to the hypnotist evidenced in some Ss. The theory of Shor (1979) and the empirical work of Sheehan and Dolby (1979) strongly suggest that an intense involvement with the hypnotist (archaic involvement) is a distinctive feature of the hypnotizable S's experience. The present work corroborates Sheehan and

Dolby's (1979) finding that, among high hypnotizable Ss, this involvement is not equivalent to overt response to the demands of standard test suggestions.

"Three findings further suggest that AIM scores assess an important aspect of the hypnotic S's experience which is relatively unrelated to behavioral task performance. First, AIM scores correlated significantly with a measure of subjective depth during hypnosis (Hypnotic Depth Inventory, Field, 1966). Second, the correlation between hypnotic depth and AIM scores was substantial for both low and high hypnotizable Ss. Thus, for high hypnotizable Ss, AIM scores were significantly correlated with hypnotic depth, even though they were unrelated to behavioral task performance. Finally, regression analysis suggested that AIM scores accounted for variance in hypnotic depth which was not explained by task performance scores. These findings, then, conform to Shor's proposition and Sheehan's (1971, 1980) later observations that archaic involvement with the hypnotist is a fundamental dimension of hypnotic experience which may not be directly related to the extent of behavioral response to hypnotic suggestions (see Shor, 1979, p. 119)."

"It is of some interest that the mean AIM score for low hypnotizable Ss was roughly equivalent to that of control Ss who had listened to a lecture prior to AIM administration. Only Ss who were exposed to hypnosis and who were behaviorally responsive to hypnotic suggestions evidenced elevated AIM scores" (pp. 140).

Spanos, Nicholas P.; Flynn, Deborah M. (1989). Compliance, imaginal correlates and skill training. [Comment/Discussion] .

#### NOTES

The authors defend the Carlton skill training program against accusation that the trained Ss are simply complying in the context of social pressure. They also discuss characteristics of high hypnotizables (absorption and imagery), noting that the majority of lows do not have low absorption/imagery scores (citing de Groh, 1988, and noting the research on context dependency for absorption).

"Despite all of this, it is worth noting that the results of our modification studies are not inconsistent with the hypothesis that high hypnotizability requires imaginative skills that some subjects do not possess in sufficient degrees. For example, two recent studies (Spanos et al., 1987; Cross and Spanos, 1988) found that the extent to which low hypnotizables showed gains following administration of the CSTP was predicted by their pre-tested levels of imagery vividness. Lows with good imagery benefitted substantially more from the CSTP than did lows with poor imagery ability. When it is kept in mind that most low hypnotizables do not score low on measures of imagery/absorption (de Groh, 1988), then the findings that substantial numbers of low hypnotizables can be taught to attain high hypnotizability is not at all inconsistent with the notion that high hypnotizability requires at least moderate levels of imagery/absorption ability" (p. 14).

Spanos, Nicholas P.; Flynn, Deborah M. (1989). Simulation, compliance and skill training in the enhancement of hypnotizability. British Journal of Experimental and Clinical Hypnosis, 6, 1-8.

Subjects who underwent cognitive skill training were compared to no treatment controls and to subjects in two simulation treatments on the behavioural and subjective dimensions of two hypnotizability post-tests. Ss in a trained simulation treatment received skill training but were instructed to fake the responses of someone who had been transformed by training into an excellent hypnotic subject. Standard simulators did not receive skill training, but were instructed to fake their responses to the two post- tests. A final group of untrained Ss (i.e. naturals) who attained the same behavioural scores on a hypnotizability index as did post-tested skill-trained Ss, was also compared to the treated groups. Ss in the two simulation treatments performed similarly on all hypnotizability indexes. Simulators outperformed both skill-trained and natural subjects (who failed to differ from one another) on all indexes, and skill-trained and natural subjects, in turn, outperformed the no treatment controls. These findings suggest that sustained faking cannot account adequately for the enhancements in hypnotizability produced by skill training.

1988

Coons, P. M. (1988). Misuse of forensic hypnosis: A hypnotically elicited false confession with the apparent creation of a multiple personality. International Journal of Clinical and Experimental Hypnosis, 36 (1), 1-11.

A case is presented in which there was flagrant misuse of forensic hypnosis. The patient, a woman in her early 30s, was accused of shooting her 2 children. During a hypnotic interview, the police hypnotist used an extremely suggestive interrogative technique, and the suspect produced an apparent secondary personality who confessed to the shootings. Subsequently the prosecutor tried to enter the "hypnotic confession" as evidence against the defendant. The evidence was dis-allowed because of the manner in which it was obtained and because of the lack of verification from other sources. The literature regarding the use of forensic hypnosis is reviewed as is the literature regarding multiple personality and the experimental production of multiple personality-like phenomena.

Gudjonsson, Gisli H. (1988). The relationship of intelligence and memory to interrogative suggestibility: The importance of range effects. British Journal of Clinical Psychology, 27 (2), 185-187.

60 normal adults and 100 adult psychiatric patients completed a suggestibility scale and the Wechsler Adult Intelligence Scale (WAIS). Clear range effects of IQ and memory were evident in their relationship with suggestibility

Spanos, Nicholas P.; Cross, Wendi P.; Menary, Evelyn; Smith, Janet (1988). Long term effects of cognitive-skill training for the enhancement of hypnotic susceptibility. British Journal of Experimental and Clinical Hypnosis, 5 (2), 73-78.

Twelve initially low susceptible subjects, who scored in the medium or high susceptibility range on the Carleton University Responsiveness to Suggestion Scale (CURSS) following skill training, were posttested 9 to 30 months later with a group version of the Stanford Hypnotic Susceptibility Scale, Form C. Skill trained subjects scored significantly higher on behavioral and subjective dimensions of the Stanford Hypnotic Susceptibility Scale, Form C than low susceptible untrained control subjects who were posttested after an equivalent interval. Furthermore, the posttraining CURSS scores of the skill trained subjects were matched to those of subjects who received the same CURSS scores without training. Matched subjects were posttested on the Stanford Hypnotic Susceptibility Scale, Form C after only a brief delay. Skill trained and matched subjects failed to differ significantly on Stanford Hypnotic Susceptibility Scale, Form C susceptibility dimensions, but skill trained subjects showed higher levels of suggested amnesia than matched subjects. These findings support the idea that hypnotic susceptibility is modifiable and that training induced gains in susceptibility can be enduring.

Evans, Frederick J.; McGlashan, Thomas H. (1987). Specific and non-specific factors in hypnotic analgesia: A reply to Wagstaff. British Journal of Experimental and Clinical Hypnosis, 4, 141-147. (Comment in response to Wagstaff, G. (1987). Is hypnotherapy a placebo? Hypnosis, 4, 135-140.)

#### NOTES

This article is a reply to Wagstaff's (1984) critique of the McGlashan, Evans & Orne (1969) article which was entitled "The nature of hypnotic analgesia and the placebo response to experimental pain," published in Psychosomatic Medicine, 31, 227-246. The paper to which the authors are replying is Wagstaff, G. F. (1984). Is hypnotherapy a placebo? Paper given at the First Annual Conference of the British Society of Experimental and Clinical Hypnosis, University College, London. An abridged version appeared in the British Journal of Experimental and Clinical Hypnosis, 1987, 4, 135-140.

The closing comments of this Evans & McGlashan 1987 paper read as follows: "The strategy in this study [i.e. McGlashan, Evans & Orne, 1969] was quite different from the usual experimental design. Our goal was to maximize all of those non-specific factors that we could build into the experimental procedure. Only by attempting to maximize non-specific effects is it possible to see whether hypnosis in appropriately responsive subjects can exceed that degree of pain control which occurs due to the maximal operation of these non-specific effects. These non-specific components of the hypnotic situation may account for a great deal of clinical change. ... The critical finding was that hypnosis did add a level of pain control that occurred after maximizing clinically related non-specific factors contributing to change in pain tolerance, and that this increased tolerance occurred only in subjects markedly responsive to hypnosis, in contrast to the significant non-specific effects which were uncorrelated with measured hypnotizability" (pp. 143-144).

The principal findings of the McGlashan, Evans & Orne (1969) study were: "(a) The improved ability to tolerate pain following the ingestion of placebo was roughly

the same for high hypnotizable and low hypnotizable subjects. (b) The response to the non-specific aspects of taking a 'drug' among low hypnotizable subjects was identical to, and highly correlated (.76) with, their response to the legitimized expectation that change would occur under hypnosis for low hypnotizable subjects. The placebo component of a believe-in 'drug' ingestion was the same as the placebo component of a believed-in hypnotic experience for these low hypnotizable subjects. (c) The performance of the highly hypnotizable subjects was significantly greater under hypnotic analgesia conditions than it was under placebo conditions.

"This last finding is important conceptually, though of less clinical relevance. It should be noted that not all high hypnotizable subjects showed this result. Even among highly hypnotizable subjects, not all of them had the experience that profound analgesia had occurred! Thus, based on their subjective experience of the relatively small degree of analgesia, 6 of the 12 highly hypnotizable subjects behaved exactly as the low hypnotizable subjects had -- their placebo and hypnotic responses were small, significant, but equal. Only 6 out of 12 carefully screened hypnotizable subjects who subjectively experienced marked analgesia showed dramatic objective changes in pain endurance. Dr. Wagstaff might consider the physiological implications of the observation that we became somewhat frightened about the possibility of tissue damage with two of these six subjects. We had to stop their performance at a point where physiologists had assured us that tissue damage could be expected. They had also assured us, wrongly for these subjects, that we did not have to worry about such a critical point because nobody could endure such a degree of occlusion with this procedure. In fact, for these two subjects, anoxia and muscle cramping were not even apparent!" ( p. 144).

1986

Milne, Gordon (1986). Hypnotic compliance and other hazards. Australian Journal of Clinical and Experimental Hypnosis, 14, 15-29.

Hypnosis is not an external 'force' or 'power' but a special kind of interaction between two persons. The outcome depends on the skill and intentions of the hypnotist and the responsiveness and compliance of the subject. Skill may be marred by procedural errors, 'sins of omission'; intentions by a self-centred rather than a patient-centred approach, 'sins of commission'. A hazard peculiar to the use of hypnosis is a fallacious belief in the power it enables the operator to wield over the subject.

1985

Stone, Jennifer A.; Lundy, Richard M. (1985). Behavioral compliance with direct and indirect body movement suggestions. Journal of Abnormal Psychology, 94 (3), 256-263.

Investigated the effectiveness of 2 types of suggestions in eliciting body movement by presenting 96 high-, medium-, and low-susceptible undergraduates, in hypnotic or nonhypnotic conditions, with either of 2 series of body movement suggestions. The indirect suggestions were designed to represent the approach of M. H. Erickson (see

PA, vol 60:11116 and 12262) and resulted in greater compliance in the hypnotic condition. Direct suggestions resulted in greater compliance in the nonhypnotic condition. Susceptibility to hypnosis was related to compliance in the hypnosis condition, but no interactions were found between susceptibility and type of suggestion. Sense of volition in responding was unrelated to the major findings. Discussion of the results includes a call for the accurate reporting of the wording of hypnotic suggestions in future research.

1983

Levitt, Eugene E.; Baker, Elgan L. (1983). The hypnotic relationship--another look at coercion, compliance and resistance: A brief communication. International Journal of Clinical and Experimental Hypnosis, 31, 125-131.

The purpose of the present investigation was to assess the ability of hypnotic Ss to voluntarily resist neutral suggestions on a monetary reward incentive. The results were ambiguous; Ss resisted with a mean of 1.2 of 2 suggestions each. Postexperimental interviews disclosed that all Ss felt that the instructions to resist were asking them to be disloyal to the hypnotist or to betray him. Ability to resist was positively correlated with Ss' impressions of the "resistance instructor" and tended to be negatively correlated with the impression of the hypnotist. These findings are interpreted to suggest support for an interactional conception of the hypnotic state.

Spanos, Nicholas P.; Dubreuil, Debora L., Saad, Carol L., Gorassini, Donald (1983). Hypnotic elimination of prism-induced aftereffects: Perceptual effect or responses to experimental demands?. Journal of Abnormal Psychology, 92 (2), 216-222.

Two experiments assessed adaptation to displacing prisms in hypnotically limb-anesthetized Ss. Experiment I with 18 college students disconfirmed the hypothesis that the displacement aftereffect is eliminated in limb-anesthetized hypnotic Ss who adapt to prisms in the absence of a visual target. Such Ss showed as large a displacement aftereffect as control Ss who received neither a hypnotic induction procedure nor an anesthesia suggestion. Experiment II with 30 undergraduates demonstrated that under some testing conditions hypnotic Ss complied with experimental demands and eliminated the behavioral but not the perceptual component of the aftereffect.

Wagstaff, Graham F. (1983). Comment on McConkey's "Challenging hypnotic effects: The impact of conflicting influences on response to hypnotic suggestion". [Comment/Discussion] .

## NOTES

"Probably the most consistent finding to emerge from McConkey's review is that hypnotic subjects tend to respond in accordance with what they feel the hypnotist really wants, regardless of conflicting experimental demands" (p. 13).

**Conn, J. H. (1981). The myth of coercion through hypnosis: A brief communication. International Journal of Clinical and Experimental Hypnosis, 29 (2), 95-99.**

A brief history of coercion through hypnosis is presented. Hypnosis is not an external "force," which can be used to overcome a subject's "will power." It can be used as an alibi, a folie a deux, a neurotic compromise, a legitimatization, or rationalization of behavior, as well as being genuine, involuntary, automatic hypnosis. Unwitting simulation occurs frequently. Laboratory crimes and stage hypnosis are "make believe" performances occurring in a completely protected situation. Neither a long-term relationship, nor an attempt to distort perception is a necessary or sufficient cause of coercion. The possibility of "motivated helplessness," a "self-fulfilling prophecy" or a "believed in efficacy" must be considered. Coercion through hypnosis is a myth which will not disappear so long as it is fostered by uninformed hypnotists, who believe that all initiative and self-determination is surrendered by the subject to an "all powerful" hypnotist.

**1981**

**Graham, K. R.; Greene, L. D. (1981). Hypnotic susceptibility related to an independent measure of compliance - Alumni annual giving: A brief communication. International Journal of Clinical and Experimental Hypnosis, 29 (4), 351-354.**

An attempt was made to relate hypnotic susceptibility to an objective measure of compliance in a real-life setting. Hypnotic susceptibility scores for 235 college graduates, who graduated between the years 1971-1979, were compared to their records for alumni annual giving. Those who had made at least 1 contribution to the college since graduation were significantly higher in hypnotic susceptibility than those who had made no contribution. The results suggest that willingness to respond to a persuasive appeal may be related to a person's susceptibility to hypnosis.

**1980**

**Sheehan, Peter W. (1980). Factors influencing rapport in hypnosis. Journal of Abnormal Psychology, 89 (2), 263-281.**

The phenomenon of countering expresses the tendency of some highly susceptible subjects to favor the intent of the hypnotist when placed in a conflict situation where social influences of another kind dictate an alternative response. The present research explored the parameters of this objective index of involvement with the hypnotist to investigate the special relevance of rapport processes to the hypnotic setting. Rapport was manipulated in five different experiments, varying either the warmth or genuineness of the hypnotist. It was predicted from transference theorizing that countering would decrease in the negative context and increase in the positive one. Results confirmed predictions for highly susceptible subjects tested in the former context but not the latter. In the negative setting, subjects were inhibited in their rate of countering, but maintained their previous level of response

to the hypnotist when rapport was facilitated. Results highlighted the relevance of interpersonal processes to theorizing about hypnosis.

**1979**

Perry, Campbell (1979). Hypnotic coercion and compliance to it: A review of evidence presented in a legal case. International Journal of Clinical and Experimental Hypnosis, 27 (3), 187-218.

There are 2 main positions concerning the potential of hypnosis to coerce unconsenting behavior. One position asserts that coercion is possible through the induction of distorted perceptions which delude the hypnotized person into believing that the behavior suggested is not transgressive. The other position asserts that where hypnosis appears to be a causal factor in coercing behavior, other elements in the situation -- especially a close hypnotist-client relationship -- were the main determinants of behavior. The present paper analyzes the court transcript of a recent case in Australia in which a lay hypnotist was found guilty of 3 sexual offenses against 2 female clients. The uniqueness of the case is that it pits the 2 main positions on hypnotic coercion against each other. The hypnotist admitted the acts attributed to him; his defense was that hypnotic coercion is impossible since a hypnotized person would resist immediately any transgressive suggestion. The women involved stated that they were aware of what was happening but that, because they were hypnotized, they were unable to resist. Analysis of the court transcript indicates that neither a hypothesis of hypnotically induced perceptual distortion, nor one of a close hypnotist-client relationship can account for the events that occurred. Other alternative explanations are discussed within the context of the inherent difficulties of analyzing a court transcript.

**1977**

Wickramasekera, Ian (1977). The placebo effect and medical instruments in biofeedback. Journal of Clinical Engineering, 2 (3), 227-230.

This article defines a "placebo effect" and identifies some of its parameters in pain control and in other areas of medicine. It proposes a new model of the placebo effect and advances the hypothesis that biomedical instruments used in biofeedback studies, like drugs, can acquire and generate placebo effects. Such placebo effects can complicate the interpretation of specific experimental treatments in human clinical research in which biomedical instruments are used.

**1963**

Sarbin, Theodore R.; Lim, Donald T. (1963). Some evidence in support of the role-taking hypothesis in hypnosis. International Journal of Clinical and Experimental Hypnosis, 11, 98-103.

A study was conducted to test the hypothesis that hypnosis is a form of role-taking behavior. Independent measures of hypnotizability as measured on the Freidlander-

Sarbin Scale and role-taking ability (improvisations) as judged by the Dramatics Department faculty were found to be significantly related. Those rated high in role-taking were above the mean in hypnotizability, but some high on hypnotizability were low in dramatics ability. (PsycINFO Database Record (c) 2002 APA, all rights reserved)

1958

Rosenberg, M. J.; Gardner, C. W. (1958). Some dynamic aspects of posthypnotic compliance. Journal of Abnormal and Social Psychology, 57, 351-366.

Within the context of a general, psychoanalytically-oriented theory of hypnosis there were presented two hypotheses on the nature of compliance with posthypnotic suggestions. According to the first, such compliance is viewed as facilitated by the subjects being able to interpret the posthypnotic suggestion in a manner consistent with the mechanisms and affective reactions that, for him, characterize and maintain the hypnotic relationship. In the second, compliance with a posthypnotic suggestion is viewed as facilitated if that suggestion permits the subject safely to express and indulge a previously warded-off and conflicted drive. Case record data drawn from a recent experimental study were presented which tend to confirm these two hypotheses.

## CONDITIONING

1996

Montgomery, Guy H.; Kirsch, Irving (1996, August). Conditioned placebo effects: Stimulus substitution or expectancy change. [Paper] Presented at the annual meeting of the American Psychological Association, Toronto, Canada.

Stimulus substitution models posit that placebo responses are due to pairings of conditional and unconditional stimuli. Expectancy theory maintains that conditioning trials produce placebo response expectancies, rather than placebo responses, and that the expectancies elicit the responses. I tested these opposing models by providing some participants with information intended to impede the formation of placebo expectancies during conditioning trials and by assessing placebo expectancies. Although conditioning trials significantly enhanced placebo responding, this effect was eliminated by adding expectancies to the regression equation, indicating that the effect of pairing trials on placebo response was mediated completely by expectancy. Verbal information reversed the effect of conditioning trials on both placebo expectancies and placebo responses, and the magnitude of the placebo effect increased significantly over 10 extinction trials. These data disconfirm stimulus substitution models and provide strong support for an expectancy interpretation of conditioned placebo effects. (ABSTRACT from Bulletin of Division 30, Psychological Hypnosis, Fall, 1996, Vol. 5, No. 3.)

1995

Montgomery, Guy H. (1995). Mechanisms of placebo analgesia: Expectancy theory and classical conditioning (Dissertation, University of Connecticut). Bulletin of Division 30, Psychological Hypnosis, APA, 5 (3), 2.

Stimulus substitution models posit that placebo responses are due to pairings of conditional and unconditional stimuli. Expectancy theory maintains that conditioning trials produce placebo response expectancies, rather than placebo responses, and that the expectancies elicit the responses. I tested these opposing models by providing some participants with information intended to impede the formation of placebo expectancies during conditioning trials and by assessing placebo expectancies. Although conditioning trials significantly enhanced placebo responding, this effect was eliminated by adding expectancies to the regression equation, indicating that the effect of pairing trials on placebo response was mediated completely by expectancy. Verbal information reversed the effect of conditioning trials on both placebo expectancies and placebo responses, and the magnitude of the placebo effect increased significantly over 10 extinction trials. These data disconfirm stimulus substitution models and provide strong support for an expectancy interpretation of conditioned placebo effects. 1993

Kraft, Tom (1993). Using hypnosis with cancer patients: Six case studies. Contemporary Hypnosis, 10, 43-48.

Hypnosis can be used in a number of different ways for helping patients suffering from cancer. As well as pain relief, hypnosis may be used to correct insomnia that does not respond to sleeping tablets; for the reduction in skin irritation and dyspnoea when these are due to organic causes, and for treatment-related over-eating. Some patients will use hypnosis in a symbolic way. When this occurs, just as in dream interpretation, it is important to ask the patient for associations, so that these symbols can be understood. Hypnosis can be an extremely useful addition to the medical armamentarium, and should be employed as an adjunct to standard forms of cancer treatment. This paper reports six case studies in which hypnosis was used to help cancer patients.

Wickramasekera, Ian (1993). Observations, speculations and an experimentally testable hypothesis on the mechanism of the presumed efficacy of the Peniston and Kulkosky procedure. Biofeedback, 21, 17-20.

Raises the speculation that alpha/theta EEG brainwave training procedures that have shown preliminary effectiveness with alcoholics and PTSD war veterans may be effective, at least in part, because of an enhancement of hypnotizability resulting from such training. Research to evaluate this is suggested.

1992

Kay, L. M. (1992, October). The effects of hypnosis, relaxation, and suggestion on visual acuity (Dissertation, California School of Professional Psychology, San Diego). Dissertation Abstracts International, 53 (4), 2065-B. (Order No. DA 9221587)

Evaluated the relative efficacy of several aspects of the hypnotic process on facilitating change in hypnotic state-dependent visual acuity in myopic student subjects. Five conditions included hypnosis with suggestions, neutral hypnosis, nonhypnotic suggestion, progressive relaxation, and a control (comedy). Visual acuity was assessed as baseline (a task-motivational situation where they were to try to see as well as possible) and after the experimental condition. Results found that hypnosis facilitated a significant improvement in visual acuity ( $p = .002$ ), although no differences were found in the other conditions" (p. 2065).

Page, Roger A. (1992). Clark Hull and his role in the study of hypnosis. American Journal of Clinical Hypnosis, 34, 178-184.

#### NOTES

The contributions of Hull include his attempts to dispel misconceptions about hypnosis, comparisons of capacities in the hypnotic state with those in the awake state, a sampling of early findings that are still valid today, and examples of his contributions to methodology. Additionally, the roots of many modern-day models and concepts are to be found in his early works.

"Bernheim (1902) had believed hypnosis was identical to natural sleep, while Braid (1899) had believed the resemblance between hypnosis and natural sleep was just superficial. Pavlov (1923) held an intermediate position; he hypothesized that hypnosis was a transition to true sleep involving selective inhibition of certain brain centers" (p. 179).

"His proposition that hypnosis conforms to the basic principles of habit formation was supported by his own work (1933) and, with few exceptions, holds true today. For example, many studies have found that hypnotic responding improves with practice and eventually reaches a plateau (e.g., As, Hilgard, & Weitzenhoffer, 1963; Evans & Schmeidler, 1966). Parenthetically, one can see a resemblance here to the later notion of 'plateau hypnotizability' (Shor, Orne, & O'Connell, 1966). Although Barber and Calverley (1966) did demonstrate that an exception to this proposition will occur if subjects become bored and disinterested, it is still true that hypnosis is generally facilitated by practice" (p. 181).

"Yet another example from the same work can be found in the following description of the results of a conditioning experiment: '... it is possible that the hypnotic group were conditioned more readily because they were the kind of individuals who are susceptible to hypnosis rather than because they were actually in the trance when subjected to the conditioning procedure.' (p. 219) In this statement, one can see the now taken-for-granted distinction between hypnotic susceptibility and being hypnotized, as discussed, for example, by Graham and Leibowitz (1972)" (p. 182).

"Still other now familiar concepts can be gleaned from his 1933 book. One would be the notion of trance having a kind of 'inertia.' Yet another stems from his hypothesis

that hypnotic suggestions produce relaxation, which in turn suppresses '... the spontaneous activity of the symbolic or thought processes.' (p. 310) This may well be the first conceptualization of what most recently has been referred to by Plotkin and Schwartz (1985) as the lack of a disposition or capacity to generate final-order appraisals" (p. 183).

Wall, Patrick D. (1992). The placebo effect: An unpopular topic [Editorial]. Pain, 51, 1-3.

## NOTES

The author presents a useful, brief review of the placebo effect. He suggests three hypotheses about the placebo response mechanism: 1. The effect is attributable to a decrease in anxiety (Evans, 1974). This view has not been validated (White, Tursky, & Schwartz, 1985). 2. Expectation, cognitively mediated, leads to behavioral effects. Certain personalities, described as placebo responders, report a stronger analgesia with a fixed dose of morphine than do people who are placebo non-responders (Beecher, 1968). White et al. (1985) proposed that simply asking what is expected of a medicine will identify who the placebo responders will be. Also, the placebo response to morphine is stronger than the placebo response to aspirin. Physician or nurse expectancy is influential as well as patient expectancy, and that means that 'blind' experimental trials are not truly blind. Kanto et al. (1966) found that the placebo effect is stronger when the placebo is given second than when it is given first in a crossover design. 3. The effect is due to a classical conditioned Pavlovian response (Wickramasekera 1980). Support for this comes from experiments on normal subjects whose pain and tolerance threshold had been established (Voudouris et al. 1989, 1990). For example, in one experiment in which electric current was the stimulus, a purportedly anesthetic ointment was applied to the locus of stimulation; some of the subjects showed a placebo response of diminished pain. A second group, treated in the same manner, had the pain producing electric current secretly reduced by the Experimenter. This second group, who had experienced reduction in pain that suggested the cream was truly analgesic, subsequently became strong placebo responders to the originally painful current and cream.

The author views the expectancy hypothesis and the conditioning hypothesis as not necessarily incompatible. Unlike the cognitively mediated expectation hypothesis, conditioning does not necessarily require cognition. But there is little support for the idea that human conditioning does not involve cognition [See Brewer, W. F. (1974). There is no convincing evidence for operant or classical conditioning in adult humans. In W. B. Weimer and D. S. Palermo (Eds.) *Cognition and the Symbolic Processes*. N.Y.: Wiley, pp 1-42.]

"If then the expectation and conditioning hypotheses are not clearly separate, it may be relevant to add an apparently unrelated group of phenomena. Humans and animals frequently show no signs of pain in the presence of overt injury (Wall 1979). It seems that pain appears only when reaction to injury is biologically appropriate. Could it be that expectation-conditioning is one of the factors which determines which item of our behavioural repertoire with its associated sensation is appropriate?" (p. 3).

1991

Rapee, Ronald M. (1991). The conceptual overlap between cognition and conditioning in clinical psychology. Clinical Psychology Review, 11, 193-203.

Given the fact that contemporary theories of conditioning regularly utilize information processing concepts such as memory and expectancies, classifying clinical theories as either cognitive or conditioned appears to be outdated. Yet, this dichotomy is still upheld in many clinical writings. Such a false dichotomy seems to serve more of a political function than a theoretical one and thus is likely to interfere with a complete understanding of psychopathology. While the terms conditioning and cognition are often used to imply unconscious learning on the one hand versus conscious, rational learning on the other, this usage is not consistent. A more empirically useful way to describe pathological behavior may be in terms of the amount of attentional resources utilized.

Russell, Christine; Davey, Graham C. (1991). The effects of false response feedback on human 'fear' conditioning. Behaviour Research and Therapy, 29 (2), 191-196.

Describes a human electrodermal conditioning experiment in which 28 students (aged 19-30 yrs) were given false skin conductance feedback during conditioned stimulus/stimuli (CS) presentation. In comparison with attentional control groups, Ss who believed they were exhibiting a strong conditioned response (CR) did actually emit a greater magnitude CR, while Ss who believed they were exhibiting a weak CR emitted a lower magnitude CR. When both self-report and behavioral measures of unconditioned stimulus/stimuli (UCS) evaluation were taken after conditioning, response feedback (RFB) had not differentially affected Ss' evaluation of the aversiveness of the UCS. The response modulating effects of RFB may not be caused by RFB influencing evaluation of the UCS, but they are consistent with the hypothesis that beliefs about the nature of RFB influence the strength of the UCS representation itself.

Badia, Pietro (1990). Memories in sleep: Old and new. In Bootzin, Richard R.; Kihlstrom, John F.; Schacter, Daniel L. (Ed.), Sleep and cognition (pp. 67-76). Washington, DC: American Psychological Association.

#### NOTES

Reviews literature. Conclusion: First, with reinforcement for responding, control of learned behavior can be maintained reliably by stimuli presented during sleep. Second, when stimuli are presented 4 min or more apart, behavioral control results in little or no change in sleep structure, in daytime sleepiness, or in perceptions of sleep quality. Neither perceived wakefulness nor wakefulness as it is scored on the sleep record are necessary for responding, although stimulus/response events typically result in brief EEG or EMG change. Third, within-subject, within-night variance in responsiveness is complexly related to time of night, sleep stage, and REM/NREM cycle.

Evans, Frederick J. (1990). Behavioral responses during sleep. In Bootzin, Richard R.; Kihlstrom, John F.; Schacter, Daniel L. (Ed.), Sleep and Cognition (pp. 77-87). Washington, DC: American Psychological Association.

#### NOTES

Subjects were 19 male student nurses who met a criterion of having EEG alpha density of at least 40% during an eyes closed, waking condition. They slept in the laboratory for two nights in succession, while being monitored by an EEG, and were told only that sleep cycles were being studied. Suggestions were presented while they were sleeping, e.g. "Whenever I say the word itch, your nose will feel itchy until you scratch it" "Whenever I say the word pillow, your pillow will feel uncomfortable until you move it." Then they were tested by Experimenter saying the cue word ("itch" or "pillow") during subsequent REM periods later that night and again on the next night. (The suggestions were not repeated on the second night; but two new suggestions were given on the second night when possible.)

After the Subjects awakened in the morning, they were interviewed to test their memory for the events that had occurred, and also cue words were presented in the context of a word association test to assess memory indirectly by observing behavioral and physiological responses. A more detailed inquiry was made after the second night.

The results were as follows. Ss responded to a mean of 21% of cue words administered. Ss continued to demonstrate REM sleep for at least 30 seconds for 71% of all cues administered, indicating that they were not aroused by the cue. When a suggestion was successfully completed (i.e., without eliciting alpha activity) it was not repeated. However, the cue words were tested in several subsequent REM periods. Cue word testing occurred immediately (during the same REM period as the suggestion) on the same night, as well as in a later REM period, and during REM on Night 2 (after the suggestion had been given during Night 1).

Correct responses were given for 20% of immediate, 23% of delayed, and 23% of carry-over conditions. Ss did not remember the suggestion, verbal cues, or their responses when they awoke. Since Ss often responded to the cue the next night without repetition of the suggestion itself, the authors inferred amnesia rather than forgetting had occurred. Responses were not elicited by repeating the cue word in the waking state, but appeared to be specific to the sleep condition.

Six Ss returned five months later for a third night of testing. Four had shown carryover response on Night 2 to a Night 1 suggestion. When verbal cues were presented (without re-administering the suggestion) those 4 Ss responded, even though there was no intervening waking memory about the procedure or the suggestions. Some Ss responded even more frequently than during the original two nights; hypnotic depth did not seem to account for the increased responsivity. Experimenters attempted to reverse the amnesia observed during the waking condition by using hypnosis, age regression, and other hypnotic techniques, with some positive effect. The author speculates that perhaps the techniques originally used to probe morning recall were not sufficiently sensitive. He also raises the

question of whether this waking state amnesia is related to the amnesia for night dreams when people awaken in the morning.

The relationship between hypnotizability and sleep suggestibility was analyzed. Hypnotizability was measured with the Harvard Group Scale, several weeks later, by Experimenters who were blind to the Ss' rate of responding to suggestions given during sleep. More hypnotizable Ss slept through the verbal stimuli more than low hypnotizable Ss; so they slept longer and more cues could be tested. Ss who responded most frequently to sleep-induced suggestions were more responsive to hypnosis. Analysis of response rate percentage (which controls for higher number of cues administered when Ss slept longer) showed that correlations between sleep suggestibility and hypnotizability were higher for percentage of delayed responses than for percentage of immediate responses.

Analysis by type of item on the hypnotizability scales suggested that the correlation with sleep suggestibility was due to the hallucinatory-reverie and the posthypnotic-dissociative clusters of hypnotic behavior, which are more difficult kinds of items. Correlations were significant for carry-over responses but not for immediate responses. These items represent phenomena experienced by Subjects who can be deeply hypnotized. The author reports that this relationship observed between hypnotizability and response to sleep-induced suggestions was not significant in a later study by Perry et al. (1978).

This author raises a question about why high hypnotizable subjects sleep better than low hypnotizables. The 6 Ss who were least susceptible accounted for 48% of all awakenings that occurred during the 2 experimental nights; the 6 Ss who were most hypnotizable accounted for only 26% of the awakenings ( $p < .01$ ).

Because sleep learning ("hypnopedia") has been extensively practiced in Russia and Eastern Europe, especially for language learning, the author investigated language learning with nine subjects. (Hoskovec, 1966, and Rubin, 1968, have reviewed the hypnopedia literature, which suggests that only "suggestible" subjects respond; it is not clear whether "suggestible" refers to hypnotizable, or whether expectation of success is cultivated by information given in the waking state.) The nine Ss had responded to the suggestions at least twice while remaining asleep, had no waking recall of the suggestions, but were given pre-sleep instructions (increasing expectancy) that they would learn during sleep.

The verbal association material ("A is for apple; P is for palace;" etc.) was given during EEG sleep stages 2, 4, and REM. (Eight letter-word stimuli pairs were given, two per sleep stage whenever possible.) When they awakened, Ss were asked to check "any familiar word" on a list of 10 words beginning with the letter A, with the letter P, etc. So the probability was .10 for each of the eight lists that they might check one correct word by guessing. They also responded to two dummy lists containing letter-word pairs not used during sleep.

None of the dummy list words were checked, whereas 28% of the administered words were correctly checked; also, Ss selected the correct letter (without identifying the word and with instructions not to "guess") in an additional 17% of all lists. Words were rarely recalled from Stages 2 and 4, but Ss often recognized letters from those stages. False positives (incorrectly recalled words or letters) was

almost never observed. Furthermore, no control Subjects (people who had not received a presleep set that they would recall) recalled any words correctly.

It was observed that whenever words presented during REM were later recalled, a transient slower frequency alpha (10.25 Hz vs. 9.64 Hz,  $p < .01$ ) had been evoked within 30 sec after the presentation of the stimuli during sleep.

Total recall of words correlated with the Harvard Group Scale of Hypnotic Susceptibility .69 and the Stanford individually administered scale .42, for the 7 Ss administered hypnotizability tests.

The author concludes that under optimal conditions, sleep learning of relatively easy material can occur with subsequent waking recall.

Hajek, P.; Jakoubek, B.; Radil, T. (1990). Gradual increase in cutaneous threshold induced by repeated hypnosis of healthy individuals and patients with atopic eczema. Perceptual and Motor Skills, 70, 549-550.

Gradual increase in cutaneous pain threshold was found in healthy subjects and patients with atopic eczema during repeated hypnotic sessions with specific suggestions. This increase was less in the former than in the latter group. Repeated threshold measurements did not influence the threshold. The analgesic effect outlasted the hypnotic sessions by several months. It could be, however, suddenly reduced by appropriate hypnotic suggestion.

#### NOTES

Cutaneous pain threshold was measured in "time in seconds from onset of heat source of defined size, distance from skin, and temperature, to subjective threshold percept of pain" (p. 549). Used two symmetrical locations on both forearms, at healthy areas of the skin. Ten hypnotic sessions were induced in each S three times weekly, each lasting one hour.

Suggestions were the following type: "The "conduction of switch to the brain is interrupted." Your "immunologic system will digest the damaged skin cells like a shark."

Subjects were 14 healthy subjects and 13 patients with atopic eczema treated for years with the usual medications, unsuccessfully or with complications.

There was gradual increase in cutaneous pain threshold across the 10 sessions, especially for the patient group. Control experiments with repeated threshold measurements in repeated sessions without hypnosis showed no changes.

"Time of increases in cutaneous pain threshold was associated with improvement of atopic eczema. Both effects correlated significantly ( $r = 0.8$ ) with hypnotizability as measured by the Stanford scale" (pp. 549-550).

"In 9 patients without further hypnotic sessions a slow spontaneous decay of the cutaneous pain threshold was observed during a 17-mo. period. Special experiments performed with six repeatedly hypnotized healthy subjects showing increased thresholds did prove, however, that the cumulative analgesic effect could be reduced to control values immediately by using the hypnotic suggestion that the 'skin sensitivity returns to normal values.'

"These results suggest a close association between hypnosis and activation and/or deactivation of endogenous analgesic systems (irrespectively whether they are of opioid or nonopioid nature)" (p.550)

McNally, Richard J. (1990). Psychological approaches to panic disorder: A review. Psychological Bulletin, 108 (3), 403-419.

Panic disorder has been the subject of considerable research and controversy. Though biological conceptualizations have been predominant, psychological theorists have recently advanced conditioning, personality, and cognitive hypotheses to explain the etiology of panic disorder. The purpose of this article is to provide an empirical and conceptual analysis of these psychological hypotheses. This review covers variants of the "fear-of-fear" construal of panic disorder (i.e., Pavlovian interoceptive conditioning, catastrophic misinterpretation of bodily sensations, anxiety sensitivity), research on predictability (i.e., expectancies) and controllability, and research on information-processing biases believed to underlie the phenomenology of panic. Suggestions for future research are made

Alexieva, A.; Nicolov, N.A. (1989). Brain mechanisms in classical conditioning. Behavioral and Brain Sciences, 12, 137.

#### NOTES

This is a Commentary on article by J. S. Turkkan (1989), Classical Conditioning: The new hegemony. In Behavioral and Brain Sciences.

Commentators note that the objective of the target article is to show how current thinking about Pavlovian conditioning differs substantially from the historical view; also that this has been recently emphasized by Rescorla (1988). Commentators note that the neural pathways and neural mechanisms involved in Pavlovian conditioning are of great interest and are investigated by many neuroscientists all over the world (Grigoryan & Tchilingaryan 1988; Kositsyn N.S. & Dorochoy 1986; Onifer & Durkovic 1988; Storzhuk 1986; Vartanyan & Pirrgov 1986). Commentators also note the work of Ramachandran & Pearce (1987) and Uryvaev Yu.V. et al. (1988).

They express the opinion that Turkkan's review affords a thorough description and interpretation not only of basic data and new conceptual views, but also of certain key notions in the modern theories of Pavlovian associative learning.

1989

Gardner, Beatrix T.; Gardner, Allen R. (1989). Beyond Pavlovian classical conditioning. Behavioral and Brain Sciences, 12, 143-144.

#### NOTES

This is a commentary on the article by Turkkan (1989) entitled "Classical conditioning: The new hegemony" in Behavioral and Brain Sciences, 12, 121-179. (Pavlov's theory of hypnosis was based on a conditioning model, which is why this material may be relevant.)

"Traditionally, the mechanism of stimulus association proposed by Pavlov early in this century is invoked to account for conditioning that is independent of the positive and negative consequences of responding. ... Pavlov attributed this result to stimulus substitution (i.e., the subject responds to the Sa as if it were the S\*) and this has been the dominant view throughout this century" (p. 143).

'In Pavlov's classical procedure, only increases and decreases in the original consummatory or defensive response are counted as conditioned responses. ... Pavlov's classical procedure is only a special case of a much broader case of a phenomena" (p. 143).

"Key-pecking by pigeons and lever-pressing by rats are responses that were long held up as prototypes of arbitrary behaviors that could only be shaped by response-contingent reinforcement. In the autoshaping procedure, however, these same responses have been easily conditioned to an arbitrarily selected stimulus (Sa) when the delivery of food was entirely independent of the response of the subjects. Not only that, but robust rates of responding have been maintained when food was withheld if the pigeons pecked the key or the rats pressed the lever, that is, when the contingency was negative (Williams & Williams 1969)" (p. 143).

"Turkkan follows a grand tradition when she discusses the similarities between associative conditioning and fundamental aspects of human verbal behavior. Yet an essential characteristic of verbal behavior is the difference between the response to an object and the response to a word for the object. The response to the spoken or written word 'apple' must be distinctly different from the response to an actual apple. Whatever we learn when we acquire vocabulary, it cannot be the simple stimulus-stimulus connection advocated in Pavlov's classical theory. Even the popular Rescorla (1967) design for separating stimulus-stimulus contiguity from stimulus-stimulus contingency only succeeds in comparing two sources of stimulus-stimulus association. Meanwhile, the recently discovered autoshaping experiment does offer us a laboratory model in which associative conditioning can result in a response to the Sa that is different from the consummatory response to the S\*" (p. 144).

"The theory of stimulus-stimulus association that Pavlov built upon the results of his special procedure is inadequate to deal with the wide range of phenomena of associative conditioning that have been discovered since his time.

"We wholeheartedly agree with Turkkan regarding the enormous theoretical and practical significance of the new discoveries but we are convinced that the terms 'Pavlovian conditioning' and 'classical conditioning' serve us best in their historical usage. ... The new discoveries seem to us to show that a wide range of significant phenomena fall outside the boundary conditions of traditional Pavlovian and Skinnerian theories" (p. 144).

Griffiths, M. D.; Gillett, C. A.; Davies, P. (1989). Hypnotic suppression of conditioned electrodermal responses. Perceptual and Motor Skills, 69, 186.

## NOTES

With 5 subjects who had previously been aversively conditioned to a stimulus, during hypnosis previously acquired electrodermal responses were found to be

significantly lower than in 12 control Ss. Thus previously conditioned electrodermal responses were suppressed. This contradicts findings of Edmonston (1968) who found that neutral hypnosis does not influence conditioned electrodermal responses and the validity of Pavlov's (1927) conditioning (inhibition) theory of hypnosis.

Holroyd, Jean; Maguen, Ezra (1989). And so to sleep: Hypnotherapy for lagophthalmos. American Journal of Clinical Hypnosis.

**ABSTRACT:** We used hypnosis to facilitate eye closure during sleep for a 44-year-old woman whose nocturnal lagophthalmos prevented use of a contact lens following cataract surgery and could have resulted in severe corneal damage. On three separate occasions the symptoms remitted following a very brief course of treatment. We discuss the results in terms of alternate theories of hypnotic performance.

#### NOTES

The Discussion section notes, "There was an excellent correlation between the onset of hypnotherapy and the cessation of the recurrent corneal erosion secondary to nocturnal lagophthalmos. Healing of corneal erosion, disappearance of the superficial punctate keratopathy, and alleviation of ocular foreign body sensation occurred promptly

following hypnotherapy (with two separate therapists)" (pp. 267-268). The authors present the view that "heightened suggestibility, more vivid imagery, and more specific influence of thoughts upon organ systems probably came into play (Brown & Fromm, 1986; Holroyd, 1987). Social influence explanations (role taking, expectancy, compliance) seem less relevant as explanations. This highly motivated patient had not been able to keep her eyes closed during sleep despite her conscious efforts, her "good-patient" role, her positive expectations about the benefits of standard treatments, and respectful incorporation of the assistance provided by her ophthalmologist" (p. 268).

Borgeat, Francois; Rezanowicz, Thaddeus; Chaloult, Louis (1988). La stimulation preconsciente et consciente de l'imaginaire erotique. Revue Canadienne de Psychiatrie, 33, 394-398.

The stimulation of erotic fantasies through the association of relaxation and erotic conscious or preconscious suggestions has been evaluated. This study was attempted following positive results in the stimulation of fantasmatic activity in alexithymic subjects with a similar procedure. Thirty female subjects, allocated into three groups practiced relaxation daily for two weeks including three sessions with psychological measures. During the second week, erotic suggestions, preconscious for one group and conscious for another one were added. The third group (control) received only relaxation throughout. Results have shown an increase of sexual arousal and erotic imagery during the sessions with erotic suggestions. Sexual activities and desire increased in the two experimental groups. There was no

difference between the effects of the preconscious and conscious suggestions. Possible clinical applications of such a procedure are discussed.

Davies, Peter (1988). Some considerations of the physiological effects of hypnosis. In Heap, Michael (Ed.), Hypnosis: Current clinical, experimental and forensic practices (pp. 61-67). London: Croom Helm Ltd.

#### NOTES

This chapter reviews literature on physiological correlates of hypnosis, but these notes are limited to only one fact reported in the review. The author writes, 'A recently completed, and as yet unpublished study by C. Gillett and H. D. Griffiths at Bradford University investigated the relation between hypnosis and classical conditioning of psychophysiological responses. In a complex design involving both normal conditioning and normal test trials and a repetition of both acquisition and test trials under hypnosis, they found not only suppression of the conditioned response but also suppression of skin conductance responses to the half-second bursts of a 115-dB tone used as the unconditioned stimulus. Not to produce a significant autonomic response to such an intrinsically aversive stimulus is a remarkable feat which is probably outside the repertoire of simulators. However, even such results are not conclusive as the design did not include simulator control groups nor even neutrally instructed non-hypnotized group' (pp. 64-65).

Malone, M.; Strube, M. (1988). Meta-analysis of non-medical treatment for chronic pain. Pain, 34, 231-234.

Conducted a meta-analysis of 109 published studies which assessed the outcome of various nonmedical treatments for chronic pain, 48 of which had sufficient information to calculate effect sizes. The remainder were examined according to proportion of patients rated as improved. Mood and number of subjective symptoms consistently showed greater responses to treatment than did pain intensity, pain duration, or frequency of pain, indicating the importance of using a multidimensional framework for pain assessment. Effect sizes for treatments were 2.74 for autogenic training, 2.67 for hypnosis, 2.23 for pill placebo, 1.33 for package treatments that allowed patients to choose from diverse pain management strategies, .95 for biofeedback, .76 for cognitive therapy, .67 for relaxation, .55 for operant conditioning, and .46 for TENS units. However, the largest numbers of studies were in the area of biofeedback, a treatment package, and relaxation, and we must be cautious in interpreting the effect sizes due to the small number of studies in the sample.

Tsushima, W. T. (1988). Current psychological treatments for stress-related skin disorders. Cutis, 42, 402-404.

Surveys current methods used by psychologists in the management of stress-related skin disorders, including hypnosis, relaxation training, biofeedback, operant conditioning, and cognitive behavioral therapy. These techniques offer promise in

the treatment of certain dermatologic conditions, but the limited amount of well-controlled and replicated studies of their use suggests that caution be taken in their application.

Minichiello, William E. (1987). Treatment of hyperhidrosis of amputation site with hypnosis and suggestions involving classical conditioning. International Journal of Psychosomatics, 7-8.

Hyperhidrosis of an amputation site utilizing hypnosis and/or behavioral strategies has not been reported in the literature. This case report is on the successful use of hypnosis utilizing principles of classical conditioning in the treatment of a patient with hyperhidrosis of an amputated limb with two previous unsuccessful sympathectomies. The patient possessing moderate hypnotic ability as measured by the Stanford Hypnotic Clinical Scale (SHCS), reported a pre-treatment score of 10 on a 0-10 severity and intensity of sweating scale, and a post-treatment score of 0. All gains were maintained at the two-year follow-up.

#### NOTES

The patient was hypnotized while an electric fan was blowing on his stump and prosthesis. Direct suggestions were given according to procedures of thermal biofeedback. The suggestions were: 1. You will notice in days ahead that your stump feels increasingly cooler and drier. 2. You will feel throughout the day as if a cool breeze from a fan is blowing on your stump. 3. Whenever you pay attention to your leg during the day, particularly after the first few hours of the morning, you will associate that leg with a cool dry breeze from a fan blowing on it. 4. You will increasingly develop the power to cool and dry your stump.

The results were that 2 1/2 weeks later patient reported reduced frequency and intensity of sweating and significant healing of the stump ulcers; rating = 2. One month later, patient reported continued progress with almost normal skin color and stump condition; the patient discontinued disability, and returned to work. Patient returned one month later reporting, "It's cured and my physician can't believe it." Rating = 0.

Author concludes that hypnosis should be tried prior to more invasive traditional procedures. In this case two previous sympathectomies failed to correct the condition and a third sympathectomy was being contemplated.

1984

Fogel, Barry S. (1984). The 'sympathetic ear': Case reports of a self-hypnotic approach to chronic pain. American Journal of Clinical Hypnosis, 27 (2), 103-106.

Secondary gain issues may limit the success of hypnotherapeutic approaches to chronic pain. A self-hypnotic suggestion that promotes patients' awareness of the interpersonal aspects of their pain complaints was used in the treatment of two patients with chronic headache. Hypnotic suggestions that help make secondary gains conscious may be a useful addition to hypnotic techniques of pain management.

Kolb, Lawrence C. (1984, October/1986). Comments on post-traumatic stress disorder and dissociation. In Quen, Jacques M. (Ed.), Split minds/split brains (pp. 171-178). New York: New York University Press. (Based on symposium in Bear Mt., N.Y., by Section on the History of Psychiatry of Cornell University Medical Center)

**NOTES:**

Kolb indicates that people may not be able to overcome the neurological changes consequent upon trauma. In this event, post traumatic stress disorder would have lasting, irremediable effects.

Venturino, Michael (1984, August). Perceptual monitoring and allocation of attention (Dissertation, University of Maine). Dissertation Abstracts International, 45 (2), 707-B.

The processing ability of perceptual monitoring was investigated using a dichotic listening and shadowing task. Individual differences in the effectiveness of perceptual monitoring were also investigated by using susceptibility to hypnosis as a grouping factor. Subjects' skin conductance response (SCR) was conditioned to specific words by an electric shock. These conditioned words, and words semantically and acoustically related to them were presented in the relevant and irrelevant messages of the dichotic listening and shadowing task. Probability and magnitude measures of SCRs and subjects' verbal shadowing accuracy were used to assess performance. SCRs to critical words were significantly greater than to control words in both the relevant and irrelevant messages. However, the SCRs to words in the irrelevant messages were not as great as those responses elicited to words in the relevant message. The pattern of responding to the semantically and acoustically related words was similar for both the relevant and irrelevant messages. Subjects low in hypnotic susceptibility responded to critical words with significantly greater probability and magnitude of response than did subjects high in hypnotic susceptibility. Analysis of the shadowing performance data showed that the perceptual monitoring process was quite effective. The occurrence of the conditioned word in the irrelevant message caused a shift in attention to the irrelevant message, manifested by a shadowing error. Subjects shadowing the message in their left ear committed significantly more shadowing errors than subjects shadowing the message in their right ear. No differences in shadowing performance were obtained for the hypnosis factor. The results were interpreted in terms of the deployment of attention to the environment, and the relationship of this deployment to the perceptual monitoring process" (p. 707).

Spanos, Nicholas P.; Dubreuil, Debora L., Saad, Carol L., Gorassini, Donald (1983). Hypnotic elimination of prism-induced aftereffects: Perceptual effect or responses to experimental demands?. Journal of Abnormal Psychology, 92 (2), 216-222.

Two experiments assessed adaptation to displacing prisms in hypnotically limb-anesthetized Ss. Experiment I with 18 college students disconfirmed the hypothesis that the displacement aftereffect is eliminated in limb-anesthetized hypnotic Ss who adapt to prisms in the absence of a visual target. Such Ss showed as large a displacement aftereffect as control Ss who received neither a hypnotic induction procedure nor an anesthesia suggestion. Experiment II with 30 undergraduates demonstrated that under some testing conditions hypnotic Ss complied with experimental demands and eliminated the behavioral but not the perceptual component of the aftereffect.

Hoffman, Mark L. (1982/83). Hypnotic desensitization for the management of anticipatory emesis in chemotherapy. American Journal of Clinical Hypnosis, 25 (2-3), 173-176.

A hypnotic treatment employing systematic desensitization was used to alleviate anticipatory nausea and vomiting in a middle-aged man undergoing chemotherapy for Hodgkin's Disease. After four treatment sessions, all nausea associated with chemotherapy was eliminated. Results of this treatment are compared with those of another hypnotic treatment recently reported by Redd et al (1982), and reasons for differences are discussed. [Redd, W. H., Andersen, G. V. & Minagawa, R. Y. (1982). Hypnotic control of anticipatory emesis in patients receiving cancer chemotherapy. Journal of Consulting and Clinical Psychology, 50, 14-19.]

1982

Redd, William H.; Andrykowski, Michael A. (1982). Behavioral intervention in cancer treatment: Controlling aversion reactions to chemotherapy. Journal of Consulting and Clinical Psychology, 50 (6), 1018-1029.

**ABSTRACT:** During the protracted course of cancer chemotherapy, approximately 25% of patients develop aversion reactions to treatment by becoming nauseated and/or vomiting before their chemotherapy treatments. This phenomenon has been conceptualized as a result of respondent conditioning. Since commonly used antiemetic drugs do not reliably control anticipatory nausea/emesis, behavioral techniques of control have been studied. They include hypnosis used in conjunction with guided-relaxation imagery, progressive muscle relaxation with guided imagery, and systematic desensitization. (67 ref)

Redd, William H.; Andresen, Graciela V.; Minagawa, Rahn Y. (1982). Hypnotic control of anticipatory emesis in patients receiving cancer chemotherapy. Journal of Consulting and Clinical Psychology, 50 (1), 14-19.

## NOTES

Deep muscle relaxation hypnosis controlled nausea, gagging, retching in all cases. Anticipatory emesis recurred when hypnosis was not used. During subsequent sessions in which hypnosis was reinstated, anticipatory emesis was again controlled.

Redd, William H.; Rosenberger, Patricia H.; Hendler, Cobie S. (1982-83). Controlling chemotherapy side effects. American Journal of Clinical Hypnosis, 25 (2-3), 161-172.

Severe nausea and vomiting are commonly experienced by cancer patients after receiving chemotherapy treatments. Moreover, approximately 25% of these patients develop conditioned aversions to treatment and become nauseated before they receive their chemotherapy injections. The use of deep muscle relaxation hypnosis in conjunction with guided imagery to control pre- and post-chemotherapy nausea and emesis is discussed. Theoretical and clinical issues raised by this application of hypnosis in cancer treatment are also addressed.

Werner, William E. F.; Schauble, Paul G.; Knudson, Marshall S. (1982). An argument for the revival of hypnosis in obstetrics. American Journal of Clinical Hypnosis, 24, 149-171.

Available research, clinical reports, and extensive personal experience demonstrate that hypnosis, and especially the hypnoreflexogenous technique, facilitates the mother's comfort in pregnancy, labor, and delivery; is superior to the use of chemicals or other psychophysical methods as the primary aid in childbirth; and results in lasting benefit for the mother, the child, and the family as a whole. Prior to delivery, with the patient in hypnotic trance, a verbal conditioning technique is used that (1) neutralizes the fear of delivery with a positive emotion that exalts maternity as a sublime experience, (2) substitutes the uterine contraction concept for the pain concept, and (3) presumably lowers the excitability of the cortex by psychological sedation. While hypnosis experienced a temporary decrease in popularity due to a number of misconceptions, there has been renewed and promising application of hypnosis to obstetrics and other areas of medicine.

1979

Clarke, Christopher (1979). Hypnotherapy in the treatment of alcoholism. Australian Journal of Clinical and Experimental Hypnosis, 7 (1), 1-5.

If an aversive technique is used as a part of a hypnotic or behavior therapy treatment programme for problem drinking, the therapist is faced with the question of which aversive stimulus (or image) to use. This question has been given little in the way of systematic attention because of the widespread belief that there are no grounds for choosing between aversive stimuli which are equally safe, convenient and, of course, noxious. However, recent research in behavioural biology as well as certain clinical results call this assumption into question. Instead this work supports the contrary view: that the quality of the aversive stimulus is a crucial determinant of the effectiveness of aversion therapy. Specifically, this research strongly suggests that an illness or "malaise" experience must occur in conjunction with the alcohol for the conditioning (of an aversion) to be successful. Specific suggestions for the conduct of hypnotic aversion therapy are made in light of this work.

1978

Slutsky, Jeffrey; Allen, George J. (1978). Influence of contextual cues on the efficacy of desensitization and a credible placebo in alleviating public speaking anxiety. Journal of Consulting and Clinical Psychology, 46 (1), 119-125.

This investigation was designed to determine the extent to which contextual cues mediated the effectiveness of systematic desensitization and a plausible placebo in alleviating public speaking anxiety. After participating in a public speaking situation that allowed the collection of self-report, physiological, and behavioral manifestations of anxiety, 67 subjects were randomly assigned to receive five sessions of either desensitization, "T scope" therapy, or no treatment. Each of these conditions was conducted in a context that either stressed the clinical relevance of the procedure or presented the procedure as a laboratory investigation of fear without therapeutic implications. Analysis of changes both between groups and within individuals indicated that desensitization reduced public speaking anxiety in both contexts, whereas the placebo was effective only in the therapeutic setting. The superiority of desensitization was most pronounced on the physiological variables. The results are interpreted as indicating support for a counterconditioning, rather than an expectancy, interpretation of desensitization.

1977

Avila, Donald; Nummela, Renate (1977). Transcendental meditation: A psychological interpretation. Journal of Clinical Psychology, 33 (3), 842-844.

The authors suggest that Transcendental Meditation offers a great deal of promise for use in helping relationships. They also suggest that the technique might receive wider acceptance if it could be explained in other than a purely philosophical or mystical way. For that reason, in their article they offer a psychological interpretation of the TM process.

Wickramasekera, Ian (1977). The placebo effect and medical instruments in biofeedback. Journal of Clinical Engineering, 2 (3), 227-230.

This article defines a "placebo effect" and identifies some of its parameters in pain control and in other areas of medicine. It proposes a new model of the placebo effect and advances the hypothesis that biomedical instruments used in biofeedback studies, like drugs, can acquire and generate placebo effects. Such placebo effects can complicate the interpretation of specific experimental treatments in human clinical research in which biomedical instruments are used.

1976

King, Dennis R.; McDonald, Roy D. (1976). Hypnotic susceptibility and verbal conditioning. International Journal of Clinical and Experimental Hypnosis, 24, 29-37.

18 Subjects highly susceptible to hypnosis and 18 Subjects refractory to hypnosis were studied in a verbal conditioning task modeled after the one used by Taffel (1955). Results indicated that the highly susceptible group showed significantly greater conditioning than the low group. Awareness of the reinforcement contingency by S was not related to the learning task nor to hypnotic susceptibility. A measure of S's attitude toward the reinforcement cue during learning showed that the highly susceptible group had a more positive set toward the cue, whereas the low group tended to respond to it in a neutral or negative manner. Results were interpreted in terms of the theoretical nature of hypnotic susceptibility.

## NOTES

They review literature on attempts to correlate hypnotizability with verbal conditioning ability.

Volunteer students participated; screened by HGSHS:A: highs 10-12, lows 0-4.

Verbal conditioning procedure: S viewed 100 3x5 cards on which were a two-syllable, past tense verb, below which typed in upper case letters on one line were the pronouns I, WE, HE, SHE, THEY, and YOU (randomly assigned to different orders). E was blind to hypnotizability. E instructed S to make up a sentence using the verb and a pronoun; gave no response for first 20 trials; said "good" to usage of I or WE during conditioning.

Afterwards, S filled in an Awareness Questionnaire (What was purpose? If E gave cues, what were they? If you noticed cues, what do you think they indicated?) and attitude toward the reinforcement cue (Did you notice that I did anything special? What? Did I say "good" for a special reason? What was the reason for my saying "good"? How did hearing the word "good" affect you during the experiment? IN a positive, negative, or neutral way?

Results. Groups did not differ at baseline but did differ at Blocks 2 (highs 9.7 vs lows 6.3;  $p < .05$ ) and 3 (highs 10.4 vs lows 6.3;  $p < .05$ ). Although the High group continued to maintain a somewhat higher level of responding than the Low group during extinction (9.8 vs 7.6), this difference did not reach statistical significance. (The graph shows an increase for Lows during extinction!)

Using a liberal definition of awareness and a learning index computed for each S by subtracting his operant level of response from the mean number of correct responses shown during the 3 blocks of acquisition trials, Subjects were ordered and a median test applied; contingency coefficient of .28 not significant ( $p < .10$ ).

Attitude significantly differentiated High and Low hypnotizability groups (see Table 2) with Highs more often responding in positive manner to reinforcement cue and Lows giving a neutral rating. Awareness of reinforcement contingency was equally represented in High and Low groups. The Aware High Positive groups learning index differed significantly from Aware Low Neutral group ( $p < .01$ ); the Unaware Low Positive group ( $p < .05$ ); and the Unaware Low Neutral group ( $p < .001$ ).

Thus, the Aware High Positive group's learning index score was significantly higher than that of the 3 Low groups. Also, the Unaware High Positive group differed significantly from the Unaware Low Neutral group ( $p < .05$ ). No other High groups differed from the Low groups and none of the High groups differed among themselves.

Among the Low groups, only the Unaware Low Positive group differed significantly from the Unaware Low Neutral group ( $p < .05$ ).

Discussion. Data show that hypnotizability is important in response to verbal conditioning, extending findings of Das (1958) by showing that primary suggestibility is associated with operant as well as classical conditioning but also those of Weiss et al. (1960) in illustrating that higher hypnotic susceptibility leads to enhanced verbal conditioning, using an improved measure of hypnotic susceptibility.

Awareness of reinforcement contingencies is not sufficient to account for subject differences in verbal conditioning; the characteristics tapped by HGSHS:A produce conditioning which cannot be accounted for by awareness alone.

The fact that high susceptible Subjects here rated E's cue more positively than low susceptible Subjects is further consistent with some of the personological descriptions associated with hypnotic susceptibility which have been offered by Hilgard (1968). In addition, Cairns and Lewis (1962) and Spielberger et al. (1962) found that persons who assigned more positive value to the kind of reinforcement present in verbal conditioning experiments produced greater conditioning than Subjects whose attitudes were less favorable or non-committal toward the reinforcement. This relationship is not clear-cut in the present data in that although the High groups had an overall more positive attitude regarding reinforcement, only the Aware High Positive group learned better than all the Low groups, while the only other High group learning better than a Low group was the Unaware High Positive which had a significantly better learning index score than the Unaware Low Neutral group. Moreover, positive attitude did not differentiate learning within the High groups or the Low groups. Thus, the present data are unclear regarding the role attitude plays in the acquisition of verbally conditioned responses.

The roles of awareness and attitude could probably be better defined in future research using larger experimental groups. The attitude measure employed here was a gross one and a more sophisticated assessment of the valence characteristics of reinforcement cues could reveal more complex relationships in subsequent research. In addition, a more careful assessment than was done here of the role of cooperation and demand characteristics would contribute substantially to understanding more completely the effect of awareness on these phenomena.

The general indications regarding attitude may in part account for the increased interest in production of conditioned responses in Figure 1 shown by the Low group (graph) during the extinction phase of this experiment. Although highly susceptible Subjects show a decrease in the correct response with nonreinforcement, low susceptible Subjects begin to evidence an increase in the correct response. The attitude measure indicates that Subjects in the Low group did not respond positively to the reinforcement cue, and one of these Subjects reported in the interview that he did not like being told what to do by the E. It can be speculated that these Subjects were aware of the reinforcement contingency but did not "cooperate" until the reinforcement was absent. This follows the interpretation of Farber (1963) who found that aware Subjects who conformed to the demand characteristics of the experimental situation showed greater verbal conditioning than those who were aware and nonconforming. It thus appears that a willingness to go along with E's

expectations and a positive, cooperative attitude are common features in individuals who make good hypnotic Subjects and who evidence an enhanced propensity for verbal conditioning.

1975

Bender, V. L.; Navarett, F. J.; Nuttman, D. (1975). Effects of neutral hypnosis on a conditioned physiological response. Psychological Reports, 37, 1155-1160.

The objective of the present experiment was to determine whether hypnosis without explicit suggestion of analgesia would diminish physiological responses to an operationally defined painful shock stimulus. Muscle tension (EMG) was significantly lower during hypnosis than pre- or posthypnosis. Pulse rate remained stable throughout all conditions. Also, the question of whether a tone paired with shock might acquire some unique property because of that association was investigated. It was found that EMG response to the tone alone was significantly greater than to the tone-shock combination, in prehypnosis and posthypnosis, but not during hypnosis.

Carli, G. (1975). Some evidence of analgesia during animal hypnosis [Abstract]. Experimental Brain Research, 23, 35

The purpose of this study was to investigate the response to painful stimuli during animal hypnosis. The experiments were performed on unanesthetized, free-moving rabbits carrying implanted electrodes for recording the EEG and EMG activity and nerve stimulation. Injection of formaline into the dorsal region of the foot produced long lasting EEG desynchronization and motor pain reactions. In some rabbits a procedure of habituation was used to reduce hypnosis duration below 45 sec. Hypnosis was induced by inversion. The following results were obtained: 1) Polysynaptic reflexes elicited [sic] by electrical stimulation of cutaneous and muscle afferents were depressed during hypnosis. 2) Hypnosis transitorily suppressed all the painful manifestations due to formaline injection and was characterized by high [sic] voltage slow wave activity in the EEG, 3) In habituated rabbits, a significant increase in hypnotic duration and EEG synchronization was observed when hypnosis was preceded by formaline injection. Hypnosis duration was not potentiated by painful stimuli when Naloxone (5mg/Kg i.v.) was injected before hypnosis induction. 4) In habituated rabbits a recovery in hypnotic duration coupled to EEG synchronization was obtained, in absence of painful stimuli, following subanalgesic injection of Morphine (1mg/Kg). It has been previously shown that in the rabbit administration of 5-20 mg/Kg of Morphine produces EEG synchronization and strong reduction of pain reactions. It is suggested that, during animal hypnosis in a condition of continuous nociceptive stimulation, the pain response is blocked by a mechanism which exhibit [sic] similar effects of Morphine both at spinal cord (polysynaptic reflexes) and at cortical levels (EEG synchronization).

Lick, John R. (1975). Expectancy, false galvanic skin response feedback, and systematic desensitization in the modification of phobic behavior. Journal of Consulting and Clinical Psychology, 43 (4), 557-567.

This study compared systematic desensitization and two pseudotherapy manipulations with and without false galvanic skin response feedback after every session suggesting improvement in the modification of intense snake and spider fear. The results indicated no consistent differences between the three treatment groups, although all treatments were significantly more effective than no treatment in modifying physiological, behavioral, and self-report measures of fear. A 4-month follow-up showed stability in fear reduction on self-report measures for the three treatment groups. Overall, the results of this experiment were interpreted as contradicting a traditional conditioning explanation of systematic desensitization. An alternate explanation for the operation of systematic desensitization emphasizing the motivational as opposed to conditioning aspects of the procedure is discussed.

Tori, Christopher; Worell, Leonard (1973). Reduction of human avoidant behavior: A comparison of counterconditioning, expectancy, and cognitive information approaches. Journal of Consulting and Clinical Psychology, 41 (2), 269-278.

This study was designed to compare the fear-reducing efficacy of procedures based on three major theories that have been proposed to account for the success of systematic desensitization therapy: (a) cognitive information storage and retrieval, (b) cognitive expectancy, and (c) counterconditioning. Predictions were confirmed in that the outcome measures of the high-expectancy placebo group and the two cognitive-coping groups were significantly superior to those of the counterconditioning and no-treatment groups. Thus, this experiment supports the supposition that changes in human avoidant behavior may be attributed to demand and expectancy variables rather than the conditioning of "antagonistic responses" as has been previously suggested.

1972

Greene, R. J.; Reyher, J. (1972). Pain tolerance on hypnotic analgesic and imagination states. Journal of Abnormal Psychology, 79 (1), 29-38.

NOTES

Found that a hypnotic-analgesic-plus-pleasant-imagery condition was not as effective as was an analgesia suggestion only, in modifying tolerance.

1969

Graham, Kenneth (1969). Brightness contrast by hypnotic hallucination. International Journal of Clinical and Experimental Hypnosis, 17, 62-73

Tested the veridicality of a hypnotic hallucination elicited by a buzzer through a conditioning procedure. The stimulus to be hallucinated consisted of 2 gray circles, 3

in. in diameter, mounted on a white card. 11 highly susceptible Ss were able to produce this hallucination upon hearing the buzzer during a series of test trials following the training. Following a 2nd training series, a black and white background was provided for the hallucination and Ss tended to report the hallucinated circles as a brightness contrast. A 2nd group of highly susceptible Ss was not hypnotized, but was asked to respond as if hypnotized. These Ss tended not to report the contrast. #### NOTES

Examines Hull's 1933 theory that hypnotic susceptibility is a habit phenomenon, which he derived from a review of the literature and an experiment. Also presents his own experiment to test it.

Davison, Gerald C. (1965, June). Anxiety under total curarization: Implications for the role of muscular relaxation in the desensitization of neurotic fears. [Paper] Presented at the annual meeting of the Western Psychological Association, Honolulu.

#### NOTES

I began by describing the Jacobson-Wolpe position on the use of deep muscular relaxation as an anxiety-inhibitor: these writers assume that the considerable reduction in proprioceptive feedback from muscles which are in a relaxed state is incompatible with a state of anxiety. Then I mentioned the evidence that at least modern neuromuscular blocking-agents operate solely at the myoneural junction, with no direct central effects. I went on to discuss the various studies which have used paralytic drugs, primarily d- tubocurarine chloride, to show the learning of fear-responses under complete striate muscle paralysis: the fact that these animals are able to acquire classically-conditioned fear-responses under curare was taken as evidence inconsistent with the views of Jacobson and Wolpe. Several studies were then reviewed which purport to furnish confirmatory evidence for the Jacobson position: these studies showed considerable central depression during curare paralysis. I re-interpreted these studies in the light of the over-riding importance of exteroceptive stimulation, stressing that the animals in the curare learning experiments were likewise deprived of proprioceptive feedback and yet were hardly non- anxious: the important difference was that the animals in the conditioning experiments were stimulated frequently from the environment while curarized, this stimulation maintaining an alert, often anxious state. Finally, two hypotheses were put forward as to why training in muscular relaxation does, in fact, inhibit anxiety: the one suggested that relaxing one's muscles generates strong positive affect states, which in turn inhibit anxiety; the other hypothesis called attention to the fact that

the states of muscular relaxation under curare versus under self-induced relaxation differ in the important respect that only with self-induced relaxation is there a reduction in efferent activity--perhaps this elimination of efferents, rather than afferents, inhibits anxiety.

Mysterious phenomena of the human psyche. New York: University Books. (Abstracted in *American Journal of Clinical Hypnosis*, 1965, 8:2, 146-147)

NOTES:

The review of this book by Leo Wollman (*American Journal of Clinical Hypnosis*, 1965, vol. 8, pp. 146-147) states, "Many interesting theories about hypnosis are aired in this book. The opinions Pavlov propounded many years ago, about cortical inhibition are assiduously asserted, yet some statements made bear investigation. The mere sight of the experimenter in B. N. Birman's experiments with dogs put the dog into a hypnotic state. The appearance in the room of other people, who had not participated in the experiments, had no sleep inducing effect. For the experimental animal, therefore, the experimenter himself had been transformed into a conditioned hypnogenous stimulus. Similarly, in group hypnotherapy, the entrance of the physician-hypnotist into the room often effects a hypnotic state in some of the subjects. The doctor has become the stimulus for the conditioned response, that of hypnotic trance state induction.

" An interesting and perhaps little known fact elicited from Chapter III (Hypnotism and Suggestion) is the high percentage (12%) of those replies to questionnaires during the First International Congress on Experimental Psychology held in Paris in 1899, which indicated that 3,000 respondents had hallucinations while in a normal state of health. The majority were visual; auditory and tactile hallucinations were less frequent" (pp. 146-147).

**1961**

Stolzenberg, Jacob (1961). Technique in conditioning and hypnosis for control of gagging. International Journal of Clinical and Experimental Hypnosis, 9, 97-104.

**Author's Conclusion** The practitioner who is competently trained in hypnosis will find that there is a diminished need for the use of hypnosis per se, with most of his patients. His understanding of the psychodynamics will aid immeasurably in establishing rapport with his patients, and develop an excellent patient-dentist relationship. His semantics will be a vocabulary of positive words which will not trigger off negative reactions in his patients. The dentist as a rule, who has been exposed to hypnosis indoctrination, usually displays kindness and understanding, and treats his patients with tender loving care.

"The highest achievement in a dentist-patient relationship is attained when the parent says, "You know, doctor, I would almost think you had hypnotized my daughter when I see how nicely she cooperates"" (p. 104).

**1960**

Tinterow, Maurice M. (1960). The use of hypnoanalgesia in the relief of intractable pain. American Surgeon, 26, 30-34.

**NOTES:**

The author begins with a statement that the experience of pain requires consciousness. He continues by suggesting that hypnotic control of pain requires establishing selective thinking and bypassing the critical thinking aspect of consciousness. "[Hypnosis] raises the threshold of pain and is the only means of anesthesia which carries no danger to the patient. ... Hypnosis obeys the laws which govern conditioning in general, and suggestion causes new conditioned patterns to be developed" (p. 30).

"Success in hypnotherapy depends on the ability of the individual and, of importance, on constant practice. ... Under the influence of hypnosis the sensory end organs continue to function but the patient's attitude may be altered that the pain is no longer experienced the same way. ... Intractable pain is not responsive to conservative measures. It is usually produced by a disease which cannot be treated directly. Drug therapy will usually give relief, particularly opium and its derivatives, but with continued usage the severity of pain has no relationship to the amount of narcotic necessary. ... Hypnosis is nothing more than the suggestive placebo effect presented in a specific personal setting" (p. 31).

"Nearly all of the patients with intractable pain reach debilitating states through exhaustion, loss of sleep, decrease of appetite and weight loss. ... The use of suggestive therapy should be attempted early and before addiction to narcotics or alcohol has occurred. ... The word hypnosis is not used because of the fear the patient has toward the mystery and the unknown. The term 'medical relaxation' is referred to as the method of therapy" (p. 31).

"Hypnotherapy was attempted in 15 cases of intractable pain. Success depended upon the early referral of the cases and before addiction to narcotics has occurred. Five of the eight cases with metastatic carcinoma were relieved of the severe intractable pain. Of the two patients with intractable pain following herpes zoster, relief was successful in one of them. A patient with diabetic neuropathy had no pain after five sessions of hypnosis. After an operation for repair of a hiatal hernia, the patient had severe intractable pain which was relieved with hypnotic therapy. Another patient, who developed pain after a subtotal gastrectomy, was also successful in returning to a normal life. Two other patients ... were unable to be hypnotized" (p. 32).

Das, J. P. (1959). A theory of hypnosis. International Journal of Clinical and Experimental Hypnosis, 7 (2), 69-77.

NOTES

1:

"Summary

"The present theory of hypnosis assumes two things -- that hypnosis is a form of conditioning and that it is a state of inhibition. Evidence relevant to the assumptions is presented briefly. The theory views hypnosis as a learned state of partial cortical inhibition and formalises it as a multiplicative function of learning and inhibition:  $H = f(L \times I)$ . Some predictions are made and explanations provided for several phenomena associated with hypnosis. The orientation of the theory is Pavlovian" (p. 75).

H = Hypnosis, L = Learning (conditionability, habit formation, etc.), I = partial cortical inhibition.

"Purely mechanically produced monotonous stimuli may induce a state of inhibition. But the task of the hypnotist is to select the cortical points to keep in a state of excitation, thus preventing inhibition from spreading over the entire cortex to produce sleep" (p. 71).

Pascal, G. R.; Salzberg, H. C. (1959). A systematic approach to inducing hypnotic behavior. International Journal of Clinical and Experimental Hypnosis, 7 (3), 161-167.

NOTES

1:

"Summary

The paper reports an experiment in inducing hypnotic behavior. Hypnotic behavior is considered as operant behavior subject to the principles of such behavior. Using a procedure based on this systematic position 52 per cent of 56 subjects were brought to the deep trance state in one session, a considerable gain over results reported in the literature. It is felt that the approach presented suggests that hypnosis may be brought into the realm of behavioral science" (p. 166).

A detailed description of the procedure is provided. It begins with providing information, establishing rapport, using demonstrations of hypnotic-like behavior (the Kohnstamm phenomenon and body sway suggestions), followed by relaxation in a stimulus-attenuated room with verbal suggestions and operant (verbal) reinforcement. It proceeds with a series of frankly hypnotic suggestions for arm analgesia and lightness/floating, amnesia, etc.

NOTES

1:

NOTES: On pp. 75-76 the author discusses conditioning in hypnosis. Most of the theoretical material is in the first part of the book; the rest consists of case studies. He presents the position that the activity of the cortex and subcortex are different during states of waking and suggested sleep.

Note: Much of the Russian research done during "suggested sleep" involves subjects who are hypnotized for a long period of time--sometimes hours. Routinely, in

treatment, they would give corrective suggestions and then tell the person to "sleep" and would leave them in the "sleep" for an hour or longer.

"Thus, it appears from the foregoing that the basic peculiarities of the activity of the cerebral cortex manifesting themselves in the state of suggested sleep are as follows: 1. In addition to the division of the cerebral hemispheres into sections of sleep and wakefulness typical of the hypnotic sleep of an animal, there is also a functional dissociation of the two signal systems and within the second signal system. 2. The activity of the second signal system under these conditions is not only confined to the narrow framework of the rapport zone, but is also frequently of a passive nature being directly dependent on the verbal influences of the hypnotist. Outside these influences there is no (or hardly any) activity. 3. A considerable increase in the coupling function with respect to the stimuli of the second signal system is noted at the same time in the rapport zone. This especially favours the formation of new cortical dynamic structures under the verbal influences of the hypnotist, these structures representing the physiological basis for effectuating the suggested actions and states.

"The foregoing peculiarities manifest themselves in the fact that the entire external second signal activity of the subject is reduced only to direct answers to the questions of the hypnotist with no independent reactions to any influences, including verbal, coming from other people (so-called isolated rapport). This is understandable, since the activity of the second signal system lying outside the rapport zone is inhibited" (pp. 73-74).

"As to the problem of the peculiarities of the conditioned reflex activity during suggested sleep, it will be noted that this problem has not been very extensively studied as yet. Nevertheless, the data of various authors are of indubitable interest, since they have revealed a number of specific peculiarities in the state of the higher nervous activity under these conditions.

"According to these data the conditioned reflex activity in suggested sleep undergoes certain changes. Thus, S. Levin observed in his early studies (1931) that in children under conditions of suggested sleep the motor and secretory conditioned reflexes elaborated earlier in the waking state grew very much weaker and that there was a dissociation both between the motor and secretory conditioned reflexes and between the unconditioned reflexes of salivation and mastication; he also observed the transitional (phasic) states--paradoxical, ultraparadoxical and inhibitory phases, all the way to the onset of complete sleep" (pp. 74-75).

Platonov indicates that conditioned reflexes may disappear during suggested sleep (Povorinsky & Traugott, 1936). Arousal from suggested sleep results in gradual restoration of the reflexes, with speech reactions inhibited first and restored last. Pen & Jigarov (1936) also showed that there is a weakening of conditioned reflexes, with increased latency, in suggested sleep. These authors showed that it is impossible to form new conditioned reflexes in deep states of suggested sleep, and the conditioning is difficult in lighter states.

"Y. Povorinsky's data (1937) indicate that the conditioned reflexes elaborated in the waking state have a longer latent period during suggested sleep and in some subjects they are completely absent. Under these circumstances, the reactions to the verbal influences of the hypnotist are retained even during the deepest suggested sleep. The

more complex and ontogenetically later conditioned bonds of the speech-motor analyzer are inhibited first as the subject lapses into a state of suggested sleep and are disinhibited the last as the subject awakens from this state" (p. 75).

"B. Pavlov and Y. Povorinsky observe (1953) that the conditioned bonds reinforced by the words of the hypnotist are formed during suggested sleep faster than in the waking state. In this case, during the somnambulistic phase of suggested sleep verbal reinforcements, as a rule, provoke a stronger and longer reaction with a shorter latent period than a direct first signal stimulus" (p. 76). The conditioning that occurs during suggested sleep does not manifest during waking periods unless suggestions are given during the sleep to react after waking. The author takes this to be evidence that conditioned reflex activity can be modified by verbal suggestions. During the somnambulistic stage of suggested sleep, subjects are less adept at performing addition. This indicates that inhibition has spread to the second signal system. However, inhibition of different sensory systems seems to vary from person to person. Krasnogorsky (1951) reported one subject did not react to light, but hearing seemed to be more sensitive than in the waking state.

"All of the above testifies to the considerable changes in the character of cortical activity regularly occurring during suggested sleep and determining, on the whole, the specific nature of higher nervous activity, the systematic study of which should be the object of further research" (p. 77).

Weitzenhoffer, Andre M. (1957). Posthypnotic behavior and the recall of the hypnotic suggestion. Journal of Clinical and Experimental Hypnosis, 5 (2), 41-58.

### Summary

1. Posthypnotic phenomena may be spontaneous or suggested in origin. Although no single mechanism appears to exist which will account for all of the spontaneous manifestations, their explanations are relatively straightforward. On the other hand, suggested posthypnotic phenomena are not so readily dealt with.

2. ... It seems likely that a relation exists between posthypnotic suggestions and waking instructions of the everyday variety; however, lack of basic information regarding the retention and activation of the latter has made this line of approach unproductive to date. Nor is it possible to talk of posthypnotic phenomena as learned if one regards the posthypnotic signal as stimulus and the suggested act as response. The definition of learning excludes this case because of the presence of hypnosis at the time the response is acquired. In addition, the acquisition and evocation of the posthypnotic effect does not follow any standard paradigm for learning.

3. If, however, one views the posthypnotic suggestion as a whole as being the stimulus, and the act of subjectively, if not objectively, giving reality to the content of the suggestion as the response, then suggested posthypnotic phenomena can be fitted within the framework of modern learning theory. They appear to arise through some form of classical conditioning, abstract conditioning being the most likely form at present. Seen in these terms, posthypnotic suggestions function through the same mechanisms as any other hypnotic suggestion, being merely a

special instance of a deferred suggestion. It must be emphasized that posthypnotic phenomena are learned in the sense only that they are brought into being through the use of previously acquired response tendencies. The learning process has usually reached completion by the time the hypnotic subject is capable of giving good posthypnotic responses.

4. The posthypnotic signal holds a unique position in posthypnotic phenomena which allows it to acquire unique and distinctive features with respect to the elicitation of the suggested behavior, among which is the capacity to cause reintegration.

5. The spontaneous [sic] trance said to accompany the initiation of any posthypnotic act appears to be a natural outcome of the learning process involved in the acquisition of posthypnotic behavior. There is a reinstatement of the original trance state because the posthypnotic trance is the result of associations taking place between the stimulus-suggestion and the symptoms of the initial hypnosis, these symptoms acting as responses.

6. Acquisition and retention of the contents of the suggested posthypnotic act may need to be differentiated from the acquisition and retention by the posthypnotic signal of the capacity to initiate the posthypnotic act. In the light of this observation, experimental data showing that posthypnotic suggestions are forgotten just like any other instructions may hold true only for the memory of the content. The capacity to initiate posthypnotic action, although subject to the same laws of forgetting may be far more enduring because of certain features of the learning process which underlie it" (pp. 55-56).

Solovey, Galina; Milechnin, Anatol (1956). Concerning some points about the nature of hypnosis. Journal of Clinical and Experimental Hypnosis, 4 (2), 83-88.

#### NOTES

Two experiments with young children explored the similarity between mothers' sleep inducing speech and hypnotic induction. The first group were six normal children ranging in age from 25 to 37 months. Author interviewed their mothers for details on their sleep inducing behavior. Then "we followed a procedure that as a rule consisted in leaning over the little one, dedicating all our attention to him, repeating the mother's own series of soothing diminutives in a softly-modulated voice, and stroking gently the child's hair, forehead, or arm. In four to thirty-five minutes, the children relaxed, stopped moving, let their eyelids droop, and showed a particularly placid facial expression. Their appearance was completely similar to that of a hypnotized person" (p. 83). Signs of catalepsy (e.g. following suggestions of holding a teddy bear more and more tightly) and concentration of attention to the exclusion of outside stimuli were taken to indicate the hypnotic state.

The second experiment involved infants 3 to 24 months old, lulling them into a state of quiet relaxation. "The difficulty does not consist in producing this special state, but in demonstrating that it is really hypnosis. However, if we consider the identity of the means employed in bringing it about, and the similarity of the results to those occurring at a slightly later age, it would be unreasonable to think that there is a

certain reaction up to a certain age and a fundamentally different one from that age on" (p. 85).

The author relates her findings to those of investigators who studied populations of infants and children who, lacking "psychological mothering" failed to thrive or even died. She concludes that the "psychological mothering" in normal families "produces hypnotic states in the infant daily, from the moment of birth" (p. 88).

Leuba, Clarence (1955). Conditioning during hypnosis. Journal of Clinical and Experimental Hypnosis, 3 (4), 256-259.

#### NOTES

The author is responding to an article that concludes that conditioning during hypnosis leads to effects better accounted for by the research subjects' attempts to conform or please the Experimenter (Fisher, Seymour. An investigation of alleged conditioning phenomena under hypnosis. *J. clin. exp. hypnosis*, 1955, 3, 71-103).

"Informal attempts have been made to eliminate the personal subjective influence of the hypnotist when testing for the effects of 'alleged' conditioning under hypnosis. The conditioned stimulus has been administered post-hypnotically by other persons than the hypnotist, or when S was occupied, offguard, and presumably not set to please the hypnotist. The results have been equivocal. Usually, the conditioned responses occurred when the conditioned stimulus was administered by others than the hypnotist and in a variety of situations; when caught offguard, however, the S may not respond, at least not overtly; he may, for instance, only feel a tendency to cough when touched. This might be, of course, because coughing is often inhibited in social circumstances and the tendency, therefore, does not become overt. Sometimes when told by the hypnotist post-hypnotically that the experiments were over, the alleged conditioning disappeared; sometimes, on the other hand, when the hypnotist emphatically stated post-hypnotically that there was no odor present and that it had been just hallucinated, the S nevertheless smelled it when the cue was again present" (p. 258).

1955

McCranie, E. J.; Crasilneck, H. B. (1955). The conditioned reflex in hypnotic age regression. Journal of Clinical and Experimental Psychopathology, 16, 120-123.

#### NOTES

During age regression and testing of reflexes, voluntary hand withdrawal was lost; however the conditioned eyelid reflex was not lost.

Naruse, Gosaku; Obonai, Torao (1955). Decomposition and fusion of mental images in the post-hypnotic hallucinatory state. II: Mechanism of image composing activity. Journal of Clinical and Experimental Hypnosis, 3 (1), 2-23.

#### NOTES

"Summary. This is a report of the studies continued from the previous work, as regards the mode and law of modification of images, by experiments on the image-

fusion which is observed in a post-hypnotic hallucinatory state. The writers investigated the configuration law of the Gestalt school, also whether there was nothing other than the overlapping of images. Various experiments were performed using accorded figures (Fig.1), discorded figures (Fig. 3), the composed image partly changed in size (Fig. 4), the incomplete figures with concrete meaning (Fig. 5,A) and the figures in which the perception and meaning were discorded with each other (Fig. 6). The results were as follows:

(1) There were some subjects whose images were clear, and others whose images were vague. In general, the images were clear in deep hypnotic trance, and vague in the medium trance.

(2) In the case of the clear images, they were prominently overlapping while in the case of the vague images, they overlapped one another and were disjointed or integrated.

(3) After conditioning two kinds of figures with two kinds of sounds, a composed image could be aroused by the two stimuli; in this case, by changing the tempo of one kind, a part of the composed image was changed. This fact would prove that the composed images were combinations of elements.

(4) In the case of the integrated images, the modification of both clear and vague images could be explained satisfactorily not by the Gestalt theory but by the intervention of the meaning. Moreover, the hypothesis of the integration or hierarchy of cerebral functions corresponding to these phenomena was possible.

(5) Modification through meaning was more frequent in the vague images than in the clear ones.

(6) The spontaneous effect of meaning of the image was dependent on the depth of trance. This effect was comparatively weak in deep trance and strong in medium trance. It was assumed that in medium trance which reproduced the integrated images, meaning activity still remained.

(7) Having presented incomplete figures with concrete meanings to examine the effect of meaning, it was clear that the modification of images by meaning took place distinctly under the influence of suggestion.

(8) If perception and meaning of the figure were made to be in discord with each other, the meaning suggested at the time of conditioning produced more effect on the modification of the image than that at the time of recall" (p. 22).

1954

Dittborn, Julio (1954). Dehypnotization and associated words. Journal of Clinical and Experimental Hypnosis, 2 (2), 136-138.

#### NOTES

Author tested Freud's hypotheses about signs of emotional conflict gleaned from a word association test. A highly hypnotizable subject who had been accused of theft was tested with the word association test repeatedly. He had been given the suggestion, while in deep hypnosis, that any word provoking emotional conflict would automatically bring him out of hypnosis. That is, "dehypnotization was used as a new method to investigate the conflict-provoking quality of certain stimulus-

words in an association word test" (p. 139). Freud's predictions were only partially supported.

Howarth, Edgar (1954). Postscript to a new theory of hypnosis. Journal of Clinical and Experimental Hypnosis, 2, 91-92.

#### NOTES

Referring to a theory of internal and external signalling systems, the author describes situations in which an individual's behavior comes under other than willed control by virtue of external circumstances. "In normal behavior the individual provides his own 'will' and may, to some extent, choose among a variety of alternative action sequences on the basis of guiding integrations between the second (externally directed) signalling system and the primary (internally directed) signalling system. ... it appears that a considerable degree of control may be obtained by the 'top' semantic command system over internal process, particularly those 'inhibited' by the cranial and sacral subdivisions of the 'autonomic' nervous system. .. [In anecdotal case reports] control was gained over breathing, heart rate and bladder and the person may feign death for several days. In such cases surface wounds do not exude other than lymph. The method for such control remains for experimental examination, but a necessary part of the procedure seems to be the use of mild occasional reward during a prolonged period of fasting. Solitary confinement is also necessary and both deserts and prison cells are reported ... to have been used" (pp. 91-92).

#### 1953

Dittborn, Julio (1953). Conditioning of hypnosis to different signs of the same significance. Journal of Clinical and Experimental Hypnosis, 1 (3), 1-3.

BSTRACT: No Abstract or Summary available. The author's conclusions state, in part:

1. The difference of the periods of latency to condition a deep hypnotic trance between the different signs of the number six, is remarkable. This difference is significant between the pair (6; six,) and the pair (VI; 12:2).
2. The mean periods of latency are peculiar to each subject, but the subjects tend to gather themselves into two groups: a more rapid (subjects C and D) and a slow one (subjects A and B).
3. It is worthy of notice that one of the subjects, B, did not respond to the idea of six when this was not presented explicitly, but had to be deducted from a calculation (12:2=).

..... It is suggestive that with three somnambulists the idea was enough to produce the phenomenon, while the other always required the objectivation of the idea, even though the sign implied it in a very evident and simple way. It might be worth while to ask if this phenomenon might not be another way to measure the depth of a somnambulant trance.

Guze, Henry (1953). Posture, postural redintegration and hypnotherapy. Journal of Clinical and Experimental Hypnosis, 1, 76-82. (Abstracted in Psychological Abstracts 53: 6559)

#### **SUMMARY**

The use of postural analysis, and directives regarding posture and their importance in hypnotherapy are discussed. Theoretically, it is indicated that a chronic postural condition may act to elicit an emotional state with which it was originally associated. Such an emotional condition may have caused the posture in the first place, and then established a feed-back relationship with it. The breaking of feed-back mechanisms of this kind depends largely upon postural change when a chronic situation is established in the absence of realistic cause for the emotion. Posture may also act redintegratively, when directly suggested, in rearousing traumatic memories. Several clinical cases are reported.

Howarth, Edgar (1953). A new theory of hypnosis. Journal of Clinical and Experimental Hypnosis, 1 (4), 42-46.

Author's Summary - A new theory of hypnosis was suggested on the basis of interaction between the neural representations of the primary and secondary systems. It was suggested that the hypnotizer was able to integrate his own semantic commands into the neural representations as previously conditioned within the brain of the subject from past experience from semantic visual/auditory distal invariants. This was done by input contiguity between the verbal "commands" or "suggestions" from the experimenter accompanying stimulus or input reduction and the later "necessary events." We realize that our terminology is "new" (or may seem new to some) but the older terminology is largely anthropomorphic, and certainly does not offer explanations of psychological phenomena, such as hypnosis. (p. 46).

Naruse, Gosaku; Obonai, Torao (1953). Decomposition and fusion of mental images in the drowsy and post-hypnotic hallucinatory state. Journal of Clinical and Experimental Hypnosis, 1 (4), 23-41.

#### **Summary of Part I**

"From the above we can conclude the following main facts.

- 1) When one sensory stimulus is given to a subject in a drowsy state, images of other objects associated with it often appear.
- 2) These images sometimes have forms, and sometimes are devoid of forms, only light and color being present. This phenomenon resembles the experience of color-hearing, and is called a new type of synaesthesia [sic] by Bachen.
- 3) These images are sure to disappear when they are observed attentively, a passive attitude being necessary for the image observation.

- 4) The remarkable character of these images are such that elements of forms and colors of various objects have been disjointed and connected with each other in different relationships which construct new images.
- 5) The longer and stronger persistence of stimulus, the more easily and clearly conditioned images appear. Conversely if the stimulus is momentary, the recalled images appear also momentarily.
- 6) Not only the visual images but also the sensory images can be elicited in a similar way" (p. 25).

#### **Summary of Part II**

"The chief results of Naruse's experiments with the various subjects are as follows:

1. When one stimulus (C.S.) is given in the normal waking state after a conditioning procedure in which a conditioned bond is formed between two sensory stimuli in deep hypnotic trance, a mental image corresponding to the other stimulus (U.C.S.) appears with amnesia for the conditioning situation. When the stimulus is removed, the image also disappears.
2. The images attained have various degrees of clearness which may be classified on a continuum from hallucinations to memory images.
3. Such images tend to disappear when subjects try to observe them attentively.
4. Images which are broken into elements of the original figure appear as distinct images.
5. Modifications of images may be made by distortion, vagueness of the image, and by decomposition of the image.
6. When two C.S.'s, which were already conditioned individually to two U.C.S.'s are presented at the same time, the images corresponding to each stimulus appear to overlap. This is the composed image.
7. In image composing, which involves the strong-weak stimulus relationship or the spatial positions of two C.S.'s, the clear-vague or positional relationships of the composed images are changed.
8. In the complex of meaningful images, there are two types, primarily. The one grasps the image as a whole, the other observes it in many mosaic elements. The latter can recall the original figure more correctly in an image form than the former.
9. Some positive and negative reports on sensory conditioning in the normal waking state are reviewed" (p. 36).

#### **NOTES**

The investigators do not show that hypnosis enhances imagery, compared with the waking state. They studied sensory-sensory conditioning under hypnosis, with amnesia suggestions, followed by testing for the conditioning effect. This study is relevant to studies of amnesia, "repression." In some studies they paired sound of a buzzer or metronome (the Conditioned Stimulus) with images (the Unconditioned Stimuli) as in [Oo, X); other studies compared a color patch (CS) with an image (Oo, X). Some studies presented both CS's together, in different spatial arrangements (in the instance of the color patch CS).

Results (partial) included: "1. When one stimulus (CS.) Is given in the normal waking state after a conditioning procedure in which a conditioned bond is formed

between two sensory stimuli in a deep hypnotic trance, a mental image corresponding to the other stimulus (UCS) appears with amnesia for the conditioning situation. When the stimulus is removed, the image also disappears. 2. The images attained have various degrees of clearness which may be classified on a continuum from hallucinations to memory images. 3. Such images tend to disappear when Ss try to observe them attentively. ... 5. Modifications of images may be made by distortion, vagueness of the image, and by decomposition of the image. 6. When two CS's, which are already conditioned individually to two UCS's, are presented at the same time, the images corresponding to each stimulus appear to overlap. ..." (P. 36).

## CONSCIOUSNESS

Gibbons, Don E.; Sanchez, George P. (undated). Hyperempiria, a new 'altered state of consciousness'. [Unpublished manuscript]

### NOTES

The authors suggest that any induction procedure legitimizes acceptance of primary-type suggestions that are at variance with everyday experience. Such primary (i.e. "waking") suggestions are actually accepted at a higher rate than most people think (Barber & Calverley, 1962), and passing those suggestions convinces the subject he must be "hypnotized." However, inductions with the word "sleep" tend to retard subject's response to suggestions. An induction that is more oriented to alert states would be very useful for many people and situations. "Hyperempiria" in Greek means hyper-experience or enhanced quality of experience. The hyperempiric induction contains suggestions of increased alertness, mind expansion, enhanced awareness, and enhanced sensitivity.

Gibbons, Don E. (2001). Experience as an art form: Hypnosis, hyperempiria, and the Best Me technique. San Jose CA: Authors Choice Press. (([available online:] <http://www.iuniverse.com/bookstore/marketplace>))

#### NOTES

The Best Me Technique is a procedure for constructing suggestions which incorporates many different dimensions of experience -- beliefs, emotions, sensations, thoughts, motives, and expectations -- for maximum involvement and effectiveness. Best Me suggestions may be used with either hyperempiria, an alert induction based on suggestions of mind expansion and increased alertness and sensitivity, or with more traditional forms of hypnotic induction.

2000

Gibbons, Don (2000). Applied hypnosis and hyperempiria. New York NY: Plenum Press. ([available online:] <http://www.iuniverse.com/bookstore>)

#### NOTES

The book features both traditional hypnotic procedures and hyperempiric inductions based on suggestions of increased awareness, mind expansion, and increased alertness and sensitivity. It contains sections on the use of suggestion as an instrument of personal growth in areas such as improving study skills, taking examinations, achievement motivation, artistic expression, emotional enrichment, aesthetic appreciation and enjoyment, interpersonal effectiveness, musical performance, problem solving, public speaking, salesmanship, sports performance, theatrical performance, and writing ability.

1999

Barabasz, A.; Barabasz, M.; Jensen, S.; Calvin, S.; Trevisian, M.; Warner, D. (1999). Cortical event-related potentials show the structure of hypnotic suggestions is crucial. International Journal of Clinical and Experimental Hypnosis, 47 (1), 5-22.

Electroencephalographic cortical event-related potentials (ERPs) are affected by information processing strategies and are particularly appropriate for the examination of hypnotic alterations in perception. The effects of positive obstructive and negative obliterating instructions on visual and auditory P300 ERPs were tested. Twenty participants, stringently selected for hypnotizability, were requested to perform identical tasks during waking and alert hypnotic conditions. High hypnotizables showed greater ERP amplitudes while experiencing negative hallucinations and lower ERP amplitudes while experiencing positive obstructive hallucinations, in contrast to low hypnotizables and their own waking imagination-only conditions. The data show that when participants are carefully selected for hypnotizability and responses are time locked to events, rather robust physiological markers of hypnosis emerge. These reflect alterations in consciousness that correspond to participants' subjective experiences of perceptual alteration. Accounting for suggestion type reveals remarkable consistency of findings among dozens of researchers.

## NOTES

In their Discussion the authors note that not all of the highly hypnotizable subjects demonstrated the changes predicted, consistent with Hilgard's (1992) observation that individual differences in response remain even among high hypnotizables. Post-experimental inquiry revealed the sources of (non-predicted) response for these two people. "One, showing only a moderate ERP amplitude attenuation in the obstructive condition, noted she pictured a cardboard box in front of the computer monitor, but 'I pictured a rather small box that didn't block the entire screen!' Another showed an apparently contradictory response, a markedly diminished amplitude in the negative hallucination that called for deafness during the auditory stimuli. This participant reported the perception of complete obliteration of all sounds and, therefore, showed no surprise ERP effect. 'It was kind of scary when he (AB) said 'deaf' the second time. I couldn't hear anything at all. I was glad when he touched my shoulder and it was OK to hear again. I don't think I would do that again ... I mean do the hypnotic suggestion as much!'" (pp. 17-18).

Bargh, John A.; Chartrand, Tanya L. (1999). The unbearable automaticity of being. American Psychologist, 54 (7), 462-479.

What was noted by E. J. Langer (1978) remains true today: that much of contemporary psychological research is based on the assumption that people are consciously and systematically processing incoming information in order to construe and interpret their world and to plan and engage in courses of action. As did E.J. Langer, the authors question this assumption. First, they review evidence that the ability to exercise such conscious, intentional control is actually quite limited, so that most of moment-to-moment psychological life must occur through nonconscious means if it is to occur at all. The authors then describe the different possible mechanisms that produce automatic, environmental control over these various phenomena and review evidence establishing both the existence of these mechanisms as well as their consequences for judgments, emotions, and behavior. Three major forms of automatic self-regulation are identified: an automatic effect of perception on action, automatic goal pursuit, and a continual automatic evaluation of one's experience. From the accumulating evidence, the authors conclude that these various nonconscious mental systems perform the lion's share of the self-regulatory burden, beneficently keeping the individual grounded in his or her current environment.

1998

Chapman, C. Richard; Nakamura, Yoshio (1998). Hypnotic analgesia: A constructivist framework. International Journal of Clinical and Experimental Hypnosis, 46 (1), 6-27.

Hypnotic analgesia remains an enigma. Recent neuroscience studies demonstrate that widespread distributed processing occurs in the brains of individuals experiencing pain. Emerging research and theory on the mechanisms of consciousness, along with this evidence, suggest that a constructivist framework may

facilitate both pain research and the study of hypnosis. The authors propose that the brain constructs elements of pain experience (pain schemata) and embeds them in ongoing consciousness. The contents of immediate consciousness feed back to nonconscious, parallel distributed processes to help shape the character of future moments of consciousness. Hypnotic suggestion may interact with such processing through feedback mechanisms that prime associations and memories and thus shape the formation of future experience.

#### NOTES

The authors suggest that emerging paradigms for the study of consciousness may be useful in bridging research on hypnotic analgesia with advances in research on pain control. The constructivist framework emphasizes central processing of nociceptive signals, and consciousness as "an emergent property of a self-organizing process in a distributed neural network" (p. 14). The Dennett & Kinsbourne (1992) 'multiple drafts model' of consciousness and the authors' constructivist framework provide a way of understanding phantom limb pain, which classical models of pain cannot do. Pain is experienced as the brain blends schemata reflecting current stimuli, memories, associations formed by conditioning, emotions, and cognitions. "Hypnotic suggestions can engender temporally dominant schemata that influence ongoing consciousness construction of the subject" (p. 20). They suggest that "hypnotic analgesia depends heavily on the formation of suggestion-related schemata and subsequent priming effects, that somatosensory imagery is the key element in the contents consciousness [sic], and that the mechanisms behind hypnotic analgesia phenomena are largely related to the competition among schemata for a dominant position within the contents of consciousness" (p. 23). Jean Holroyd

Gibbons, Don (1998). Suggestion as an art form: Alternative paradigm for hypnosis?. [Paper] Presented at annual meeting of American Psychological Association, San Francisco. ([available online:] <ftp://members.aol.com/gibbonsdon/artform.txt>)

This paper proposes a change in the manner in which we think about suggestion-induced phenomena, moving from primary reliance upon a medical/counseling model to a concurrent view of suggestion as an art form and hypnosis as an artistic medium. the rationale for such an alternative paradigm is discussed, and a procedure for scripting suggestions within the new paradigm -- the Best Me technique -- is presented, along with a specific illustration of its application, possible implications for current clinical practice, and suggestions for transition to the new paradigm.

1996

Rosenbaum, Robert & Dyckman, John (1996). No self? No problem! Actualizing empty self in psychotherapy . In Hoyt , Michael F. (Ed.), Constructive therapies (2, pp. 238-274). New York NY: Guilford.

## NOTES

In this book chapter, Rosenbaum and Dyckman (1996) argue that self has no permanently fixed, defining, thing-like characteristics (p. 270). They thus dispute the classical notion--commensurate with the position of philosophical realism --that the self is a substance, with fixed qualities and measurable qualities. The authors refer to this classical self as a full self, contained inside the skin and delimited by its participation in linear time. Instead, they propose an empty self, not to be construed as a void, but as a fluid, connected, relational self that overflows the traditional boundaries of the skin and is open to greater possibilities for change. To support their view of an empty self, the authors include several case examples of working with hypnosis and strategic/narrative therapy with clients experiencing a variety of psychological and physical symptoms. The authors further contend that self is not unitary, but the product of multiple drafts (p. 248)[Editor note: See Dennett, 1991, in this database]. In the narrative-constructivist tradition, they argue, if we speak in terms of multiple contextual selves for us all...[then, people diagnosed with MPD/DID] are not so different from the rest of us (p. 249). The chapter draws from western & Buddhist philosophy, strategic/systemic and narrative therapies, Ericksonian hypnosis, and, cognitive science theories regarding memory, consciousness, embodiment, and language, to support their alternative view of, and treatment for, the self

## 1995

Pribram, Karl H. (1995). Brain in perception: From Kohler's fields to Gabor's quanta of information. In Proceeding of the 39th Congress of German Society for Psychology (pp. 53-69).

## NOTES

[The following material was taken from a paper provided by the author as a replacement for a presentation he made on the same topic at the Annual Meeting of the American Psychological Association, 1994, Los Angeles.]

Pribram presents the view that neuroelectric field theory (similar to theories proposed by Kohler and by Lashley earlier in this century) account for complexities observed in the relationship between awareness/perception and sensation. "Nerve impulse generation and transmission in neuronal circuits is but one of the important electrical characteristics of neural tissue. Another characteristic is the production of patterns of pre- and post-synaptic polarizations in axonal and dendritic arborizations. ... [which] are produced everywhere in the brain cortex when nerve impulses arrive at synapses as a result of the fact that the impulses become attenuated due to decreased fiber size resulting from the branching of axons" (p. 53). The polarizations develop a wave front.

Georg von Bekesy performed experiments on tactile perception that demonstrated the complex relationship between sensation and awareness. We often 'perceive' an object as external to us, even though the immediate specific neural stimulation is of receptors and from there activity is transmitted to the neurons of the brain. Thus we 'see' an object as external to us, even though the light reflected from that object

produces an image on our retina. The same kind of externalized projection occurs for hearing. Touch is ordinarily perceived as at the same location as the stimulation (i.e. in the body), except that the von Bekesy experiments demonstrated that touch could also be perceived at a distance, that is, outside the body, if conditions were appropriate.

In the von Bekesy experiments, a pair of vibrators were used to stimulate two fingers, with each vibrator actuated by the same series of clicks and with the delay of time between the clicks varied. "The interesting point in this experiment is that for the condition in which there is no time delay the vibrations are localized between the two fingers where no skin is present" (p. 55). When two vibrators are placed on the thighs, the experimental subject can, by moving the knees apart, experience the vibratory sensation localized in the open space between the knees! Such an externalization of tactile perception is observed in everyday life, as when in using a knife we seem to sense the edge of the knife in order to make the appropriate movements.

Following from von Bekesy's work, it seems that only some neural processes lead to awareness. "In fact, instrumental (often automatized) behavior and awareness are to a large extent opposed; the more efficient a performance, the less aware we become. ... for the neuroscientist, the question becomes: What kinds of neural activity allow awareness to be inversely related to automatized action?"

"Patterns of synaptodendritic polarizations and nerve impulses are two kinds of processes that function reciprocally. A simple hypothesis states that the more or less persistent designs of dendritic field polarization patterns are coordinate with awareness (Pribram, 1971, Chapter 6). This view carries the corollary that circuits of nerve impulses per se and the behavior they generate are unavailable to immediate awareness. Even the production of speech is 'unconscious' at the moment the words are spoken" (pp. 55-56).

Some additional information comes from the experimental work of Ben Libet (1966, 1994), in which direct stimulation of brain tissue in waking subjects yields reports of awareness (of a particular part of the body tingling or being in a certain position). However, the awareness occurs 0.5 to 5 seconds post-stimulus, indicating that "electrical stimulation must set up some state in the brain tissue, and only when that state has been attained does the patient become aware" (p. 56).

The evidence of electrical fields comes from using both high pass filters and low pass filters on the electrical activity generated by the brain and picked up on EEG. There are 'bursts' of spikes, and onset of the field effect precedes the initiation of spikes. "Just as depolarization of axon membranes is a necessary precursor of the generation of action potentials, so also is the local build up of synaptodendritic field potentials a precursor to the recruitment of action potentials in post synaptic neurons" (p. 57).

Maps of the receptive field of an axon can be developed (e.g. using Kuffler's procedure). However, stimulation outside of that receptive field can change that axon's response--a field effect "produced in a more extended field of potentials occurring in neighboring synaptodendritic fields" (p. 58). In this investigation, the relationship between local field potentials of the rat somatosensory system (whisker stimulation) is studied using the Kuffler procedure. Whiskers were stimulated by

rotating cylinders which varied in spacing of grooves and speed of rotation. The resulting variation in density of stimulation yielded a map or manifold of cortical bursts/spikes. Pribram's research fits the experimentally generated data to a theoretical model derived from signal processing theory, using "a rectangular window in the spatiotemporal domain to constrain the two dimensional sinusoidal signal" (p. 62). They noted that the manifolds obtained from somatosensory cortex recordings were similar to receptive field characteristics measured at the primary visual cortex, which "suggests that this process is ubiquitous in the cortical synaptodendritic network" (p. 63).

Referring to the Fourier theorem (that "the original pattern can be reconstituted, reconstructed, by performing the inverse transform" p. 65), the author notes that experimental data are more complex than would be predicted. The author suggests that it would be helpful to employ the Gabor uncertainty principle, in which Gabor (1946) described as a fundamental unit a 'quantum' of information. "Gabor became interested in describing a joint spacetime-spectral domain because he noted that there is a limit on the precision to which simultaneous measurement of spectral components and [space]time can be made. ... the Gabor relation describes the composition of a sensory channel, and the residual uncertainty defines the limits of channel processing span" (p. 65). The Gabor relationships are similar to those described in quantum physics by Heisenberg, so Gabor referred to a quantum of information, which he named a Logon.

The author describes his experimental results as exhibiting Gabor elementary functions, which "are composed in dendritic arborizations, receptive fields of the neurons from which we are recording. ... Each logon, i.e. each such receptive field module, is a channel. According to Gabor, the ensemble of such channels is a measure of the degrees of freedom, the number of distinguishable dimensions or features (e.g., spatial and temporal frequency, degrees of orientations, preferred direction, color). The minimum uncertainty relation expressed by Gabor elementary functions sets the limits on the information processing competence of each of these channels" (pp. 65-66).

In a Coda to this chapter, the author notes that there is a discrepancy between fields (composed of arrival and departure patterns of synapto-dendritic polarizations) and perceptual awareness which "occurs within spacetime coordinates." Discussion of the discrepancy may be found in Pribram and Carlton (1986). Holonomic brain theory in imaging and object perception. *Acta Psychologica*, 63, 175-210; and in Pribram (1991), Lecture 6 of *Brain and Perception*. Basically, there is top-down organization imposed by the cortical system on peripheral sensation/perception. "These various systems not only relate to one another in a hierarchical manner but that the higher order systems operate on lower order systems by interpenetrating. Thus, we ordinarily, immediately perceive named and categorized objects, not just sets of images (though we are capable of 'imaging' by suspending the higher order processes). There is abundant evidence of such top-down penetration in the visual, auditory and somatosensory neural systems" (p. 66).

1994

Epstein, Seymour (1994). Integration of the cognitive and the psychodynamic unconscious. American Psychologist, 49 (8), 709-724.

Cognitive-experiential self-theory integrates the cognitive and the psychodynamic unconscious by assuming the existence of two parallel, interacting modes of information processing: a rational system and an emotionally driven experiential system. Support for the theory is provided by the convergence of a wide variety of theoretical positions on two similar processing modes; by real-life phenomena--such as conflicts between the heart and the head; the appeal of concrete, imagistic, and narrative representations; superstitious thinking; and the ubiquity of religion throughout recorded history--and by laboratory research, including the prediction of new phenomena in heuristic reasoning.

1993

Kokoszka, Andrzej (1993). Occurrence of altered states of consciousness among students: Profoundly and superficially altered states in wakefulness. Imagination, Cognition and Personality, 12, 231-247.

In a questionnaire survey waking altered states of consciousness (ASC) are found to be common among 174 Polish students. The experience of Superficially Altered States of Consciousness (SASC) was reported by 96 percent of subjects and more than half of them had such experiences often. Whereas an experience of Profoundly Altered States of Consciousness (PASC) was confirmed by 75 percent and about one-third of them had them often. The comparison of the experiences accompanying the ASC indicates that SASC are characterized by disturbances in experiencing the reality and oneself combined with positive, pleasant feelings and with quietness. On the other hand, PASC are accompanied by experiences related to an absolute, universal, eternal, and existential or religious matters. PASC are accompanied by extremely strong positive emotions of happiness, total love, etc. and are experienced as more rational than SASC, and with significantly less feelings of cognitive disturbances than in SASC. The comparison of circumstances of the ASC occurrence indicates that SASC occur in usual and common states and situation of everyday life, whereas PASC mainly in the context of religion and nature. The congruence of these findings with an integrated model of the main states of consciousness suggests a natural tendency for a cyclical occurrence of ASC, or more precisely, the differentiated waking states of consciousness.

1993

Pekala, Ronald J.; Ersek, Barrett (1993). Firewalking versus hypnosis: A preliminary study concerning consciousness, attention, and fire immunity. Imagination, Cognition and Personality, 12, 207-229.

This study assessed the subjective effects associated with firewalking, and compared them with the subjective effects associated with hypnosis and a baseline condition (eyes closed sitting quietly). Twenty-seven subjects, who walked over hot coals during a firewalk ceremony, completed questionnaires about what they subjectively

experienced during the firewalk. Their experiences were subsequently compared with those of subjects (n = 246) who experienced hypnosis and a baseline condition. The data suggested that firewalking, as assessed across all subjects, is characterized by high levels of volitional control and rationality, and a very absorbed attentional style wherein the mind is one-pointed, and consciousness is characterized by strong feelings of joy and high levels of internal dialogue. Firewalking was also found to be associated with significantly more joy, one-pointedness of thought, absorption, and internal dialogue than hypnosis or the baseline condition. In addition, a cluster analysis suggested two subgroups of firewalkers based on their subjective experiences of the firewalk. Interestingly, analyzing the attentional experiences among these firewalkers who got slightly burned, versus those who did not, revealed significant differences. A one-pointed and absorbed attentional focus may be the critical variable for the fire immunity observed in firewalking.

#### NOTES

About 500 people walked across coals, in 3-4 steps. At end of weekend, 71 said they would complete a questionnaire and it was mailed to them. Of those, 27 responded (25 of 26 in an average of 23 days). Hence, 5% of the population who walked responded to the questionnaire, and it was some time later. Three of 24 reported minor blisters. Those who didn't get burned reported less detachment, less of a feeling of being out of their bodies, and more thoughts than the firewalkers who got slightly burned.

Pekala has defined an altered state of consciousness as associated with the perception of being in an altered state of awareness (the subjective sense of altered state --SSAS [30]), and a change in the patterning or configuration of the subsystems or dimensions of consciousness. A discrete state of consciousness, as defined by Pekala, is associated with a significant pattern change but no perceived alteration in state of consciousness (no SSAS). An identity state of consciousness, on the other hand, is defined as having neither a significantly perceived alteration in state of awareness nor a perceived pattern change among dimensions of consciousness in reference to another state of consciousness. Since the PCI can measure both intensity and pattern effects, it can be used to assess for altered, discrete, and identity states of consciousness.

Using a cluster analysis they found that one group of 16 subjects reported the firewalk experience to be characterized by a significant alteration in awareness and experience (body image, time sense, etc.), and significant intensities of internal dialogue, positive and negative affect, and arousal, while a second group of six subjects reported little alteration in consciousness or experience, little losses in rationality or control, and less internal dialogue, positive and negative affect or arousal than the larger group.

Whereas hypnosis is usually associated with a loss in control (the classic suggestion effect), firewalking was found to be associated with increased control, a more aroused state, and more fear! Firewalking appears to be a more absorbed and one-pointed state than even hypnosis.

The nature of attentional experience is similar across firewalkers (DAQ results).

Both firewalking and hypnosis meet the criteria for altered states of consciousness (different pattern and different subjective experience), but they are not altered states in reference to each other; they are discrete states of consciousness in reference to each other, because there is a significantly different patterning of PCI dimensions between the two conditions, but no significant SSAS. This suggests that the firewalk state is qualitatively different from the hypnotic state (as induced by the induction procedure to the Harvard Scale) and probably represents a different type of state of consciousness than hypnosis. Firewalkers obtained a lower mean hypnoidal state score than hypnosis subjects, so it does not appear that the fire immunity is due to being in a "hypnotized" state.

The fact that there appears to be two groups of successful firewalkers, one of which did not report much alteration in consciousness, calls into question the theorizing concerning the importance of alteration in state of consciousness as being etiologically related to successful firewalking. Since about 25 percent of the firewalkers clustered into what appears to be a nonaltered state of awareness, this suggests a sizable percentage of subjects who did not report any significant alteration in consciousness and experience.

Hence, what may be important is not an alteration in consciousness, but rather an alteration in attention. The cluster analysis revealed a relatively unitary attentional state across all subjects suggesting that attention was deployed in a rather similar manner across all subjects, that is, with very high absorption and one-pointedness. It was also the DAQ dimensions, and not the PCI dimensions, that successfully discriminated a trend between the blistered and nonblistered firewalkers. Hence, high levels of one-pointedness and absorption, that is, how attention is deployed during firewalking may be more critical (than an alteration in consciousness in general) for the fire immunity observed during firewalking.

Bindler, Paul (1992, October). Hypnosis and Psychotherapy: The clinical utility of altered states of consciousness. [Paper] Presented at the annual meeting of the Society for Clinical and Experimental Hypnosis, Arlington, VA.

NOTES

Author assesses state, especially attentional changes, with Multidimensional Consciousness Scale (receptivity, arousal, .... etc.)

Clinical management of anxiety is goal. Cites Nash as characterizing anxiety disorders with cognitive/affective characteristics similar to hypnotized state. Wickramasekera's model has people high in neuroticism and high in hypnotizable being hypersensitive to stress, with physiological hyperarousal. Lows have alexithymia, may be unresponsive to symbolic events but very responsive to concrete events; poor verbalization of alexithymics leads to somatization.

Author focuses on relaxation and anxiety reduction. Suggests that Crawford's attention model (highs better able to shift cognitive and attentional strategies) is useful.

Instructions facilitate focusing attention inward so external stimuli become irrelevant. Therapist helps patient focus attention on the link between cognitions and tension.

**Merikle, Philip M. (1992). Perception without awareness: Critical issues. American Psychologist, 47, 792-795.**

#### **NOTES**

**This is the introduction to a group of articles. "To a large extent, this entire controversy over perception without awareness has centered on the issue, What constitutes an adequate behavioral measure of conscious perceptual experience? Depending upon one's answer to this question, the evidence for perception without awareness is either overwhelming or nonexistent.**

**The distinction is much more significant and interesting if conscious and unconscious processes lead to qualitatively different consequences than if unconscious processes are simply quantitatively weaker versions of unconscious processes. Three different qualitative differences have been established: 1. Groeger (1984, 1988) has demonstrated that words are coded differently depending on whether they are perceived with or without awareness. 2. Stroop effect research showed that prediction based on stimulus redundancy only occurs when subjects consciously perceive the predictive stimuli (Cheesman & Merikle, 1986). The fact that the color word predicted the name of the color patch on 75% of the trials was only used by the subjects to facilitate naming of the color patches when the words were clearly visible. 3. Marcel (1980) showed that conscious awareness is necessary for the selection of a context-relevant interpretation of a stimulus.**

**The important findings are that performance differs qualitatively across the aware and nonaware conditions.**

**1991**

**Brown, Jason W. (1991). Self and process: Brain states and the conscious present. New York: Springer-Verlag.**

#### **NOTES**

**Author, from the Department of Neurology at New York University Medical School, presents a theory about the genetic unfolding of mental content (mind) through stages, from mental state into consciousness or into behavior. He relates the genesis of mind to brain development but avoids assuming that there is a straightforward correlation between brain development (e.g. myelination) and cognitive development or perception. To some degree, the theory is based on subjective report data and psychological symptoms. The author discusses issues that bear on the phenomena of nonvoluntary responding and dissociation that are reported or described by hypnotized persons.**

**"The nature of the mental state will determine the relation between self and world, and thus the interpretation given to agency and choice. ... The crossing of the boundary from self to world is a shift from one level in mind to another" (pp. 10-11).**

**"... if we begin with mind as primary and seek to explain objects from inner states and private experience, the discontinuity between inner and outer evaporates: mind**

is everywhere, a universe. ... Whereas before we thought to perceive objects, now we understand that we think them" (p. 19).

"The concept of a stratified cognition is central to the notion of a mental state .... This entails an unfolding from depth to surface, not from one surface to the next, a direction crucial to agency and the causal or decisional properties of consciousness" (p. 52). By unfolding from depth to surface, he means from Core, through Subconscious, then Conscious Private Events, and finally Extra-Personal Space.

He goes on to provide a definition of mental states. "A mental state is the minimal state of a mind, an absolute unit from the standpoint of its spatial and temporal structure. ... The state also has to include the prehistory of the organism. ... The concept of a mental state implies a fundamental unit that has gestalt-like properties, in that specific contents-- words, thoughts, percepts--appear in the context of mind as a whole (p. 53).

"The entire multitiered system arborizes like a tree, with levels in each component linked to corresponding levels in other components. For example, an early (e.g., limbic) state in language (e.g., word meaning) is linked to an early stage in action (e.g., drive, proximal motility) and perception (e.g., hallucination, personal memory) .... In sum, a description of the spatial and temporal features of a single unfolding series amounts to a description of the minimal unit of mind, the absolute mental state" (p. 54).

The author's discussion of an individual's physical movement relates to the concept of nonvoluntary movement (or movement without awareness of volition) in hypnosis. "More precisely, levels in the brain state constitute the action structure. As it unfolds, this structure generates the conviction that a self-initiated act has occurred. This structure--the action representation--does not elaborate content in consciousness. ... As with the sensory-perceptual interface, the transition to movement occurs across an abrupt boundary. In some manner, perhaps through a translation of cognitive rhythms in the action to kinetic patterns in the movement, levels in the emerging act discharge into motor (physical) events" (p. 57).

"The self has the nature of a global image or early representation within which objects-to-be are embedded. ... The self is the accumulation of all the momentary cognitions developing in a brain configured by heredity and experience in a particular way (p. 70).

"The deposition of a holistic representation ... creates the deception of a self that stands behind and propagates events. The feeling of the self as an agent is reinforced by the forward thrust of the process and the deeper locus of the self in relation to surface objects. The self appears to be an instigator of acts and images when in fact it is given up in their formation. The self does not cause or initiate, it only anticipates (p. 70).

The foregoing notes cover only the first five chapters, less than half the book. Other chapters relevant to hypnosis would be those titled 'The Nature of Voluntary Action,' 'Psychology of Time Awareness,' 'From Will to Compassion,' and 'Mind and Brain.'

## NOTES

Notes are taken from a review of this book: Diamond, Michael (1993). Book review. *Bulletin of the Menninger Clinic*, 57 (Winter), 120-121.

Brown "posits that because the fundamental matrix of the human brain is metaphoric, hypnosis results from skillful matching of metaphorical communication with the brain's biological, rhythmic alterations. The most significant feature of trance experience is thereby located in the hypnotist-subject interaction" (p. 120).

"The middle section [of the book is comprised largely of] literature reviews in support of Rossi's (1986) ultradian rhythm theory of hypnosis and Lakoff and Johnson's (Johnson, 1987; Lakoff & Johnson, 1980) experientialist theory of conceptual thought" (p. 120). The final section includes "research evidence on medical uses of hypnosis, a theory of dissociation and multiple personality disorders, and an uncritical discussion of Milton Erickson's naturalistic hypnotherapeutic approach ... [and also] a brief discussion of the social-cultural functions of possession states among the Mayotte culture" (p. 120).

Dennett, Daniel C. (1991). Consciousness explained. Boston: Little, Brown & Co..

## NOTES

1:

NOTES: Material in this book is relevant to discussions about 'nonvoluntary' behavior and (un)conscious experiencing. It combines information from cognitive neuroscience with the philosophy of mind. The author presents a view that consciousness (the 'mind') is the consequence of the brain's activities which give rise to illusions about their own properties. He presents the Multiple Drafts model of consciousness, which reformulates the concept of a 'stream of consciousness.' This provides a basis for consideration of concepts central to cognitive neuroscience and phenomena associated with hypnosis, e.g. experiential states and the nature of the self.

The author gives various examples of phenomenology and notes that although these examples are familiar to us, they are totally inaccessible to materialistic science; e.g. the way the sunset looks to someone. He treats people's descriptions of what they experience as a record of speech acts. Thus, observing and interpreting speech acts, inferring from them the speaker's inner states, is like a reader who is interpreting a work of fiction. He gives as examples of how one can scientifically study what does not 'exist' (a) literary theorists who describe fictional entities, (b) anthropologists who study cultural artifacts like gods and witches, and (c) physicists who study a center of gravity.

In Dennett's theory, multitrack processes of interpretation of sensory inputs and elaboration of those inputs amounts to a kind of 'editorial revision' by the brain. For example in the phi phenomenon a red dot is displayed, followed by a green dot in a different location; the first spot seems to begin moving and then change color in the middle of its illusory passage toward the second location. He points out that awareness of the change in color must occur after seeing the green spot, but one consciously experiences a single spot first red, then red-turning-to-green, finally green. In an example that relates directly to the words used for his theory, he cites contemporary publishing practices, in which several different drafts of an article are in circulation even while the author is revising it. Deciding on some specific

moment of brain processing as the moment of consciousness is arbitrary, according to his Multiple Drafts model.

"Visual stimuli evoke trains of events in the cortex that gradually yield discriminations of greater and greater specificity. At different times and different places, various 'decisions' or 'judgments' are made; more literally, parts of the brain are caused to go into states that discriminate different features, e.g., first mere onset of stimulus, then location, then shape, later color (in a different pathway), later still (apparent) motion, and eventually object recognition. These localized discriminative states transmit effects to other places, contributing to further discriminations, and so forth. The natural but naive question to ask is: 'Where does it all come together'? The answer is: Nowhere. Some of these distributed contentful states soon die out, leaving no further traces. Others do leave traces, on subsequent verbal reports of experience and memory, on 'semantic readiness' and other varieties of perceptual set, on emotional state, behavioral proclivities, and so forth. Some of these effects--for instance, influences on subsequent verbal reports--are at least symptomatic of consciousness. But there is no one place in the brain through which all these causal trains must pass in order to deposit their content 'in consciousness'" (pp. 134-135).

The author describes the evolution of the brain, along Darwinian lines, and introduces the idea of culture as a repository and transmission medium for innovations (including innovations of consciousness) as a medium of evolution. Through learning, we humans evolve an American or a Japanese brain. Once we have evolved the 'entrance and exit pathways' for language, they become 'parasitized' by memes (entities that have evolved to thrive in such a niche).

Richard Dawkins coined the term memes to describe the smallest idea elements that replicate themselves reliably (e.g. wheel, alphabet, wearing clothes, right triangle). "The transformation of a human brain by infestations of memes is a major alteration in the competence of that organ" (p. 209).

Dennett discusses the similarities and dissimilarities of brains and computers. He suggests that human minds are like serial virtual machines implemented on parallel processing hardware. The stream of consciousness results from our rehearsal of brief experiences, to commit them to memory; language then permits us to describe to ourselves the process of thinking which leads to judgement and action.

The author's discussion of how a verbal expression evolves and becomes manifest is related to how so-called intentional action occurs. [This relates to discussions of nonvoluntary actions in hypnosis.] We assume that because our actions make sense, they are the product of serial reasoning. However, there are multiple channels "in which specialist circuits try, in parallel pandemoniums, to do their various things ... (pp. 253- 254). Bernard Baars has suggested "that consciousness is accomplished by a 'distributed society of specialists that is equipped with a working memory, called a global workspace, whose contents can be broadcast to the system as a whole (p. 42)" (p. 257). Dennett states that there is no line dividing the events that are definitely in consciousness from those that are outside consciousness. He urges scientists to forgo the concept of the 'inner observer' implied by Cartesian materialism.

Examples of perception that is unaccompanied by consciousness include blindsight (in which the subject does better than chance on visual tests but denies

consciousness, and the denials are given credence by neurological evidence of brain damage) and hysterical blindness, which is given less credence because subjects often use the visually provided information in ways blindsight Ss do not. Other behaviors not controlled by conscious thought include blinking when things approach the eye, walking without falling over, regulating our body temperature, adjusting our metabolism, etc. "If I am trying to see a bird that I hear, and stare at the spot but do not distinguish the bird from its background, can I say that it is present in the background of my (visual) consciousness or not?" (p. 336).

The author maintains that if an event doesn't linger and the person is unable to identify and reidentify the effect, it cannot be reported. But such reportability can be improved, as with training the palate of wine tasters. Often, however, we continue disregarding stimuli that impinge on us. There are minor oversights, such as our 'blind spots' or proof reading errors, and major oversights such as a brain-damaged patient's hemi-neglect. In the Multiple Drafts theory, the Observer is replaced by 'coalitions of specialists' that are distributed around in the brain, distributed in both time and space.

Though discrimination or discernment happens, there is no one Discerner doing the work. However, Dennett takes the middle ground on the question of whether a self exists: it is simply a creation like the nest of the Bower bird, or the organized colony of termite ants. "So wonderful is the organization of a termite colony that it seemed to some observers that each termite colony had to have a soul (Marais, 1937). We now understand that its organization is simply the result of a million semi-independent little agents, each itself an automaton, doing its thing. So wonderful is the organization of a human self that to many observers it has seemed that each human being had a soul, too: a benevolent Dictator ruling from Headquarters" (p. 416). The sense of self is a creation, like a physicist's center of gravity.

Thus, multiple personality disorder is viewed as a self that has gaps; and our sense of self might include different aspects from one year to the other. Hence, "selves are not independently existing soul-pearls, but artifacts of the social processes that create us, and, like other such artifacts, subject to sudden shifts in status. The only 'momentum' that accrues to the trajectory of a self, or a club, is the stability imparted to it by the web of beliefs that constitute it, and when those beliefs lapse, it lapses, either permanently or temporarily" (p. 423).

Finally, the author has an extensive discussion of the concepts of 'qualia' and of 'epiphenomena' and seems to have little use for either term in trying to understand Mind.

Kunzendorf, Robert G.; Beltz, Susan McLaughlin; Tymowicz, Gina (1991-92). Self-awareness in autistic subjects and deeply hypnotized subjects: Dissociation of self-concept versus self-consciousness. Imagination, Cognition and Personality, 11, 129-141.

By refining past tests of self-awareness in mirrors, current testing demonstrates that autistic subjects' percepts are dissociated from self-concept, whereas hypnotized subjects' sensations are dissociated from self-consciousness. In the current test of self-concept, subjects could not directly see a line inside the box on their lap, but

subjects could see the line indirectly in a televised mirror image. When instructed to touch the line, autistic subjects reached towards the televised line, whereas nonautistic subjects reached towards the actual line occluded inside the box. This first result suggests that the autistic subject's visual percept of the televised line is dissociated from its spatial relationship to the subject's self-concept. In the current test of self-consciousness, subjects were told to use a televised mirror-image to move their hands together until touching, but were not told that they were actually seeing a pre-recorded tape of their hands struggling unsuccessfully to touch. When queried, hypnotized subjects denied that their tactually joined hands were touching, whereas nonhypnotized subjects confirmed that their hands were touching. This latter result suggests that the hypnotized subject's hand-touching sensations are dissociated from the immediate and incontrovertible self-consciousness that one is perceiving the hands touching (not imaging them touching).

Neill, W. Trammell (1991, August). Consciousness and the inhibitory control of cognition. [Paper] Presented at the annual meeting of the American Psychological Association, San Francisco.

#### NOTES

This review mentions an association between Tellegen's Absorption Scale and a cognitive inhibitory process called negative priming. Westberry and colleagues, including Anker and Neill, found that people high on the Absorption Scale show an extremely large negative priming effect.

Attention is usually attributed to facilitation (selectively processing stimuli that meet our needs) but might also be due to inhibition of competing stimuli. If, after stimulus S2 has been ignored, we now require a response to either S2 or a new stimulus, S3, according to the facilitation theory S2 should be processed as easily as S3; according to the inhibition theory, processing of the recently ignored stimulus may be hampered by the persistence of inhibition.

Dalrymple-Alford provided evidence of inhibition using a Stroop color naming task in which each printed word in a list named the ink color of the next word in the list. Dalrymple-Alford concluded that the response to each word had to be suppressed in order to name its ink color, thereby making it harder to make that same response to the next item. Neill replicated it: color naming was slower when the current color matched the previous distractor (e.g., YELLOW in green ink, after GREEN in red ink) than when the current and previous trial were unrelated (e.g., YELLOW in green ink, after BLUE in red ink).

Tipper, Weaver, Cameron, Brehaut, & Bastedo (1991) had subjects name a picture at fixation, ignoring another picture to the left or right, and Tipper (1985) had subjects ignore picture drawn in another color. If the ignored picture subsequently becomes the target, it is named more slowly than an unrelated target. A particularly interesting finding is that the inhibition generalizes to semantic associates (e.g. if a picture of a dog is ignored, a picture of a cat will then be named more slowly). Yee (1991) demonstrated the effect with ignored words. Tipper (1985) called the inhibitory effects "negative priming".

Neill used a task in which S is shown a string of five letters, and is instructed to judge the second and fourth letters as "same" (e.g., ABABA) or "different" (e.g., ABACA). Negative priming was shown by slower reaction time to target letters that matched the previous ignored distractors (in case below, ABABA):

ABABA - Reaction times are 779 for CACAC and 766 for CDCDC because the A appears in both ABABA and CACAC.

Negative priming does not appear to be perceptual, since it occurs between physically dissimilar stimuli, e.g. in the Stroop task ignoring a printed word inhibits responding to a color. And Tipper and Driver (1988) found negative priming between pictures and corresponding words. By default, the locus of inhibition appears to be at the level of a central cognitive representation. That is, it occurs at a level in which the word GREEN and the color green are related to the same abstract concept, but have not yet accessed an overt response.

However, in the letter-matching task, negative priming occurred only if the ignored distractor letter and subsequent target shared the same letter case. If the ignored distractor and subsequent target were in opposite case (e.g., ABABA, then cacac), positive priming was obtained instead. Because the letter-matching task could be performed on the basis of perceptual similarity, it appears that inhibition can be specific to the perceptual representation when attention is directed to that level of processing.

Individual differences in negative priming appear to be related to more global cognitive effectiveness. N.B. Stroop interference is greatest at age 7, decreasing to adolescence, then plateaus through adulthood (Comalli, Wapner & Werner, 1962). Children in second grade also show less negative priming than young adults in picture naming task (Tipper et al. 1989). (Same thing was found for the elderly, and it is associated with distractibility).

Negative priming research suggests the inhibition of irrelevant processing that is critical for effective functioning. Beech, Baylis & Claridge, 1989, and Beech & Claridge, 1987, studied schizophrenics and college students with schizotypal traits using negative priming task, where these appear to be associated with a failure to inhibit distracting information.

Broadbent et al's (1982) Cognitive Failures Questionnaire measures self-reported lapses of perception, memory, and motor function. Tipper and Baylis (1987) found that negative priming was negatively correlated with cognitive failures; i.e. cognitive failures are associated with less inhibition of distracting information.

Westberry, 1984; Westberry, Anker & Neill, in preparation - found that people high on the Absorption Scale show an extremely large negative priming effect, while the effect for "low absorbers" was negligible.

1990

Biasutti, M. (1990). Music ability and altered states of consciousness: An experimental study. International Journal of Psychosomatics, 37, 82-85

The relationship between music and altered states of consciousness was studied with 30 subjects divided into hypnosis and control groups. The "Test di abilità musicale" was applied. The hypnosis group did the retest after posthypnotic suggestions and

the second in waking conditions. The hypnosis group had better results than the control group, especially in the rhythm test ( $p < 0.0001$ ).

**Tinnin, L. (1990). Mental unity, altered states of consciousness, and dissociation. Dissociation, 3, 154-159.**

This model for understanding altered states of consciousness and dissociation is based on the hypothesis that normal consciousness depends on an illusion of mental unity generated by dynamic brain processes. When these processes are altered and the illusion of unity lost, the individual experiences an altered state in which normal consciousness is latent or "dissociated." Mental organizations formed during an altered state will also become dissociated when the altered state is terminated and mental unity returns. In some cases, recurrent altered states may lead to multiple dissociated mental systems or states. Therapeutic resolution of dissociation requires that the individual gain access to the memory, transcend the obligatory illusion of unity, and consciously avow the ego state formed during the traumatic altered state of consciousness.

**1989**

**Kunzendorf, Robert G. (1989-90). Posthypnotic amnesia: Dissociation of self-concept or self-consciousness?. Imagination, Cognition and Personality, 9, 321-334.**

**ABSTRACT:** Two studies of posthypnotic amnesia tested predictions derived from the 'source' monitoring theory of self-consciousness. Experiment 1 tested the prediction that posthypnotic source amnesia is irreversible, because hypnosis attenuates self-consciousness of whether one's sensations have an imaginal source or a perceptual source. In this initial study, recall amnesia was reversed by posthypnotic cueing with a prearranged signal, but source amnesia was not reversed by such cueing. Experiment 2 examined whether the cued reversal of recall amnesia is attributable, in part, to the hypnotic attenuation of self-conscious 'source monitoring' and, in part, to the reversal of recall criteria: from a criterion rejecting 'seemingly imaginary' or 'sourceless' memories, to a criterion accepting 'sourceless but familiar' memories. In this latter study, posthypnotic recall amnesia was breached when subjects were instructed to trust their seemingly imaginary memories, but not when they were instructed to try harder to remember [emphasis removed from quoted text].

**Pekala, Ronald J.; Bieber, Stephen L. (1989-90). Operationalizing pattern approaches to consciousness: An analysis of phenomenological patterns of consciousness among individuals of differing susceptibility. Imagination, Cognition and Personality, 9 (4), 303-320.**

Pattern differences in subjective experience, as assessed by a self-report inventory, the Phenomenology of Consciousness Inventory (PCI), were compared across low, low-medium, high-medium, and high hypnotically susceptible individuals during hypnosis and eyes-closed. A hierarchical factor analytic approach was utilized that allowed for the determination of pattern differences among PCI dimensions as a

function of hypnotic susceptibility. The factor analyses found that the four susceptibility (sic) groups were 'pattern equivalent' during eyes-closed, partially pattern dissimilar during hypnosis, and partially pattern dissimilar when comparing hypnosis against eyes-closed. The nature of these results support previous analyses (1) which compared pattern structure differences as a function of correlational matrices. The results suggest the complementarity of Bieber's (2) and Pekala's (3) approaches for assessing pattern differences in consciousness and are congruent with the theorizing of Tart (4), Izard (5), and the PDP researchers on the importance of pattern structure changes in understanding states of consciousness.

#### NOTES

This paper is based on the presentation at SCEH in Ashville, 1988.

Pekala, Ronald J.; Kumar, V. K. (1989). Phenomenological patterns of consciousness during hypnosis: Relevance to cognition and individual differences. Australian Journal of Clinical and Experimental Hypnosis, 17 (1), 1-20.

Relationships among phenomenological subsystems of consciousness associated with a baseline condition and an hypnotic induction condition were compared across individuals of differing hypnotic susceptibility. Phenomenological experience on 12 subsystems of consciousness was quantified by means of the Phenomenology of Consciousness Inventory (PCI) and the relationships between dimensions were statistically assessed. The results replicated previous findings and suggested that hypnosis has differential effects upon the reported organization of phenomenological structures of consciousness across subjects of differing susceptibility. The data from the previous and present studies were pooled and the combined data were reanalyzed. The results provided further support for the differential pattern structure across low and high susceptibles during hypnosis. Furthermore, differences in pattern structure were augmented when comparing very low versus very high susceptible individuals.

#### NOTES

This paper is based on a paper presented to Division 30, Psychological Hypnosis, at annual meeting of the American Psychological Association, Aug 1987.

1989

Van der Hart, O.; Friedman, B. (1989). A reader's guide to Pierre Janet on dissociation: A neglected intellectual heritage. Dissociation, 2 (1), 3-16.

A century ago there was a peak of interest in dissociation and dissociative disorders. Janet (1859-1947) was the most important scientific and clinical investigator of this period, whose work is reviewed in this article. The evolution of dissociation theory and its major principles are traced throughout his writings. His introduction of the term 'subconscious' and his concept of the existence of consciousness outside of personal awareness are explained. The validity and reliability of dissociation as the underlying phenomenon in a wide range of disorders is presented. It is proposed

that Janet's theory and methodology of psychological analysis and dynamic psychotherapy are cogent and relevant for today.

## NOTES

Hypnosis is discussed in terms of inhibition/excitation mechanisms in the central nervous system, with both feedback and feedforward controls and lateralizing controls. The author employs a concept of engrams (neural representations of an idea, represented throughout the neocortex) to discuss sensation and perception as well as conscious and unconscious processes. Sensory information is processed serially with encoding of information mostly on the conscious level (but sometimes, less efficiently, on the unconscious level); and it also is processed in parallel. Parallel processing operates almost entirely at the unconscious level and is basic to perception.

Associative phenomena are explained in terms of overlapping engrams, so that two 'related hypercomplex engrams' could be assumed to have at least one simple engram in common. With Premack, he describes three types of engrams: veridical (primary sensory data perceived), abstract (formalized representations of concepts like line drawings of dog or house; Premack's iconic representations), and symbolic (more complex entities that encompass an entire class of objects, actions, or ideas and may have artificial symbols such as words).

With Neiser he suggests that thinking (verbal and nonverbal) involves logical sequential processing of cognitive engrams of external (environmental), internal (visceral), and intracerebral (ideational) origin. Evoked response investigations shed light on the nature of such engrams, their distribution in brain tissue. John, Bartlett, Slumokochi, & Kleiman (1973) found that an error in choice discrimination learning (cats learning colors) is accompanied by the cortical evoked potential of the stimulus associated with that (erroneous) behavior, not the evoked potential of the true stimulus. In other words, ERPs represented the idea, not the actual visual stimulus provided to the cat.

Emotional/motivational influences are part of every cognition (R. S. Lazarus's position). Interaction of motivational-emotional and cognitive engrams seems to occur primarily in the inferior temporal lobe and the entorhinal cortex. The interaction involves the upper rhinencephalon, the amygdaloid-hippocampal complex, the septal region, the cingulate gyrus, and the inferior and medial aspects of temporal lobe of the cortex. He also explains classical and operant conditioning (on pp. 75-76) in terms of the association of engrams.

The author's position is that consciousness is the subjective equivalent of brain activity in the 'alerting' and 'awareness' systems. Awareness of the environment ('general, vague') appears to involve the limbic area (thalamus and basal ganglia), while more specific awareness of the self entails a system stretching from the basal ganglia through the parietal lobe (posterior aspect).

Normal alert consciousness involves the noradrenergic reticular activating system, as well as associated excitation of the general awareness system in the involved thalamic- basal gangliar nuclei and the self-awareness system in the posterior inferior parietal lobe system. Altered states of consciousness characterized by a relaxed hazy sense of the world involves thalamic activation of the self-awareness system. Dreaming involves activation from cholinergic cells in the pons. "Impaired general awareness occurs with lesions of the thalamic-basal gangliar centers while impaired self-awareness occurs with lesions in the posterior inferior parietal lobes. Finally, in certain physiological states such as sleep, hypnosis, and so on, the entire awareness system--the thalamic-basal gangliar and posterior inferior parietal nuclei--may be activated by different activation systems, such as the cholinergic in the pons or the dopaminergic in the thalamus, to produce different states of consciousness" (p. 82).

Consciousness is described as having seven dimensions: alertness, attention, arousal (heart rate, GSR), activation (EEG, evoked potential), affect, and the two awarenesses. The seven are related, so that changes in any one usually are correlated with changes in others (though dissociation among the seven also can be demonstrated). Motivational-emotional arousal produces electrophysiological activation of the brain, which is translated epiphenomenally into alertness and awareness; awareness is focused through attention onto the cognitively and motivationally significant events in the internal and external environments to determine the final sequence of drive-oriented behavioral responses.

The EEG is useful for diagnosing different states of consciousness: beta and gamma waves alertness, stemming from locus coeruleus and reticular activating system delta (2-4/sec) waves coma alpha synchronized relaxing influences stemming from thalamus; low level of awareness as in twilight sleep or hypnagogic states theta, delta inactivity due to less stimulus from locus coeruleus reticular activating system influences; associated with increased inhibitory thalamic and septal-hippocampal impulses radiating upward to the cortex.

In some altered states of consciousness there is theta-wave activity, indicating influences from the inhibitory septal-hippocampal circuit.

The reticular activating system (RAS) and thalamus interact in complex ways. The RAS is essential to maintain consciousness, but if destroyed stepwise (in animal research) a low-grade type of consciousness can be maintained by thalamus and basal ganglia. The thalamus has two kinds of influence: it inhibits the cortex, as in sleep; and stimulates the cortex in the form of activating alpha waves. "The median thalamus is also related in a feedforward-feedback circuit with the inhibitory septal-hippocampal complex which generates theta-wave activity, thus accounting for the close association between alpha and theta wave activity in sleep and in other altered states of consciousness" (p. 86).

Thus there are two different activating systems originating in the lower brain stem: the norepinephrine locus coeruleus system that is associated with normal behavior, and the cholinergic FTG neurone system of REM sleep. The relationship of the

latter to consciousness, awareness, self awareness, etc. is unknown, since the only time that it is readily observed is during REM sleep. The author reports that altered states of consciousness (e.g. hypnosis, fugue, alpha state) resemble Stage 1 sleep, rather than REM sleep, physiologically, with the central locus of activation in the medial thalamus rather than the RAS and locus coeruleus.

"It appears then that consciousness may be driven by one or another of three different activation centers: the norepinephrine RAS (emanating from the locus coeruleus), the cholinergic FTG cell system in the pons, and the dopaminergic alpha rhythm system radiating upward from the thalamus (Fig. 6-2). Brain activation by each of these centers is associated with a different state of awareness" (p. 91). The relative contribution from each center determines qualitative aspects of awareness.

The author refers to Mesulam and Geschwind (1978) who traced the self-awareness system from amygdala/hippocampus/midbrain to the inferior parietal lobe where they converge with the body's proprioceptive neural tracts. What results is "a sense of self that was not necessarily present in the sense of general awareness stemming from the median thalamic-basal gangliar complex" (p. 97).

The thalamic-basal gangliar complex is both a center for emotional reception and a relay station for somatosensory events. Both somatic sensory reception and somatosensory elements of emotion are also represented in the parietal lobe. "Affective and somatosensory stimuli, which are constant and persistent even though we are unaware of them most of the time, produce the sense of one's body which is the most basic element in the 'sense of self.'... It is most probable that a major component of the sense of self is produced by the constant barrage of affective and somatosensory stimuli converging from all parts of the body; the majority of these stimuli may not reach consciousness most of the time but they must register a sense of feeling in the thalamus and parietal cortex even though the individual may be unconscious of it" (p. 100).

The author presumes that most of the incoming stimuli that define self are unconscious. "Whether sense-of-self stimuli are unconscious because of constant habituation ... or whether they are unconscious because they are transmitted predominantly to the right hemisphere ..., it appears that the major components of the self-concept are unconscious rather than conscious" (p. 102).

"Even the acutely self-aware component of the self-concept, by definition conscious, varies markedly in different altered states of consciousness. The conscious awareness of oneself in the alert condition is different from (1) that in the twilight state, (2) that in dreams, (3) that in hypnosis, (4) that under the influence of alcohol, (5) that under the influence of other sedatives, (6) that under the influence of stimulants, and (7) that under the influence of hallucinogens. In that sense the acute sense of self is a function of the momentary chemical and physiological state of the brain" (p. 102).

"... the decision-making apparatus of the brain is lodged largely in a consortium of neocortical centers including the prefrontal lobes (integration), the posterior inferior lobes (motivation and emotion), the anterior and posterior associational areas (cognition), the posterior inferior parietal lobes (self-awareness), the left-hemispheric language centers (language), and the precentral frontal lobe motor area (motor). Within the context of this integrated cortical complex, self-awareness

functions are somewhat stronger on the right hemisphere while language and decisional activities are somewhat stronger on the left" (pp. 102-103). The Chapter titled "Attention as directed consciousness" is relevant for investigations of hypnosis but is not included in these notes.

1985

Stumpfe, Von Klaus-Dietrich (1985). Psychosomatic reactions of near-death experiences. A state of affective dissociation. Zeitschrift fur Psychosomatische Medizin, 31, 215-225.

The feelings of persons who had encountered life-threatening danger were analyzed and compared with the feelings of persons, who are in hypnosés or trained in autogenic training. The symptoms are widely alike. The result of the comparison is, that there exists a state of affective dissociation, which can be caused by conscious or unconscious actions.

1984

Malott, James M. (1984). Active-alert hypnosis: Replication and extension of previous research. Journal of Abnormal Psychology, 93 (2), 246-249.

#### NOTES

Compared levels of hypnotic responsiveness resulting from 4 induction procedures: (a) verbal active-alert induction alone, (b) bicycle pedaling alone, (c) verbal active-alert induction plus bicycle pedaling and (d) traditional relaxation induction. Ss were 48 undergraduates. Stanford Hypnotic Susceptibility Scale scores indicated that the verbal induction plus pedaling procedure was significantly more effective than either the verbal- or pedaling-alone procedures. There were no significant differences in scores produced by the verbal plus pedaling and traditional relaxation inductions. Findings are consistent with A. M. Ludwig's (1966) proposal that there exists a range of stimulation necessary for the maintenance of normal waking consciousness and that levels of stimulation above or below that range are conducive to the production of altered states of consciousness.

This study adds experimental controls to the research design used by Banyai for active alert induction.

1983

Baars, B. J. (1983). Conscious contents provide the nervous system with coherent, global information. In Davidson, Richard J.; Schwartz, Gary E.; Shapiro, David (Ed.), Consciousness and self regulation (3, ). New York: Plenum Press.

#### NOTES

We are conscious of some content when there exists an internal representation that is global, stable, and informative.

Author views nervous system as a distributed information. processing system, in which highly complex & efficient processing is performed by specialized processors in a relatively independent way. These processors may be 'data driven'--i.e. they

may decide by their own criteria what is worth processing..." p. 41 [See also Gazzaniga's (1985 Psychology Today article) idea that mind/brain consists of modules.]

p.44 gives references substantiating the above, e.g. Geschwind, Hilgard, La Berge, Shiffrin & Schneider.

p. 45 We are in habit of thinking hierarchically about nervous system rather than distributively.

p. 45 "Consciousness seems to be closely associated with a mechanism that permits interaction between specialized, dedicated processors" The 'global' data base' is like a TV station sending out information that can be processed or not by the viewer. It is not an executive, and in fact can sometimes be controlled by the processors. 'Consciousness ...[is] a certain operating mode of this medium, & consciousness can likewise be used by processors acting as executives, without itself being an executive "(p.49).

The global data base is a lingua franca, so that one sense modality can communicate with others. p. 51. [Synesthesia reported by high hypnotizables implicates this system--either the communicating tracks are greased between color and smell, or the name of the destination, in computer language, is lost, or equivalent.]

p. 52 Repression and the dynamic unconscious. explained in terms of controlled access to the global data base, with certain specialized processors given high priority.

Context, taken by itself, is unconscious; & input, taken by itself & in the absence of the appropriate context, is also unconscious. Only when both of these conditions exist- -when there is input that can be organized within a current context--are we conscious of some percept.

Contextual factors become conscious only when they are challenged.

NOTES

1:

NOTES: This third volume of four has 2 sections (7 subsections) with chapters as follows. I. General and Historical Surveys of Hypnotism

1. A brief survey of hypnotism

2. Hypnosis: A general review

3. Hypnotism

4. The basis of hypnosis: Panel discussion on hypnosis II. Psychodynamic Processes: Hypnotic Approaches to the Unconscious Section 1: Amnesia

5. The investigation of a specific amnesia

6. Development of apparent unconsciousness during hypnotic reliving of a traumatic experience

7. Clinical and experimental observations on hypnotic amnesia: Introdution to an unpublished paper

8. The problem of amnesia in waking and hypnotic states

9. Varieties of hypnotic amnesia Section 2: Literalness

10. Literalness: An experimental study

11. Literalness and the use of trance in neurosis Section 3: Age Regression
12. Age regression: Two unpublished fragments of a student's study
13. Past weekday determination in hypnotic and waking states
14. On the possible occurrence of a dream in an eight-month-old infant
15. The successful treatment of a case of acute hysterical depression by a return under hypnosis to a critical phase of childhood Section 4: Automatic Writing and Drawing
16. The experimental demonstration of unconscious mentation by automatic writing
17. The use of automatic drawing in the interpretation and relief of a state of acute obsessional depression
18. The translation of the cryptic automatic writing of one hypnotic subject by another in a trancelike dissociated state Section 5: Mental Mechanisms
19. Experimental demonstrations of the psychopathology of everyday life
20. Demonstration of mental mechanisms by hypnosis
21. Unconscious mental activity in hypnosis--psychoanalytic implications
22. Negation or reversal of legal testimony Section 6: Dual Personality
23. The permanent relief of an obsessional phobia by means of communication with an unsuspected dual personality
24. The clinical discovery of a dual personality
25. Findings on the nature of the personality structures in two different dual personalities by means of projective and psychometric tests Section 7: Experimental Neuroses
26. A clinical note on a word-association test
27. A study of hypnotically induced complexes by means of the luria technique
28. A study of an experimental neurosis hypnotically induced in a case of ejaculatio praecox
29. The method employed to formulate a complex story for the induction of an experimental neurosis in hypnotic subject

Schuman, Marjorie (1980). The psychophysiological model of meditation and altered states of consciousness: A critical review. In Davidson, J. M.; Davidson, R. J. (Ed.), The psychobiology of consciousness (pp. 333-378). New York: Plenum Press.

Psychophysiological changes have been found to occur as correlates of meditation. Major emphasis has been placed on changes in alpha brainwave activity and on changes in alpha blocking response to sensory stimuli. Taken together, these changes in baseline EEG and electrocortical responsiveness to sensory stimulation have been interpreted to be evidence of a unique meditative state of consciousness. The literature on the psychophysiology of meditation, including EEG and autonomic changes, is reviewed with careful attention to different types of meditation practice and various physiological measures of arousal and attentional set. The phenomenology of meditative states and their relationship to trance states is also considered. It is concluded that EEG and autonomic data cannot be used to define states of consciousness; the state of consciousness must be known before the significance of physiological changes can be inferred.

1979

Barmark, Susanne M.; Gaunitz, Samuel C. B. (1979). Transcendental meditation and heterohypnosis as altered states of consciousness. International Journal of Clinical and Experimental Hypnosis, 27 (3), 227-239.

The effects of transcendental meditation and relaxation-heterohypnosis on subjective phenomena and physiological arousal were examined. One group of Ss, who were experienced meditators, participated in meditation, and a second group of Ss, who were highly susceptible to hypnosis but with little hypnotic experience, were exposed to hypnosis. A period of quiet sitting served as control for Ss in each group. Neither heterohypnosis nor transcendental meditation were identified as low-arousal states. They were assumed to be similar phenomenologically altered states of consciousness, mainly characterized by changes in the distribution of attention and in body image.

1979

Barrett, Deirdre (1979). The hypnotic dream: Its relation to nocturnal dreams and waking fantasies. Journal of Abnormal Psychology, 88 (5), 584-591.

A review of the literature in the area of hypnotic dreams suggests that physiological correlates of hypnotic dreams are better established than content characteristics. A study is also reported that examined the content of hypnotic dreams in relation to that of nocturnal dreams and daydreams from the same subjects. Subjects were 16 undergraduates divided into deep-trance and medium-trance groups. Deep trance subjects' hypnotic dreams were similar to their nocturnal dreams and different from daydreams on a wide variety of characteristics including length, emotional themes, characters, setting, and amount of distortion. Medium trance subjects' hypnotic dreams were found to fall between their nocturnal dreams and daydreams on most of these measures.

Bennett, Henry L.; Giannini, Jeffrey A.; Kline, Mark D. (1979, September). Consequences of hearing during general anesthesia. [Paper] Presented at the annual meeting of the American Psychological Association, New York.

A double blind 2X2 study exposed 23 herniorrhaphy and cholecystectomy patients to either a 45 minute suggestion tape or to the actual sounds of the operation. Structured interviews conducted postoperatively assessed hypnotic susceptibility and regressed patients under hypnosis to operative events. Ten patients accurately recalled significant events from surgery but only under hypnosis. Recall was greater and more accurate in patients scoring high on the Stanford Clinical Hypnosis Scale. Fewest number of pain medications were given postoperatively to patients receiving the suggestion tape. Hernia patients showed better recall than gallbladder patients.

**Davidson, R. J.; Goleman, D. J. (1977). The role of attention in meditation and hypnosis: A psychobiological perspective on transformations of consciousness. International Journal of Clinical and Experimental Hypnosis, 25, 291-308.**

**ABSTRACT:** A temporally based scheme for investigation of changes in consciousness, applicable to areas such as meditation and hypnosis, is proposed and is divided into 3 basic epochs: before -- predispositional variables that affect response to consciousness altering techniques; during -- the state effects of the particular technique; and after -- the trait effects of the practice. Research is surveyed which indicates the role of attentional processes during each of these 3 basic epochs in both meditation and hypnosis. Attentional flexibility is a predispositional variable affecting response to both meditation and hypnosis. The state effects of concentrative meditation involve alterations in stimulus set while the state effects of hypnosis may reflect primarily response set. The trait effects elicited by meditation depend critically on the psychobiological systems which are called into play. Evidence is discussed which suggests that concentrative meditation shares with relaxation an autonomic quiescence, but in addition enhances some attentional skills. A mindfulness technique involving the adoption of a particular attentional stance toward all objects of awareness appears to enhance cortical specificity, but a concentration technique does not. Some implications of attentional self-regulation are discussed.

**Fromm, Erika (1977). Altered states of consciousness and hypnosis: A discussion. International Journal of Clinical and Experimental Hypnosis, 25, 325-334.**

The author explains why it is important at this juncture in time to acquaint researchers and clinicians in the field of hypnosis with the current serious research

in altered states of consciousness, and vice versa. In a 1975 SCEH symposium, the author brought together both well-established and young researchers coming from orientations as widely differing as neurophysiology, cognitive theory, and psychoanalytic ego psychology. This discussion summarizes, critically evaluates, and attempts to integrate with each other the findings of meditative researchers, Davidson and Goleman, and Daniel Brown; the altered states of consciousness model-maker Roland Fischer; the hypnotherapist, Sacerdote; and the generalist in altered states of consciousness and hypnosis, Krippner. A short summary of the author's own new ego-psychological theory of hypnosis and 12 other altered states of consciousness is also presented.

Fromm, Erika (1977). An ego-psychological theory of altered states of consciousness. International Journal of Clinical and Experimental Hypnosis, 25, 372-387.

In this paper a new ego-psychological theory is proposed for the understanding of altered states of consciousness. The dichotomies of primary and secondary process, ego activity and ego receptivity, and automatization and de-automatization of ego functions in daydreaming, in the inspirational phase of creativity, in hypnosis, in psychedelic states, and in meditation are discussed; so are the roles of fantasy, imagery, and various forms of attention.

#### NOTES

The author provides a table titled "Typology of Waking State and Several Altered States of Consciousness by Attention Mode." The states listed in the table are: Waking, normally alert, and concentrated; Waking, fascinated, entranced; Free association; Daydreaming; Dreaming; Psychedelic drugs; Hypnosis; Self-hypnosis; Biofeedback; Transcendental meditation; Concentrative meditation; Satipatthana [mindfulness of body, feelings, mind, and mental events]; Classical vipasyana [Clear intuitive insight into physical and mental phenomena as they arise and disappear, seeing them for what they actually are]. She summarizes, "In general, the present author strongly feels that the advantage of hypnotherapy over therapy in the waking state is that hypnosis allows the therapist to help patients work with more primary process thinking, more fantasy, more imagery, more ego receptivity than they would employ in the waking state" (p. 385). "What helps the therapy is not the depth itself; it is that in the hypnotic state there is greater mobility, a greater ability to dip into the unconscious and to bring the unconscious material back into the waking state of consciousness" (p. 385).

1975

Spear, J. E. (1975). The utilization of non-drug induced altered states of consciousness in borderline recidivists. American Journal of Clinical Hypnosis, 18, 111-126.

Utilizing non-drug induced altered states of consciousness, various modes of interior reflection, behavior modification and reprogramming of conscious attitudes and

values were utilized with 49 borderline recidivists. Such offenders were so determined by the Department of Corrections, Probation and Parole Office, District II. No coercion was used to induce such individuals to enter the program and there was no reprisal for stopping therapy at any time. Over a two and one-half year period the recidivist rate among this group was less than 5%. It is suggested that non-drug induced altered states of consciousness combined with indirect as well as symbolic techniques may prove to be the most effective means of criminal rehabilitation.

#### NOTES

Borderline recidivists were "individuals, who, in the opinion of the P.O. [probation officer] were, in all probability, to be returned to prison within a few months, or less, if there wasn't a major change in attitude and actions" (p. 111). Therapy employed closed circuit TV with bi-directional audio and induction of altered state of consciousness using an ophthalmology-type rotary prism. Therapy involved (s) recall of relaxed state when under stress, (2) exploration of early conditioning events, (3) self evaluation during the ASC, (4) use of symbolic mental exercises and mental practice for similar circumstances in normal waking state, (5) suggestions for setting goals and ideals, (7) a type of logotherapy, (7) 'nudging' the person to examine their relationship with their concept of God. The author noted in the parolees: (1) low levels of self esteem, (2) depression, (3) going into deep levels of altered states once trust was established with the therapist.

1974

Galin, David (1974). Implications for psychiatry of left and right cerebral specialization: A neurophysiological context for unconscious processes. Archives of General Psychiatry, 31 (4), 572-583

A brief review is presented of hemispheric specialization for different cognitive modes, and of the symptoms that follow disconnection of the two hemispheres by commissurotomy. Our present knowledge of the hemispheres' cognitive specialization and potential for independent functioning provides a framework for thinking about the interaction of cognitive structures, defensive maneuvers, and variations in awareness. Parallels are noted between some aspects of the mental processes of the disconnected right hemisphere and some aspects of primary process thinking and repression. The hypothesis is proposed that in normal intact people mental events in the right hemisphere can become disconnected functionally from the left hemisphere (by inhibition of neuronal transmission across the cerebral commissures), and can continue a life of their own. This hypothesis suggests a neurophysiological mechanisms for at least some instances of repression and an anatomical locus for the unconscious mental contents.

1971

Kihlstrom, J. F.; Edmonston, W. E., Jr. (1971). Alterations in consciousness in neutral hypnosis: Distortions in semantic space. American Journal of Clinical Hypnosis, 13, 243-248.

30 highly hypnotizable Ss were equally divided into three groups, equated for age, sex and hypnotic susceptibility. A semantic differential scale was administered to each S in waking, individual sessions. An oral form of the same scale was administered during: (a) hypnosis (E), (b) waking -- post hypnosis (C1), and (c) waking -- no hypnosis (C2). All groups showed significant change between administrations of the scale; E showed more change than C1, and the latter more than C2. Ratings of "My Self" changed toward the negative pole in the evaluative factor. Results were interpreted as indicating a distortion in semantic space and an alteration in ego-state occurring spontaneously with hypnosis.

Fromm, Erika; Oberlander, Mark I.; Gruenewald, Doris (1970). Perceptual and cognitive processes in different states of consciousness: The waking state and hypnosis. Journal of Projective Techniques and Personality Assessment, 34, 375-387.

Hypnosis was assumed to influence perceptual and cognitive functioning in the direction of increased primary process ideation and adaptive regression. The Rorschach test was administered to 32 Ss in the waking state and under hypnosis in counterbalanced order. Hypnosis was induced by a standardized procedure. Ss received identical instructions for the Rorschach in both conditions. Protocols were scored according to Holt's system for manifestations and control of primary process. Hypnotic Rorschachs showed an increase in primary process manifestations, but no changes in defensive and coping functioning, and no overall changes in the Adaptive Regression Score. However, the nature of the data was found to be influenced by Ss' sex and level of adjustment.

The authors used High hypnotizables (SHSS>9) in this investigation.

1963

King, C. D. (1963). The states of human consciousness. New York, NY: University Books. (Reviewed in *American Journal of Clinical Hypnosis* 7, 1964, 96.)

#### NOTES

From the book review by Stanley Abrams, *AJCH*: [The book] "is more philosophical and mystical than scientific. ... [and describes] the four states of consciousness: sleep, waking, awakensness, and objective consciousness. ... For man to attain completeness and normalcy he must achieve the state of awakensness. According to the author, however, only a relatively few have approached this stage of consciousness and his description of it is quite vague. When one has reached awakensness he is able to understand and actually perceive the world in a novel and unique manner. ... The final stage of awareness, objective consciousness, is characterized as the experiencing of cosmic phenomena in the same fashion as external reality is understood in the awakened state. The author indicated that this

stage has not as yet been attained by man, but it does lie within his potential. ... The only treatment of hypnosis is the author's statement that the waking state is the same as the hypnotic state because suggestibility exists in both" (p. 96).

## CONTEXT

1998

Page, Roger A. (1998). Mental imagery, hypnotizability, differential item difficulty, and context effects. American Journal of Clinical Hypnosis, 41 (2), 162-167

This study attempted to determine the relationship of mental imagery to general hypnotizability and differential difficulty of susceptibility scale items, as well as the effect of context on these relationships. Undergraduates completed a mental imagery questionnaire in or out of a hypnotic context prior to being administered a group susceptibility scale. Most predicted correlations between sensory modalities on the imagery questionnaire scale item performance were small and nonsignificant. The relationship of imagery to hypnotizability was significant for an out-of-context condition, but not for an in-context condition. Reasons for the largely negative results are discussed.

1997

Council, James R. (1997). Context and consistency: The Canadian connection. International Journal of Clinical and Experimental Hypnosis, 45 (3), 204-211.

Issues related to context effects in hypnosis research are briefly reviewed. The contributions of Canadian hypnosis researchers to current theory and research on context effects are acknowledged. Bowers and colleagues at the University of Waterloo emphasized the scope and subtlety of contextual influences on correlates of hypnotic suggestibility, and they promoted the development of a consistency motivation theory of context effects. Spanos and colleagues at Carleton University generalized context effects within the domain of hypnosis, prompting extension of this work to general personality measurement. Implications of findings on consistency motivation for hypnosis research are discussed in terms of person-by-situation interactions. -- Journal Abstract

Ready, David J.; Bothwell, Robert K.; Brigham, John C. (1997). The effects of hypnosis, context reinstatement, and anxiety on eyewitness memory. International Journal of Clinical and Experimental Hypnosis, 45 (1), 55-68.

The effects of hypnosis, context reinstatement, and motivational instructions on accuracy of recall for factual information and facial recognition accuracy following a stressful event were assessed. None of the three techniques had a significant effect on factual memory or susceptibility to suggestion as assessed by true-false and multiple-choice tests. However, participants high in hypnotic susceptibility showed somewhat better memory on the true-false test, and hypnosis affected performance on the two photograph line-ups. In addition, hypnosis appeared to enhance facial

recognition accuracy for participants who were low in anxiety, but not for those high in anxiety. Finally, there was evidence of a curvilinear relationship between self-reported anxiety at time of retrieval and facial recognition accuracy. -- Journal Abstract

Aronoff, J.; Green, J. P.; Malinoski, P.; Zelikovsky, N.; Lynn, S. J. (1994, October). Hypnosis and autobiographical memories: The impact of contextual factors. [Paper] Presented at the annual meeting of the Society for Clinical and Experimental Hypnosis, San Francisco.

#### NOTES

We examined the individual differences in recall for early memories, in a college population, using the Autobiographical Memory Scale (AMS) along with other scales and with a hypnotizability scale (measured in same and different contexts). 75 male and 171 females subjects participated.

Presented as two separate experiments, so Ss would not make an explicit link between autobiographical memories and things measured in the second study.

Exper 1. Administered AMS which indicates we are interested in their memories of events, and not what they were later told about the events. First 5 birthdays, first day of school, etc. Rate the detail, vividness, and accuracy.

Exper 2. Administered Fantasy Proneness (Wilson & Barber), Cognition, Imagery Control Scale, Derogatis, SAC (Brier's symptoms of child abuse), and Dissociative Experiences Scale.

Final sample of 247 Ss.

Earliest memory was 3.8 years.

Ss ratings of details, vividness, and accuracy were highly correlated. These were negatively correlated with age of first memory.

#### 1994

Spanos, Nicholas P. (1994). Multiple identity enactments and multiple personality disorder: A sociocognitive perspective. Psychological Bulletin, 116, 143-165.

People who enact multiple identities behave as if they possess 2 or more selves, each with its own characteristic moods, memories, and behavioral repertoire. Under different names, this phenomenon occurs in many cultures; in North American culture, it is frequently labeled multiple personality disorder (MPD). This article reviews experimental, cross-cultural, historical, and clinical findings concerning multiplicity and examines the implications of these findings for an understanding of MPD. Multiplicity is viewed from a sociocognitive perspective, and it is concluded that MPD, like other forms of multiplicity, is socially constructed. It is context bounded, goal-directed, social behavior geared to the expectations of significant others, and its characteristics have changed over time to meet changing

#### 1993

Council, James R.; Grant, Debora L. (1993, October). Context effects: They're not just for hypnosis anymore. [Paper] Presented at the annual meeting of the Society for Clinical and Experimental Hypnosis, Arlington Heights, IL.

#### NOTES

Context effects in Absorption research are found in correlations, not in mean differences. Original paper has been replicated and yet results are not always significant. Now we are trying to generalize the effect to other areas: an individually administered measure will influence other measures made in the same session.

Other tests that correlate with hypnosis are studied with 2 x 2 design, enabling order effects and same vs separate contexts to be studied. Or two tests are administered at two points in time, with "bridges" between the two sessions (e.g. same experimenter, same consent forms, etc.) As one adds more and more bridging cues, the correlation of Absorption with other Tellegen MPQ subscales increases.

Same context assessment increases correlation between hypnotizability and 6-8 other scales; with childhood trauma scale when trauma scale is administered first; with beliefs in paranormal phenomena when the measure is related to an adjustment scale. The same inflation of correlations was found in Beck Depression scale research.

These results are of concern because we may have to re-do a lot of personality research that suggested correlation between personality test variables, as the correlations may be inflated by the effects of testing in the same context.

Frischholz, Edward J. (1993, October). The many roles of context in clinical and experimental hypnosis. [Paper] Presented at the annual meeting of the Society for Clinical and Experimental Hypnosis, Arlington Heights, IL.

#### NOTES

There are two potential sources of dissociation: 1. Person Effect - genetic factors, personality types 2. Situation Effect - situations like environmental causes, contextually dependent

Person Effects and Hypnotizability. Morgan (1973 Journal of Abnormal Psychology) Intraclass correlation determines heritability index: 62% of score is accounted for by genetic factors (though the twins were not reared apart, so family influences also were present). Piccione's research demonstrated long-term stability for hypnotizability scores; 25 years' test-retest  $r = .71$ ,  $N = 50$

Situational Effects and Hypnotizability. Norman Katz (1979) varied context before giving the Stanford Form C for a second time (sleep/trance induction, social learning induction, social learning relaxation induction). The latter two inductions showed significant gains of 3.33 and 2.87 on the scale, compared to .80.

Context effects must always be placed in perspective. When reanalyzing Katz with ANOVA, according to the recommendation of Cronbach for change score analysis, situation accounts for 17% of effect while person effect accounts for 49% (See Spiegel & Frischholz, 1992.)

Sivec, Harry; Lynn, Steven Jay (1993, October). Negative posthypnotic effects: The influence of prehypnotic experiences. [Paper] Presented at the annual meeting of the Society for Clinical and Experimental Hypnosis, Arlington Heights, IL.

NOTES

1:

NOTES: Ss and Experimenters may mis-attribute negative experiential effects to hypnosis because of temporal contiguity. This study required Ss to complete the experiences scale before and after hypnosis and before and after a non-hypnotic control procedure. The PES is a 65 item scale and has a stable factor structure assessing pleasant, perceptual/kinesthetic, anger, and anxiety experiences.

49 Ss completed the test before and after the Harvard Group Scale, minus the word "hypnosis" in the induction, though it was presented as a study of hypnosis; 33 had the study presented as study of body awareness, and were to focus on body parts corresponding to the parts mentioned on the Harvard.

RESULTS. Ss in both groups reported more perceptual/kinesthetic effects after than before the experience. Research failed to find hypnosis was associated with unique effects that were negative. The single increase might be due to focusing on the body. The only difference between groups was that hypnosis Ss reported fewer anger experiences than those in the other group.

This data disconfirms the belief that hypnosis is associated with negative effects.

Spinhoven, Philip; Vanderlinden, Johan; ter-Kuile, Moniek M.; Linseen, A. Corry G. (1993). Assessment of hypnotic processes and responsiveness in a clinical context. International Journal of Clinical and Experimental Hypnosis, 41 (3), 210-224.

The present study was designed to investigate in a clinical situation whether differences in measured hypnotizability validly reflect differences in hypnotic processes and to what extent factors deemed extraneous to hypnosis -- such as resistance -- influence hypnotic responding. To answer this question, Dutch versions of relevant scales had to first be developed. The factorial validity and reliability of a Dutch translation of the Resistance Toward Hypnosis Scale (DRHS) and a shortened Dutch version of the Phenomenology of Consciousness Inventory (DPCI) were investigated in a sample of 205 psychiatric patients. The DRHS proved to be factorially valid and reliable, and two subscales, Trance and Reality Orientation, derived empirically from the DPCI showed good to satisfactory reliability. In a second study with a subsample of 99 psychiatric patients, hypnotizability as measured by the Stanford Hypnotic Clinical Scale for Adults was strongly and positively related to DPCI Trance scores and moderately and negatively related to DPCI Reality Orientation and DRHS Resistance scores. It is concluded that hypnotizability as measured in a clinical context under standard conditions is strongly related to hypnotic experiences over and above the moderate effects of resistance toward hypnosis and hypnotic suggestions. Standard hypnotizability assessments appear to be similar in their meaning in an experimental and clinical context.

Zivney, Olivia; Lynn, Steven Jay; Zelikovsky, Nataliya; Sivec, Harry; Marsden, Kim; Stewart, Kay; Valdez, Gail (1993, October). Hypnotizability modification

**training: Gains are not mediated by context.** [Paper] Presented at the annual meeting of the Society for Clinical and Experimental Hypnosis, Arlington Heights, IL.

#### NOTES

Spanos' program to enhance hypnotizability was examined by Bates et al to determine whether improvement was due to context. They had a problem because they required Ss to sign up for five sessions, and their attempt to do a retest independently of the training sessions was therefore challenged. Also, Bates admitted that the rapport characteristic of Spanos' lab was not present.

This research replicated Bates, with improvement in the research design. The sessions were separated by having the hypnosis done in the medical school. None of the low demand group realized that they were being trained for improving hypnosis. 50% of the low demand group and same of the replication group scored as Highs on retest.

This failed to support Bates' contention that demands for compliance mediate training gains. Magnitude of gains was the same as reported earlier in the Carlton (Spanos lab) research. Trained Ss could not be distinguished from natural highs. Training related gains are not only robust but are generalizable to novel tasks. Trained Ss have a more internal locus of attribution, consistent with the educational approach.

Clinicians need to investigate this in a variety of clinical situations.

#### 1992

Kirsch, Irving (1992, August). **Cognitive-behavioral hypnotherapy.** [Paper] Presented at the annual meeting of the American Psychological Association, Washington, DC.

The use of hypnosis to augment cognitive behavior therapy was described. Hypnotic inductions establish a context in which the effects of therapeutic interventions can be potentiated for clients with positive attitudes and expectancies toward it. Hypnosis can also provide a disinhibiting context for both clients and therapists, allowing them to behave in ways that are therapeutic, but that might seem awkward in other contexts. A meta-analysis of outcome studies in which the effects of a cognitive-behavioral treatment were compared to the effects of the same treatments supplemented by hypnosis resulted in a mean effect size of 0.87 standard deviations, indicating the average client receiving cognitive-behavioral hypnotherapy is better off at the end of it than more than 80 percent of clients who receive the same treatment in a nonhypnotic context. (ABSTRACT from the Bulletin of Division 30, Psychological Hypnosis, Fall, 1992, Vol. 1, No. 3.)

Kvaal, Steven; Lynn, Steven Jay; Myers, Brian (1992, October). **The Gulf war: Effects on hypnotizability.** [Paper] Presented at the annual meeting of the Society for Clinical and Experimental Hypnosis, Arlington, VA.

#### NOTES

We did a study that follows the line that volunteers may differ from nonvolunteers for hypnosis experiments (Authors cite 3 studies, including one with Hilgard as later author; Brodsky; Zamansky). Also, Ss who volunteer early in the quarter at the university are motivated for hypnosis; later volunteers want course credit. The former want to experience hypnosis.

Previously we did a study on authoritative vs permissive suggestions with Ss who volunteered early or late in the quarter; Ss were tested twice. For Ss who volunteered in first 2 weeks of the quarter, scores decreased across testing; for Ss volunteering late, scores remained stable across testing. This implies that if an experiment were conducted late in a quarter we would conclude that repeated testing has no effect; if done earlier, we would have concluded repeated testing decreases scores.

This result has been replicated. It is therefore important to run Ss across an entire quarter or year.

The present study differs from the foregoing study. It addresses the question: Do life events affect scores on the Harvard Scale? Do tension, uncertainty, etc. affect scores? Would they depress scores? Are scores reactive to environmental events?

On January 14 the U.S. issued an ultimative to Iraq; that very day we administered a tape recorded version of the Harvard Scale of Hypnotic Susceptibility, preceded by the Tellegen Absorption Scale. The hypnotizability tests were self-scored for involvement and involuntariness. Tension throughout the day escalated, culminating with bombing 2 hours before the hypnosis screening. The graduate student announced war had started and told Ss they could leave if they wanted. All 52 Ss stayed!

Control group was 58 Ss tested at same time of the quarter, one year before (10 days into the quarter).

Analysis was by a 3 x 2 ANOVA. There was no main effect for time of testing, sex, or interaction for any measures on hypnotizability, or subjective involvement.

The Tellegen Absorption scale showed a significant timing x sex interaction: males on outbreak of war scored lower than all other groups (15 vs 21 or more for all other groups). Tensions had no effect on subjective or objective scores of hypnotizability. Thus the males were affected on the Absorption Scale by outbreak of war.

The fact the Tellegen Scale was more reactive suggests hypnotizability may be more stable than Absorption. Absorption might have been depressed because males were more upset by images of military services.

Little research has been conducted to examine the possible positive effects on hypnotizability of positive events in real life.

Lyons, Larry C. (1992, October). Absorption and hypnotizability: Meta-analysis of studies to determine if contextual effects are important. [Paper] Presented at the annual meeting of the Society for Clinical and Experimental Hypnosis, Arlington, VA

NOTES

Correlations between hypnotizability and Absorption range from .20 to .40; Council et al. suggest the correlation between these variables is a context effect (expectancy). In our review there was no statistically significant difference between correlations that were found in and out of context (.26 and .23, weighted means) in more than 40 studies with more than one correlation per study.

When Absorption was measured before hypnosis experience the  $r = .25$ ; after the hypnosis experience,  $r = .32$  (significantly different), which also was different from what context hypothesis would predict. Any context difference may be a function of length of time between the Absorption and hypnosis sessions.

Data does not support the context hypothesis. Measuring Absorption after hypnosis resulted in higher mean correlations with susceptibility. However, the magnitude of this relationship was small. Variation due to test reliability and small sample size are likely explanations of the differences in the magnitude of the correlations across studies. We also must consider scale reliability and sample error (samples less than 1000 have departures from the population correlation that are fairly large).

#### CONCLUSION

We should construct confidence intervals around observed correlations and look at the overlap; don't look only at the significance of the difference between correlations.

Author is in the process of conducting a mail survey to obtain unpublished results on context effect.

Nadon, Robert; Dywan, Jane; Adams, Barbara (1992, October). The social psychology of depth reports: Skirting the important data. [Paper] Presented at the annual meeting of the Society for Clinical and Experimental Hypnosis, Arlington, VA.

#### NOTES

Radke & Spanos used a new 7-point scale that permitted Ss to say they passed an item but were not hypnotized, and only 25% (instead of 88% on usual 4-point scale) said that they were hypnotized.

Do we delude ourselves in thinking reports of hypnotic depth just reflect scale wording, or is something genuine being measured? Radke & Spanos found that breaking down Ss into low, medium, and high hypnotizable groups, the mediums are the ones who are affected by scale manipulations.

Spanos, Nicholas P.; Simulates, Ann; de Faye, Barbara; Mondoux, Thomas J.; Gabora, Natalie J. (1992-93). A comparison of hypnotic and nonhypnotic treatments for smoking. Imagination, Cognition and Personality, 12, 23-43.

Three experiments administered variants of Spiegel's (1970) smoking cessation procedure to smokers in hypnotic and nonhypnotic treatments. Follow-up periods were from twelve to twenty-four weeks depending on the experiment. Complete abstinence was an infrequent outcome in all three experiments. Greater-than-control reductions in smoking for treated subjects were obtained in two of the experiments but, in both cases treatment and control subjects failed to differ significantly before the end of the follow-up period. Hypnotic and nonhypnotic treatments produced equivalent smoking reductions in all studies, and neither hypnotizability nor questionnaire assessments of motivation to quit correlated significantly with treatment outcome. Implications are discussed.

## NOTES

When the experimenters compared number of treatments they simply compared two sessions of Spiegel's one-session treatment with four sessions of it. The authors make the point that perhaps they should vary the four sessions.

"In all three of the present experiments the abstinence rates associated with the Spiegel treatment were very low. Our abstinence rates were similar to those reported in one earlier study [4 - Perry et al.], but substantially lower than those reported in three other studies [2, 22, 25]. The reasons for these discrepancies between studies remains unclear, but experiment 3 suggests that these discrepancies cannot be accounted for simply in terms of whether the subjects were drawn from a university or nonuniversity population, and experiment 2 suggests that the discrepancies are unrelated to the number of treatment sessions administered to subjects.

"The finding that hypnotic and nonhypnotic subjects in all three experiments attained equivalent reductions in smoking is consistent with other comparison studies in this area which indicate that hypnotic treatments are no more effective than various nonhypnotic procedures at inducing reductions in smoking [22, 25, 30]. More generally, these findings are consistent with comparison studies on a wide variety of clinical disorders (headache pain, warts, phobias, obesity) which indicate that hypnotic treatments are no more effective than nonhypnotic ones at producing therapeutic change (see [3] for a review).

"The failure to find significant correlations between smoking reduction and hypnotizability among treated subjects is also consistent with the findings of most studies in this area [3], but the reasons why significant correlations between these variables are found in some studies and not others remains unclear. Spanos [3] suggested that significant correlations between these variables are particularly likely when hypnotizability testing is integrated into the treatment protocol. Under these circumstances subjects are likely to form strong expectations about treatment success on the basis of their self-observed responses to the hypnotizability scale. Such expectations may, in turn, influence subjects' motivations to comply with the treatment regimen, the self-statements they make concerning their likelihood of quitting, etc. In all of the present experiments hypnotizability was assessed at the end of the follow-up period and, therefore, could not influence subjects' expectations of treatment success" (pp. 40-41).

Spinhoven, Philip; van Wijk, Jorrit (1992). Hypnotic age regression in an experimental and clinical context. American Journal of Clinical Hypnosis, 35, 40-46.

Investigated role of a clinical context in the experience of hypnotic age regression. 25 patients experienced hypnotic age regression in an experimental and clinical context in counterbalanced order. Patients obtained significantly lower scores for experimental age regression than for clinical age regression, in particular when the experimental assessment preceded the clinical assessment of age regression. Moreover, scores for clinical and experimental age regression were only significantly and positively correlated when the clinical assessment of age regression

preceded the experience assessment. These findings give a tentative indication that more patients are able to experience clinical age regression than can be predicted from their responses to an experimental suggestion for hypnotic age regression where almost no opportunities for patient contact or maximizing of hypnotic responsiveness are provided.

1991

Campbell, Laura; St. Jean, Richard (1991, August). Attentional processing and hypnotic time estimation. [Paper] Presented at the annual meeting of the American Psychological Association, San Francisco.

The tendency of subjects to substantially underestimate the duration of the hypnotic period is, by now, well-documented (St. Jean, 1989). Recent attempts to account for this phenomenon have focused on the attentional processing requirements of the hypnotic role and hypnotic task. St. Jean, McInnis, and Swainson (1990) presented a "busy-beaver" hypothesis which views the hypnotic subject as so occupied with the demands of task and role that little attention may be spared for the processing of unrelated stimuli. Consequently, when stimuli such as contextual changes, or other cues denoting the passage of time, are unattended the result is a reduction in subjective duration. St. Jean et al. (1990) reported a study in which the attentional demands of a listening task, presented in a hypnotic context, were varied by placing additional processing demands, in the form of a complex problem-solving task, on some subjects, but not on others. Subjects in the attentionally-demanding condition underestimated the duration of the listening period to a far greater degree than their passive listening counterparts. Estimates were not related to hypnotic susceptibility. St. Jean et al. (1990) did not employ a waking comparison condition. Such a comparison is important in determining whether the hypnotic role, or context, apart from the processing demands they usually impose, contribute to the underestimation effect. The present study provides such a comparison by presenting the same attentional manipulation in both a waking and a hypnotic context. The findings of the previous study were strongly corroborated; subjects in the attentional condition gave significantly shorter duration estimates than those who passively listened. The nature of the context, hypnotic or waking, did not, however, influence the magnitude of time estimates. These results, together with similar findings in the time-perception literature, appear to lend considerable support to the "busy-beaver" hypothesis. (ABSTRACT from Bulletin of Division 30, Psychological Hypnosis, Provided by former Editor, James Council.)

Nadon, R.; Hoyt, I. P.; Register, P. A.; Kihlstrom, J. F. (1991). Absorption and hypnotizability: Contextual effects re-examined. Journal of Personality and Social Psychology, 60, 144-153.

Two independent studies failed to find evidence consistent with Council, Kirsch, and Hafner (1986), who argued that the repeatedly observed correlations between Tellegen's (1981) Absorption Scale (TAS) and hypnosis measures were artifacts of testing context, and de Groot, Gwynn, and Spanos (1988), who claimed evidence for

a Gender x Context moderator effect. In the present studies, subjects completed the TAS and other personality questionnaires during an independent survey and later immediately prior to an assessment of hypnotizability. In Experiment 1 (N - 475), the effect of context on the relation between questionnaire scores and hypnotizability was weak and variable; in Experience 2 (N - 434), these weak effects were reversed. The results reaffirmed the construct validity of absorption as both a major dimension of personality and as a predictor of hypnotic responsiveness.

Sheehan, Peter W. (1991). Hypnosis, context, and commitment. In Lynn, S. J.; Rhue, J. W. (Ed.), Theories of hypnosis: Current models and perspectives (pp. 520-541). New York: Guilford Press.

#### NOTES

There are several different ways to classify the model that is expounded in this chapter. One may view it ... as an individual-differences model of hypnosis, because it emphasizes the significance of intragroup differences in the pattern of hypnotic performance. Alternatively, one may view it as a phenomenologically based model.... Invariably, however, single categories fail to do justice to the nature of theories, and hence it is perhaps wisest to view this theory as a means of exploring particular hypotheses about hypnotic phenomena that focus primarily on the meaning of suggestion as perceived by susceptible subjects. This model focuses, in a way that most other theories do not, on the motivational implications of the cognitive involvement of the susceptible subject in the events of the hypnotic setting. It offers a variant of contextual theories of psychological functioning, but is experiential in its emphasis rather than simply behavioral" (p. 537).

Sheehan, Peter W.; Statham, Dixie; Jamieson, Graham A. (1991). Pseudomemory effects over time in the hypnotic setting. Journal of Abnormal Psychology, 100 (1), 39-44.

Highly (n=36), moderately (n=26), and low (n=48) susceptible Ss were administered either hypnosis or waking instruction to examine the hypothesis that pseudomemory will occur for hypnotic Ss as long as 2 weeks after suggestions are given for accepting false events. Accuracy and confidence of memory were measured for all ss, and memory was examined for free recall, structured recall, and recognition. Results indicated persistence of pseudomemory for the 2-wk period for both highly and moderately susceptible ss. Data highlighted the multifaceted operation of skill, contextual, and state instruction factors, and a hypothesis that ambiguity of communication when suggestion is delivered plays a part in the maintenance of pseudomemory over time is offered for further testing.

Drake, Stephen D.; Nash, Michael R.; Cawood, Glenn N. (1990-91). Imaginative involvement and hypnotic susceptibility: A re-examination of the relationship. Imagination, Cognition and Personality, 10, 141-155.

Several researchers have reported that significant correlations between hypnotic susceptibility and absorption result from the reactive effects of administering scales immediately before measurement of hypnotizability. The present study was conducted to determine whether interview measures of imaginative involvement are similarly reactive. Three groups of 48, 43, and 43 Ss each were first administered 3 scales of absorption/imaginativeness. This was followed by administration of a hypnotizability scale. Ss in Group 1 who were administered the 3 scales immediately prior to hypnosis evidenced the usual significant positive correlation between each of the 3 scales and hypnotizability. Ss in Groups 2 and 3 were administered the 3 scales 24 to 36 hours prior to hypnosis. Group 2 Ss were informed that administration of these scales was part of a hypnosis experiment. Group 3 Ss were not aware that the scales were part of a hypnosis experiment. No significant correlation between hypnotizability and the 3 measures of imagination/absorption was evidenced for either Group 2 or Group 3. Our findings suggest that any relationship between these two constructs may be quite dependent on how and when the measures are administered.

1989

Malott, James M.; Bourg, Audrey L.; Crawford, Helen J. (1989). The effects of hypnosis upon cognitive responses to persuasive communication. International Journal of Clinical and Experimental Hypnosis, 37, 31-40.

Several writers have suggested that hypnotic responsiveness is directly related to the content of S's covert self-statements. To test this notion, low and high hypnotizable subjects in either hypnosis or waking conditions were exposed to a recorded message advocating that college seniors be required to pass a comprehensive exam in order to graduate. Following message presentation, subjects listed all of the thoughts which occurred to them while listening to the message; these thoughts were later coded as counterarguments, favorable thoughts, or neutral thoughts. Hypnotized subjects generated significantly fewer counterarguments and agreed more with the message than waking subjects. In addition, high hypnotizable subjects (in both waking and hypnosis conditions) produced significantly more favorable thoughts and agreed more with the message than low hypnotizability subjects. Results, therefore, provided a demonstration of the differential impact of context (induction) and trait (hypnotizability level) upon different cognitive phenomena. Implications for the occurrence of hypersuggestible behavior are discussed.

NOTES:

N = 48 (24 highs, 24 lows, blocked on sex and hypnotizability level, then randomly assigned to one of two conditions).

Hypnosis subjects generated significantly fewer counterarguments than waking subjects (12% vs 45%). Main effect for hypnotizability level was nonsignificant, as was the condition x hypnotizability interaction.

High hypnotizable subjects generated significantly more favorable thoughts than low hypnotizable subjects (28% vs 12%). The main effect for condition was nonsignificant, as was the condition x hypnotizability interaction.

Unexpectedly, hypnosis subjects produced a significantly greater number of neutral thoughts. The main effect for hypnotizability level did not reach significance, nor did the condition x hypnotizability interaction.

"Thus, as suggested by McConkey (1984), it may be the hypnotic context, rather than a hypnotic "state" which is responsible for reduced levels of counterarguing. ... the data indicate that an induction decreases counterarguing among high and low hypnotizable subjects alike; on the other hand, the incidence of favorable thoughts is related only to hypnotizability level and not to the hypnosis context. ... the present findings suggest that both context and trait play a role in the occurrence of hypnotic behavior, although each may do so by impacting upon different cognitive responses.

There appears to be a relationship between counterarguing and acceptance of the persuasive communication in the present study. First, there was a significant negative correlation between those two measures (collapsing across conditions), indicating that higher levels of counterarguing were associated with lower levels of communication acceptance. Second, subjects in the hypnosis condition who counterargued less than waking subjects, also indicated significantly higher levels of communication acceptance than waking subjects.

In a similar fashion, there appears to be a relationship between favorable thought production and communication acceptance. There was a significant positive correlation between the two measures, and high hypnotizable subjects who generated significantly more favorable thoughts than low hypnotizables, also produced higher scores on the attitude measure.

They attribute the greater number of neutral thoughts for hypnosis subjects to minor differences in the instructions (p. 38).

1989

Nash, Michael R.; Spinler, Dwayne (1989). Hypnosis and transference: A measure of archaic involvement. International Journal of Clinical and Experimental Hypnosis, 37, 129-144.

20 Likert-type items were derived directly from Shor's theoretical propositions concerning the occurrence of transference-like experiences among hypnotic Ss. In 3 separate experiments, this 20-item Archaic Involvement Measure (AIM) was administered to 452 Ss following termination of both group and individually administered hypnosis procedures. Results suggest that: (a) AIM is internally consistent, and is significantly correlated with hypnotizability; (b) among high hypnotizable Ss, AIM scores assess an important aspect of hypnotic experience which is relatively unrelated to behavioral response to hypnotic suggestions; (c) there is no change in AIM scores associated with the sex of the hypnotist or S; and (d) there are 3 clusters of AIM items; perceived power of the hypnotist, positive emotional bond to the hypnotist, and fear of negative appraisal. Possible validation and clinical research applications of AIM are presented, along with a plea for further empirical examination of the relational dimensions of hypnosis.

## NOTES

Relates these findings to 'countering' (Sheehan, P., *Countering preconceptions about hypnosis: An objective index of involvement with the hypnotist. Journal of Abnormal Psychology*, 1971, 78, 299-322). "Countering is the tendency of some highly hypnotizable Subjects to comply with the intent of the hypnotist, even when there are strong nonhypnotic influences (e.g., social influences, expectations derived from previous lectures, perceptual constraints) to perform otherwise. ... Sheehan and Dolby (1979) found that hypnotic Subjects' dreams about the hypnotist were different than nonhypnotic Subjects' dreams, by being more positive and more often containing themes of protection, care, and authority. Interestingly, these themes were especially evident in the dreams of hypnotic Subjects who countered" (p. 130). The several experiments in this study investigate reliability, concurrent validity, and factor structure of the AIM. In their discussion, Nash and Spinler make the following points. As is the case with hypnotizability, AIM scores may have a bimodal distribution, at least when administered in the same context as a hypnosis measure. It is possible that these two modes define qualitatively different kinds of involvement with the hypnotist. "For high hypnotizable Ss, behavioral response to hypnotic suggestions appeared unrelated to the extent of archaic involvement with the hypnotist across both Experiments 2 and 3. Considering only the overall correlation between AIM and hypnotic responsiveness, one might argue that both scales measure general behavioral compliance and conformity, and that this explains their degree of association. It may indeed be correct to associate AIM scores with an overall conformity to respond, but only among low hypnotizable Subjects. For high hypnotizable Subjects, behavioral compliance (task performance) was not associated with AIM scores. Just as Sheehan's (1971, 1980) 'countering' studies suggest, among high hypnotizable Ss there appears to be no clear-cut relationship between the ability to perform hypnotic tasks and the special, motivated commitment to the hypnotist evidenced in some Ss. The theory of Shor (1979) and the empirical work of Sheehan and Dolby (1979) strongly suggest that an intense involvement with the hypnotist (archaic involvement) is a distinctive feature of the hypnotizable S's experience. The present work corroborates Sheehan and Dolby's (1979) finding that, among high hypnotizable Ss, this involvement is not equivalent to overt response to the demands of standard test suggestions.

"Three findings further suggest that AIM scores assess an important aspect of the hypnotic S's experience which is relatively unrelated to behavioral task performance. First, AIM scores correlated significantly with a measure of subjective depth during hypnosis (Hypnotic Depth Inventory, Field, 1966). Second, the correlation between hypnotic depth and AIM scores was substantial for both low and high hypnotizable Ss. Thus, for high hypnotizable Ss, AIM scores were significantly correlated with hypnotic depth, even though they were unrelated to behavioral task performance. Finally, regression analysis suggested that AIM scores accounted for variance in hypnotic depth which was not explained by task performance scores. These findings, then, conform to Shor's proposition and Sheehan's (1971, 1980) later observations that archaic involvement with the hypnotist is a fundamental dimension of hypnotic experience which may not be

directly related to the extent of behavioral response to hypnotic suggestions (see Shor, 1979, p. 119).|

"It is of some interest that the mean AIM score for low hypnotizable Ss was roughly equivalent to that of control Ss who had listened to a lecture prior to AIM administration. Only Ss who were exposed to hypnosis and who were behaviorally responsive to hypnotic suggestions evidenced elevated AIM scores" (pp. 140).

**Ronnestad, Michael Helge (1989). Hypnosis and autonomy: A moderator analysis. International Journal of Clinical and Experimental Hypnosis, 37, 154-168.**

The study focused on autonomy as a moderator variable in the prediction of subjectively reported hypnotic depth. Ss in the experimental part of the study were 56 undergraduate psychology and education majors classified as either high or low in autonomy. Ss who were equated on capacity for absorption were individually administered 1 of 3 hypnotic inductions: an authoritarian induction, a permissive hetero- induction, or a self-hypnosis induction. The study had a double-blind design. The data suggest that situational manipulation has greater impact on low than on high autonomy Ss. Individual-difference variables such as absorption, have greater impact on hypnotic depth for high than for low autonomy Ss. The data indicate that the hypnotic behavior of high autonomy Ss is more likely to be self-congruent and less likely to be demand-congruent. A factor-analytic inquiry of absorption confirmed the importance of affective/regressive capacity for hypnotic functioning for high autonomy Ss. The study supported the alternate-path perspective of hypnosis.

#### NOTES

There is very little research on autonomy and hypnosis. The authors cite studies showing only a modest relationship between hypnotizability and locus of control.

In this study, 176 students were assigned to the high autonomy group if they were in the upper 1/3 of two of 3 autonomy scales (Rotter's Locus of Control Scale, the Inner- Directedness Subscale of the Shostrom Personal Orientation Inventory, and the Autonomy subscale of Jackson's Personality Research Form) and not in the lower 1/3 of the third scale. Ss were designated as low autonomy if the obverse obtained. This procedure yielded 27 high and 29 low autonomy Ss.

Ss were hypnotized with one of three inductions: authoritarian with many motor items (Barber Suggestibility Scale), permissive with mostly imagery (Barber & Wilson's Creative Imagination Scale), or guided self-hypnosis with mostly imagery (taken from Fromm et al, 1981). After hypnosis, Ss rated their own hypnotic depth on a 1-10 scale, and their perception of E or the procedure as authoritarian and directive. Ss' attitude, expectations, motivation, and experienced effortlessness were measured. E rated Ss for pre-hypnosis rapport and post-hypnosis rapport.

The results indicated that there was no difference in hypnotizability level between high and low autonomy Ss. The correlation between effortlessness of experience and hypnotic depth was high for low autonomy Ss (.51) but not significant for high autonomy Ss (.12). In general the two groups were very similar in terms of mean scores on most variables. The differences appeared in the correlations between self-

reported hypnotic depth and the other variables. For low autonomy Ss correlations were not significant between depth and pre-hypnotic variables (rapport-pre, absorption, expectation) but for highs the same correlations were significant (rapport-pre .47, absorption .54, expectation .48).

But for post-hypnosis variables, low autonomy Ss had significant correlations between depth and the two variables measured from post-hypnosis interviews (perceived authoritarian/directiveness .40, effortlessness .51) and the highs did not have significant correlations. The multiple correlation between these variables and depth was  $R = .28$  for low autonomy Ss (with no contribution from rapport-pre) and  $R = .72$  for high autonomy Ss, with absorption contributing most. The more they perceived the induction as authoritarian or directive, the greater depth reported by low autonomy Ss. Although low and high absorption Ss did not differ on the Absorption Scale, absorption predicted hypnotic depth better for the highs.

The author divided the Absorption Scale into four rational factors: Affective/Regressive, Perceptual/Cognitive, Dissociative, and Mystical. Low and high autonomy Ss scored at approximately the same level on these categories, but correlations between these categories and depth for low and high autonomy Ss were somewhat different. (See Table.)

**Correlations between Categories of Absorption and Hypnotic Depth for Low and High Autonomy Ss**

Absorption Category	Low Autonomy Ss	High Autonomy Ss	All Ss
Affective/Regressive	.14	.56**	.33**
Perceptual/Cognitive	.25	.33*	.29*
Dissociative	.32*	.57**	.47**
"Mystical"	.07	.16	.11

In their discussion, the authors note that one might assume that high autonomy Ss would be less affected by variations in hypnosis procedures than low autonomy Ss. The differences found in depth scores for these two groups were supportive of this expectation. "Fluctuations in subjectively reported depth scores for low autonomy Ss only, clearly suggest autonomy to be a moderator variable" (p. 163).

Moreover, the results indicate "that high autonomy Ss in comparison to low autonomy Ss are more likely to express their inner dispositions, such as absorption and expectation, in the hypnotic setting. High autonomy Ss may be more reflective of and attuned to individual predisposing characteristics and less influenced by situational demands. ... the hypnotic behavior of high autonomy Ss is more likely to be self- congruent and less likely to be demand-congruent. Low autonomy Ss, however, are more likely to be demand congruent and less likely to be self-congruent. The latter finding was suggested both by the significant F ratio for low autonomy Ss across treatments, and also by the stronger relationship found for this group between depth and how authoritarian/directive they perceived the procedure to be" (p. 163).

[Paradoxically, among low autonomy Ss an authoritarian approach yields less depth but greater suggestibility (higher hypnotizability scores).] "The tendency for low autonomy Ss to have a higher behavioral score on the authoritarian procedure is consistent with Tellegen's (1979) assumption that there are two pervasive dimensions in current hypnotizability measures--a compliance dimension and a true hypnotic responsiveness dimension. According to Tellegen, motor items may be more saturated with compliance, while cognitive items may be more saturated with

true hypnotic responsiveness. The BSS has a motor emphasis, and the higher behavioral scores for the low autonomy group of Ss may be interpreted as an expression of compliance.

"In addition to the inner-directedness and self-congruence hypothesis of why autonomy may be a moderator variable, another possible explanation is related to accuracy of self-perception. The intercorrelational and multiple regression data showed repeatedly that a stronger relationship existed between prehypnotic variables and hypnotic depth for high autonomy than for low autonomy Ss. The relational capacity, as tapped by the rapport-pre variable, absorption, which may be conceptualized as a personality trait; and expectation, a cognitive variable, were all related to depth for high autonomy Ss. For low autonomy Ss, none of these variables were individually related to depth. Differences in Ss' accuracy of self-reporting may explain this. According to ego-psychology theory, highly individuated Ss, with clear self-other differentiation and congruence in self-perception, are better able to make accurate statements about themselves. The self-assessments of Ss with low differentiation capability may be less accurate and possibly more affected by demand characteristics and response set. In other words, their self-assessments have more error. The generally lower correlations for the low autonomy Ss may reflect this" (p. 164).

"A report of subjectively reported hypnotic depth following CIS and the self-hypnosis scales may reflect clarity of imagery, while a report of depth following BSS may reflect experiences of kinesthetic/bodily changes" (p. 165).

Schuyler, Bradley A.; Coe, William C. (1989). More on volitional experiences and breaching posthypnotic amnesia. International Journal of Clinical and Experimental Hypnosis, 37, 320-331

Highly responsive hypnotic subjects, who were classified as having control over remembering (voluntaries) or not having control over remembering (involuntaries) during posthypnotic amnesia, were compared with each other on four physiological measures (heart rate, electrodermal response, respiration rate, muscle tension) during posthypnotic recall. Two contextual conditions were employed: One was meant to create pressure to breach posthypnotic amnesia (lie detector instructions); the other, a relax condition, served as a control. The recall data confirmed earlier findings of Howard and Coe and showed that voluntary subjects under the lie detector condition recalled more than the other three samples that did not differ from each other. However, using another measure of voluntariness showed that both voluntary and involuntary subjects breached under lie detector conditions. Electrodermal response supported the subjects' reports of control in this case. Physiological measures were otherwise insignificant. The results are discussed as they relate to (a) studies attempting to breach posthypnotic amnesia, (b) the voluntary/involuntary classification of subjects, and (c) theories of hypnosis.

#### NOTES

The authors suggest that subjects observe themselves not remembering (i.e. not reporting memories) and conclude that they therefore could not remember. Such

subjects, they say, are deceiving themselves in so far as they could remember if they were to direct their attention to salient cues.

#### NOTES

The author refers to one of his papers for a critique of the Spanos position that demand characteristics of the hypnotic situation account for hypnotic phenomena such as amnesia, analgesia, and "trance logic." The paper is Hilgard, E. R. (1987). Research advances in hypnosis: Issues and methods. International Journal of Clinical and Experimental Hypnosis, 35, 248-264.

Pavia, M.; Stanley, R. O. (1988). Effect of defining induction as hypnosis or relaxation. Australian Journal of Clinical and Experimental Hypnosis, 16, 11-21.

Previous studies have shown that the perceived definition of an induction may sometimes affect the subject's responses to the induction. These variations in the effect of induction definition may be due to interactions between a subject's motivations and expectations of the induction technique and the way the induction is defined. These authors explored this interaction with groups of clinical and student subjects. Differing definitions of induction as 'hypnosis' or 'relaxation' did not result in significant differences in response among either group, though subjects in neither group were found to have high expectations of motivation (sic).

1987

McCann, Terry; Sheehan, Peter W. (1987, October). Pseudomemory creation and confidence in the experimental hypnosis context. [Paper] Presented at the annual meeting of the Society for Clinical and Experimental Hypnosis, Los Angeles.

After watching a video-tape of a bank robbery incident, 34 out of 40 highly hypnotizable subjects displayed pseudomemory reports subsequent to the administration of false memory suggestions given after hypnotic induction

instructions. Incorporation of elements of pseudomemory into recall reports was accompanied by increased confidence ratings, but confidence ratings for those subjects displaying most pseudomemory distortion at recall fell appreciably when subjects were confronted with the reality constraints associated with recognition testing. Data imply that pseudomemories associated with hypnotic suggestion are not always accompanied by increased conviction or certitude, nor are they resistant to change in the face of contrary evidence. Data further indicate that subjects adapt both accuracy and confidence responses to the stimulus conditions of testing, implying that accuracy and confidence ratings may covary meaningfully.

Stam, Henderikus J.; Spanos, Nicholas P. (1987). Hypnotic analgesia, placebo analgesia, and ischemic pain: The effects of contextual variables. Journal of Abnormal Psychology, 96, 313-320.

**ABSTRACT:** Two experiments examined the relation between hypnotic and placebo analgesia using ischemic pain. The first experiment examined an artifact in a previously used ischemic-pain stimulus. Experiment 2 investigated the relation between hypnotic and placebo analgesia using a submaximum-effort tourniquet technique to produce ischemic pain. High- and low-susceptible subjects who received placebo analgesia followed on a subsequent trial by hypnotic analgesia showed significant increases in tolerance from placebo to hypnotic analgesia. When presented in the reverse order, however, placebo analgesia and hypnotic analgesia led to equivalent levels of tolerance in both high- and low-susceptible subjects. A similar pattern of findings emerged for Ss' magnitude estimates of pain, but it was not related to hypnotic susceptibility. These findings indicate that both hypnotic and placebo analgesia may be contextually dependent phenomena.

1986

Council, James R.; Kirsch, Irving; Hafner, L. P. (1986). Expectancy versus absorption in the prediction of hypnotic responding. Journal of Personality and Social Psychology, 50, 182-189.

The Absorption Scale was administered to subjects in the context of a hypnosis experiment and in a context unrelated to hypnosis. Expectancies of responding to hypnotic suggestions were assessed both before and after trance induction, but before administration of suggestions. Hypnotic depth was assessed by different methods before suggestions were given, and after hypnosis. Absorption was correlated with hypnotic responsivity and expectancy, but only when assessed in a hypnotic context. Completing the Absorption Scale in a hypnotic context appeared to affect responsiveness by altering expectancies. Only postinduction expectancies were predictive of response to suggestions. Results of path analysis suggest that trance inductions alter expectancies for responding to hypnotic suggestions and that these altered expectancies determine subsequent hypnotic behavior.

Laurence, Jean-Roch; Nadon, Robert (1986). Reports of hypnotic depth: Are they more than mere words?. International Journal of Clinical and Experimental Hypnosis, 34, 215-233.

The empirical work relating hypnotizability, the hypnotic situation, and the reports of hypnotic depth is reviewed and evaluated. Asking Ss to assess their hypnotic depth is a complex task involving the interaction of experiential, cognitive, and contextual variables. Accordingly, future experimental work should take into account this multidimensionality; phenomenological, situational, cognitive, and motivational factors implicated in verbal reports should be explored in terms of their respective relationships with both hypnotizability and self-ratings of hypnotic depth. More sophistication in the experimental inquiries of hypnotic depth is required in order to further our understanding of the cognitive and affective structures underlying the hypnotic experience.

#### NOTES

In past years, hypnotic susceptibility and hypnotic depth were regarded as the same thing, and depth was inferred from responses to test suggestions on hypnotizability scales (e.g. Davis & Husband, 1931; LeCron, 1953).

There has been little investigation of the relationship between Subjects' subjective experiences and reported "depth." Research suggests that "hypnotic depth reports are usually significantly higher for Ss who have undergone a hypnotic treatment than for those who have received task-motivation (Ham & Spanos, 1974; Spanos & Barber, 1968; Spanos, Stam, D'Eon, Pawlak, & Radtke-Bodorik, 1980); imagination-control; or relaxation-control instructions (Connors & Sheehan, 1978; Gilbert & Barber, 1972; Spanos & Barber, 1968; Spanos, Radtke-Bodorik, & Stam, 1980, Experiment 2)" (pp. 217-218). Others have found that changes in inward experiencing (e.g. feelings of unreality, a sense of disappearance of body parts) could not be attributed simply to sitting quietly with the eyes closed (Barber & Calverley, 1979). [A footnote on p. 218 indicates some studies didn't find this difference between a hypnosis group and a task-motivation control group.]

When Ss are asked to estimate subjective depth after having experienced hypnotizability test items, they are likely to infer depth from whether or not they passed the items (and indeed, early scales promoted that assumption). Reports of subjective depth taken before rather than after the test items still correlate with overall hypnotizability score, though not to as high a degree (E. R. Hilgard & Tart, 1966; Tart, 1970). Although usually depth estimates correlate with hypnotizability in the .50 to .75 range (Perry & Laurence, 1980), the correlations were obtained in the hypnotic context, and Ss may use their own behaviors as one determinant of their estimated depth.

From another line of study it is observed that Ss' subjective depth may be at variance with behavioral performance on hypnosis scales (Bowers, 1981). High hypnotizables judge their own depth from their performance on cognitive items (e.g. amnesia, hallucinations) while mediums and lows judge their own performance based on their responses to motor items and challenge items (Kihlstrom, 1981). In one experiment on amnesia, it appeared that Ss did not judge their own depth by how well they did on the amnesia task (Spanos, Stam, D'Eon, Pawlak, and Radtke-Bodorik, 1980). "M. T. Orne (1966, 1980) has emphasized that although it is necessary to operationalize S's responses to hypnotic suggestions, behavioral

concomitants are only valid if they accurately reflect subjective alterations in an individual's experience" (p. 221).

"The social-psychological approach (see Barber, 1969; Radtke & Spanos, 1981, 1982; Spanos, 1982; Wagstaff, 1981) rejects the notion of hypnotic depth as an indicator of a unique state. These authors argue that the reports of having been hypnotized reflect attributions made by Ss when confronted with a hypnotic context. ... Bem (1972) and Kelley (1972) have emphasized the idea that the more ambiguous an experience is, the more a person is likely to base his or her judgment primarily on available external information" (p. 222). In this case, defining the situation as involving "hypnosis" is one of the most potent predictors of Ss' reports of subjective experience (Spanos, Radtke- Bodorik, and Stam, 1980). Other variables that influence subjective depth estimates are the wording of the hypnotizability scale, expectancy, and information provided directly or indirectly. On the other hand, McCord (1961) found that his patients had widely disparate expectations for how they thought they would feel when hypnotized, so expectancy as a predictor would not necessarily determine specific experience.

Direct experimental work on predicting response to hypnosis test items from expectancies (Council, Kirsch, Vickery, & Carlson, 1983; Kirsch, Council, & Vickery, 1984) suggests that expectations may predict test response when people are given a cognitive skill type of induction, but not when given a 'typical trance' type of induction. Also, another study from that laboratory (Council & Kirsch, 1983) established that only when expectancies are assessed after an induction (but before the test items) do they effectively predict hypnotic behaviors. The present authors express the view that these results are difficult to account for on the basis of social psychology theories that weight heavily the role of expectancy in generating hypnotic response.

When Ss are permitted to use several different descriptors for their experience (being hypnotized, experiencing the effects, being absorbed, and responding to the suggestions), most Ss rated their own experiences as nonhypnotic (Radtke & Spanos, 1982). This was particularly true for medium hypnotizable Ss. Thus, unidimensional scales purporting to measure "depth" actually force Ss to interpret their multi-aspect experience in terms of the investigator's frame of reference, in this case "hypnotic depth." Nevertheless, the highly hypnotizable Ss were the least likely to be swayed from their self description of being "deep" when offered alternative ways of describing their experience. This is concordant with results reported earlier by Barber et al. (1968).

"The attribution literature may provide clues as to why most highly hypnotizability Ss retain their high ratings of experienced depth when confronted with situational manipulations. Self-perception theory strictly applies when Ss' experiences are ambiguous, forcing them to fall back on contextual factors to make self-appraisals. The relationship between expectancies, absorption, effect of scale wording, and hypnotizability scores suggest, however, that high hypnotizable Ss do not rely heavily on contextual factors when assessing their levels of hypnotic depth. Most of these Ss maintain their reports of altered experiences, even when situational determinants are changed (Harackiewicz, 1979; Kihlstrom, 1984; Lepper, Greene, & Nisbett, 1973). Thus, the hypnotizability by depth scale interaction found by

Radtke and Spanos (1981) may suggest that experiences reported by high hypnotizable S are not inherently ambiguous. Accordingly, self-perception theory may not apply to them" (pp.226-227).

In their Discussion, the authors state, "Several studies have attempted to relate personal, real-life events to the experience of hypnosis. A number of studies (e.g., As, 1963; Field, 1965; Shor et al., 1962; Wilson & Barber, 1982) have shown that absorption, tolerance of unusual experiences, automaticity, compulsion, and trust are related to the capacity to be hypnotized. Other studies (Bowers & Brenneman, 1981; Tellegen & Atkinson, 1974; Van Nuys, 1973) have shown that certain variants of attention are also related to hypnotizability. Extensive work by J. R. Hilgard (1970, 1979) has shown that patterns of personal development relate to hypnotizability in adult life. It appears then that hypnotizable individuals bring a host of experiences and abilities with them to the hypnotic context. It makes intuitive sense which is supported by the available empirical data, that a complex interaction among these experiences and abilities, the hypnotic context, and hypnotic responsiveness is implicated in Ss' assessments of their hypnotic depth. Studies are needed in which all of these potential determinants of hypnotic depth reports are taken into account. Only then will a clearer picture of their respective importance emerge" (p. 228).

Meagher, Christopher Roberts (1986). Suggestion and posthypnotic amnesia: Altered context or altered state? (Dissertation, University of Oregon). Dissertation Abstracts International, 47 (n1-B), 409-410. (Order No. DA 8605846)

"Posthypnotic amnesia has been investigated in the past and subsequently alluded to as either role enacted behavior or evidence for an altered state of consciousness. In order to gain further understanding of the circumstances which facilitate amnesic behavior, an experiment was carried out which was designed to vary the usual context in which recall and recognition memory are observed during posthypnotic amnesia. The suggestion for posthypnotic amnesia was altered from its usual form in that specific suggestions for recall amnesia and recognition amnesia replaced the usual general suggestion for overall memory impairment. Some Ss received the amnesia suggestion before presentation of the stimulus material rather than after stimulus presentation. In addition to the usual verbal stimuli, nonverbal stimuli were used. "A group of 44 highly hypnotizable, undergraduate Ss was divided into four treatment conditions. Three groups were hypnotized and given instructions to repeat a list of nine words taken from the Rey Auditory Verbal Learning Test, and to copy the nine figures of the Bender Gestalt Test. A fourth group performed these tasks in a normal waking state. One hypnotic group was given prestimulus suggestions for recall and recognition amnesia. Another was given poststimulus suggestions for recall and recognition amnesia, and the third hypnotic group received no amnesia suggestions. The dependent measures consisted of the scores on tests of recall and recognition of the stimulus words and figures. "A repeated measures multivariate analysis of variance revealed significant effects for hypnosis /suggestion condition, type of stimulus, and type of test. Further analysis determined that the two hypnotic groups given amnesia suggestions did not differ

from each other but did show significantly greater amnesia than did either the no suggestion hypnotic control group or the waking control group. Recognition performance was significantly better than was recall performance for all groups in both stimulus situations. Nonverbal recall was significantly better than verbal recall for the two control groups given no amnesia suggestion. There was no stimulus effect for any other group and testing condition. The results of this experiment are discussed in terms of theories of hypnosis and memory, contextual variables of the hypnotic situation, and previous germane research" (pp. 409-410).

**Register, Patricia A.; Kihlstrom, John F. (1986). Finding the hypnotic virtuoso. International Journal of Clinical and Experimental Hypnosis, 34, 84-97.**

Measures of hypnotizability based on the Harvard Group Scale of Hypnotic Susceptibility, Form A (HGSHS:A) correlate only moderately with those based on the Stanford Hypnotic Susceptibility Scale, Form C (SHSS:C). Ss (N = 148) scoring in the high range (10-12) on HGSHS:A were classified according to whether they scored in the "virtuoso" range (11-12) or not on a subsequent administration of SHSS:C. Significant group differences were found on items comprising the cognitive distortion subscale of HGSHS:A, whether assessed in terms of overt behavior or subjective impressions of success. The 2 groups also differed on global self-ratings of hypnotic depth and on those subscales of Field's Inventory Scale of Hypnotic Depth concerned with subjective feelings of loss of control, automaticity, transcendence of normal functioning, and fluctuating depth. Assessments of hypnotizability are enhanced when investigators consider subjective involvement as well as behavioral measures of hypnotic response. This is particularly important when the more dissociative aspects of hypnosis are under scrutiny.

#### NOTES

The correlation between Harvard Group and Stanford Scale scores is usually about  $r = .60$  (Bentler & Roberts, 1963; Coe, 1964; Evans & Schmeidler, 1966). This is much lower than one would expect ( $r = .82$ ), based on the tests' individual reliabilities (Evans & Schmeidler, 1966).

The authors developed a Table to show the cross-classification of Ss in terms of Harvard and SHSS:C. Only a minority (33%) of Ss scoring in the highest range of HGSHS:A also scored in the highest range on the SHSS:C (or 50% if cutting points are different).

The Absorption scale correlated  $r = .38$  ( $p < .001$ ) with the Harvard Scale, which fell to  $r = .31$  ( $p < .01$ ) when corrected for expansion of range. The correlation between Absorption and SHSS:C was  $.35$  ( $p < .001$ ).

The issue of predicting Stanford 'virtuosos' from Harvard 'virtuosos' was addressed. HGSHS:A predictor variables were used to determine which items determined whether or not one of the HGSHS:A 'virtuosos' (the 20% who scored 11-12) would also be a SHSS:C 'virtuoso.' It was found that 70% of the SHSS:C virtuosos, but only 53% of the nonvirtuosos, had reversible posthypnotic amnesia on the HGSHS:A. None of the ideomotor or challenge subscale items demonstrated this ability to predict group association. Although the 'virtuosos' differed from the

'nonvirtuosos' in self reported depth, none of the coding categories associated with the depth variable differentiated the groups; also, judges could not predict who would be a Stanford 'virtuoso' based on subjects' descriptions of depth following the Harvard scale administration.

The Experimenters also could not predict who among the Harvard 'virtuosos' would be classified as a Stanford 'virtuoso' based on either their Absorption Scale score or previous experience with hypnosis.

It was found that subjects' subjective experience of the suggestions for hallucinations, amnesia, and posthypnotic behavior (all considered to be cognitive alterations) were the most highly correlated with the subsequent total SHSS:C score. On the Field scale, which measures subjective experience, the most predictive items had to do with feelings of automaticity and loss of control (referred to as nonvoluntary behavior in other literature). Predicting SHSS:C score by 5 items (Harvard behavioral score, Harvard subjective score, Field total score, Tellegen Absorption total score, and self reported depth rating),  $r = .44$ . "The 5-element regression, employing only total scores, explained 17% ... of the variance of SHSS:C; thus, the feelings of subjective success accounted for the vast proportion (79%) of the explainable variance. For the 16 element regression, employing subscales derived from factor analysis of HGSHS:A and Inventory Scale of Hypnotic Depth, the cognitive subscale was dominant, accounting for 65.5% of explainable variance" (p. 92).

A discriminant function analysis employing the same five total score variables correctly classified 63.3% of the virtuosos.

In their Discussion, the authors suggest that investigators use subjective response as well as behavioral response when identifying hypnotic talent (virtuosos) for research. Particularly, the subjective experience of success seems to be important. Little is known, to date, about the determinants of that sense of success with hypnotic suggestions. "In part, they may relate to the 'classic suggestion effect' (K. S. Bowers, 1981; P. G. Bowers, 1982; Weitzenhoffer, 1974): the quasi-automatic, compulsory, involuntary quality which distinguishes hypnotic response from compliance with simple social requests. If so, then a direct assessment of perceived involuntariness might enhance the predictive validity of HGSHS:A even more. This is especially true for the perceptual-cognitive alterations which relate to Ss' capacity for dissociation" (p. 94).

The authors further recommend, "In those situations where HGSHS:A must stand alone for economic reasons, however, and especially where HGSHS:A is employed as a convenient preliminary screening device in the search for hypnotic virtuosos, it would seem that some assessment of the subjective experience of hypnosis would provide useful supplementary information at very little cost" (p. 94).

1985

Spanos, Nicholas P.; Weekes, John R.; Bertrand, Lorne D. (1985). Multiple personality: A social psychological perspective. Journal of Abnormal Psychology, 94, 362-376.

The part of an accused murderer remanded for pretrial psychiatric evaluation was role played by 48 college students. Role players were assigned to interview

treatments that varied in how extensively they cued for symptoms of multiple personality. The most explicit treatment (i.e., Bianchi treatment, n = 16) included a hypnotic interview that was used in diagnosing a suspect in the "Hillside strangler" rape- murder cases as suffering from multiple personality. A less explicit hypnotic treatment (n = 16) and a nonhypnotic treatment (n = 16) were administered to the remaining role players. Most subjects in the Bianchi treatment displayed the major signs of multiple personality (e.g., adoption of a different name, spontaneous posthypnotic amnesia). In a later session subjects who role played as multiple personalities performed very differently on psychological tests administered separately to each role-played identity. Those who failed to enact the multiple personality role performed similarly when tested twice. Findings are discussed in terms of a social psychological formulation that emphasizes the roles of active cognizing, contextual cueing, and social legitimization in the genesis of multiple personality.

Zamansky, Harold S.; Bartis, Scott P. (1985). The dissociation of an experience: The hidden observer observed. Journal of Abnormal Psychology, 94 (3), 243-248.

Addressed methodological weaknesses in previous studies of the hidden observer phenomenon presented by E. R. Hilgard (1977) using a modified procedure with 11 undergraduates highly susceptible to hypnosis. The critical modifications were that no prior practice in dissociation was given before the hidden observer was assessed, the notion of hidden information was introduced only after the stimulus was no longer present, and independently verifiable stimuli were employed. Despite this more rigorous procedure, a hidden observer response was still observed in more than 90% of Ss. This finding makes much less tenable interpretations that attribute the hidden observer effect solely to social expectancies and situational demands. It is concluded that it is possible for some hypnotized individuals to monitor the actual state of events while experiencing a variety of perceptual distortions.

1984

Spanos, Nicholas P.; Kennedy, Sharon; Gwynn, Maxwell I. (1984). The moderating effects of contextual variables on the relationship between hypnotic susceptibility and suggested analgesia. Journal of Abnormal Psychology, 93 (3), 285-294.

Assessed 75 undergraduates high, medium, or low on hypnotic susceptibility (the Carleton University Responsiveness to Suggestion Scale) on the cold pressor task before and after 1 of 3 instructional treatments. The treatments were (a) brief instructions to try to reduce pain, (b) the same analgesia instructions preceded by a hypnotic induction procedure, and (c) no hypnotic induction or instructions. In the hypnotic treatment, susceptibility correlated significantly with reductions in reported pain, and high-susceptible Ss reported significantly larger pain reductions than did control ss. In the instruction-alone treatment, there was no significant relationship between susceptibility and pain reduction, and Ss at all 3 susceptibility levels reduced reported pain significantly more than did controls and as much as did high-susceptible hypnotic Ss. Findings suggest that the correlation between

hypnotic susceptibility and hypnotic analgesia is moderated by Ss attitudes and expectancies concerning their own performance in situations defined as related to hypnosis

Nogrady, Heather; McConkey, Kevin M.; Laurence, Jean-Roch; Perry, Campbell (1983). Dissociation, duality, and demand characteristics in hypnosis. Journal of Abnormal Psychology.

Examined hypnotic dissociation (as indexed by the "hidden-observer" method), duality in age regression, and the potential impact of situational cues on these phenomena. 12 high- and 9 low-susceptible undergraduates (as determined by the Stanford Hypnotic Susceptibility Scale) were tested in an application of the real-simulating paradigm of hypnosis; 10 high- to medium-susceptible Ss were also employed. Inquiry into Ss' experiences was conducted through the experiential analysis technique, which involves Ss viewing and commenting on a videotape playback of their hypnotic session. Results demonstrate that neither the hidden-observer effect nor duality could be explained solely in terms of the demand characteristics of the test situation. The hidden-observer effect was observed in high-susceptible Ss only; all Ss who displayed the hidden-observer effect also displayed duality in age regression. High-susceptible Ss were distinctive in their reports of multiple levels of awareness during hypnosis. Findings are discussed in terms of the cognitive skills that Ss bring to hypnosis and the degree to which the hypnotic setting encourages the use of dissociative cognitive processes. (43 ref).

1982

Schuyler, Bradley A. (1982). Further investigation of volitional and nonvolitional experience during posthypnotic amnesia (Dissertation, California School of Professional Psychology, Fresno). Dissertation Abstracts International, 44 (n6-B), 1977. (Order No. DA 8324472)

Electrodermal responses were compared between highly responsive hypnotic Ss who were classified as having control over remembering (voluntaries) or not having control over remembering (involuntaries) during posthypnotic amnesia. Three contextual conditions were employed: Two were meant to create pressure to breach posthypnotic amnesia (lie detector instructions alone or with feedback that Ss had been detected as not having told all they could remember); the other provided feedback, in addition to the lie detector instructions, that Ss had told all they could remember. The recall data confirmed earlier findings of Coe and Yashinski and showed that voluntary and involuntary Ss did not differ in response to the contextual conditions. However, lie detector instructions alone did not create pressure to breach as in previous studies. In addition, electrodermal results were insignificant. The results are discussed as they relate to (a) amnesia, (b) the physiological detection of deception and physiological activation, (c) the voluntary/involuntary classification of Ss, and (d) theories of hypnosis" (p. 1977).

Spanos, Nicholas P.; Bridgeman, M.; Stam, H. J.; Gwynn, M. I.; Saad, C. I. (1982-83). When seeing is not believing: The effects of contextual variables on the reports of hypnotic hallucinations. Imagination, Cognition and Personality, 2, 195-209.

When administered a hallucination suggestion most high susceptible hypnotic and task-motivated subjects reported that they "saw" the suggested object. When asked what they meant by "saw," however, almost all indicated that they had imagined the object but did not believe that it had actually been present. On the other hand, simulating subjects maintained that the suggested object had been "really there." Simulators were also more likely than non-simulators to provide "life-like" descriptions of the suggested object (e.g., solid rather than transparent, colored, highly vivid). These findings are consistent with the view that hypnotic hallucinations are context-generated imaginings. They also indicate that unique or unusual psychological processes like "trance logic" need not be posited to account for the descriptions of "hallucinatory" experiences proffered by hypnotic subjects.

#### NOTES

It was observed that hypnotized Ss reported more vivid (and longer sustained) imagery than task motivated Subjects. Hypnotized Ss did not differ from high susceptible simulators on vividness of imagery or how long they experienced the imagery, but did report shorter and less vivid imagery than simulators who were low hypnotizables.

Tellegen, Auke (1981). Practicing the two disciplines for relaxation and enlightenment: Comment on 'Role of the feedback signal in electromyograph biofeedback: the relevance of attention' by Qualls and Sheehan. Journal of Experimental Psychology: General, 110, 217-226.

High and Low Absorption Ss differ in set rather than in capability for attending to external or internal stimuli, as Qualls and Sheehan suggest. Trait x Treatment interaction for Absorption illustrates concept of personality dispositions being inherently interactive functional units. Provides a content analysis of Absorption scale (subscales) and relates absorption to other constructs in psychology. "It is not the internal versus external focus per se that play a decisive role but the subject's experiential versus instrumental set. For example, with two treatment levels, one would expect to obtain an Absorption x Treatment interaction even if both treatment conditions required an external attentional focus, as long as they contrasted an experiential and an instrumental set" (pp 223-224).

Kihlstrom, John F.; Evans, Frederick J.; Orne, Emily C.; Orne, Martin T. (1980). Attempting to breach posthypnotic amnesia. Journal of Abnormal Psychology, 89 (5), 603-616.

Traditionally, posthypnotic amnesia has been construed as a subjectively compelling deficit in memory retrieval. Alternatively, it may represent a motivated failure to utilize appropriate retrieval cues, lack of effort in recall, active suppression of memory, or unwillingness to verbalize the critical material. In an effort to test the

alternative hypothesis of amnesia, 488 college students were presented with 4 kinds of instructions (using 4 modifications of the Harvard Group Scale of Hypnotizability, Form A) designed to overcome the effects of suggested posthypnotic amnesia. The instructions particularly affected Ss of low and moderate hypnotizability who failed the criterion for amnesia. For those of moderate and high hypnotizability who met the criterion for amnesia, however, explicit requests for temporal organization, exhortations to maximize recall, and demands for honesty in reporting produced no greater effect on memory than did a simple retest. Results place some boundaries on both the traditional and alternative views of posthypnotic amnesia and invite further exploration of both cognitive and contextual models of the phenomenon.

1980

Sheehan, Peter W. (1980). Factors influencing rapport in hypnosis. Journal of Abnormal Psychology, 89 (2), 263-281.

The phenomenon of countering expresses the tendency of some highly susceptible subjects to favor the intent of the hypnotist when placed in a conflict situation where social influences of another kind dictate an alternative response. The present research explored the parameters of this objective index of involvement with the hypnotist to investigate the special relevance of rapport processes to the hypnotic setting. Rapport was manipulated in five different experiments, varying either the warmth or genuineness of the hypnotist. It was predicted from transference theorizing that countering would decrease in the negative context and increase in the positive one. Results confirmed predictions for highly susceptible subjects tested in the former context but not the latter. In the negative setting, subjects were inhibited in their rate of countering, but maintained their previous level of response to the hypnotist when rapport was facilitated. Results highlighted the relevance of interpersonal processes to theorizing about hypnosis.

1979

Perry, Campbell; Gelfand, Robert; Marcovitch, Phillip (1979). The relevance of hypnotic susceptibility in the clinical context. Journal of Abnormal Psychology, 88 (5), 592-603.

Despite experimental evidence that hypnotic susceptibility is a relatively stable characteristic of the individual, and one that is very difficult to modify, clinical investigators tend to see susceptibility as irrelevant to therapeutic outcome. Such investigators view motivational and interpersonal variables as more essential to the therapeutic change. The evidence for the clinical relevance of hypnotizability is sparse and contradictory. Most existing studies stem from medical hypnosis and indicate that susceptibility plays an important role in the successful treatment of such conditions as clinical pain, warts, and asthma. Two studies are reported that seek to pursue a contrary finding reported by Perry and Mullen, who found that susceptibility was unrelated to the successful treatment of a socially learned behavior (cigarette smoking). Both studies confirmed the earlier finding of a lack of

relation. In Study 1, however, stepwise multiple regression analysis located three inventory items concerning the motivation of cigarette smokers. The combination of items was found to predict outcome for 67.39% of 46 clients treated either by hypnosis or by rapid smoking. The finding was replicated in Study 2, which utilized a combined hypnosis - rapid smoking technique and employed a different therapist. The outcome for 9 of the 13 quitters and 37 of the 62 nonquitters across the two studies could be predicted by the three motivational questionnaire variables.

Tellegen, Auke (1979). On measures and conceptions of hypnosis. American Journal of Clinical Hypnosis, 21 (2-3), 219-237.

In this paper a number of issues are discussed relating to the assessment of hypnotism. First, some questions concerning the function of standardization and the use of norms are considered. Next, a relatively neutral definition of hypnotic susceptibility is proposed as a context within which important variations in its assessment are subsequently discussed. These variations are grouped according to whether they concern context, content, internal structure or external relations. A final section considers the enterprise of hypnotic state assessment.

Coe, William C. (1978). The credibility of posthypnotic amnesia: A contextualist's view. International Journal of Clinical and Experimental Hypnosis, 26 (4), 218-245.

This paper attempts to demonstrate how the contextual view rather than the formist-mechanistic view may be more helpful in understanding posthypnotic amnesia. As a point of departure, the criterion for credible posthypnotic amnesia is defined as Ss' phenomenal experiences which are observed indirectly through their counterfactual statements expressed with a high degree of conviction. To make sense of such self-reports, concepts flowing from contextualism, the view of man as an active person in an everchanging series of contexts, are employed. Concepts such as plots, reinforcement contingencies, trust, belief systems, involvement, ambiguousness, and self-observation may be postulated in understanding how people come to believe in their own counterfactual reports and to convince others of their credibility. Recent research on source amnesia, disrupted retrieval, and breaching posthypnotic amnesia is also critically evaluated. The conclusion is reached that the data are not compelling and their interpretations have been overstated

Hearn, Greg (1978, November). Susceptibility and the process of social interaction in the hypnotic context. [Unpublished manuscript] (Submitted as a partial requirement for the B. S. degree with honours in psychology at the Univ of Queensland)

**ABSTRACT:** The hypothesis was tested that the process of social interaction between hypnotist and subject is dependent upon the susceptibility level of subjects. Using Interaction Process Analysis (Bales, 1950), the interaction patterns of 16 high susceptibles and 16 low susceptibles were analyzed. Susceptibility level had been pretested with the HGSHS:A. The hypnotist was then instructed on how to control for differences in the process of interaction which were isolated and the initial

hypnotic session was repeated on a new sample. This time the performance and interaction patterns of six high susceptibles and six low susceptibles were compared. Results suggested that trait differences give rise spontaneously to differences in the process of interaction and some combination of these effect the subjects final hypnotic performance. Hence it is argued that an interactionist framework would aid the understanding hypnotic responsivity.

**Kihlstrom, John F. (1978). Context and cognition in posthypnotic amnesia. International Journal of Clinical and Experimental Hypnosis, 26, 246-267.**

Coe's (1978) contextualist analysis of posthypnotic amnesia appears to be predicated no the mistaken assumption that the amnesic S actually remembers the critical material. This position leads Coe to place inappropriate emphasis on the social context in which amnesia takes place and to focus on the social-psychological processes that might lead Ss to say that they do not remember something, be believed by others, and even believe themselves. An alternative view is outlined which affirms the surface similarities between posthypnotic amnesia and other failures of memory. From this vantage point, the investigator seeks to understand the cognitive processes that produce subjectively compelling disruptions of memory retrieval, whether found in association with hypnosis or in other circumstances.

**Schwartz, W. (1978). Time and context during hypnotic involvement. International Journal of Clinical and Experimental Hypnosis, 26 (4), 307-316.**

A recent conceptualization of hypnosis suggests that hypnotized Ss should show a disruption in episodic memory which would reflect a diminished awareness of duration and sequence. Specifically, the predictions were that hypnotized Ss would exhibit less accurate estimates of duration, and less sequence in their recall of activities, than would nonhypnotized Ss. The empirical task consisted of giving Ss the Stanford Hypnotic Susceptibility Scaloe, Form C (Weitzenhoffer & Hilgard, 1962), either with the induction (hypnosis condition), or without the induction (control condition). Prior to the termination of the scale, Ss were asked to recall the activities they had performed and the time that had elapsed since they began the scale. Hypnotized Ss (N = 10) were significantly less sequential in their recall of activities, and less accurate in their estimations of the passage of time, than were nonhypnotized Ss (N = 10). These results suggest that persons who respond to hypnosis are less concerned with the context which the world provides for their actions than are nonhypnotized controls.

**Slutsky, Jeffrey; Allen, George J. (1978). Influence of contextual cues on the efficacy of desensitization and a credible placebo in alleviating public speaking anxiety. Journal of Consulting and Clinical Psychology, 46 (1), 119-125.**

This investigation was designed to determine the extent to which contextual cues mediated the effectiveness of systematic desensitization and a plausible placebo in

alleviating public speaking anxiety. After participating in a public speaking situation that allowed the collection of self-report, physiological, and behavioral manifestations of anxiety, 67 subjects were randomly assigned to receive five sessions of either desensitization, "T scope" therapy, or no treatment. Each of these conditions was conducted in a context that either stressed the clinical relevance of the procedure or presented the procedure as a laboratory investigation of fear without therapeutic implications. Analysis of changes both between groups and within individuals indicated that desensitization reduced public speaking anxiety in both contexts, whereas the placebo was effective only in the therapeutic setting. The superiority of desensitization was most pronounced on the physiological variables. The results are interpreted as indicating support for a counterconditioning, rather than an expectancy, interpretation of desensitization.

Hoen, P. (1978). Effects of hypnotizability and visualizing ability on imagery mediated learning. International Journal of Clinical and Experimental Hypnosis, 26, 45-54.

The Ss selected for hypnotizability and visualizing ability were tested for their performance on an imagery-mediated, paired-associates task in which the stimulus materials were varied in imagery and concreteness. Imagery and concreteness showed significant main effects and an additive interaction facilitating learning. Neither hypnotizability nor visualizing ability showed main effects, thereby contradicting the conjecture that those 2 factors would facilitate imagery-mediated learning. However, high hypnotizable Ss learned more high imagery words than the low hypnotizables, and visualizing ability was shown to interact with word concreteness. It is concluded that the effects of hypnotizability and visualizing ability on verbal learning are, at least in part, a function of the content of the words to be learned.

**1961**

**Glass, Louis B.; Barber, Theodore X. (1961). A note on hypnotic behavior, the definition of the situation and the placebo effect. Journal of Nervous and Mental Disease, 132, 539-541.**

Subjects were tested for responses to hypnotizability tests under three conditions: after 20 minute induction, after being told they would not be hypnotized but would take tests of imagination (with motivating instructions to do well), after taking a placebo pill that "would make them deeply hypnotized." Of 12 Ss who dropped in score between Session 1 and Session 2, 11 attained higher scores following placebo than during the control session; mean scores under placebo and control (5.8 and 3.7) differed significantly,  $p < .01$ . Scores were as high in the third as the first session (5.8 and 6.3 respectively).

**1998**

**Eimer, Bruce; Freeman, Arthur (1998). Pain management psychotherapy: A practical guide. New York NY: John Wiley & Sons, Inc..**

#### **NOTES**

"Pain Management Psychotherapy" (PMP) provides a clear and methodical look at pain management psychotherapy beginning with the initial consultation and work-up of the patient and continuing through termination of treatment. It is a thoughtful and thorough presentation that covers methods for psychologically assessing the chronic pain patient (structured interviews, pain assessment tests and rating scales, instruments for evaluating beliefs, attitudes, pain behavior, disability, depression, anxiety, anger and alienation), treatment planning, cognitive-behavioral therapy techniques, and a range of hypnotic approaches to pain management. The book covers both traditional (cognitive and behavior therapy, biofeedback, assessing hypnotizability, choice of inductions, designing an individualized self-hypnosis exercise) as well as newer innovative techniques (e.g., EMDR, pain-relief imagery, hypno-projective methods, hypno-analytic reprocessing of pain-related negative experiences). An extensive appendix reproduces in their entirety numerous forms, rating scale, inventories, assessment instruments, and scripts.

The senior author, Bruce Eimer, states in his online comments on Amazon.com that "most therapists hold the belief that 'real' chronic pain patients are quite impossible to help. This book attempts to dispel these misguided beliefs by providing a body of knowledge, theory, and techniques that have proven value in understanding and

relieving chronic physical pain." He also states that "the challenge for the therapist is to persuade the would-be patient/client that he or she has something to offer that can help take away pain and bring back more pleasure. This challenge is negotiated through the therapeutic relationship. However, the therapist just can't be 'warm, accepting, non-judgmental and empathic'. The therapist must also have knowledge and skills relevant to relieving pain. Only then can the therapist impart such knowledge, and in teaching these skills to the pain patient, help the patient become something of a 'self-therapist'. . . I dedicate this book to everyone who wants to find ways to make living with pain more comfortable, and to the ongoing search for better ways to relieve pain."

Moene, Franny C.; Hoogduin, Kees A. L.; Van Dyck, Richard (1998). The inpatient treatment of patients suffering from (motor) conversion symptoms: A description of eight cases. International Journal of Clinical and Experimental Hypnosis, 46 (2), 171-190.

This article presents a preliminary study that used two controlled randomized trials to study the effect of hypnosis in the treatment of eight patients with (motor) conversion symptoms. Controlled research into the treatment of conversion symptoms is scarce and can often be criticized on methodological grounds. It would appear, however, that both the use of suggestive and behavioral therapeutic techniques and eclectic treatment programs yield good results in the treatment of conversion symptoms. The results of the study suggest that comprehensive clinical treatment including hypnosis has enough promise to be studied in clinical trials. In the interpretation of the results, special attention is given to primary diagnosis, duration of complaints, traumatic experiences in childhood, dissociative capacity, and hypnotizability.

Wickramasekera, Ian (1998). Secrets kept from the mind but not the body or behavior: the unsolved problems of identifying and treating somatization and psychophysiological disease. Advances in Mind-Body Medicine, 14, 18-132.

The identification and therapy of somatoform and psychophysiological disorders are major problems for medicine. This paper identifies three measurable risk factors (Wickramasekera 1979, 1988, 1993a, b, 1995) that are empirically associated with somatoform and psychophysiological disorders. These risk factors are high hypnotic ability, low hypnotic ability, and high Marlowe Crowne scores. Patients who are positive on one or more of these risk factors (all of which can constrict consciousness) have a high likelihood of having somatoform and psychophysiological disorders and should be studied with the additional risk factors proposed in the High Risk Model of Threat Perception (HRMTP). Treatment of patients should begin with the Trojan Horse Role Induction procedure (Wickramasekera 1988), which enables patients, who might otherwise resist psychological interpretations of their physical problems, to recognize that unconscious threat perception could be driving their somatic symptoms, an understanding that reduces their resistance to psychotherapy. A case study is

presented of a patient without identifiable pathophysiology or psychopathology to account for somatic symptoms that were largely resistant to standard medical therapy. The patient was positive for several of the psychosocial and psychophysiological risk factors of the HRMTP and after experiencing the Trojan Horse Role Induction showed improvement in somatic symptoms.

1996

Wickramasekera, Ian; Pope, Alan T.; Kolm, Paul (1996). On the interaction of hypnotizability and negative affect in chronic pain: Implications for the somatization of trauma. Journal of Nervous and Mental Disease, 184 (10), 628-635.

The high risk model of threat perception predicts that high hypnotizability is a risk factor for trauma-related somatization. It is hypothesized that high hypnotizability can increase experimentally induced threat or negative affect, as measured by skin conductance level, in a linear or dose-response manner. This hypothesized interaction of hypnotic ability and negative affect was found in a consecutive series of 118 adult patients with chronic pain symptoms. Larger increases in skin conductance levels during cognitive threat were significantly related to higher levels of hypnotizability. In addition, individuals with high hypnotizability retained higher skin conductance levels than individuals with low hypnotizability after stress. The clinical implications of the interaction of hypnotizability and negative affect during threat perception and delayed recovery from threat perception are discussed in terms of cognitive mechanisms in the etiology and therapy of trauma-related dissociative disorders.

Bowers, Kenneth S. (1995, November). Revisiting a Century-Old Freudian Slip -- from Suggestion Disavowed to the Truth Repressed. [Paper] Presented at the annual meeting of the Society for Clinical and Experimental Hypnosis, San Antonio, TX.

#### NOTES

Cites J. Herman, Mason, and Miller who accused Freud of retreating from trauma theory to save his theory. Feminists view the Oedipal theory as a coverup for the denial of child sexual abuse. This moral position fuels trauma theory and practice. It is the moral dimension of this debate that gives so many problems for the investigation of traumatic memory.

The intellectual origins of repressed trauma are examined here. Freud's early trauma theory, his later conflict theory.

Etiology of Hysteria (1896) presents Freud's argument, based on 18 patients: child is passive victim of experience imposed on them; memory is repressed and hysterical symptoms are derivatives of these repressed memories; when memories return as pictures the task of therapy is easier than if returning as thoughts. Bartlett's memory research showed visual image is followed by sense of confidence that surpasses what should be there.

The fact that patients had to be compelled to remember was offered by Freud as evidence against the idea that the memories were suggested. The patients initially would deny the reality of their memories, which Freud used in saying that we should not think that patients would falsely accuse themselves. In letter to Fleiss, he presented the conflict theory, which he presented in 1905 in Three Essays on Sexuality and later in My Views...on Etiology of Neurosis.

In 1905 Freud indicated he was unable to distinguish fantasy from true reports (and did not deny the existence of the latter). Freud often reconstructed the "memories" from dreams, transference, signs, symptoms, fantasies, etc. They were not produced as conscious memories, and it was Freud who inferred the sexual abuse. From signs of distress he took evidence of proof.

Freud presented his theory to his patients and then sought confirmation.

Freud asks us to abandon historical for narrative truth. The problems with Freud's first theory became worse with his second theory. In Introductory Lectures Freud states that opponents say his treatment talks patients into confirming his theories. He relies on the patient's inner reality confirming the theoretical ideas given to him. Success depends on overcoming internal resistance, however. The danger in leading a patient astray by suggestion has been exaggerated, because the analyst would have had to not allow the patient to "have his say." Freud denied strongly ever having done this.

Incorrect interpretations would not be accepted by the patients, and if believed would be suggestion. Brunbaum, another writer, said that this doesn't mean acceptance of a faulty idea won't occur. Both Milton Erickson and especially Pierre Janet reported cases in which suggestions were used to give benign memories to replace malignant ones.

Freud also viewed patient resistance to his interpretations as evidence that the interpretations were correct. Thus both resistance and acquiescence were thought to be validating. Popper's critiques using philosophy of science note that this makes his theory untestable.

Freud could not distinguish between the patient's reluctant acceptance of the truth and reluctant acceptance of a suggestion.

Contemporary theorists struggle less than Freud did with the problem of suggestion and suggestibility (and Freud did not have available the research on those areas!) Emotional upheaval that accompanies "insight" is readily taken to be validating. It may be true that bad memories are repressed, but that doesn't mean that all bad memories are true.

Treatment groups focus on recalling memories and sharing memories with others in the group, not on current relationships. Hermann states that the group provides powerful stimulus for remembering. The group, of course, is reinforced by others remembering. Repeatedly considering the possibility of abuse can increase the sense of familiarity.

Current views expressed by some clinicians that certain symptoms and syndromes (eating disorders, etc.) indicate early sexual trauma are similar to Freud's theory of hysteria. In these proposals, the inability to recall abuse becomes evidence that it occurred; and it tallies with the patient not having a sense of remembering.

Because some believe it is necessary to bring memory to light for cure to occur, there is a tendency to believe the reports of early childhood abuse.

Recognizing that some "memories" may have been a product of a therapist's suggestion helps prevent untoward effects. Modern therapists recapitulate Freud's "slip" when they do not acknowledge the role of suggestion.

Endorsing repression does not commit us to a belief that recovered memories must be accurate in all particulars. A memory that is repressed does not escape the usual kinds of degradation of memory.

And just because the material comes from unconscious sources, or has emotional accompaniments, it doesn't mean it is true. (Bowers gave an example of his dream that Israel and Venezuela shared a common border, which was rectified by his waking awareness of the Atlantic Ocean and the Mediterranean. He noted that nothing like the Atlantic can be called upon if the dream is that one's parent molested oneself at the age of six.)

Ian Hacking, in *Rewriting the Soul*, labels a more fundamental indeterminacy (for the historical past itself). Bathing rituals in childhood can be redescribed as abuse, which determines the historical past rather than describing it. It is thus easier to justify abuse if the event is something that can be reinterpreted. For example, the conflicts of adolescents with their parents, may be reinterpreted later if personality problems continue. If in adulthood one concludes that abuse occurred, then bathing rituals can be reinterpreted as if it were earlier abuse, as if the abuse has continued for years.

#### NOTES

I have concerns about the construction of the Diagnostic and Statistical Manual (DSM) as a whole. It was initially a research document, but it has come to dominate clinical diagnostic practice, and worse, it governs what treatment third party payers will compensate.

Dissociative Identity Disorder (DID) to replace Multiple Personality Disorder (MPD) may well change the way the condition is viewed, and we may see fewer alters in each person.

I have difficulty understanding the precise nature of dissociation--especially with its powers to produce amnesia. The dissociative disorders are part of the legacy of hysteria; though some parts of hysteria are represented in other DSM categories. The influence of environmental factors and imagination were suspected when the diagnosis was hysteria; everyone knew the picture was complicated, and subject to contagion, etc. The DSM makes little attempt to take that into account in the section on Dissociative Disorder.

Questions we must address: 1. How voluntary is clinical dissociation? To what extent can we expect the patient to claim agency for it, e.g. if it is claimed that a crime was committed by an alter? 2. To what extent does the clinical manifestation

of dissociation overlap with absorption and attention? 3. How does morbid preoccupation with images differ from regression? How much is the patient the willing agent of that kind of behavior? 4. To what extent are flashbacks remembering or imaginings? 5. How do we control for contagion or imitation on the dissociative disorder inpatient units? 6. Could we be creating things to fit our theories? 7. Are other diagnoses being displaced here? The dissociative disorders being put on center stage may lead us to do disservice to the patient in dealing with their other life crisis. 8. If the shock of the trauma is associated with impaired perception, altered attention, and memory problems, how dependable are the reports that are ultimately retrieved--perhaps decades later? 9. What do we in truth understand by the word dissociation? Is it a psychological event with underlying physiology, or just a metaphor?

Psychiatry is subject to diseases rising and falling, e.g. the disappearance of hysteria itself.

Vijselaar Joost; Van der Hart, Onno (1992). The first report of hypnotic treatment of traumatic grief: A brief communication. International Journal of Clinical and Experimental Hypnosis, 40 (1), 1-6.

In 1813 the Dutch physicians Wolthers, Hendriksz, De Waal, and Bakker reported the hypnotic treatment of a woman suffering from traumatic grief, in which the therapist had to deal directly with the patient's spontaneous reenactments of the circumstances surrounding the death. This report, summarized in the present article, has historical value, as it is probably the first known precursor of the uncovering hypnotic approach. The original authors' views on the case are discussed, and a modern view for understanding the patient's traumatic grief and its treatment is presented.

Cardena, Etzel; Spiegel, David (1991, August). Dissociative reactions following the Bay Area earthquake. [Paper] Presented at the annual meeting of the American Psychological Association, San Francisco.

This study systematically evaluates the psychological reactions of a non-clinical population to the October 1989 Bay Area earthquake. Within a week of the earthquake we administered a checklist of anxiety and dissociative symptoms and conducted a follow-up study four months afterwards. In both instances, a representative sample of close to 100 graduate students from two different institutions in the Bay Area volunteered to participate in the study. Analyses of variance for time of testing show that during or shortly after the earthquake respondents experienced significantly greater number and frequency of time distortions, alterations in cognition, memory and somatic sensation, derealization, depersonalization and, to a lesser degree, anxiety symptoms and Schneiderian first-

rank symptoms. These results suggest that among non-clinical populations extreme distress significantly increases the prevalence not only of anxiety but of transient dissociative phenomena as well, a fact of considerable clinical and theoretical import particularly considering the lifetime prevalence of traumatic experiences among the general population. Ross, Colin A.; Fast, E.; Anderson, G.; Auty, A.; Todd, J. (1990). Somatic symptoms in multiple sclerosis and MPD. Dissociation, 3, 102-106.

Fifty subjects with multiple sclerosis (MS) were compared to 50 subjects with multiple personality disorder (MPD). MS patients endorsed an average of 3.0 somatic symptoms on structured interview, and MPD subjects an average of 14.5. Somatic symptoms characteristic of neurological illness were trouble walking, paralysis, and muscle weakness, while those characteristic of psychiatric illness were genitourinary and gastrointestinal symptoms.

Bryant, Richard A.; McConkey, Kevin M. (1989). Hypnotic blindness: A behavioral and experiential analysis. Journal of Abnormal Psychology, 98, 71-77.

**NOTES**

This research examined the influence of visual information on a decision task that subjects were administered during hypnotically suggested blindness. Real, hypnotizable subjects and simulating, unhypnotizable subjects were tested in two experiments. Experiment 1 focused on behavioral responses, and Exper. 2 focused on experiential reactions. In both experiments, the findings indicated that the behavioral responses of reals were influenced by visual info. despite their reported blindness. The behavioral responses of reals and simulators were essentially similar. The experiential data in Experiment 2 provided information about the phenomenal nature of subjects' reported blindness. The experiential reactions of reals and simulators were essentially different. The research is discussed in terms of the issues that need to be considered in the development of a model of hypnotic blindness" (p. 71).

Examined the influence of visual information on a decision task that was administered to an individual with monocular visual conversion disorder. Findings indicated that his performance was influenced by the visual information and by motivation instructions. The findings are discussed in terms of a model of hysterical

blindness that recognizes the interplay of cognitive and motivational processes" (p. 326).

Ross, Colin A.; Heber, S.; Norton, G. R.; Anderson, D.; Anderson, G.; Barchet, P. (1989). The Dissociative Disorders Interview Schedule: A structured interview. Dissociation, 2, 169-189.

The Dissociative Disorders Interview Schedule (DDIS), a structured interview, has been developed to make DSM-III diagnoses of the dissociative disorders, somatization disorder, major depressive episode, and borderline personality disorder. Additional items provide information about substance abuse, childhood physical and sexual abuse, and secondary features of multiple personality disorder. These items provide information useful in the differential diagnosis of dissociative disorders. The DDIS is published in this article. It has an overall interrater reliability of 0.68. For the Diagnosis of MPD it has a specificity and a sensitivity of 90%.

Wickramasekera, Ian (1989). Enabling the somatizing patient to exit the somatic closet: A high-risk model. Psychotherapy: Theory, Research and Practice, 26 (4), 530-544.

Problems in establishing a therapeutic alliance make somatizing patients poor candidates for psychotherapy. A logical analysis is presented of the conspiracy of silence between the somatizing patient, the medical doctor, and the health insurance industry regarding the psychosocial factors contributing to somatization. Alternatives are sought to repeated biomedical tests and therapies that are clinically unproductive and iatrogenic. Two psychophysiological pathways are proposed that are promising to reduce the distance between the medical doctors' and the psychologists' procedures. The new profile of illness has produced a paradigm shift with implications for an expansion of the definition of the word "physician".

1988

Pettinati, Helen M. (1988). Hypnosis and memory. New York and London: Guilford Press.

NOTES

From a review in British Journal of Experimental and Clinical Hypnosis, 7, 175-178, by Vernon H. Gregg]:

Book has 5 sections: 1. method, theory 2. mechanisms of memory enhancement 3. hypnotic and other forms of reversible amnesia 4. clinical uses of hypnosis for increasing accessibility of memories and fantasies 5. Summary

The chapter by Martin Orne et al presents a comprehensive review. Perry, Lawrence, d'Eon and Tallant contribute a lively assessment of age regression procedures in the elicitation of inaccessible memories. They provide a description of procedures, a brief historical review, and discuss problems of confabulation and creation of pseudomemories. Their account is illustrated by clinical and forensic

examples and gives an interesting account of belief in reincarnation in terms of source amnesia.

Section 3 has Hollander's chapter on hysteria and memory, which illustrates the concept of reversibility of amnesia with two types of hysterical conditions: one of these types, the dissociative disorders, has the potential for amnesia to be reversed but the other, histrionic personality disorders, is characterized by no reversibility. In the section on clinical studies of memory enhancement Frankel and Kolb both accept that uncovering repressed memories and fantasies is therapeutically beneficial and that the faithfulness of recovered memories is often not important for therapeutic success. Frankel illustrates the usefulness of hypnosis with several case studies. But he thinks that clinical issues are dealt with too briefly in this book. In her summary chapter Pettinati points to the dearth of systematic research into the effectiveness of hypnosis in clinical settings.

**1985**

**Bliss, Eugene L.; Larson, Esther M. (1985). Sexual criminality and hypnotizability. Journal of Nervous and Mental Disease, 173, 522-526.**

Investigated 33 17-35 yr old sexual offenders, 18 of whom had been convicted of rape, 9 of pedophilia, and 6 of incest. Ss completed a questionnaire containing a list of 15 factors that might have contributed to their crime, a self-report containing 305 items that are symptoms characteristic of 11 major psychiatric syndromes, and the Stanford Hypnotic Susceptibility Scale. Controls for the self-report were 48 individuals taken from a church group, nurses, technicians, and graduate students. Controls for the hypnotizability scale were cigarette smokers who smoked 1 1/2 pack/day and S data taken from the literature. Results show that two-thirds of the Ss had histories of spontaneous self-hypnotic experiences (dissociations); 7 of these were DSM-III multiples and 6 were probable multiples. This group had very high hypnotizability scores. The other one-third without histories of spontaneous self-hypnosis had normal scores. It is concluded that spontaneous self-hypnosis contributed to the perpetration of the crimes in many of these cases, although other factors also directed the antisocial behaviors. (22 ref).

**Hoffman, William (1985). Hypnosis as a diagnostic tool. American Journal of Psychiatry, 142 (2), 272-273.**

Discusses the case of a 22-yr-old Swedish female who became withdrawn and depressed and developed suicidal ideation and paranoid and grandiose delusions. S was also disoriented to time and place and displayed poor memory, insight, and judgment. After a diagnosis of brief reactive psychosis, S was placed on a regimen of oral haloperidol (2 mg, 4 times/day), but she remained confused and disoriented. After induction into a trance state, S coherently recollected the events leading to hospitalization, after which medication was discontinued. It is suggested that trance induction be attempted before treatment in individuals with symptoms of hysterical psychosis.

Steingard, Sandra; Frankel, Fred H. (1985). Dissociation and psychotic symptoms. American Journal of Psychiatry, 142 (8), 953-5.

The literature on hysterical or brief reactive psychosis reflects great diversity both in clinical description and theoretical formulation. The authors describe the case of a 17-year-old girl who presented with a diagnosis of bipolar affective disorder, rapid cycling type, but who, in fact, was experiencing dissociative episodes manifested as psychotic states. The patient's successful treatment with hypnosis is described, along with the clinical and theoretical implications of the case.

Bliss, Eugene L. (1984). Hysteria and hypnosis. Journal of Nervous and Mental Disease, 172 (4), 203-206.

Studied 33 female patients with Briquet's syndrome to investigate the possibility that severe hysteria might be a spontaneous self-hypnotic disorder. Excellent hypnotic Ss were defined clinically as those who entered a trance rapidly, experienced lid closure and arm and elbow elevation, perceived hypnotic events with realism, could regress to early experiences, and usually had amnesic capabilities. Ss were administered the Stanford Hypnotic Susceptibility Scale, Form C. 17 of the 33 Ss were clinically tested for hypnotizability. 14 were found to be excellent hypnotic Ss, 2 were found to be good, and 1 was found to be a poor hypnotic S. 14 of the 33 Ss met the DSM-III criteria for multiple personalities. It is concluded that patients suffering from Briquet's syndrome are usually good or excellent hypnotic Ss with few exceptions, and many have multiple personalities. Evidence is also discussed that patients with major conversion symptoms are excellent hypnotic Ss. (39 ref).

Jensen, Peter S. (1984). Case report of conversion catatonia: Indication for hypnosis. American Journal of Psychotherapy, 38 (4), 566-570.

Describes the successful hypnotic treatment of a 25-yr-old Black male who displayed symptoms of suicidal ideation, insomnia, and feelings of depression alternating with emptiness and boredom that led to an acute catatonic reaction. S met DSM-III criteria for borderline personality disorder. It is contended that since conversion mechanisms may underlie some presentations of catatonia, hypnosis may assist clinicians in the differential diagnosis of acute catatonic conditions.

Suryani, L. K. (1984). Culture and mental disorder: The case of bebainan in Bali. In Culture, medicine and psychiatry. D. Reidel Publishing Company

#### NOTES

Bebainan is a form of dissociation which is culturally associated with Bali. Thought to be caused by sorcery, a bebainan attack lasts up to an hour and is manifested by confusion, crying, screaming, and shouting, with inability to control one's actions.

However, it seems most victims maintain awareness of their own behavior and are not amnesic for it afterwards.

In this study, the author interviewed 27 people, mostly female, most of whom experienced their first attack between 16-30 years of age. The author concluded that the attacks permitted release of feelings of frustration and anger without stigma. Author concluded it is not a form of psychosis, is not organic, and is not a neurosis.

Wilson, Ian (1984). Jesus--The evidence. London England: Weidenfeld and Nicolson.

#### NOTES

Miracles of Jesus are attributed to hypnosis, in a culture that had already experienced faith healers. Many of those healed had diseases that today might fall into the 'hysteria' or 'psychosomatic' categories (paralysis, lameness, fever, catalepsy, haemorrhage, skin disease, mental disorder), which diseases are frequently responsive to hypnosis. Further, Jesus' reputation preceded him, and the fact that his cure rate was low in his home town is evidence of both the veridicality of the written record (Mark 6: 1-6) and the expectancy factor. "The significance of this episode is that Jesus failed precisely where as a hypnotist we would most expect him to fail, among those who knew him best, those who had seen him grow up as an ordinary child. Largely responsible for any hypnotist's success are the awe and mystery with which he surrounds himself, and these essential factors would have been entirely lacking in Jesus' home town" (pp. 111-112). The author also assigns other miracles (his transfiguration into dazzling light before three disciples; turning water into wine) to hypnosis [which other writers might ascribe to suggestion].

1979

Spanos, Nicholas P.; Gottlieb, Jack (1979). Demonic possession, Mesmerism, and hysteria: A social psychological perspective on their historical interrelations. Journal of Abnormal Psychology, 88 (5), 527-546.

Provides a social psychological interpretation of the interrelations among demonic possession, mesmerism, and hysteria. It is argued that the reciprocal role relationship of mesmerist and magnetized S in the 18th and 19th centuries involved the secularization of the role relation that had existed between exorcist and demonically possessed. The commonalities between these 2 sets of social roles are delineated, some of the variables leading an individual to learn and enact the possessed role are outlined, and several lines of historical evidence pertaining to the influence of the exorcist-demoniac relationship on the mesmeric relationship are outlined. The influence of the possessed role in shaping the role of the hysterical patient is also discussed. The use of hysteria as a modern explanatory concept in histories of possession and mesmerism, however, is criticized. (198 ref).

1978

Nichols, Michael P.; Bierenbaum, Howard (1978). Success of cathartic therapy as a function of patient variables. Journal of Clinical Psychology, 34 (3), 726-8.

Treated sample of 42 patients with cathartic psychotherapy and evaluated differential effectiveness on types of patients. Patients without mental disorders experienced more emotional catharsis than all others, and those with obsessive compulsive personality disorders improved more than all others as a result of emotive treatment. Contrary to popular notions, neither women nor hysterics experienced more catharsis or improved more in cathartic therapy. Although women and hysterics may cry more easily in daily life, obsessives are apparently more able to maintain focus on unhappy experiences and are therefore able to express more emotion in cathartic therapy. Furthermore, it seems that cathartic treatment is beneficial by disrupting long-standing defenses against emotional experience, rather than by releasing stored-up affects.

1972

Cedercreutz, C. (1972). The big mistakes: A note. International Journal of Clinical and Experimental Hypnosis, 20, 15-16.

In his book, *A System of Medical Hypnosis*, Ainslie Meares writes, "Most books on hypnosis, from Bernheim to the present time, devote a great deal of space to the description of successful and dramatic cures. These accounts may be of prestige value to the author, and may do something to inform the profession of the potential value of hypnosis in medicine, but these success stories are really of little help to those who would learn the technique of hypnotherapy because the emphasis is always on the success of the treatment rather than on analysis of the psychodynamic mechanisms which brought it about. As in everything else, we learn most from a study of our failures [p. 3]." These comments remain as true today as they were ten years ago. With the notable exception of Meares, few colleagues have been willing to share their errors, allowing us to profit from their experience. Thus, when Dr. Cedercreutz sent along a note describing his experience with one of his patients, I was struck by his generosity, and it seemed most appropriate for all of us to share his experience by way of the Journal. Hopefully, this may encourage other colleagues to share their failures as well as their successes so that all of us may learn to be more effective therapists and better scientists. M.T.O. [Martin Orne]

#### NOTES

The case reported involves a patient who had migraine headache removed with hypnosis, but later developed gastrointestinal symptoms that were operated surgically with absence of positive (physical) pathology noted. Subsequent investigation of the psychological component of the problem with hypnosis revealed an early trauma (seeing a soldier killed with a bayonette) that led to migraine-like pain in the head and vomiting.

Arluck, Edward Wiltcher (1964). Hypnoanalysis, a case study. New York: Random House.

## NOTES

Details transcripts (90 pages) and comments of a 28 session hypnoanalysis (Jungian) of a World War II soldier with traumatic war neurosis in a military setting shortly after the end of the war, for a conversion reaction with onset just prior to return to the States. Author cautions he found this amount of success in only about 15 of more than 70 individually treated cases. Emphasizes giving suggestions to dream about his condition/problem and utilizing dream interpretation. 53 references.

1964

Moskowitz, Arnold E. (1964). A clinical and experimental approach to the evaluation and treatment of a conversion reaction with hypnosis. International Journal of Clinical and Experimental Hypnosis, 12 (4), 218-227.

A combination of hypnotherapeutic techniques within a clinical and experimental context provided a method of understanding, evaluating, and predicting the course of a conversion reaction. During waking and hypnotic conditions, 5 trials of dynamometer presses were obtained from a patient having primary symptoms of paralysis of his left arm. Difference scores between the left and right hands during waking and hypnotic conditions were evaluated. Findings were: (a) At the beginning of treatment, significant differences were found between the waking and hypnotic conditions (b) The largest differences between the waking and hypnotic conditions occurred during the early stages of treatment, while the smallest differences occurred on the final day of treatment. (c) With a complete remission of the patient's symptoms, no significant differences between the waking and hypnotic conditions were found. 1963

Slater, Roger C.; Flores, Louis S. (1963). Hypnosis in organic symptom removal: A temporary removal of an organic paralysis by hypnosis. American Journal of Clinical Hypnosis, 5 (4), 248-255.

## NOTES

Summary and Conclusions. A detailed case study is reported on the use of hypnosis with beneficial results in an instance of eventually proved organic brain disease. Three other confirmatory case reports of organic disease definitely benefitted by the use of hypnosis are briefly cited.

" The first patient had been adequately studied repeatedly for organic brain disease. Because the studies led to an uncertain indefinite unconfirmed suspicion of psychogenic epilepsy, the patient was returned with a recommendation for continued treatment and observation by the author, a general practitioner. Hence, she was, after still further study for organic disease, treated symptomatically by hypnosis with beneficial results. This led to the erroneous conclusion that the patient's disability was probably functional. A sudden fatal outcome of the actual but unrecognized brain disease led to a correct but post- mortem diagnosis of astrocytoma of the brain, Grade IV.

**"This report and those given to supplement it raise significant questions about the importance and value of hypnosis in organic disease. These include the challenging question of the extent to which the use of hypnosis can potentiate the natural corrective forces of the body; the need to recognize the value of hypnosis in effecting beneficial results in organic disease; the need to qualify the reliability of hypnosis as a differential diagnostic procedure in relation to psychogenic and organic disability; and the possibility and extent of the amelioration or actual correction of known organic illness" (p. 254).**

**Levendula, Dezso (1961). Two case presentations: Treatment of central pain with reconstruction of the body-image -- hypnoanalysis of a travel phobia. International Journal of Clinical and Experimental Hypnosis, 9, 283-289.**

#### **NOTES**

**Uses analogy of phantom limb (hallucinated pain which is a central pain) with a multiple sclerosis patient who had "excruciating" pain between her thighs despite paralysis from waist down due to multiple sclerosis. She valued her sex life though she couldn't feel sexual response, and felt that she "didn't have any legs" and her husband "had to carry her."**

**In giving her history the patient noted an increasing numbness and weakness in her legs five years earlier. At that time she also entered menopause and developed severe vaginitis. She became depressed when she became increasingly unable control her excretory functions. As the pain in the genital region increased, her ability to feel pleasant vaginal sensations diminished. Ultimately the pain was continually present.**

**The therapist attributed her problem to a faulty body image because she "denied the existence of her legs which were actually physically present, although, she could neither feel, nor see, nor move them" (p. 285). Secondly, it was most necessary for her to hold on to the myth [sic], that her vagina existed, because it made her feel wanted and needed by her husband. She was unconsciously afraid that by giving up her vagina she would lose the most important bond between herself and her husband" (p. 285).**

The therapist speculated that "the pain, which was the last sensation perceived before the total sensory loss occurred, was fixated centrally. This "pain-image" served to maintain the pretense, unconsciously of course, that there was still feeling in the vagina even though it was only pain and not pleasure. The pain permitted her to avoid facing reality, just as in the case of an amputee who develops the fantasy of a phantom limb, because he cannot readjust his pre-existing body-image to the acceptance of mutilation" (p. 285). He offered the patient "the rather simple explanation... that because she really did not feel where her lower body ended or began, the pain served her need to know where the body halves were separated. If she could learn to imagine and to accept herself as a full, whole person, the pain probably would leave her. This theory seemed very logical and acceptable to the patient" (p. 285).

"Hypnosis was extensively utilized in the following sessions to regress the patient toward her youth. She went again for long walks with her boyfriend, now her husband. It was fun to re-experience the feeling of walking in her father's apple orchard and stretch up for a red apple. Autohypnosis was taught and [he] told her to exercise "walking" while hypnotized twice daily" (p. 285-286). He also tapped on the soles of her feet repeatedly, until she could localize the vibrations. "She finally learned that she did have legs and also that other sensations besides pain could originate below the waist.... Gradually with the acceptance of her "wholeness and tallness" the pain became less and less. She was able to "forget" the pain for a longer period of time. ... Occasionally she does call. She tells [the therapist] that in a stressful situation, such as moving into a new house and not knowing where things are, the pain comes back temporarily, but it is much less and after [they] talk an hour she is relieved" (p. 287). The patient had a total of 20 visits.

The author describes a second case, which is not described in these notes.

1959

Hodge, James R. (1959). The management of dissociative reactions with hypnosis. International Journal of Clinical and Experimental Hypnosis, 7 (4), 217-221. (Abstracted in Psychological Abstracts 61:920)

A case report is given of an unusual type of dissociative reaction, and treatment by a variety of hypnotic techniques is described. A distinction is made between the emergency and long term aspects of treatment by hypnosis, and emphasis is laid upon understanding the symptom and avoiding a too rapid challenge of the symptom. Special mention is made of the technique of predicting the future of the symptom" (p. 221).

"The patient was a 19 year old white Marine who became subject to hysterical seizures in which he acted the part of his own dog which had died several years before. The attacks occurred at irregular intervals; but when the patient was first seen they were occurring about twice weekly. During these seizures, which came on without warning, the patient would get down on all fours, bark and growl like a dog, attack ward personnel, paw at the floor, and respond to simple commands like those given to a dog such as 'Down, boy' or 'Play dead'. He would become motorically hyperactive and sometimes pound his head against the floor or walls. The really

dangerous act which he performed, however, was to attempt to gouge out his own eyes with his hands; and for this reason cuff restraints had to be applied during each attack. There were no methods, until hypnosis was tried, which could control or terminate these attacks, which usually lasted from 30 to 60 minutes" (p. 217).

**Platonov, K. I. (1959). The word as a physiological and therapeutic factor: The theory and practice of psychotherapy according to I. P. Pavlov. ( 2nd). Moscow: Foreign Languages Publishing House.**

## **NOTES**

**On pp. 75-76 the author discusses conditioning in hypnosis. Most of the theoretical material is in the first part of the book; the rest consists of case studies. He presents the position that the activity of the cortex and subcortex are different during states of waking and suggested sleep.**

**Note: Much of the Russian research done during "suggested sleep" involves subjects who are hypnotized for a long period of time--sometimes hours. Routinely, in treatment, they would give corrective suggestions and then tell the person to "sleep" and would leave them in the "sleep" for an hour or longer.**

**"Thus, it appears from the foregoing that the basic peculiarities of the activity of the cerebral cortex manifesting themselves in the state of suggested sleep are as follows: 1. In addition to the division of the cerebral hemispheres into sections of sleep and wakefulness typical of the hypnotic sleep of an animal, there is also a functional dissociation of the two signal systems and within the second signal system. 2. The activity of the second signal system under these conditions is not only confined to the narrow framework of the rapport zone, but is also frequently of a passive nature being directly dependent on the verbal influences of the hypnotist. Outside these influences there is no (or hardly any) activity. 3. A considerable increase in the coupling function with respect to the stimuli of the second signal system is noted at the same time in the rapport zone. This especially favours the formation of new cortical dynamic structures under the verbal influences of the hypnotist, these structures representing the physiological basis for effectuating the suggested actions and states.**

**"The foregoing peculiarities manifest themselves in the fact that the entire external second signal activity of the subject is reduced only to direct answers to the questions of the hypnotist with no independent reactions to any influences, including verbal, coming from other people (so-called isolated rapport). This is understandable, since the activity of the second signal system lying outside the rapport zone is inhibited" (pp. 73-74).**

**"As to the problem of the peculiarities of the conditioned reflex activity during suggested sleep, it will be noted that this problem has not been very extensively studied as yet. Nevertheless, the data of various authors are of indubitable interest, since they have revealed a number of specific peculiarities in the state of the higher nervous activity under these conditions.**

**"According to these data the conditioned reflex activity in suggested sleep undergoes certain changes. Thus, S. Levin observed in his early studies (1931) that**

in children under conditions of suggested sleep the motor and secretory conditioned reflexes elaborated earlier in the waking state grew very much weaker and that there was a dissociation both between the motor and secretory conditioned reflexes and between the unconditioned reflexes of salivation and mastication; he also observed the transitional (phasic) states--paradoxical, ultraparadoxical and inhibitory phases, all the way to the onset of complete sleep" (pp. 74-75).

Platonov indicates that conditioned reflexes may disappear during suggested sleep (Povorinsky & Traugott, 1936). Arousal from suggested sleep results in gradual restoration of the reflexes, with speech reactions inhibited first and restored last. Pen & Jigarov (1936) also showed that there is a weakening of conditioned reflexes, with increased latency, in suggested sleep. These authors showed that it is impossible to form new conditioned reflexes in deep states of suggested sleep, and the conditioning is difficult in lighter states.

"Y. Povorinsky's data (1937) indicate that the conditioned reflexes elaborated in the waking state have a longer latent period during suggested sleep and in some subjects they are completely absent. Under these circumstances, the reactions to the verbal influences of the hypnotist are retained even during the deepest suggested sleep. The more complex and ontogenetically later conditioned bonds of the speech-motor analyzer are inhibited first as the subject lapses into a state of suggested sleep and are disinhibited the last as the subject awakens from this state" (p. 75).

"B. Pavlov and Y. Povorinsky observe (1953) that the conditioned bonds reinforced by the words of the hypnotist are formed during suggested sleep faster than in the waking state. In this case, during the somnambulistic phase of suggested sleep verbal reinforcements, as a rule, provoke a stronger and longer reaction with a shorter latent period than a direct first signal stimulus" (p. 76). The conditioning that occurs during suggested sleep does not manifest during waking periods unless suggestions are given during the sleep to react after awakening. The author takes this to be evidence that conditioned reflex activity can be modified by verbal suggestions. During the somnambulistic stage of suggested sleep, subjects are less adept at performing addition. This indicates that inhibition has spread to the second signal system. However, inhibition of different sensory systems seems to vary from person to person. Krasnogorsky (1951) reported one subject did not react to light, but hearing seemed to be more sensitive than in the waking state.

"All of the above testifies to the considerable changes in the character of cortical activity regularly occurring during suggested sleep and determining, on the whole, the specific nature of higher nervous activity, the systematic study of which should be the object of further research" (p. 77).

1957

Schneck, Jerome M. (1957). An unusual conversion reaction during the induction of hypnosis. Journal of Clinical and Experimental Hypnosis, 5 (1), 39-40. (Abstracted in Psychological Abstracts 58: 1711)

NOTES

"A 27-63a4-old patient in psychiatric hypnotherapy had effectively entered a hypnotic state on initial induction with a two-stage hand levitation technique (2). At

her second induction she started to enter a hypnotic state, yet her eyes did not close. She attempted voluntary closure unsuccessfully and then extricated herself from the procedure" (p. 39). The author opined that the interpersonal relationship of hypnosis was in this case affected by concerns about seeing or observing, or about being observed. He cites another case reported in the literature.

Schneck, Jerome M. (1957). Hypnoanalytic observations on the psychopathology of fainting. Journal of Clinical and Experimental Hypnosis, 5 (4), 167-171. (Abstracted in Psychological Abstracts 62: 3 II 67S)

## NOTES

### Summary

Varieties of fainting have been described as hysterical syncope, vasodepressor syncope, and carotid sinus reactions, among others. Fainting has been linked in general with personality problems, emotional instability, and immaturity. It has been called a mechanism for blocking of ego functions in its role of primitive defense against overwhelming stimuli. The present paper gives in greater detail the specific dynamics in a patient with fainting episodes. A crucial event incorporating major dynamic ingredients was an operative procedure in childhood. The psychological impact of this trauma was revived during a spontaneous hypnotic regression. The personality matrix significant for this patient in relation to the fainting episodes consisted of passive, masochistic submission to a dominant, highly influential mother whose pressure was felt by the patient as pervasive and stifling. Circumstances associated psychologically with this feeling apparently triggered the fainting reactions. As he matured through the years and cast off increasingly this type of maternal influence, the tendency toward fainting reactions diminished" (p. 170).

Erickson, Milton H. (1954). Special techniques of brief hypnotherapy. Journal of Clinical and Experimental Hypnosis, 2, 109-129. (Abstracted in Psychological Abstracts 55: 2508)

## NOTES

Author describes techniques used with patients who aren't able, for internal or environmental reasons, to undertake comprehensive therapy, "Intentionally utilizing neurotic symptomatology to meet the unique needs of the patient" (p. 109). He provides 8 case reports.

Patient 1 was reassured, in hypnosis, that his arm paralysis was due to "inertia syndrome" which he would continue to have, but it wouldn't interfere with his work.

Patient 2, also with arm paralysis had another comparable, non-incapacitating, symptom substituted.

Patients 3 and 4, for whom restrictions on therapy were the limits of time and situational realities, had their symptoms transformed (e.g. by introducing in hypnosis the obsessional thought or worry that he would NOT have the symptom for which he sought help).

Patients 5 and 6 were helped, through hypnosis, to symptom amelioration. (Patient 5 had an IQ of 65.)

Patient 7 "Therapy was achieved ... by a deliberate correction of immediate emotional responses without rejecting them and the utilization of time to palliate and to force a correction of the problem by the intensity of the emotional reaction to its definition" (p. 121)

Patient 8 "the procedure was the deliberate development, at a near conscious level, of an immediately stronger emotion in a situation compelling an emotional response corrective, in turn, upon the actual problem" (p. 121).

1954

Malmö, Robert B.; Boag, Thomas J.; Raginsky, Bernard B. (1954). Electromyographic study of hypnotic deafness. Journal of Clinical and Experimental Hypnosis, 2 (4), 305-317.

#### Summary and Conclusions.

The main purpose of the present study was to investigate the question of similarities and differences between hysterical deafness, previously studied, and hypnotically induced deafness. The study was designed to repeat the objective physiological tests previously carried out with a case of 'total hysterical deafness.' There was also the more general aim of securing objective data to enrich our general understanding of hypnosis.

"Similarities between hysteria and hypnosis which we observed may be listed as follows: (a) Significantly reduced motor reaction (exclusive of blink) to strong auditory stimulation in the deaf state. (b) Complete hearing loss in the hysteric and in one of the hypnotic subjects, even with strong auditory stimulation (i.e., denial of any auditory sensation). (c) With elicitation of strong startle reaction to the first stimulus in the deaf state, much smaller reaction to the next stimulus than would have been predicted on the basis of habituation. (d) Suggestion of substitution of somesthetic for auditory sensations in all subjects (although this was much less definite in the hypnotic subjects than the hysteric).

"The most outstanding dissimilarity lay in the absence of emotional reaction when 'hypnotic defense against sound' was broken through, in contrast to marked affective reaction in the hysterical subject under these conditions.

"The question of inhibitory mechanisms in hysteria and hypnosis was discussed" (pp. 316-317).

## COPING

2001

Yapko, Michael (2001). Treating depression with hypnosis: Integrating cognitive-behavioral and strategic approaches. New York NY: Brunner-Routledge.

#### NOTES

(From the cover) Focuses on structuring and delivering of hypnotic interventions

for major depression, with a substantial use of concepts and techniques from cognitive-behavioral and strategic approaches as a foundation. Current research on depression is used to emphasize the still growing knowledge of depression. Hypnosis has shown itself to be effective in not only reducing symptoms, but in teaching the skills (such as rational thinking, effective problem-solving and coping strategies, and positive relationship skills) that can prevent recurrences. (PsycINFO Database Record (c) 2002 APA, all rights reserved).

Received the Arthur Shapiro Award for best book published in 2001, from the Society for Clinical and Experimental Hypnosis.

**2000**

Eimer, Bruce. N. (2000). Clinical applications of hypnosis for brief and efficient pain management psychotherapy. American Journal of Clinical Hypnosis, 43 (1), 17-40. (July)

This paper describes four specific clinical applications of hypnosis that can make psychotherapy for pain management briefer, more goal-oriented, and more efficient: (1) the assessment of hypnotizability; (2) the induction of hypnotic analgesia and development of individualized pain coping strategies; (3) direct suggestion, cognitive reframing, hypnotic metaphors, and pain relief imagery; and (4) brief psychodynamic reprocessing during the trance state of emotional factors in the patient's experience of chronic pain. Important theoretical and clinical issues regarding the relationship between hypnotizability to the induction of hypnotic analgesia are presented, and attempts to individualize pain treatment strategies on the basis of assessed differences in hypnotizability and patients' preferred coping strategies are described. Some ways are also presented of integrating direct hypnotic suggestion, COGNITIVE-EVALUATIVE reframing, hypnotic metaphors, and imagery for alleviating the SENSORY and AFFECTIVE-MOTIVATIONAL components of pain, with an exploratory, insight-oriented, and brief psychodynamic reprocessing approach during trance for resolving unconscious sources of resistance to treatment, and reducing the emotional overlay associated with chronic pain. Some basic assumptions underlying the use of this approach are discussed, and a brief step-by-step protocol is outlined.

Capafons, A. (1999). Applications of emotional self-regulation therapy. In Kirsch, I.; Capafons, A.; Cardega, E.; Amigs, S. (Ed.), Clinical hypnosis and self-regulation: Cognitive-behavioral perspectives (pp. 331-349). Washington, D.C.: American Psychological Association.

This chapter reviews the main applications of emotional self-regulation therapy, which have received empirical support: smoking reduction, obesity, fear of flying, drug addictions, and premenstrual distress and dysmenorrhea. The logic of each treatment and main empirical results are summarized.

**1998**

Alden, Phyllis; Heap, Michael (1998). Hypnotic pain control: Some theoretical and practical issues. International Journal of Clinical and Experimental Hypnosis, 46 (1), 62-76.

Pain management programs assist patients to use their behavioral and cognitive skills for the purpose of rendering their experience of pain as more tolerable in some way. Hypnotic procedures may be included in this perspective. Thus, hypnosis may be best conceived as a set of skills to be deployed by the individual rather than as a state. The authors contend that such an emphasis is more compatible with the approaches of some pain management practitioners who have been generally slow to acknowledge the value of hypnosis and to incorporate hypnosis in their range of treatment skills. In this article, the authors present a minimal and atheoretical definition of hypnosis, and they list the basic properties of hypnosis that may be used in the treatment of pain. For a number of reasons, it is suggested that undertaking hypnosis as though the individual were indeed being placed into a special trance state may in some cases promote an effective outcome. However, it should be acknowledged that there may be instances when the relevant skills may be more effectively engaged at the expense of a strict special trance state by targeting the specific skills that are to be used for therapeutic benefit.

Barber, Joseph (1998). The mysterious persistence of hypnotic analgesia. International Journal of Clinical and Experimental Hypnosis, 46 (1), 28-43.

Hypnotic treatment of pain has a long history and, among hypnotic phenomena, pain relief is a relatively commonplace focus for intervention, yet we lack a conceptual explanation for this treatment. Hilgard's neodissociation theory accounts for the phenomenon of acute hypnotic analgesia, but not of persistent pain relief. Perhaps the enduring effect of hypnotic treatment can be explained at either of two levels: a neurophysiological model or a learning model. This explanation leads to the further question: How does hypnotic treatment of recurring pain achieve enduring relief? Clinical experience suggests a two-component model. First, the clinician communicates specific ideas that strengthen the patient's ability to derive therapeutic support and to develop a sense of openness to the unexplored possibilities for pain relief within the security of a nurturing therapeutic relationship. Second, the clinician employs posthypnotic suggestions that capitalize on the patient's particular pain experiences, which simultaneously ameliorate the pain experience, and which, in small, repetitive increments, tend to maintain persistent pain relief over increasing periods of time.

#### NOTES

Author's Summary: "When a patient who suffers from recurring pain is treated with hypnotic methods and then reports substantial relief over time, what is significant is that the relief is so long-lasting, and that it endures through the patient's various daily activities. Although I believe that the initial alteration of consciousness via the hypnotic experience greatly facilitates subsequent analgesia, it is not necessary to believe, nor is it even plausible, that subsequent analgesia is

accomplished through re-creation of the hypnotic condition. Rather, it appears that the patient is able to generalize from these initial experiences to achieve this analgesia independent of a hypnotic intervention.

"Laboratory research and clinical experience suggest that the persistence of hypnotic analgesia is a function of learning, the therapeutic relationship that fosters that learning, and the neurophysiological changes that subserve that learning. The patient's understanding of the meaning and purpose of the clinician's suggestions is a primary determiner of their efficacy" (pp. 39-40).

Capafons, A. (1998). Rapid self-hypnosis: A suggestion method for self-control. Psychotema, 10 (3), 571-581.

A structured self-hypnosis method -rapid self-hypnosis- is described. This method has been created from a cognitive-behavioral perspective, and has received empirical validation. Some clinical applications of rapid self-hypnosis are shown from a coping skills and self-control orientation. From this perspective, the use of the method in everyday activities are emphasized. Clients can use suggestions while keeping their eyes open and being active. Mention of altered states of consciousness, trance or esoteric ideas is absolutely avoided.

Easterlin, Barbara L.; Cardena, Etzel (1998-99). Cognitive and emotional differences between short- and long-term Vipassana meditators. Imagination, Cognition and Personality, 18 (1), 69-81.

This study compared perceived stress and cognitive and emotional differences between two groups of Buddhist mindfulness [Vipassana] meditators. Nineteen beginning and twenty-four advanced meditators carried electronic pagers for five days and responded to daily random signals by completing an Experience Sampling form (ESF) containing items related to the dependent variables. As compared with beginners, advanced practitioners reported greater self-awareness, positive mood, and acceptance. Greater stress lowered mood and self-acceptance in both groups, but the deleterious effect of stress on acceptance was more marked for the beginners. These findings validate in a naturalistic setting some of the effects described in traditional Buddhist texts on mindfulness.

#### NOTES

"Meditation can be defined as the deliberate deployment of mental attention to obtain a particular patterning of consciousness. The aim of such control may be the stabilization of the stream of thought, greater relaxation, the attainment of an altered state, or the development of insights into the nature of mind [12]. Mindfulness meditation has sometimes been contrasted with concentration meditation as one of two main forms of meditation practice [13, 14]. The usual distinction is that mindfulness involves opening awareness to all contents and processes of mind, whereas concentrative forms of meditation involve shutting out all stimuli extraneous to a single object of attention" (p. 70). Long-term meditators averaged 103 months and 85 days of retreat training. They did not differ from

short-term meditators on measures of absorption, neuroticism, trait anxiety, or cognitive style; however they evidenced greater self-awareness and acceptance. The short-term meditators actually had more than a year of meditation experience so that differences between groups are not likely to be due to self-selection. The authors conclude that "meditation brings about sustainable changes in people's lives, above and beyond relaxation. ... [and] that greater conscious awareness through mindfulness techniques such as Vipassana meditation, increases acceptance, positive mood, and the ability to dispassionately observe one's mental states. These results have implications for clinical issues such as pain management and psychotherapy, in which acceptance and awareness are necessary ingredients for therapeutic change" (p. 78). JH

Weisenberg, Matisyohu (1998). Cognitive aspects of pain and pain control. International Journal of Clinical and Experimental Hypnosis, 46 (1), 44-61.

The cognitive and cognitive-behavioral approaches have been shown to be very effective in controlling pain and its sequelae both in the laboratory and in the clinical setting. As used in most research and treatment, cognitive approaches are concerned with the way the person perceives, interprets, and relates to his or her pain rather than with the elimination of the pain per se. This article reviews some of the origins of cognitive theory and pain theory, as well as examples of the techniques used and the research support for the approach. Special emphasis is given to self-efficacy, perceived control, and stress inoculation therapy. There is also discussion of some of the limitations of the cognitive approach. The overall conclusion is that the cognitive approach is a powerful and effective one for pain control despite its limitations.

A case study on dysmenorrhea and premenstrual distress is presented, using emotional self-regulation therapy. Authors show a step by step approach in how to treat this kind of problem, using suggestions in an awake, alert state. Follow-up data are included.

Kessler, Rodger; Dane, Joseph R. (1996). Psychological and hypnotic preparation for anesthesia and surgery: An individual differences perspective. International Journal of Clinical and Experimental Hypnosis, 44 (3), 189-207.

Multiple reviews indicate that psychological preparation for surgery can provide psychological, physiological, and economic benefit to the patient. Research demonstrating that hypnosis adds to this benefit is both limited and encouraging. The content and status of this literature, however, are confusing, with little coherent

theoretical basis to account for the contradictions and inconsistencies across multiple studies whose methodologies often limit generalization. A model is presented regarding pertinent individual differences that include patient coping styles, prior medical experiences, and hypnotic ability, as well as differences in types of coping demanded by different surgical procedures. This model (a) helps explain some of the confusion, (b) offers a theoretical focus for patient assessment as well as development and selection of preparation strategies, and (c) clarifies future research goals.

**1994**

Wickramasekera, Ian (1994). Psychophysiological and clinical implications of the coincidence of high hypnotic ability and high neuroticism during threat perception in somatization disorders. American Journal of Clinical Hypnosis, 37, 22-33.

The electrodermal response to cognitive threat of un hypnotized female patients with somatic symptoms and high on both hypnotic ability and neuroticism (H-H) was found to be significantly higher ( $p < .01$ ) than that of a matched group of female patients moderate on hypnotic ability and low on neuroticism (M-L). On verbal report the H-H and the M-L groups did not differ, but they were significantly different on a measure of self-deception (L scale) or repression. The above findings are consistent with predictions from the High Risk Model of Threat Perception (HRMTP), which states that people in the H-H group are both chronically and acutely more reactive to threat than the people in the M-L group. This finding may have important theoretical, clinical, and financial implications for the diagnosis, therapy, and prevention of somatization disorders seen in primary medical care.

**1993**

Bruehl, Stephen; Carlson, Charles R.; McCubbin, James A. (1993). Two brief interventions for acute pain. Pain, 54, 29-36.

This study evaluated two brief (3-5 min) interventions for controlling responses to acute pain. Eighty male subjects were randomly assigned to 1 of 2 intervention groups (Positive Emotion Induction (PEI) or Brief Relaxation (BR)) or to 1 of 2 control groups (No-instruction or Social Demand). The PEI focused on re-creating a pleasant memory, while the BR procedure involved decreasing respiration rate and positioning the body in a relaxed posture. All subjects underwent a 60-sec finger pressure pain trial. Analyses indicated that the PEI subjects reported lower ratings of pain, fear, and anxiety, and experienced greater finger temperature recovery than controls. The BR procedure resulted in greater blood pressure recovery, but did not alter ratings of pain or emotion relative to controls. Further research is needed to explore the clinical use of the PEI for acute pain management.

## NOTES

Cites three reviews: Blankenfield; Rogers & Reich; and Mumford. These reviews leave us with several questions: - What does the addition of hypnosis add? - What is importance of hypnotic ability? - What techniques are most effective? - How useful are standardized tailored interventions? - What are psychological, physiological, and biochemical markers?

We lack a general theoretical framework (see H. Bennett), and there are a broad variety of pre-surgical interventions, which may influence different aspects of functioning.

Evans & Richardson found no differences between people with and without preparatory interventions. Bonke & colleagues found no differences in length of hospitalization for people with and without preparatory interventions (except for people 55 and over). Relaxation training for surgery finds mixed results.

Blankenfield obtained negative findings in cardiac surgery. His recent IJCEH article reports those negative results.

What does presurgical intervention influence? - Psychological dimensions - Biochemical & physiological dimensions - Time/cost dimensions

Correspondence across these dimensions has not been consistently demonstrated, e.g. there is a lack of correlation between cortisol (physiological dimension) and anxiety (psychological dimension).

Why are there conflicting findings? 1. Possibly patient's coping style is responded to inappropriately, e.g. people who deny vs those who sensitize seem to require different interventions. Must assess the patient's idiosyncratic coping style. 2. Four studies suggest hypnotic ability may be a factor in recovery.

a. Disbrow, Bennett, & Owings (1993)

b. Rondi et al. (high hypnotizables use less morphine via Patient Controlled Analgesia)

c. Greenleaf et al. (hypnotizability predicts recovery independently)

d. Rapkin, Straubing, & Holroyd (high hypnotizables had less blood loss during surgery) 3. Is hypnosis per se necessary?

Comparative evaluation of strategies has been ignored. Enqist found hypnosis had a greater effect than non-hypnotic treatment in blood loss. Another study of bone marrow transplant patients found the hypnosis treatment superior.

When it comes to clinical interventions, we need to assess the patient's historic and current beliefs, their experience with medical procedures, their coping style, and then form a brief tailored intervention.

Page, Roger A.; Handley, George W. (1993). The use of hypnosis in cocaine addiction. American Journal of Clinical Hypnosis, 36, 120-123.

An unusual case is presented in which hypnosis was successfully used to overcome a \$50-0 (five grams) per day cocaine addiction. The subject was a female in her twenties. Six months into her addiction, she acquired a commercial weight-control tape that she used successfully to stop smoking cigarettes (mentally substituting the word "smoking"), as well as to bring her down from her cocaine high and allow her

to fall asleep. After approximately 8 months of addiction, she decided to use the tape in an attempt to overcome the addiction itself. Over the next 4 months, she listened to the tape three times a day, mentally substituting the word "coke." At the end of this period, her addiction was broken, and she has been drug free for the past 9 years. Her withdrawal and recovery were extraordinary because hypnosis was the only intervention, and no support network of any kind was available.

Lynn, Steven Jay; Sivec, Harry (1992). The hypnotizable subject as creative problem-solving agent. In Fromm, Erika; Nash, Michael R. (Ed.), Contemporary hypnosis research (pp. 292-333). Guilford Press.

## NOTES

These notes are taken only from the section of this chapter that deals with Hypnotic Responding, Imaginative Activity, and Expectancies, and they treat of the concept of nonvoluntary responding (pp 315-316). Other topics covered in the chapter include: Imagination, Fantasy, and Hypnosis Theories; The Hypnotizable Subject as Creative Problem-Solving Agent; Hypnosis and Subjects' Capability for Imaginative Activity; Goal-Directed Fantasy: Patterns of Imaginative Activity during Hypnosis; Hypnosis and Creativity; and a Conclusion.

Several studies manipulated expectancies re the relationship between imagination and involuntariness. When Ss were told that "good" hypnotic subjects could (or could not) resist suggestions, "this information affected their ability to resist the hypnotist and tended to affect subjects' report of suggestion-related involuntariness ... [Lynn, Nash, Rhue, Frauman, & Sweeney, 1984]. Furthermore, subjects who successfully resisted suggestions and subjects who failed to do so reported comparable levels of hypnotic depth and imaginative involvement in suggestions.

"Spanos, Cobb, and Gorassini (1985) conducted a similar experiment in which they found that hypnotizable subjects who were instructed that they could become deeply involved in suggestions and yet resist them successfully resisted 95% of the suggestions and rated themselves as maintaining voluntary control over their behavior. Thus, subjects are able to resist nearly all of the suggestions when resistance is facilitated by situational demands. It is worth noting that subjects in this research who resisted hypnotic suggestions rated themselves as just as deeply involved in the suggestions as Ss who failed to resist suggestions after being informed that deeply hypnotized subjects were incapable of resisting suggestions" (pp. 315-316).

Lynn, Snodgrass, et al. (1987). showed that hypnotizable Ss who were just "imagining" along with suggestions but instructed to resist responding to motoric suggestions acted the way hypnotized Ss did in their earlier countersuggestion research: imagining subjects tended to move in response to suggestion (that "good" Ss responded in certain ways), despite being instructed to resist. In this study, with instructions designed to increase the use of goal directed fantasies (GDFs), low and high hypnotizable subjects reported equivalent GDF absorption and frequency of GDFs. However, highs responded more and reported greater involuntariness than lows, even when their GDFs were equivalent.

"A number of other studies have examined the effects of expectancies on imaginings and hypnotic behavior. Spanos, Weekes, and de Groh (1984) informed subjects that deeply hypnotized individuals could imagine an arm movement in one direction while their unconscious caused the arm to move in the opposite direction. Even though subjects so informed moved in the opposite direction, they imagined suggested effects and described their countersuggestion behavior as involuntary" (p. 317).

Wickramasekera, Ian (1992, August). Hypnotic ability as a risk factor for psychopathology and pathophysiology. [Paper] Presented at the annual meeting of the American Psychological Association, Washington, DC

Eighty-three patients with psychophysiological disorders seen prior to therapy were tested on the seven risk factors of the High Risk Model. Thirty-two percent of these patients were high on hypnotic ability, and hypnotic ability was unrelated to all of the other six risk factors. Mean social support and coping skills were significantly below the norm. Mean catastrophizing, negative affect (neuroticism), major life change and minor hassles were significantly above the norm. There are positive and significant correlations between hassles, negative affect and catastrophizing. There are also positive and significant correlations between coping skills and number and level of satisfaction with social support. There are negative and significant correlations between coping skills, catastrophizing, negative affect and hassles. There are also negative and significant correlations between satisfaction with social support, catastrophizing, and hassles. (ABSTRACT from the Bulletin of Division 30, Psychological Hypnosis, Fall, 1992, Vol. 1, No. 3.)

Burish, Thomas G.; Snyder, Susan L.; Jenkins, Richard A. (1991). Preparing patients for cancer chemotherapy: Effect of coping preparation and relaxation interventions. Journal of Consulting and Clinical Psychology, 59 (4), 518-525.

60 cancer chemotherapy patients were randomly assigned to 1 of 4 treatments: (a) relaxation training with guided relaxation imagery (RT), (b) general coping preparation package (PREP), (c) both RT and PREP, or (d) routine clinic treatment only. All patients were assessed on self-report, nurse observation, family observation, and physiological measures and were followed for 5 sequential chemotherapy treatments. Results indicate that the PREP intervention increased patients' knowledge of the disease and its treatment, reduced anticipatory side effects, reduced negative affect, and improved general coping. RT patients showed some decrease in negative affect and vomiting, but not as great as in past studies. The data suggest that relatively simple, 1-session coping preparation intervention can reduce many different types of distress associated with cancer chemotherapy and may be more effective than often-used behavioral relaxation procedures.

1990

Avants, S. Kelly; Margolin, Arthur; Salovey, Peter (1990-91). Stress management techniques: Anxiety reduction, appeal, and individual differences. Imagination, Cognition and Personality, 10, 3-23.

## NOTES

Four stress management techniques were evaluated for their general appeal, their immediate benefits, and the subjective experiences they evoke. One hundred undergraduates were randomly assigned to one of five treatment groups: (1) progressive muscle relaxation (PMR); (2) distraction imagery; (3) focused imagery; (4) listening to music; (5) sitting quietly (control). Distraction imagery and listening to music were the only techniques found to reduce anxiety to a greater extent than simply sitting quietly. The techniques differed in the way they made subjects feel, but not in their general appeal. Individuals with a 'blunting' coping style were more likely to find all five techniques appealing.

Tests used included the Miller Behavioral Style Scale, Cognitive-Somatic Anxiety Questionnaire of Schwartz, Davidson & Golman, Life Orientation Test of Scheier & Carver, Somatic Perception Questionnaire of Landy and Stern, Body Consciousness Questionnaire of L. C. Miller, Murphy, & Buss, Betts' Questionnaire Upon Mental Imagery, Shortened Form, State-Trait Anxiety Inventory, and Technique Evaluation Questionnaire of the authors.

Progressive muscle relaxation was according to Bernstein & Borkovec. Distraction imagery involved successively imagining a walk along a beach, a stroll across a flower filled meadow, sitting by a stream, a walk into the woods, sitting in a cabin in the woods listening to the rain against the windowpane, all including images in a variety of sense modalities. Focused imagery involved creating an image of a stressor, then through symbolic imagery experiences Ss were guided through a typical day's events that might lead up to the stressor, reinterpreting cues associated with the stressor as signals that they are in control, visualizing encountering the stressor feeling strong and determined, and any physical sensations reinterpreted as 'energy' that would help them to cope, visualizing enjoying their success (from Crits-Cristoph & Singer. Music was a 20-min tape (10 min of music used in the distraction imagery tape--Natural Light by Steve Halpern & David Smith) and 10 min of music used in background of the focused imagery tape (Structures of Silence by Michael Lanz). A 5th group, Control, was instructed to sit quietly with eyes closed.

This data can be used in support of imagery-suggestion types of hypnosis (as in surgery study) reducing anxiety. It shows particularly strong effects for people high in cognitive anxiety or low in optimism, pre-treatment.

Discussion: "... we feel confident that our distraction techniques were more effective for the immediate relief of anxiety than was PMR. This conclusion is consistent with the Suls and Fletcher meta-analysis (29) that suggested that 'avoidance' is an effective short-term coping strategy. That distraction (positive) imagery may be a more useful clinical technique than focused (active involvement) imagery was concluded in a study comparing these two techniques in the treatment of phobias (24)" (p. 19. [Ref #24 is Crits-Cristoph & Singer (1983) in *Imagination, Cognition, and Personality*.])

**"Pessimism and cognitive anxiety emerged as the only individual difference variables to influence anxiety reduction. Pessimism as measured by the LOT is cognitive in nature, with most of the items relating to expectations of negative outcomes; similarly, cognitive anxiety is characterized by worry and an inability to control negative thoughts and images. That individuals who perceive their world somewhat negatively should have entered the study more anxious than individuals who do not is hardly surprising. What is surprising is that despite an inverse relation between cognitive anxiety and the ability to relax, these individuals were able to benefit from whatever technique they performed to a greater extent than were individuals with a more positive outlook. In fact, after performing the technique, pessimists had reduced their anxiety to the level of optimists" (p. 19).**

**"The stress management techniques used in the current study did not differ in their appeal" (p. 20). "Our finding that PMR produced more somatic effects than did focused imagery and less cognitive effects than did distraction imagery, listening to music, or sitting quietly is consistent with the model of anxiety proposed by Davidson and Schwartz (17). Our findings are also generally consistent with a conclusion reached by Woolfolk and Lehrer (4): that although various techniques are generally stress reducing, they seem to have highly specific effects. However, we found no support for the hypothesis that individuals who express anxiety cognitively (or somatically) prefer and benefit most from techniques that produce cognitive (or somatic) effects. In fact, the extremely high correlation found between the cognitive and somatic anxiety subscales of the Schwartz et al. measure (5) casts some doubt on the usefulness of a cognitive-somatic distinction, as does the corr between the experience of physical symptoms under stress (the Somatic Perception Questionnaire) with the cognitive, as well as the somatic, anxiety subscale.**

**"The finding that blunters experiences more 'somatic effects' regardless of the technique they were assigned may have been the result of a single response--'how much did mind-wandering interfere with performing the technique'--which was the only Factor 2 item that was highly inversely) related to blunting. Since blunters are more likely to perceive mind wandering as the essence of stress management rather than as 'interference,' we do not view this main effect as particularly illuminating" (p. 20). "However, our finding that blunters experienced all techniques as appealing is consistent with the results of Martelli et al. (1) who found that individuals with low information-preference benefitted from what the authors labeled an 'emotion-focused' intervention, but which, in fact, included many of the quite diverse stress management techniques that we compared in the current study. That 'avoiders' failed to benefit from any intervention in the Scott and Clum study (11) may be due to the nature of the stressor [postsurgical pain]. Our undergraduates may have been more like the Martelli dental patients in terms of their level of distress than were the Scott and Clum subjects who were patients undergoing major surgery (hysterectomy or cholecystectomy). Future research needs to examine possible three-way, technique by patient by stressor-type, interactions (cf. 19)" pp 20-21.**

**Gil, Karen M.; Williams, David A.; Keefe, Francis J.; Beckham, Jean C. (1990). The relationship of negative thoughts to pain and psychological distress. Behavior Therapy, 21 (3), 349-362.**

Examined the degree to which negative thoughts during flare-ups of pain are related to pain and psychological distress in 3 pain populations: sickle cell disease, rheumatoid arthritis, and chronic pain. 185 adults completed the Inventory of Negative Thoughts in Response to Pain (INTRP), a pain rating scale, the SCL-90 (revised), and a coping strategies questionnaire. Factor analysis of the INTRP revealed 3 factors: Negative Self-Statements, Negative Social Cognitions, and Self-Blame. High scorers on Negative Self-Statement and Negative Social Cognitions reported more severe pain and psychological distress. Ss with chronic daily pain had more frequent negative thoughts during flare-ups than those having intermittent pain secondary to sickle cell disease or rheumatoid arthritis. The INTRP appears to have adequate internal consistency and construct validity.

Soskis, D. A.; Orne, E. C.; Orne, M. T.; Dinges, D. F. (1989). Self-hypnosis and meditation for stress management: A brief communication. International Journal of Clinical and Experimental Hypnosis, 37, 285-289.

In a 6-month follow-up study, telephone interviews were conducted with 31 male executives who were taught either a self-hypnosis or meditation exercise as part of a stress-management program. Use of and problems with the 2 exercises were similar, with the percentage of Ss using the techniques falling over 6 months from 90% to 42%. The exercises were used primarily for physical relaxation, refreshing mental interludes, aiding sleep onset, and stress-reduction. Problems with the exercises chiefly involved difficulty in scheduling even brief uninterrupted practice times and discomfort with the techniques. The incorporation of these issues into the clinical teaching of self-hypnosis may be useful.

1989

Goldmann, Les; Ogg, T. W.; Levey, A. B. (1988). Hypnosis and daycase anaesthesia. A study to reduce preoperative anxiety and intraoperative anesthesia requirements. Anesthesia, 43, 466-469.

52 female patients having gynecological surgery as day cases received either a short preoperative hypnotic induction or a brief discussion of equal length. Hypnotized patients who underwent vaginal termination of pregnancy required significantly less methohexitone for induction of anesthesia and were significantly more relaxed as judged by their visual analogue scores for anxiety. Less than half the patients were satisfied with their knowledge about the operative procedure even after discussions with the surgeon and anesthetist. A significant correlation was found between anxiety and perceived knowledge of procedures. Results suggest that preoperative hypnosis can provide a quick and effective way to reduce preoperative patient anxiety and anesthetic requirements for gynecological daycase surgery.

1988

Gudjonsson, Gisli (1988). Interrogative suggestibility: Its relationship with assertiveness, social-evaluative anxiety, state anxiety and method of coping. British Journal of Clinical Psychology, 27 (2), 159-166.

Investigated in 30 adults some of the theoretical components related to individual differences thought by the present author and R. Clark (1986) to mediate interrogative suggestibility as measured by a scale developed by the present author (1984). The variables studied were assertiveness, social-evaluative anxiety, state anxiety, and the coping methods generated and implemented during interrogation. Low assertiveness and high evaluative anxiety correlated moderately with suggestibility, but no significant correlations emerged for social avoidance and distress. State anxiety correlated significantly with suggestibility, particularly after negative feedback had been administered. Coping methods (active-cognitive/behavioral vs. avoidance) significantly predicted suggestibility scores. The findings give strong support to the present author's theoretical model

1987

Bandura, A.; O'Leary, A.; Taylor, C. B.; Gauthier, J.; Gossard, D. (1987). Perceived self-efficacy and pain control: Opioid and non-opioid mechanisms. Journal of Personality and Social Psychology, 53, 563-571.

#### NOTES

Subjects who were trained to use psychological coping strategies (e.g. imagery, distraction, dissociation, sensation transformation) had both better pain tolerance on a cold pressor test and higher self efficacy ratings. Those subjects who were given naloxone (which blocks pain reduction effects of beta endorphins) showed more pain tolerance than subjects not given the cognitive training experiences. They attributed much of the pain tolerance increase associated with cognitive interventions to opiate release, suggesting that cognitive interventions may have physiological mediating effects on pain perception

Chaves, John; Brown, Jude (1987). Spontaneous cognitive strategies for the control of clinical pain and stress. Journal of Behavioral Medicine, 10 (3), 263-276.

The spontaneous cognitive strategies employed by 75 patients undergoing dental extractions or mandibular block injections were elicited using a structured interview. Interest focused on the relationship between these strategies and several personality variables, including state and trait anxiety, locus of control, and absorption. In addition, the effect of strategy utilization on perceived pain and stress was assessed. Forty-four percent of the patients employed cognitive strategies designed to minimize pain and stress, while 37% catastrophized, engaging in cognitive activity which exaggerated the fearful aspects of their experience. Only 19% of the patients denied any cognitive activity during the clinical procedure, and many of these used noncognitive coping strategies. Discriminant analysis revealed that situational anxiety was associated with the use of cognitive coping strategies. Catastrophizing was associated with increasing age, past dental stress, and higher

levels of stress vulnerability (high trait anxiety and external locus of control). Copers reported less stress than catastrophizers but not less pain.

Katz, Ernest R.; Kellerman, Jonathan; Ellenberg, Leah (1987). Hypnosis in the reduction of acute pain and distress in children with cancer. Journal of Pediatric Psychology, 12, 379-394.

Hypnosis has been used as a behavioral approach to help children tolerate aversive medical procedures more effectively, but empirical longitudinal research evaluating the outcome of such interventions has been limited. In the present study, 36 children with acute lymphoblastic leukemia between the ages of 6 and 12 years of age undergoing repeated bone marrow aspirations (BMAs) were randomized to hypnosis or play comparison groups. Subjects were selected on their behavioral performance on baseline procedures and received interventions prior to their next three BMA procedures. Major results indicated an improvement in self-reported distress over baseline with both interventions, with no differences between them. Girls exhibited more distress behavior than boys on three of four dependent measures used. Suggestions of an interaction effect between sex and treatment group were noted. The role of rapport between patient and therapist in therapeutic outcome was also evaluated. Results are discussed in terms of potential individual differences in responding to stress and intervention that warrant further research.

1986

Rogers, Malcolm; Reich, Peter (1986). Psychological intervention with surgical patients: Evaluation outcome. Advances in Psychosomatic Medicine, 15, 23-50.

#### NOTES

The Notes are a direct quotation of the authors' Conclusions. "There is well documented evidence that psychological and behavioral preparation prior to surgery can effect post-operative recovery. In almost all instances, except when patients are characterized by avoidance or denial defenses predominantly, the outcome results have been positive. The effect of interventions have been most consistently positive in reducing length of hospitalization and post-operative pain, but a variety of other improvements in affect and physiologic stability have been shown. As others such as Auerbach have pointed out [76], in all but a handful of studies different intervention approaches have been combined, making it impossible to sort out the specific effects of information, psychotherapeutic relationship, relaxation training, or suggestion given either with or without hypnosis. Indeed it is not only likely that each has had an effect, but there may also be synergistic effects.

"More recent investigations have begun to include measurements of personality differences between patients so that the nature of the intervention can be more specific and appropriate to the individual's coping style.

"The reduction in length of hospitalization alone (clearly shown to result from pre-operative psychologic preparation) argues forcefully on a cost benefit basis for the inclusions of careful pre-operative preparation. The reduction in pain is also of major importance, and may well reduce future avoidance behavior or post-

traumatic disorders, although these latter potential outcomes have not been investigated. It should be kept in mind that there are also a number of studies which have failed to demonstrate the efficacy of psychological intervention on these outcome measures. Moreover, it is extremely difficult in studies of this nature to control adequately for the subtle effects on behavior of experimenter and subject expectation.

"A few points can be made about future strategies in this field. The evidence accumulated to date suggests that all patients undergoing surgery or certain difficult procedures be given the option of pre-operative psychological preparation. The preparation should emphasize what the patient will experience and when, and how to cope with it, i.e., how to move, or breathe, or relax. Rapidly evolving audiovisual capabilities and hospital televisions connected by cable to health education channels will routinely offer such preparation in the future. Patients could choose or not choose to watch (thereby protecting mechanisms of denial).

"Finally, future studies should focus on outcome measures uniquely important to a particular operation and also on longer term rehabilitation outcome measures. An example of the former might be post-operative sexual functioning after prostatectomy. A study by Zokar et al. [77] has shown that the likelihood of this post-operative function is correlated with not only the level of pre-operative anxiety and general 'life satisfaction', but also whether the patient received a pre-operative explanation of what to expect from the surgery" (pp. 45-46).

Wickramasakera, Ian (1986). A model of people at high risk to develop chronic stress-related somatic symptoms: Some predictions. Professional Psychology: Research and Practice, 17, 437-447.

Certain measurable high-risk factors that predispose people to develop functionally based somatic disorders are identified. These risk factors compose a multidimensional model that encompasses variables involved in the predisposition, the precipitation, and the buffering of stress-related symptoms. These high-risk factors are (a) high or low hypnotic ability, (b) habitual catastrophizing cognitions and pessimistic belief systems, (c) autonomic lability or neuroticism, (d) multiple major life changes or multiple minor hassles over a short period of time, and (e) a deficit in support systems or coping skills or both.

1985

Gottschalk, Louis A. (1985). Hope and other deterrents to illness. American Journal of Psychotherapy, 39, 515-524.

Reviews animal and human research demonstrating that events during early development influence vulnerability to physical and mental illness. In addition, effectiveness of coping methods used to deal with problems of living can affect susceptibility to illness. The intervening mechanisms between stressful life experiences and illness appear to involve physiological homeostasis and immune competence.

Spanos, Nicholas P.; Ollerhead, Virginia Gail; Gwynn, Maxwell I. (1985-86). The effects of three instructional treatments on pain magnitude and pain tolerance: Implications for theories of hypnotic analgesia. Imagination, Cognition and Personality, 5, 321-337.

Between baseline and posttesting on the cold pressor test, subjects were assigned to four treatments: a) hypnotic analgesia, b) brief instructions to "Do whatever you can to reduce pain," c) stress inoculation, and d) no instruction control. Participants in the three instructional treatments showed significantly greater baseline to posttest decrements in pain magnitude and significantly greater increments in pain tolerance than controls. However, the instructional treatments did not differ significantly from one another in these regards. Pretested hypnotic susceptibility correlated significantly with degree of pain reduction in the hypnotic analgesia treatment but not in the "Do whatever" or stress inoculation treatments. Theoretical implications are discussed.

1984

D'Eon, Joyce Lillian (1984). Response to pressure pain as moderated by hypnotic susceptibility, type of suggestion strategy, and choice (Dissertation, Concordia University, Canada). Dissertation Abstracts International, 45 (n4-B), 1313-1314.

The present study examined the relationship between hypnotic susceptibility and ability to control pain, by comparing high and low susceptible subjects' response to pressure pain when these subjects employed either an imagery or a distraction pain attenuating strategy. The effect of providing subjects with a choice of which strategy to employ was investigated. In addition, the subjects' imagery ability and the types of cognitive strategies they engaged in were assessed. Subjects who scored either 9 or above or 4 and below on the Harvard Group Scale of Hypnotic Susceptibility: Form A, were asked to participate in a pain study. All 84 subjects first received a baseline trial on a modified version of the Forgione-Barber Strain Gauge Pain Stimulator, within susceptibility levels. Subjects who were able to keep their finger in the apparatus for 60 seconds were randomly assigned to a Choice, a No Choice, or a Control condition. The 36 high and low susceptible subjects in the Choice condition were given the option of using either an imagery suggestion strategy or a low distraction strategy on the second trial. The 32 high and low susceptible subjects in the No Choice condition were told about both strategies but were assigned randomly to either the imagery or the distraction strategy group. The 16 subjects in the Control group did not receive a strategy. Both pain intensity and pain tolerance were measured. Results indicated that an equivalent number of high and low susceptible subjects, given a choice of strategy, chose the imagery and distraction strategies. There were no differences in either pain intensity or pain tolerance between high and low susceptible subjects in the Choice conditions. The Choice condition subjects exhibited significant pain reductions from the first to the second trial. No Choice and Control subjects did not reduce pain significantly. In addition, high and low susceptible subjects who chose the imagery strategy did not have higher imagery scores than those subjects who chose the distraction strategy.

Subjects in the No Choice condition used fewer coping strategies than subjects in the Choice condition, on the second trial. The implication of these results and directions for future research are discussed" (p. ).

1983

Harris, Gina M.; Johnson, Suzanne Bennett (1983). Coping imagery and relaxation instructions in a covert modeling treatment for test anxiety. Behavior Therapy, 14, 144-157.

The present study compared the efficacy of instructing test anxious subjects to use personalized coping imagery based on nonacademic experiences of competence with coping imagery based on academic experiences of competence. The effect of relaxation was also examined and the relationship of imagery elaborateness and content to treatment effectiveness was assessed. Sixty-three subjects were randomly assigned to one of four treatments or a waiting list control group. Test anxiety as measured by a self-report instrument significantly decreased in all treatment groups. Improvement in grade point average occurred for all treatment groups except for academic coping imagery without relaxation which was also the least efficient treatment. The waiting list control group significantly deteriorated in academic performance. Relaxation training did not appear to enhance treatment effectiveness or influence the elaborateness or content of the imagery used. Test anxiety scenes elicited highly response-oriented images by all subjects. However, the stimulus/response content of the subjects' images was not influenced by treatment outcome. In contrast, successful treatment was primarily associated with reduction in negative coping imagery descriptions, although an increase in positive coping statements cured as well.

Myles, (1983, April). Cognition, hypnotic susceptibility, and laboratory induced pain (Dissertation, University of Waterloo). Dissertation Abstracts International, 43 (10), 3360-B.

Individuals' experiences of pain, and responses to pain treatments vary greatly. This study attempted to relate two areas of research concerned with this variation: (a) cognitions and pain (thoughts, images, etc.), in particular, catastrophizing versus coping; and (b) hypnotic susceptibility and analgesia. "Subjects were preselected for high or low hypnotic susceptibility. Susceptibility assessment was divorced from the laboratory study to minimize the potential bias of expectancies concerning hypnosis. High hypnotic susceptibility was expected to potentiate therapeutic effects of hypnotic-like treatment that did not involve a hypnotic induction. "Ten high and ten low-susceptible subjects were assigned to each of three groups: (a) a cognitive treatment, encouraging subjects to reduce spontaneous catastrophizing and increase self-generated coping cognitions; (b) a dissociative imagery treatment, encouraging subjects to engage in self-generated engrossing images; (c) an attention- placebo manipulation. "Pre and post-treatment assessments involved tolerance and pain-report measures during the cold-pressor task, and interview and questionnaire information concerning cognitions. "No treatment effects were evident on measures

of pain. Cognitive data indicated less catastrophizing and more coping during the post-treatment stressor across all groups. Subjects in the dissociative imagery group did report more imagery during the post-treatment assessment than subjects in the other groups, but this increased use of imagery was not associated with a decrease in pain. "Interview and questionnaire data supported prior reports that catastrophizing is related to increased pain. Low catastrophizing was associated with a high sense of control, high use of a variety of coping strategies, and lower pain reports. These relationships were altered following treatment, however, leading to a caution in generalizing about such variables. "High susceptibility did not potentiate therapeutic effects for either experimental treatment. Nor was susceptibility related in any other consistent way to pain, although high susceptibility was associated with more extensive use of post-treatment imagery. "Methodological inconsistencies and problems in laboratory pain research were discussed, and suggestions made for future work in the area" (p. 3360).

1981

Spanos, Nicholas P.; Brown, Jude M.; Jones, Bill; Horner, Donna (1981). Cognitive activity and suggestions for analgesia in the reduction of reported pain. Journal of Abnormal Psychology, 90, 554-556.

Assessed 38 undergraduates' pain magnitude and pain tolerance for arm immersion in ice water during a baseline and posttest session. Before the posttest, half the Ss received an analgesia suggestion. On the basis of their written testimony, Ss were classified as having either predominately coped (e.g., imagined event inconsistent with pain or made positive self-statements) or predominantly exaggerated (e.g., worried about and exaggerated the noxious aspects of the situation) during each immersion. On both immersions, copers reported less pain and exhibited higher pain tolerance than exaggerators. Moreover, the suggestion was associated with reductions in reported pain only when it transformed baseline exaggerators into posttest copers.

Wilson, John F. (1981). Behavioral preparation for surgery: Benefit or harm?. Journal of Behavioral Medicine, 4, 79-102.

Elective surgery patients were prepared for surgery with training in muscle relaxation or with information about sensations they would experience. Relaxation reduced hospital stay, pain, and medication for pain and increased strength, energy, and postoperative epinephrine levels. Information reduced hospital stay. Personality variables (denial, fear, aggressiveness) were associated with recovery and influenced patients' responses to preparation. Less frightened patients benefitted more from relaxation than did very frightened patients. Nonaggressive patients reacted to information with decreased hospital stay along with increased pain, medication, and epinephrine. Aggressive patients responded to information with decreased hospital stay along with decreased pain, medication, and epinephrine. Patients using denial were not harmed by preparation. A catharsis/moderation model is proposed to explain how information benefits patients. An active coping model is proposed to

explain the benefits of relaxation. This study suggests that behavioral preparation benefits even frightened, aggressive, or denying elective surgical patients.

Worthington, Everett L.; Shumate, Michael (1981). Imagery and verbal counseling methods in stress inoculation training for pain control. Journal of Counseling Psychology, 28 (1), 1-6.

Investigated 3 elements of stress inoculation training, a therapeutic package for helping clients control anxiety, anger or pain. 96 undergraduate females were tested twice for ice water tolerance. In a 3 design, the independent variables were the presence or absence of (a) pleasant imagery, (b) a conceptualization of pain as a multistage process, and (c) planned, explicit self-instructions. A multivariate analysis of covariance using the (transformed) pretest tolerance rating and 2 self-ratings of pain. Imagery users (Is) controlled their pain better than nonimagery users (NIs). There was a significant interaction of Imagery and Conceptualization. NIs had longer tolerance and less self-reported pain at withdrawal when they heard no conceptualization. The Is did not derive additional benefit from hearing the conceptualization. Self-instruction did not affect pain control. Results suggest that pleasant imagery effectively relieves pain and may account for much of the effectiveness of stress inoculation training. (23 ref)

1979

Beers, Thomas M.; Karoly, Paul (1979). Cognitive strategies, expectancy, and coping style in the control of pain. Journal of Consulting and Clinical Psychology, 47, 179-180.

Measures of tolerance, self-reported pain threshold, and overall discomfort of cold-pressor pain were obtained from 114 male subjects in a pretest-training-posttest experiment. Training consisted of brief practice in one of four cognitive strategies: rational thinking, compatible imagery, incompatible imagery, and task-irrelevant cognition. Analyses of covariance indicated (a) that cognitive-imaginal strategies facilitated endurance of pain and raised self-reported threshold, (b) that rational thinking and compatible imagery were generally the most effective treatments, (c) that expectancy alone was not a significant pain-attenuating factor, (d) that treatments did not affect discomfort ratings, and (e) that individual differences in imaginal ability and coping style did not correlate with changes in any of the dependent measures.

Spanos, Nicholas P.; Radtke-Bodorik, H. Lorraine; Ferguson, John D.; Jones, Bill (1979). The effects of hypnotic susceptibility, suggestions for analgesia, and the utilization of cognitive strategies on the reduction of pain. Journal of Abnormal Psychology, 88, 282-292.

Subjects previously stratified in terms of hypnotic susceptibility had an arm immersed in ice water for a 60-sec pretest and, afterward, were assigned to one of four treatments: (a) hypnosis plus analgesia suggestion, (b) hypnosis alone, (c) suggestion alone, or (d) no hypnosis - no suggestion. Next, the subjects were retested

in ice water and then interviewed about their experiences during the retest. High susceptibles reported the use of more cognitive strategies during the retest and showed greater pretest-to-retest pain magnitude reductions than did low susceptibles. Similar effects occurred for subjects given, as opposed to not given, a suggestion. The hypnosis variable, however, failed to affect either strategy use or pain magnitude. Strategy use facilitated pain reduction only for subjects who did not worry about, and did not exaggerate, the unpleasantness of the situation (i.e., noncatastrophizers). The very few subjects who showed dramatic pretest- to-retest reductions in pain magnitude (50% reduction or more) were all high-susceptible noncatastrophizers who used one or more cognitive strategies.

**Turk, Dennis C.; Meichenbaum, Donald H.; Berman, William H. (1979). Application of biofeedback for the regulation of pain: A critical review. Psychological Bulletin, 86 (6), 1322-1338.**

The biofeedback literature for the regulation of pain is reviewed and found wanting on both conceptual and methodological grounds. In particular, studies on the use of biofeedback for the treatment of tension and migraine headaches and chronic pain indicate that biofeedback was not found to be superior to less expensive, less instrument- oriented treatments such as relaxation and coping skills training. The relative absence of needed control comparisons was noted, and the need for caution in promoting biofeedback was stressed. Suggestions for future research are offered.

**Shipley, R. H.; Butt, J. H.; Horowitz, B.; Farbray, J. E. (1978). Preparation for a stressful medical procedure: Effect of amount of stimulus preexposure and coping style. Journal of Consulting and Clinical Psychology, 46, 499-507.**

Anxiety during the stressful medical procedure of endoscopy was studied as a function of the number of prior viewings of an explicit preparation videotape and of repression-sensitization coping style. Sixty naive patients viewed a videotaped endoscopy either zero, one, or three times. Dependent measures included heart rate, behavioral ratings, tranquilizer required, and self-report. On each dependent measure, three viewings generally resulted in the least distress; one, more distress; and zero, the most distress. Most comparisons reached statistical significance. These results are interpreted as resulting from extinction and/or habituation of anxiety. The repression-sensitization factor interacted with heart rate change. Sensitizers showed a monotonic decrease in heart rate as a function of number of tape exposures. Repressors showed an inverted-U-shaped function, with one viewing producing the highest heart rate; this is interpreted as resulting from a disruption of repressing defenses by one tape exposure followed by extinction of fear by three exposures.

**Gatchel, Robert J.; Hatch, John P.; Watson, Paur J.; Smith, Dan; Gaas, Elizabeth (1977). Comparative effectiveness of voluntary heart rate control and muscular**

relaxation as active coping skills for reducing speech anxiety. Journal of Consulting and Clinical Psychology, 1093-1100.

The present study investigated whether heart rate biofeedback training is as effective as muscular relaxation training in reducing speech anxiety. Also, a combined muscle relaxation/biofeedback treatment group was included in this study. All treatment groups were compared to a false-biofeedback placebo control group. This investigation also assessed whether the degree of autonomic nervous system awareness significantly influences the treatment process. Ten speech-anxious subjects, half of whom scored high on the Autonomic Perception Questionnaire (APQ) and half of whom scored low on the APQ, were assigned to each group. Results indicated that all four groups demonstrated a decrease in self-reported anxiety. Assessment of physiological measures (heart rate and skin conductance) indicated that the three treatment groups were associated with less physiological responding during the posttreatment assessment of anxiety, relative to the false-biofeedback group. Moreover, among the three treatment groups, the combined relaxation/biofeedback group demonstrated the lowest level of responding. The degree of autonomic awareness was not found to be related to therapeutic improvement.

Gardner, Gail G. (1976). Hypnosis and mastery: Clinical contributions and directions for research. International Journal of Clinical and Experimental Hypnosis, 24 (3), 202-214.

This paper explores the concept of mastery in relation to hypnotherapy by pulling together clinical observations and suggesting directions for research. It is suggested that a sense of mastery may enhance the effectiveness of hypnosis, either by facilitating induction, or by strengthening hypnotherapeutic suggestions, or by maintaining hypnotherapeutic gains. Moreover, the question is raised as to whether hypnotherapy, as compared with other psychotherapeutic approaches, better facilitates the development of a sense of mastery.

Gatchel, Robert J.; Proctor, Janet D. (1976). Effectiveness of voluntary heart rate control in reducing speech anxiety. Journal of Consulting and Clinical Psychology, 381-389.

The effects of learned control of heart rate deceleration and therapeutic expectancy set in reducing speech anxiety were investigated in a factorial design employing 36 speech-anxious subjects. Heart rate control training and no heart rate control training were each paired with high-therapeutic-expectancy and neutral-expectancy instructions, in order to assess the individual and combined effects of the two factors. Results demonstrated that learning to control heart rate deceleration led to a significant reduction in self-report, physiological (heart rate and skin conductance level), and overt signs of anxiety, relative to the no-heart-rate control condition. High-therapeutic-expectancy instructions also contributed to a reduction

in self-reported anxiety. These results demonstrate that learned heart rate control is an effective therapeutic technique for reducing anxiety.

1974

Chaves, John F.; Barber, Theodore Xenophon (1974). Cognitive strategies, experimenter modeling, and expectation in attenuation of pain. Journal of Abnormal Psychology, 83 (4), 356-363.

Verbal reports of pain were obtained from 120 subjects during a base-level pretest and also during a posttest conducted under one of several experimental treatments. The pain stimulus was a heavy weight applied to a finger for two minutes. During the posttest, subjects who had been asked to utilize cognitive strategies for reducing pain (to imagine pleasant events or to imagine the finger as insensitive) showed a reduction in pain as compared to uninstructed control subjects. Subjects led to expect a reduction in pain, but not provided with cognitive strategies, also showed reduced pain during the posttest as compared to control subjects, but the reduction was smaller than for subjects using cognitive strategies. An experimenter modeling procedure, used with one half of the subjects under each experimental treatment, was effective in reducing verbal reports of pain only for subjects with high pretest levels who were asked to imagine pleasant events.

## CREATIVITY/ART

2002

Manmiller, Jessica L.; Kumar, V. K.; Pekala, Ronald J. (2002). Hypnotizability, creative capacity, creativity styles, absorption and phenomenological experience. [Paper] Presented at the annual meeting of the American Psychological Association, Chicago.

The study investigated relationships between creative capacity, styles of creativity, hypnotizability, and absorption. Participants were 429 students enrolled in Introduction to Psychology classes. Students first completed questionnaires pertaining to creative capacity, creativity styles, and absorption (Tellegen's Absorption Scale). They were subsequently hypnotized using the Harvard Group Scale of Hypnotic Susceptibility and completed the Phenomenology of Consciousness Inventory. The pattern of results suggests that creative capacity is

more closely related to absorption than hypnotizability. The support for P. G. Bowers' assertion that effortless experiencing while engaged in creative tasks and hypnotic tasks is a process that is common to both high creative and high hypnotizable subjects was weak. Hypnotizability was more strongly and negatively correlated with volitional control for suggestions experienced during hypnosis, than both absorption and creative capacity. Creativity styles of belief in unconscious processes, use of techniques, final product orientation (intrinsic/extrinsic) motivation, environmental control and behavioral self-regulation, and supersition were negatively correlated with volitional control (feeling of effortlessness experiencing) during hypnosis, but the correlations were small in magnitude" (Bulletin of Division 30, Psychological Hypnosis, Fall, 2002, Vol. 11, No. 3, P. 14).

2001

Gibbons, Don E. (2001). Experience as an art form: Hypnosis, hyperempiria, and the Best Me technique. San Jose CA: Authors Choice Press. (([available online:] <http://www.iuniverse.com/bookstore/marketplace>))

#### NOTES

The Best Me Technique is a procedure for constructing suggestions which incorporates many different dimensions of experience -- beliefs, emotions, sensations, thoughts, motives, and expectations -- for maximum involvement and effectiveness. Best Me suggestions may be used with either hyperempiria, an alert induction based on suggestions of mind expansion and increased alertness and sensitivity, or with more traditional forms of hypnotic induction.

2000

Gibbons, Don (2000). Applied hypnosis and hyperempiria. New York NY: Plenum Press. ([available online:] <http://www.iuniverse.com/bookstore>)

#### NOTES

The book features both traditional hypnotic procedures and hyperempiric inductions based on suggestions of increased awareness, mind expansion, and increased alertness and sensitivity. It contains sections on the use of suggestion as an instrument of personal growth in areas such as improving study skills, taking examinations, achievement motivation, artistic expression, emotional enrichment, aesthetic appreciation and enjoyment, interpersonal effectiveness, musical performance, problem solving, public speaking, salesmanship, sports performance, theatrical performance, and writing ability.

1996

Wallace, Benjamin; Allen, Philip A.; Propper, Ruth E. (1996). Hypnotic susceptibility, imaging ability, and anagram-solving activity. International Journal of Clinical and Experimental Hypnosis, 44 (4), 324-337.

Anagram-solving activity was examined as a function of hypnotic susceptibility level and imaging ability. In Experiment 1, anagrams that were composed of sets of

letters that formed actual words (word anagrams), but when unscrambled formed other words, were compared to sets of letters that formed nonwords (nonsense anagrams). Word anagrams required more time to solve than nonsense anagrams. Also, fewer word anagrams were correctly solved compared to nonsense anagrams. Those individuals judged both high in hypnotic susceptibility and vivid in imaging ability demonstrated the best performance. In Experiment 2, anagrams that when unscrambled formed high-imagery words were compared to those that formed low-imagery words. High-imagery-word anagrams were solved more quickly and correctly than low-imagery-word anagrams. Such activity was best demonstrated by individuals who were judged to be both high in hypnotic susceptibility and vivid in imaging ability. These results are discussed in terms of strategies for solving anagrams and the individual differences that appear to be associated with using such strategies. -- Journal Abstract

1992

Lynn, Steven Jay; Sivec, Harry (1992). The hypnotizable subject as creative problem-solving agent. In Fromm, Erika; Nash, Michael R. (Ed.), Contemporary hypnosis research (pp. 292-333). Guilford Press.

#### NOTES

These notes are taken only from the section of this chapter that deals with Hypnotic Responding, Imaginative Activity, and Expectancies, and they treat of the concept of nonvoluntary responding (pp 315-316). Other topics covered in the chapter include: Imagination, Fantasy, and Hypnosis Theories; The Hypnotizable Subject as Creative Problem-Solving Agent; Hypnosis and Subjects' Capability for Imaginative Activity; Goal-Directed Fantasy: Patterns of Imaginative Activity during Hypnosis; Hypnosis and Creativity; and a Conclusion.

Several studies manipulated expectancies re the relationship between imagination and involuntariness. When Ss were told that "good" hypnotic subjects could (or could not) resist suggestions, "this information affected their ability to resist the hypnotist and tended to affect subjects' report of suggestion-related involuntariness ... [Lynn, Nash, Rhue, Frauman, & Sweeney, 1984]. Furthermore, subjects who successfully resisted suggestions and subjects who failed to do so reported comparable levels of hypnotic depth and imaginative involvement in suggestions.

"Spanos, Cobb, and Gorassini (1985) conducted a similar experiment in which they found that hypnotizable subjects who were instructed that they could become deeply involved in suggestions and yet resist them successfully resisted 95% of the suggestions and rated themselves as maintaining voluntary control over their behavior. Thus, subjects are able to resist nearly all of the suggestions when resistance is facilitated by situational demands. It is worth noting that subjects in this research who resisted hypnotic suggestions rated themselves as just as deeply involved in the suggestions as Ss who failed to resist suggestions after being informed that deeply hypnotized subjects were incapable of resisting suggestions" (pp. 315-316).

Lynn, Snodgrass, et al. (1987). showed that hypnotizable Ss who were just "imagining" along with suggestions but instructed to resist responding to motoric

suggestions acted the way hypnotized Ss did in their earlier countersuggestion research: imagining subjects tended to move in response to suggestion (that "good" Ss responded in certain ways), despite being instructed to resist. In this study, with instructions designed to increase the use of goal directed fantasies (GDFs), low and high hypnotizable subjects reported equivalent GDF absorption and frequency of GDFs. However, highs responded more and reported greater involuntariness than lows, even when their GDFs were equivalent.

"A number of other studies have examined the effects of expectancies on imaginings and hypnotic behavior. Spanos, Weekes, and de Groh (1984) informed subjects that deeply hypnotized individuals could imagine an arm movement in one direction while their unconscious caused the arm to move in the opposite direction. Even though subjects so informed moved in the opposite direction, they imagined suggested effects and described their countersuggestion behavior as involuntary" (p. 317).

**1991**

Crowson, J. Jeffrey, Jr.; Conroy Aileen M.; Chester, Traci D. (1991). Hypnotizability as related to visually induced affective reactivity: A brief communication. International Journal of Clinical and Experimental Hypnosis, 39 (3), 140-144.

Numerous studies have explored the relationship between hypnotizability and individual differences in imaginative involvement and creativity. Most have assessed imaginative or affective involvement by involving Ss in a variety of imaging tasks. Unlike these earlier studies, however, the present study made no attempt to actively involve Ss in the film viewing task. Rather, individuals assessed as high, medium, or low in hypnotizability were exposed to either a violent film, a neutral film, or no film. Results provided tentative evidence to indicate that the level of negative affect reported was significantly greater for highly hypnotizable Ss. Results were discussed in terms of the limitations of the present study and implications for future studies.

**1990**

Biasutti, M. (1990). Music ability and altered states of consciousness: An experimental study. International Journal of Psychosomatics, 37, 82-85.

The relationship between music and altered states of consciousness was studied with 30 subjects divided into hypnosis and control groups. The "Test di abilita musicale" was applied. The hypnosis group did the retest after posthypnotic suggestions and the second in waking conditions. The hypnosis group had better results than the control group, especially in the rhythm test ( $p < 0.0001$ ).

Freeman, William B., Jr.; Kessler, Marc; Vigne, Jeffery (1990). Random number generation, absorption, and hypnotizability: A brief communication. International Journal of Clinical and Experimental Hypnosis, 38, 10-16.

Graham and Evans (1977) found that a measure of random number generation (RNG) was related to hypnotizability. In 2 studies, the relationship between hypnotizability and Graham and Evans' RNG (1977) index was examined. In Study 1 Evans' (1981) measures of controlled and automatic absorption were also evaluated. In Study 1 no relationship was found between the measures of absorption or RNG and hypnotizability. Since Study 1 was carried out primarily to evaluate methods for modifying hypnotizability, Study 2 was designed to evaluate RNG measure directly. Study 2 found no consistent relationship between RNG and hypnotizability, or between RNG and measures of the experience of hypnotic depth and nonvolition.

1989

Zamore, Neal; Barrett, Deirdre (1989). Hypnotic susceptibility and dream characteristics. Psychiatry Journal of the University of Ottawa, 14 (4).

This study examined the relationship of hypnotic susceptibility to a variety of dream characteristics and types of dream content. A Dream Questionnaire was constructed synthesizing Gibson's dream inventory and Hilgard's theoretical conceptions of hypnosis. Several dream dimensions correlated significantly with hypnotizability as measured by the Harvard Group Scale of Hypnotic Susceptibility and the Field Inventory. For Ss as a whole, the strongest correlates were the frequency of dreams which they believed to be precognitive and out-of-body dreams. Ability to dream on a chosen topic also correlated significantly with hypnotic susceptibility for both genders. For females only, there was a negative correlation of hypnotizability to flying dreams. Absorption correlated positively with dream recall, ability to dream on a chosen topic, reports of conflict resolution in dreams, creative ideas occurring in dreams, amount of color in dreams, pleasantness of dreams, bizarreness of dreams, flying dreams, and precognitive dreams.

1988

Lynn, Steven Jay; Rhue, Judith W. (1988). Fantasy proneness: Hypnosis, developmental antecedents, and psychopathology. American Psychologist, 43 (1), 35-44.

This article presents a summary of the findings of our ongoing research program on the fantasy-prone person. In seven studies, nearly 6,000 college students were screened in order to obtain five samples of 156 fantasy-prone subjects. Fantasy-prone subjects (fantasizers) were selected from the upper 2%-4% of the college population on a measure of imaginative involvement and contrasted with nonfantasizers (lower 2%-4%), and medium fantasy-prone subjects (middle range). General support was secured for Wilson and Barber's construct of fantasy proneness: Fantasizers were found to differ from nonfantasizers, and in many cases also from medium-range subjects, on measures of hypnotizability, imagination, waking suggestibility, hallucinatory ability, creativity, psychopathology, and childhood experiences. Differences in hypnotizability were most reliable when subjects participated in a multisession study and were screened not only with the

screening inventory, but also with an interview that substantiated their fantasy-prone status. However, our findings indicated that less correspondence between fantasy proneness and hypnotizability exists than Wilson and Barber suggested. Hypnotic responsiveness is possible even in the absence of well-developed imaginative abilities, and not all fantasizers were highly hypnotizable. Fantasizers recollected being physically abused and punished to a greater degree than other subjects did and reported experiencing greater loneliness and isolation as children. Many fantasizers appeared to be relatively well-adjusted; however, a subset of fantasizers were clearly maladjusted based on self-report, Minnesota Multiphasic Personality Inventory (MMPI), and Rorschach test data. Because of the diversity inherent in the fantasy-prone population, it is misleading to think of individuals at the extreme end of the fantasy-proneness continuum as conforming to a unitary personality type.

1987

Lynn, Steven Jay; Rhue, Judith W. (1987). Hypnosis, imagination, and fantasy. Journal of Mental Imagery, 11, 101-112.

Considers three questions pertaining to the relationship between hypnotic responsiveness and imaginative processes: Are subjects' nonhypnotic imaginative involvements related to hypnotic susceptibility? Do some fantasy prone subjects share a unique constellation of personality attributes and experiences, including an ability to respond to hypnotic suggestions? What are the childhood developmental antecedents of persons who score at the extremes of hypnotic ability and measures of fantasy and imagination? Reviews literature.

Cole, Ronald William (1986, February). Posthypnotic suggestion and the production of creative imagination imagery (Dissertation, Mississippi State University). Dissertation Abstracts International, 47 (8), 2953-A.

This investigation assessed the effect of posthypnotic suggestions in facilitating creativity in persons highly susceptible to hypnosis. Fifty college-age subjects from educational psychology and psychology classes at Mississippi State University who scored 9 or above on the Harvard Group Scale of Hypnotic Susceptibility were used. Groups of 10 subjects were randomly assigned to one of five conditions: a) hypnosis/creative learning set instructions b) relaxation/creativity learning set instructions c) hypnosis only d) relaxation only e) posttest only "Subjects in the hypnosis/creative learning set instructions group received 25 min. of hypnosis and creativity instruction. The relaxation/creative learning set instructions group received 25 min. of relaxation and creativity instructions. The hypnosis-only group received 25 min. of hypnosis and then completed mazes. The relaxation-only group received 25 min. of relaxation and then completed mazes. And lastly, the control group received the posttest only. All groups were given the Torrance Test of Creative Thinking (TTCT), Verbal and Figural Forms A, 1 week after receiving their treatment conditions. The results indicated that the combination of hypnosis

and creativity instructions produced significantly higher mean scores on the Verbal Form A -- fluency, flexibility, and originality subtests, and Figural Form A elaboration subtest, and lend support to the contention that posthypnotic suggestions can increase creativity (as measured by the TTCT) in high susceptible subjects. The components of both hypnosis and creativity instruction had to be present to increase creative performance. There was a tendency for relaxation combined with creativity instructions to show decreases in creativity scores. "The hypnotic state was seen as necessary for the unconscious acceptance of creativity instructions (low volitional control), while the relaxed state produced conscious contamination of suggestions for creativity (high volitional control). It was postulated that it was the difference in volitional control which produced the positive responses to posthypnotic suggestions to be more creative in the group receiving hypnosis and creativity instructions" (p. 2953).

Lynn, Steven Jay; Rhue, Judith W. (1986). The fantasy-prone person: Hypnosis, imagination, and creativity. Journal of Personality and Social Psychology, 51, 404-408.

Experimenters selected subjects who ranged along the continuum of fantasy proneness and assessed hypnotizability, absorption, vividness of mental imagery (QMI; Sheehan, 1967), response to waking suggestion (Creative Imagination Scale), creativity, and social desirability (Crowne & Marlowe). Fantasy-proneness was evaluated with the Inventory of Childhood Memories and Imaginings (Wilson & Barber, 1981). Strong support was secured for J. R. Hilgard's construct of imaginative involvement and Wilson and Barber's contention that fantasy prone persons can be distinguished from others in terms of fantasy and related cognitive processes. Fantasizers were found to outscore subjects in both comparison groups on all of the measures of fantasy, imagination, and creativity, with social desirability used as a covariate. Low fantasy-prone subjects were no less creative or less responsive to hypnosis than their medium fantasy-prone counterparts.

1985

Ashton, M.A.; McDonald, R.D. (1985). Effects of hypnosis on verbal and non-verbal creativity. International Journal of Clinical and Experimental Hypnosis, 33 (1), 15-26.

60 female volunteers, 30 hypnotizable and 30 un hypnotizable, screened on 2 measures of hypnotizability, were assigned to a hypnosis, simulation, or waking motivated treatment condition to assess whether hypnosis has a differentially enhancing effect upon verbal and non-verbal creativity test performance. Verbal and figural components of the Torrance Tests of Creative Thinking (Torrance, 1974) and the Sounds and Images Test (Cunnington & Torrance, 1965) were the principal dependent variables. Postexperimental measures of absorption and effortless experiencing were also obtained. A 2 x 3 independent groups ANOVA did not sustain the prediction of an interaction effect between S hypnotizability and the presence of hypnosis on 3 composite measures of verbal and nonverbal creativity.

Although there was an absence of treatment effects, hypnotizable Ss consistently achieved higher scores on the Torrance scoring categories, and their performance was statistically superior on a composite index of overall creativity. Absorption and effortless experiencing measures were also significantly higher for hypnotizable Ss than for un hypnotizable Ss.

Kerry Buhk; Rhue, Judith; Henry, Stephanie; Lynn, Steven Jay (1985, November). Fantasy proneness: Are their word associations richer?. [Paper] Presented at the annual meeting of the Society for Clinical and Experimental Hypnosis, Asheville, NC.

**NOTES:**

Experimenters screened 7000 students to get 6 samples of fantasy prone Ss (top 2.4% on Wilson and Barber's ICMI). They found less association between fantasy proneness and hypnotizability than did Wilson and Barber.

They had fantasizers hallucinate a second cup next to a first styrofoam cup. Results were that 87% of High fantasizers, < 50% Medium fantasizers, < 25% Low fantasizers could do it, but they didn't describe seeing the hallucinated cup "as real as real" as Wilson and Barber said they did.

Experimenters were concerned about context effects (expectancy) because the Creativity and Fantasy Proneness tests were run proximal in time, so they separated in time the administration of Fantasy Prone and Creativity tests and also looked at word associations.

23 High and 20 Low fantasy prone students selected by ICMI, which was administered to Subjects 18 mos before the creativity study. At the time of the creativity study, Ss were informed they were randomly picked. There were two 90' sessions, counterbalanced.

Sessions: 1. Hallucinate image of R.A. and of styrofoam cup. Other tests were administered for intelligence and personality: Shipley-Hartford, MMPI, Crowne-Marlowe, etc. 2. Creativity tests (Revised Art Scale, Hilgard's Alternate Uses; story production which was scored on detail, imagery and fantasy and on imagery nouns.) Results of this study which was independent of context (i.e. the tests being correlated were administered independently of each other, separated by time). 1. Fantasizers were more creative than low fantasizers on both Creativity Scales. 2. Fantasizers show more divergent thinking on Hilgard Alternate Uses test, but relationship between fantasy proneness and creativity were not strong,  $r = .30$ . 3. Fantasizers and non fantasizers did not differ on the story measures! This diverges from Wilson and Barber's results. Fantasizers may have more vivid images, but storytelling does not capture that.

1984

Kearns, John S.; Zamansky, Harold S. (1984). Synthetic versus analytic imaging ability as correlates of hypnotizability. International Journal of Clinical and Experimental Hypnosis, 32, 41-50.

It was hypothesized that synthetic imaging ability, but not analytic imaging ability, is positively related to hypnotizability. The correlation of scores on a paired-associates task, used as a measure of synthetic imaging ability, with scores on the Stanford Hypnotic Susceptibility Scale, Form C (SHSS:C) of Weitzenhoffer and Hilgard (1962), indicated a statistically nonsignificant trend in the predicted direction. 2 measures of analytic imaging ability, as well as Sheehan's (1967) revision of the Betts (1909) Questionnaire Upon Mental Imagery, a measure of vividness of imagery, did not correlate significantly with SHSS:C. The results are discussed in terms of their relation to studies of creativity and goal-directed fantasy.

## NOTES

The authors review the literature on imagery and hypnotizability and propose that an important variable in hypnosis is an ability to expand imaginatively upon a given verbal input (synthetic imaging ability), akin to Spanos' (1971) concept of goal-directed fantasy. They cite studies relating creativity ("essentially a synthetic process") to hypnotizability, and predict that skill in solving spatial relations problems (analytic imaging ability) is not correlated with hypnotizability because it involves "accurately scanning visual images and converging on solutions to specific problems," (p. 42) rather than creative fantasy characteristic of hypnotic behavior. Forty Subjects had two sessions each: imagery tests in #1 and SHSS:C in #2. Imagery tests included, in this order: 1. Paired Associates (Paivio, 1972; a test of synthetic imaging), in which paired words are learned and later recalled; Experimental Ss were to learn them by combining them into an image, while Control Ss were to simply try to learn them. The nouns differed in imagery strength (potential for stimulating images). 2. Nonsense Forms (a test of analytic imaging), in which Subjects trace with their fingers an irregularly shaped Masonite form, blindfolded, and then choose one of 5 drawings that best matches the form. 3. Cube Visualization (a test of analytic imaging), in which Ss imagine a 2" wooden cube painted red on all faces, that had been sawed into 1" cubes; they are to say how many of the smaller cubes would be red on 3 faces, 2 faces, one face, and none of the faces. 4. Betts QMI.

The Paired Associates (PA) scores were a ratio of high imagery words recalled to low imagery words recalled, intended to reflect the impact of imagery availability on memory. There was a trend for hypnotizability to correlate with PA ratio scores, regardless of whether intermediate or low imagery nouns were used as baseline ( $\rho = .37$  and  $.34$ ,  $p < .10$ ) in the experimental group ("Use imagery to learn."), a trend that was not found in the control group (no imagery instructions). Neither measure of analytic imaging ability (Nonsense Forms, Cube test) correlated with hypnotizability.

In their Discussion, the authors write, "The common factor in successful performance of both imagery-mediated paired associates learning tasks and hypnotic suggestions appears to be the ability to expand imaginatively upon a given verbal input" (p. 47). They cite the literature relating hypnotizable and creative performance (p. 47). "The present findings with the Nonsense Forms Test and the Cube Visualization Test, both of which failed to correlate significantly with SHSS:C, support the hypothesis that hypnotizability is not related to analytic, spatial-

imagining skills" (p. 47). "The nonsignificant correlation between Betts QMI and SHSS:C adds to the growing body of inconsistent findings observed with Betts QMI" (p. 47).

"Given the complex nature of hypnotic susceptibility and of imagery (Monteiro et al., 1980), it is perhaps not surprising that studies attempting to relate the two variables directly frequently yield only modest relationships. Very likely, the inclusion of appropriate mediating variables would serve to clarify and, in particular instances, augment the relationships observed between hypnotic responsiveness and imaging ability. One such variable may be the capacity to become fully involved in everyday nonhypnotic experiences, commonly called absorption. This variable has been shown in numerous studies to be related to hypnotizability (e.g. Tellegen & Atkinson, 1974), as well as to creativity and vividness of imagery (P. Bowers, 1978, 1979; Monteiro et al., 1980). Even more relevant to the present study is the possible interaction between level of hypnotic susceptibility and the relationship between synthetic imaging ability and SHSS:C scores. It may be, for example, that the contribution of synthetic imaging ability becomes more critical in eliciting hypnotic behavior from Ss who are only moderately susceptible to hypnosis. Such an analysis was not possible in the present experiment, since the number of high, medium, and low susceptible Ss was approximately equal, and, therefore, the number of Ss at each level was insufficient for an adequate subgroup analysis. Clearly, however, future studies of the role of imaginal skills in hypnotic responsivity must move in directions such as these" (p. 48).

1982

Crawford, Helen J. (1982). Cognitive processing during hypnosis; much unfinished business. Research Communications in Psychology, Psychiatry and Behavior, 7, 169-179.

Studies of cognitive processing during hypnosis per se are reviewed suggesting that hypnotically responsive individuals not only experience subjective changes during hypnosis that are seen as often being discontinuous from their normal consciousness but also may exhibit measurable cognitive changes. Evidence (ego functioning changes, enhanced creativity, enhanced imagery processing, etc.) is presented to support the hypothesis that hypnosis may involve a shift in cognitive functioning away from a verbal, detail-oriented strategy towards a more imaginal, non-analytic, holistic- oriented strategy. Limitations of present research and potentially valuable research areas are discussed.

NOTES

The author reviews evidence for cognitive changes during hypnosis--evident especially in high hypnotizables but also to some degree in moderate hypnotizables. She concludes that there may be changes in ego functioning, imagery functioning, creativity, and strategy preferences and that high hypnotizables are more flexible in cognitive processing . "The question remains whether or not there are accompanying objectively measurable cognitive changes during hypnosis" (p. 170).

**"In normal waking consciousness, the hypnotically responsive individual is typically found to be more involved in nonhypnotic imaginative activities and experiences (Hilgard, 1979; Tellegen & Atkinson, 1974), more able to image things (for review, see Sheehan, 1979) and daydream vividly and positively (Crawford, 1982), more able to perceive gestalt closure figures (Crawford, 1981), more able to divert attentional process (e.g., Karlin, 1979), and more creative on certain tasks (e.g., P. Bowers, 1979). Experiential reports indicate that it is these very cognitive processes, amongst others, which are perceived to be enhanced or changed during the hypnotic state" (p. 170).**

**"Levin and Harrison (1976) found that hypnosis ego changes occurred most in those individuals who also demonstrated good capacity for adaptive regression in the waking state" (p. 171).**

**"Dave (1979) compared hypnotically induced dreams with rational-cognitive treatment as to their effects on creative problem solving of the problems or projects. 'Conditional support' was given to the significantly stronger effect form the hypnotically induced dreams" (p. 172).**

**There are many investigations of the effect of hypnosis on imagery, with a number of methodological problems. "Self-reports can be criticized on the grounds that they are easily subject to demand characteristics, subject expectations, and social desirability influences. Coe et al. (1980) found order of condition influenced their findings, while Crawford (1979) found that imagery rating scales suffered from a low ceiling effect among high imagers" (pp. 172-173).**

**"Surprisingly, while the field of cognitive psychology has devoted extensive attention to the study of the enhancing effects of imagery upon memory, few of their paradigms have been applied to the study of hypnotic processing of information. Germaine to the field of hypnosis are three operational approaches to the investigation of imagery: (a) the manipulation of the availability of imagery as a coding device, such as varying the degree to which stimuli may evoke imagery, (b) the manipulation of the processing strategy in cognitive performance, such as asking subjects to use imagery in the mediation of stimuli information, and (c) the comparing of information processing strategies and performance in subjects who are low and high in imagery ability (Paivio, 1971)" (p. 173).**

**"Several studies (Nomura, Crawford, & Slater, 1981; Walker, Garrett, & Wallace, 1976; Wallace, 1978) found that a very few high hypnotizables can successfully produce eidetic imagery, using nonfakable stereograms, during hypnosis even though they cannot during waking. Spanos, Ansari, & Stam (1979) were unable to replicate these findings. It was only self-reported childhood eidetikers who exhibited eidetic imagery during hypnosis, and then only a few. This research suggests that hypnosis permits certain individuals to access the "lost" ability to image eidetically, possibly through a shift in cognitive strategies" (p. 174).**

**"An underlying emphasis of this paper is the need for hypnotic investigators to integrate findings from cognitive psychology into their research, as well as apply the many new approaches to understanding brain functioning which are now being developed, in their search for a better understanding of what occurs during hypnosis" (p. 176).**

Hilgard, Ernest R.; Sheehan, Peter W.; Monteiro, K. P.; Macdonald, Hugh (1981). Factorial structure of the Creative Imagination Scale as a measure of hypnotic responsiveness: An international comparative study. International Journal of Clinical and Experimental Hypnosis, 29, 66-76.

The factor structure of the Creative Imagination Scale (CIS) of Wilson and Barber (1978) was investigated in two studies by correlating scores on it with scores on the Harvard Group Scale of Hypnotic Susceptibility, Form A (Shor & E. Orne, 1962), the Absorption scale of Tellegen and Atkinson (1974), and Sheehan's (1967) revision of Betts' (1909) imagery scale. One of the studies was conducted at the University of Queensland in Australia (N = 237), the other at Stanford University in California (N = 92). The major finding, consistent in both investigations, was that two factors accounted for the major portion of the variance, one factor designated as a Hypnotic Performance factor, the other designated as an Absorption/Imagination factor. The CIS was weighted highly on both factors, the data bearing on earlier claims that CIS represents a single-factor scale.

1978

Bowers, Patricia G. (1978). Hypnotizability, creativity and the role of effortless experiencing. International Journal of Clinical and Experimental Hypnosis, 26, 184-202.

Creative people and highly hypnotizable people describe their experience of finding creative solutions or responding to hypnotic suggestions as "effortless." It is suggested that receptiveness to subconscious work accounts for the experience of effortlessness in both tasks. An experiment using 32 high and low hypnotizable men and women was designed to explore the hypothesis that the aptitude for such effortless experiencing accounts for the relationship found between creativity and hypnotizability.

Analyses of variance indicate highly significant effects of level of hypnotizability on composite scores reflecting effortless experiencing of several tasks and creativity. Intercorrelations of these indices are about .60. As predicted, effortless experiencing accounts for much of the relationship between high versus low hypnotizability and composite creativity. The role of imagery vividness and of absorption in both hypnotizability and creativity were also explored.

**Sanders, Shirley (1978). Creative problem-solving and psychotherapy. International Journal of Clinical and Experimental Hypnosis, 26, 15-21.**

The techniques described comprise a creative problem-solving approach to short-term individual psychotherapy which appears effective in conjunction with hypnosis. The techniques include describing and visualizing the client's problem, imagining alternative reactions, dreaming about new solutions, and trying the solutions in real life. The method is illustrated by 2 clinical examples. The discussion focuses on a comparison of the techniques used with individuals versus with small groups, the fostering of regression in the service of the ego, and the redirection of attention from the physically out of control to the recognition of the possibility of obtaining control. This shift of attention fosters active coping on the part of the client.

**1977**

**Krippner, Stanley (1977). Research in creativity and psychedelic drugs. International Journal of Clinical and Experimental Hypnosis, 25, 274-308.**

The influence of psychedelic drug experience upon various aspects of the creative process has been studied by very few researchers over the years. Although no conclusive statements can be made, it appears possible that these substances may be associated with original ideation and imagery, especially in the case of professional artists. There is no evidence that LSD-type drugs can evoke creativity on the part of individuals who are not known to be talented before drug ingestion. Creativity involves transforming fantasy into reality; the study of psychedelic experience, hypnotic experience, and other alterations in consciousness may help science to understand this process.

**1976**

**Gur, R. C.; Reyher, J. (1976). Enhancement of creativity via free-imagery and hypnosis. American Journal of Clinical Hypnosis, 18, 237-249.**

Thirty-six male, highly susceptible subjects, divided into hypnosis, simulation and waking groups, were given the Torrance Test of Creativity with modified instructions requiring them to wait passively for visual images in response to the test stimuli. Twelve waking subjects received the same test under standard instructions. The hypnotized group scored higher than all control groups on over-all creativity and on Figural creativity, but not on Verbal creativity. The results seem to support the application of the ego-analytic concept of 'adaptive regression' to both hypnosis and creativity. They also seem to confirm the association found between hypnosis and the activation of the non-verbal cerebral hemisphere.

**Raikov, V. L. (1976). The possibility of creativity in the active stage of hypnosis. International Journal of Clinical and Experimental Hypnosis, 24, 258-268.**

Creative capacity was studied by means of suggestions given to Ss under the condition of active hypnosis. In deep hypnosis it was suggested to S that he was a

famous person with a specific talent. In a series of experiments Ss performed under active hypnosis such tasks as drawing, playing musical instruments, and playing chess. The results illustrated that creative processes can be facilitated in Ss capable of deep hypnosis and there is a carry-over of the creative achievements from hypnosis to the waking state. Low hypnotic Ss and control groups did not show improvements in the tasks. A particular significant increase in creativity was observed when Ss capable of deep hypnosis performed several successive creative tasks while hypnotized. The theoretical and experimental definitions of several new approaches to active hypnosis are also discussed.

Sapp, Marty; Hitchcock, Kim (2003). Creative imagination, absorption, and dissociation with African American college students. *Sleep and Hypnosis*, 5 (2), 95-104.

The purpose of this study was to assess creative imagination, absorption, and dissociation with African American college students. Two hundred thirty-six undergraduate African American students ranging between the ages of 18 to 22 participated in this study. Students were assigned to the following experimental manipulation: (a) Creative Imagination Scale (CIS), a cognitive-behavioral measure of hypnotizability; and (b) Dissociative Experiences Scale (DES), General Dissociation Scale (GDS), and Tellegen Absorption Scale (TAS) embedded within the CIS. Results indicated that dissociation and absorption were affected by the CIS. Finally, this sample was compared with the European American sample obtained by Barber and Wilson (1978) and Wilson and Barber (1978), and clearly the two samples differed on creative imagination,  $t(405)=7.00, p<.005$ . The African American sample had a significantly lower mean CIS score than the European American sample.

Sapp, Marty; Hitchcock, Kim (2003, March). Measuring dissociation and hypnotizability with African American college students: A new dissociation scale-The General Dissociation Scale. *Australian Journal of Clinical Hypnosis*, 24 (1), 23-34.

Two hundred and two undergraduate African American college students participated in this study. Students completed the Harvard Group Scale of Hypnotic Susceptibility, Form A: (HGSHS:A), the Dissociative Experiences Scale (DES), General Dissociation Scale (GDS) and the Inner Subjective Experiences scoring for the HGSHS:A, a measure of nonvolitional hypnotic responding. The GDS produced items had a reliability of .87 and it correlated .505,  $p<.01$ , with the DES. The items of HGSHS:A behavioral scoring method produced a reliability index of .29 with African American college students. Clearly, the Inner Subjective Experiences method for scoring the HGSHS:A is more appropriate for African American college students than the behaviorally scored items of the HGSHS:A, and the items of this scale had a reliability of .88. And the GDS produced items that were reliable for African American college students and European American students. Finally, this study provided confidence intervals for the reliability of items that measured hypnotizability, dissociation and nonvolitional responding.

Court, John (1998). Not the state, but the territory. Australian Journal of Clinical and Experimental Hypnosis, 26 (2), 104-112.

With the current growth of interest in spirituality, the interface between hypnosis and religious practices takes on new significance. Cautions have traditionally been expressed about the hypnotic state, with fears about control and willpower. While developments in the ethical use of hypnosis make such concerns less pressing, there remain significant paradigm issues which are being explored in the literature. These include pursuit of the age-old question, "Who are the legitimate healers in a society?" The territory of the church and the territory of the clinic are not entirely separate, so issues arise regarding the relative authority of practitioners to intervene in people's lives, and what such interventions should look like. Many Christians who might benefit from hypnosis have been warned to be totally against it. Evidence will be brought forward to challenge this and make it safer to look to therapeutic hypnosis without compromising beliefs.

1997

Jana, Hrishikesh (1997). The development of hypnosis in India. [Unpublished manuscript]

#### NOTES

Yoga (specially Meditative Yoga or Savasana) and Transcendental Meditation are integral parts of the cultural heritage of Indians. These and the state of hypnosis possess some of the characteristics in common and all these have been grouped under the heading 'Altered States of Consciousness' by the modern psycho-physiological and biological researchers. Hindu saints used to clothe sparsely even in the midst of extreme environmental conditions and the lying down of some yogis on the nail-bed are examples of their super-human tolerance to cold, pain, etc." (p. 2). Author cites the pioneering work of Dr. James Esdaile using hypnosis for surgical anaesthesia at Hooghly Hospital (1845-1850). Despite India's culture and the record of Dr. Esdaile, hypnosis often was regarded with suspicion in India. In the early and mid-20th century, physicians (e.g. Dr. N.V. Mody, an obstetrician) had difficulty having their work accepted, but since the early 1970s Dr. Jana and others have contributed to a renaissance in the use of medical, dental, and psychological hypnosis. This paper chronicles the history of hypnosis in the late 20th century in India.

1996

Cardena, Etzel (1996). "Just floating on the sky:" A comparison of hypnotic and shamanic phenomena. In Quekelberghe, R. V.; Eigner, D. (Ed.), Yearbook of cross-cultural medicine and psychotherapy 1994 (pp. 85-98).

Despite the vastly different cultural contexts of hypnosis and shamanism, a comparison of the phenomenology of the two is warranted. The author proposes that the two types of very hypnotizable individuals, one exhibiting vivid imagery and the other showing diminished memory and

control, corresponds to the classical distinction between soul journey and spirit possession. Other cognitive traits, developmental histories and alternate experiences of hypnotic virtuosos and shamans imply other similarities. The resemblance between hypnotic and shamanic phenomenology strongly suggests a universal disposition that is independent of culture. Western culture should acknowledge, respect and study the potentials and risks of this ability.

Desmangles, Leslie G.; Cardena, Etzel (1996). Yearbook of Cross-Cultural Medicine and Psychotherapy, 1994. Berlin: Verlag fur Wissenschaft und Bildung. (Theme Issue: Trance, possession, healing rituals, and psychotherapy)

In this paper, we analyze trance possession in its cross-cultural, psychological and religious contexts, and describe its role specifically within Haitian Vodou and society. In contrast with the earlier analysis of spirit possession as a form of psychopathology, more recent scholarships (sic) has emphasized its import as a common and meaningful religious practice. Vodou is a syncretic religion that, for historical reasons, fused African traditions with Catholicism. In Haiti, the possessed individual plays a liminal function that bridges the sacred and the secular, and temporarily transcends the limitations imposed provided by social or economic status.

Zachariae, Robert; Sommerlund, Bo; Molay, Francine (1996). Danish norms for the Harvard Group Scale of Hypnotic Susceptibility, Form A. International Journal of Clinical and Experimental Hypnosis, 44 (2), 140-152.

Norms for a Danish adaptation of the Harvard Group Scale of Hypnotic Susceptibility, Form A (HGSHS:A) are presented. Four samples tested from 1988 to 1991 (n = 166, n = 54, n = 95, and n = 61) were pooled, resulting in an aggregate sample of 376 participants. The normative data were generally congruent with earlier normative studies with regard to score distribution, item difficulty levels, and reliability. Studies using the Danish adaptation of the HGSHS:A as a screening instrument have shown the predictive value of the instrument in a Danish context. Data for a comparable American sample of volunteers (n = 170) tested by the same hypnotist were included in the analysis. A comparison revealed a marked difference for the posthypnotic suggestion item, hinting that cultural differences between the Danish and American samples with regard to expectancies and attitudes toward hypnosis may play a role. Further studies comparing attitudes toward hypnosis across different cultural contexts are needed to clarify this issue. - Journal Abstract

1995

Holroyd, Jean (1995). Handbook of clinical hypnosis, by Judith W. Rhue, Steven Jay Lynn, & Irving Kirsch (Eds.) [Review]. International Journal of Clinical and Experimental Hypnosis, 43 (4), 401-403.

#### NOTES

"This is a book for the thinking clinician" (p. 401). "The editors are to be congratulated for making this volume much more coherent than most edited books" (p. 402). "My impression is that the book is best suited for an intermediate or advanced course on hypnotherapy, or for people who are already using hypnosis in treatment. Although there is some material on the basics of hypnotic inductions and a few introductory sample scripts for inductions, a beginners' course should probably use a different book, or this book could be accompanied by an inductions manual. ... I recommend it very highly" (p. 403).

#### 1994

Cardena, Etzel (1994, October). Dissociative trance disorder, amnesia, and fugue: New proposals. [Paper] Presented at the annual meeting of the Society for Clinical and Experimental Hypnosis, San Francisco.

#### NOTES

Dissociative trance disorder was proposed but not accepted for the newest revision of the Diagnostic and Statistical Manual; it is being considered for DSM IV. It is needed because the current dissociative diagnoses don't cover many of the patients. People are using the NOS characterization for those patients. Trance is a frequent type of pathology in other cultures. [Notes were not recorded for most of this paper.]

Cardena, Etzel (1994, August). Spirit possession in Haiti. [Paper] Presented at the annual meeting of the American Psychological Association, Los Angeles.

NOTES: THREE DIMENSIONS OF POSSESSION: 1. Shift from one identity into another (e.g. substituting the everyday identity for that of a spirit) 2. Transitional (you are not having one type of identity substituted for another); involves a transition between states of consciousness (e.g. confusion, dizziness) 3. Transcendent possession - you have a human identity that is not quite there, but another identity has not taken over, like the oracle.

He disagrees with Eliade and Roger Walsh who imply that shamanism is a higher form than possession because possession is "out of control."

Flight of mind - you are able to remember and bring back the information, mostly visual/imaginal.

vs Possession - involves an embodied alteration of consciousness and, frequently, amnesia.

For further information, consult Cardena, E. (1989). The varieties of possession experience. Association for the Anthropological Study of Consciousness Quarterly, 5 (2- 3), 1-17.

Spanos, Nicholas P. (1994). Multiple identity enactments and multiple personality disorder: A sociocognitive perspective. Psychological Bulletin, 116, 143-165.

People who enact multiple identities behave as if they possess 2 or more selves, each with its own characteristic moods, memories, and behavioral repertoire. Under different names, this phenomenon occurs in many cultures; in North American culture, it is frequently labeled multiple personality disorder (MPD). This article reviews experimental, cross-cultural, historical, and clinical findings concerning multiplicity and examines the implications of these findings for an understanding of MPD. Multiplicity is viewed from a sociocognitive perspective, and it is concluded that MPD, like other forms of multiplicity, is socially constructed. It is context bounded, goal-directed, social behavior geared to the expectations of significant others, and its characteristics have changed over time to meet changing expectations.

Spanos, Nicholas P.; Burgess, Cheryl A.; Burgess, Melissa Faith (1994). Past-life identities, UFO abductions, and satanic ritual abuse: The social construction of memories. International Journal of Clinical and Experimental Hypnosis, 42 (4), 433-446.

People sometimes fantasize entire complex scenarios and later define these experiences as memories of actual events rather than as imaginings. This article examines research associated with three such phenomena: past-life experiences, UFO alien contact and abduction, and memory reports of childhood ritual satanic abuse. In each case, elicitation of the fantasy events is frequently associated with hypnotic procedures and structured interviews which provide strong and repeated demands for the requisite experiences, and which then legitimate the experiences as "real memories." Research associated with these phenomena supports the hypothesis that recall is reconstructive and organized in terms of current expectations and beliefs.

1993

Cardena, Etzel (1993, October). Trance and possession as dissociative disorders: How exotic are they?. [Paper] Presented at the annual meeting of the Society for Clinical and Experimental Hypnosis, Arlington Heights, IL.

NOTES: Joke: "What happened to the possessed patient who didn't pay his exorcist?" Answer: "He got repossessed."

Began with a quotation of Lagerkvist's book describing possession of a Sybil in Greek temple. Possession is part of religious experience worldwide, that he is not discussing here.

The revised diagnostic manual, ICD-10, has included "dissociative trance disorders." To diagnose this one must have either trance (narrowing awareness or focusing and stereotyped movements, behaviors) or possession trance (replacement of sense of personal identity by a new identity, with stereotyped culturally-determined behaviors or movements that are experienced as being controlled by the

possessing agent), \*and\* full or partial amnesia for the event. Cardena emphasizes it doesn't need to be full amnesia.

To be diagnosed as dissociative trance disorder, the trance or possession state observed cannot be a normal part of a broadly accepted cultural or religious practice, and it must produce distress or maladjustment.

These are the most common type of dissociative disorders in non-Western cultures, e.g. 90% in India. So this diagnosis in India is not "atypical." "Non-Western" applies to 80% of the World and 1/3 of the USA population. DSM is trying to expand cultural relevance.

Also, even in the Western culture Allison and others have published cases of dissociative trance disorder, and others have described trance disorders:

Spiegel & Spiegel's Grade 5 personality is vulnerable to dissociative disorder. Hartman's chronic nightmare patients have "boundary thinness" (i.e. they are not clear if they are awake or asleep, lack separation from themselves and others). Lynn & Rhue's fantasy prone individuals, 22% of people, are vulnerable to maladjustment.

Cardena's recommended change in diagnosis of dissociation is critiqued in Transcultural Psychiatric Research Review (1992). Criticisms of the new diagnosis, published in that journal, are: 1. Culture-bound syndromes cut across Western diagnostic boundaries. 2. The diagnosis may be insensitive to the cultural context in which phenomena occur (e.g. distress may lead a person to participate in a cult of affliction) and it may require anthropological sophistication of diagnosticians or consultation with someone who has that knowledge. 2a. It may disregard considerations such as who has the power to "authorize" the phenomenon, under what circumstances, etc. [That would be true with any diagnosis however.] 3. Dissociative Trance Disorder may assume greater within and across-culture uniformity for the conditions than is warranted. 4. It may give validity to metaphysical explanations for spirit possession. [But in psychiatry we often use terms that don't take into consideration validating metaphysical explanations, e.g. "phantom limb" pain. 5. The medical model that underlies DSM is inappropriate for ontological considerations on the nature of the self. [But those with this diagnosis give us some understanding, not what the ultimate nature of the self and consciousness are. Diagnoses are pragmatic ways of dealing with problems.]

At the present time, the diagnosis of Dissociative Trance Disorder is included in the Appendix of DSM-IV.

For further elaboration of this material, see Cardena, E. (1992). Trance and possession as dissociative disorders. *Transcultural Psychiatric Research Review*, 29, 283- 297.

1992

Morse, Donald R.; Martin, John; Moshonov, Joshua (1992). Stress induced sudden cardiac death: Can it be prevented?. *Stress Medicine*, 8, 35-46.

Previously, psychosomatically induced death relative to stress, hypnosis, mind control, and voodoo was discussed. In this article, emphasis is on one aspect of that - stress induced sudden cardiac death (SCD). A brief review is presented of the

sympathetic aspects of the acute stress response and stress induced SCD. Findings from previous studies are presented to highlight sympathetic aspects of the acute stress response. This is followed by a presentation of various strategies to prevent or decrease the possibilities for stress induced SCD. These include long-term measures (e.g. diet control, smoking control, hypertension control, stress management strategies) and immediate measures (e.g. calm, controlled approach, elicitation of the relaxation response, selected use of drugs, and heart rate variability monitoring). Relative to prevention strategies, findings are presented both from previous studies and new investigations.

#### **NOTES**

Notes are taken from a review of this book: Diamond, Michael (1993). Book review. *Bulletin of the Menninger Clinic*, 57 (Winter), 120-121.

Brown "posits that because the fundamental matrix of the human brain is metaphoric, hypnosis results from skillful matching of metaphorical communication with the brain's biological, rhythmic alterations. The most significant feature of trance experience is thereby located in the hypnotist-subject interaction" (p. 120).

"The middle section [of the book is comprised largely of] literature reviews in support of Rossi's (1986) ultradian rhythm theory of hypnosis and Lakoff and Johnson's (Johnson, 1987; Lakoff & Johnson, 1980) experientialist theory of conceptual thought" (p. 120). The final section includes "research evidence on medical uses of hypnosis, a theory of dissociation and multiple personality disorders, and an uncritical discussion of Milton Erickson's naturalistic hypnotherapeutic approach ... [and also] a brief discussion of the social-cultural functions of possession states among the Mayotte culture" (p. 120).

**Daglish, Mark R. C.; Wright, Peter (1991). Opinions about hypnosis among medical and psychology students. Contemporary Hypnosis, 8, 51-55.**

A survey was undertaken of opinions about hypnosis among first year medical and psychology students at the University of Edinburgh. Data are presented on the effects of self-estimated hypnotizability and sex, on opinions about hypnosis. The results are compared with those from similar studies conducted in Australia and the USA. Overall, the surveyed population showed a similar level of knowledge about hypnosis to that found among the general public.

**Morse, Donald R.; Martin, John; Moshonov, Joshua (1991). Psychosomatically induced death: Relative to stress, hypnosis, mind control, and voodoo: Review and possible mechanisms. Stress Medicine, 7, 213-232.**

A common denominator in psychosomatically induced death is stress. Death can occur slowly, as from the preponderance of chronic stressor, or it can come on

suddenly, as from an acute stressor. Sudden death is more likely in an individual with preexistent serious medical conditions, which were outlined. Seven types of individuals more prone to sudden death were outlined. Most cases of sudden death are related to the presence of a severely stressful situation in which there appears to be no means of control or escape. With mind control, hypnosis, and voodoo curses, circumstances can be manipulated to achieve severe stress and uncontrollability.

**Spanos, Nicholas P.; Cross, Wendi P.; Lepage, Mark; Cristine, Marjorie (1986). Glossolalia as learned behavior: An experimental demonstration. Journal of Abnormal Psychology, 95, 21-23.**

**60 Ss listened to a 60-s sample of glossolalia (defined to them as pseudolanguage) and then attempted to produce glossolalia on a 30-s baseline trial. Afterward, half of the Ss received two training sessions that included audio- and videotaped samples of glossolalia interspersed with opportunities to practice glossolalia. Also, live modeling of glossolalia, direct instruction, and encouragement were provided by an experimenter. Both the trained subjects and untreated controls attempted to produce glossolalia on a 30-s posttest trial. About 20% of subjects exhibited fluent glossolalia on the baseline trial, and training significantly enhanced fluency. Seventy percent of trained subjects spoke fluent glossolalia on the posttest. Our findings are**

more consistent with social learning than with altered state conceptions of glossolalia.

Burnham, John C. (1984, October/1986). The fragmenting of the soul: Intellectual prerequisites for ideas of dissociation in the United States. In Quen, Jacques M. (Ed.), Split minds/split brains (pp. 63-84). New York: New York University Press. (Based on symposium in Bear Mt., N.Y., by Section on the History of Psychiatry of Cornell University Medical Center)

#### NOTES

Reductionism was a relentless pursuit of the idea that knowledge of components led to knowledge of causes. In this context, I propose to show how, in the psychological-medical realm, the initial concept was the soul, and the final intellectual product was dissociative phenomena" p. 64.

1984

Suryani, L. K. (1984). Culture and mental disorder: The case of bebainan in Bali. In Culture, medicine and psychiatry. D. Reidel Publishing Company.

#### NOTES

Bebainan is a form of dissociation which is culturally associated with Bali. Thought to be caused by sorcery, a bebainan attack lasts up to an hour and is manifested by confusion, crying, screaming, and shouting, with inability to control one's actions. However, it seems most victims maintain awareness of their own behavior and are not amnesic for it afterwards.

In this study, the author interviewed 27 people, mostly female, most of whom experienced their first attack between 16-30 years of age. The author concluded that the attacks permitted release of feelings of frustration and anger without stigma. Author concluded it is not a form of psychosis, is not organic, and is not a neurosis.

Wilson, Ian (1984). Jesus--The evidence. London England: Weidenfeld and Nicolson.

#### NOTES

Miracles of Jesus are attributed to hypnosis, in a culture that had already experienced faith healers. Many of those healed had diseases that today might fall into the 'hysteria' or 'psychosomatic' categories (paralysis, lameness, fever, catalepsy, haemorrhage, skin disease, mental disorder), which diseases are frequently responsive to hypnosis. Further, Jesus' reputation preceded him, and the fact that his cure rate was low in his home town is evidence of both the veridicality of the written record (Mark 6: 1-6) and the expectancy factor. "The significance of this episode is that Jesus failed precisely where as a hypnotist we would most expect him to fail, among those who knew him best, those who had seen him grow up as an ordinary child. Largely responsible for any hypnotist's success are the awe and mystery with which he surrounds himself, and these essential factors would have

been entirely lacking in Jesus' home town" (pp. 111-112). The author also assigns other miracles (his transfiguration into dazzling light before three disciples; turning water into wine) to hypnosis [which other writers might ascribe to suggestion].

1982

Hong, G. K.; Skiba, A. H.; Yepes, E.; O'Brien, R. M. (1982). Effects of ethnicity of hypnotist and subject on hypnotic susceptibility. International Journal of Clinical and Experimental Hypnosis, 30 (1), 23-31.

The effect of ethnic similarity of hypnotist and hypnotic S on hypnotic susceptibility was examined in a 2-part study. The first part of the study compared the performance of Anglo versus Chinese hypnotists on Anglo versus Chinese Ss. In the second half of the study, Anglo and Hispanic Ss and hypnotists were compared using the same Anglo hypnotist-S control group. In total, 112 volunteers were administered the Stanford Hypnotic Susceptibility Scale, Form A, of A. M. Weitzenhoffer and Hilgard (1959), with 16 Ss (8 males and 8 females) in each condition. A 2 x 2 ANOVA was performed on the data for each part of the study. Ethnic similarity of hypnotist and S was found not to enhance hypnotic susceptibility. The implications of these results are discussed in relation to the assumed superiority of homoethnicity in psychotherapy.

Larbig, W.; Elbert, T.; Lutzenberger W.; Rockstroh, B.; Schnerr, G.; Birbaumer, N. (1982). EEG and slow brain potentials during anticipation and control of painful stimulation. Electroencephalography and Clinical Neurophysiology, 53, 298-309.

Cerebral responses in anticipation of painful stimulation and while coping with it were investigated in a 'fakir' and 12 male volunteers. Experiment 1 consisted of 3 periods of 40 trials each. During period 1, subjects heard one of two acoustic warning stimuli of 6 sec duration signaling that either an aversive noise or a neutral tone would be presented at S1 offset. During period 2, subjects were asked to use any technique for coping with pain that they had ever found to be successful. During period 3, the neutral S2 was presented simultaneously with a weak electric shock and the aversive noise was presented simultaneously with a strong, painful shock, again under pain coping instructions. EEG activity within the theta band increased in anticipation of aversive events. Theta peak was most prominent in the fakir's EEG. A negative slow potential shift during the S1-S2 interval was generally more pronounced in anticipation of the aversive events than the neutral ones, even though no overt motor response was required. Negativity tended to increase across the three periods, opposite to the usually observed diminution. In Experiment 2, all subjects self-administered 21 strong shock-noise presentations. The fakir again showed more theta power and more pronounced EEG negativity after stimulus delivery compared with control subjects. Contrary to the controls, self-administration of shocks evoked a larger skin conductance response in the fakir than warned external application.

NOTES

A published case study by Pelletier (1977) reported EEG theta enhancement during pain control states, which were maintained by EEG feedback of alpha and theta bands. That author concluded that EEG theta was necessary for the control of pain psychologically.

The authors of this article measured slow brain potentials (SBPs) and vertical eye movements (VEMs). Principal components analysis of the EEG wave forms found three components: theta (4-5.6 c/sec), alpha band (9-10 c/sec) and high frequencies (above 14.4 c/sec) plus harmonics loading in frequencies of 3.2-4.5 c/sec, 7.5-9, and above 15 c/sec.

Alpha "decreased over periods in the parietal record and was virtually absent in the fakir's EEG during period 3" (p. 301). The fakir had a lot of non-sinusoidal, especially square wave, activity.

"Very pronounced negativity was recorded preceding the aversive S2, greater than under neutral stimulus conditions .... This difference was most pronounced at the vertex ... The late negativity increased over periods in control subjects ... especially in anticipation of the aversive S2 ... . This contrasts with the usually observed decrease of SBP components over trials. As is shown in Figure 2, the PCA [principal components analysis] yielded two components for the 2.0 sec S2 interval, a positive deflection, which can be assigned to the P300 complex (here not reported), and a negative deflection, labeled post- imperative negative variation. ... This negative component increased over periods, being more pronounced in response to the aversive stimulation ... with increasing differentiation over period ..." (p. 302-303).

The fakir undertook an elaborate self hypnosis or trance induction to achieve analgesia that he had previously demonstrated in the laboratory (thrusting 4 unsterilized metal spikes into his abdomen, tongue, and neck without bleeding). This included "long- continued fixation on a point above the eye-brows. Blank facial expression, staring eyes, and a very low rate of eye-blinks indicated a trance-like state (periods without eye-blinks more than 30 min)" (p. 299). During the experiment itself, the fakir showed few ocular movements during the second and third periods. He also demonstrated large skin conductance responses, recorded from the second phalanges of the index and middle fingers of the left hand, to the aversive S1.

Experiment 2 was designed to emulate the self-administered aversive stimulation that the fakir routinely undertook, by having the volunteer Ss hold a switch that they pressed twice/minute, giving themselves a mild shock and an aversive noise. (These were the same aversive stimuli as were used in Experiment 1.) There were 21 self-paced button presses.

Three additional measures were taken: 1. Bereitschaftspotential (BP) - the mean negative shift during the 0.3 sec interval prior to the motor response of pressing the switch 2. Postimperative component (PINV) - the mean negative shift 0.9 to 1.9 sec after stimulus onset, i.e. elicited by closing the microswitch 3. Skin conductance response (SCR) - maximum change in skin conductance level during five second interval after the motor response of pressing the switch.

The fakir, but not the control Ss, showed a pronounced precentral PINV on each single trial of Experiment 2. He also showed pronounced SCRs (indicating autonomic arousal), which was even greater than the SCRs of control Ss. His

subjective pain rating was 1 in Experiment 1 (compared with 6.4 for controls) but 8 during Experiment 2 (compared with 5.7 for controls), on a scale of 1 to 10 maximum. Thus the fakir's pain increased from Experiment 1 to 2, while for many volunteer Ss it decreased 2 or 3 points. When interviewed, he said that "intention and motor commands prevented the fakir from getting into 'trance' satisfactorily. Consequently, he reported to have experienced the aversive stimuli as more painful than in experiment 1. Thus it might be that the observed PINV indicates the noncontingency between the demand for coping and the failure to cope or the discrepancy between expected control and presently experienced control" (p. 307). In their Discussion, the authors speculate that control of pain such as can be achieved by the fakir may involve dissociation of higher (possibly thalamic and cortical) and lower (reticular formation) arousal structures. Their observation of slow brain potentials (theta) recorded in anticipation of painful or aversive stimuli is in agreement with earlier published studies. However their observation of increasing negativity in anticipation of aversive stimuli is in contrast to previous research findings, in which diminution of negativity is generally observed. Both the fakir and subjects showed a post-stimulus negative shift in response to the S2; this has been "observed in normal subjects under conditions of change from controllable to uncontrollable aversive stimuli... and/or from obvious response-consequence contingencies to unpredictable control over the S2... PINVs were associated with an unexpected change in contingency or the inability to resolve ambiguity. Since a relationship was found between PINV amplitude and subjective ratings or experienced aversiveness of the painful stimulation, it may be speculated that obvious failure in coping with pain (i.e. more experienced pain) together with the requirement to cope (induced by instructions and experimental setting, giving rise to increased expectancy for control), produced a PINV (and probably feelings of uncontrollability together with a state of reactance and frustration) in the present experiments. In accordance with this point of view, it is of particular interest that only the fakir showed a more pronounced PINV in experiment 2, in which subjects delivered the painful stimuli to themselves. A postexperimental interview revealed that intention and motor commands prevented the fakir from getting into 'trance' satisfactorily" (p. 307).

Stam, Henderikus J.; Spanos, Nicholas P. (1982). The Asclepian dream healings and hypnosis: A critique. International Journal of Clinical and Experimental Hypnosis, 30 (1), 9-22.

The present paper critically evaluates the popular contention that the dream healings which occurred in antiquity at the Asclepian temples resulted from the unwitting use of hypnosis. This contention is found wanting and it is argued instead that these reported healings can be understood better by considering them in their cultural context.

1980

Fromm, Erika (1980). Values in hypnotherapy. Psychotherapy: Theory, Research and Practice, 17 (4), 425-430.

Hypnosis is an altered state of consciousness characterized by a regression in the service of the ego along with increased access to the unconscious. This makes it possible to achieve lasting therapeutic results faster in hypnosis than in the waking state. Hypnosis is also a state of decreased vigilance, a vulnerability that involves dangers if a patient is in the hands of a poorly trained, incompetent, or unscrupulous therapist. In general, the same human and moral values that guide responsible therapists with patients in the ordinary waking state must guide them with patients in hypnosis, only more so. Contemporary permissive hypnotherapists do not superimpose their own wills or personalities onto patients but provide support, help patients face the frightening parts of the unconscious, and thus aid them in coping with conflicts and gaining full autonomy and freedom from fear. (11 ref).

Prince, Raymond (1980). Variations in psychotherapeutic procedures. In Triandis, Harry C.; Draguns, Juris G. (Ed.), Psychopathology (6, pp. 291-349). Boston: Allyn & Bacon.

#### NOTES:

Prince points out that indigenous practitioners often capitalize on the organism's endogenous healing mechanisms which develop spontaneously when the individual is distressed. "healers around the world have learned to manipulate and build upon these endogenous mechanisms in a variety of ways to bring about resolution of life's problems and alleviation of suffering" (p. 292). Prince is referring here to altered states of consciousness such as dreams, trance states, dissociations, and mystical experiences of various sorts which are cultivated and elaborated by indigenous healers for therapeutic purposes. In general, Western type practitioners have denigrated these procedures...." (from Ann. Rev. of Psychol., 1982, pp 243-244).

1979

Sheehan, Peter W.; McConkey, Kevin M. (1979). Australian norms for the Harvard Group Scale of Hypnotic Susceptibility, Form A. International Journal of Clinical and Experimental Hypnosis, 27, 294-304.

Australian norms for the Harvard Group Scale of Hypnotic Susceptibility, Form A (Shor & E. Orne, 1962) are presented and results relating to score distributions, item difficulty level, reliability, and validity are considered for 3 distinct samples of Australian students. Data are compared with both the original norms (Shor & E. Orne, 1963) and additional American (Coe, 1964) normative data. Results indicated that, in the Australian context, HGSHS:A functions as a reliable, effective predictor of hypnotic susceptibility. The psychometric properties of the scale were uniform across all of the different samples and reference groups that were considered. The accuracy of the scale appears to be most obviously limited when it is employed as a sole predictor of Ss' special aptitude for hypnosis.

Sacerdote, Paul (1977). Application of hypnotically elicited mystical states to the treatment of physical and emotional pain. International Journal of Clinical and Experimental Hypnosis, 25, 309-324.

Mystical states by-pass usual sensory perception and logical thinking. They often represent the ultimate goal of long apprenticeships in Eastern or Western monastic practices which stress self-discipline and meditation; or they correlate with sudden religious conversions. While interest has also been revived in mystical experiences stimulated by hallucinogens within the appropriate physical, intellectual, and emotional environment, less attention has been paid to those mystical experiences which appear spontaneously during hypnosis and Transcendental Meditation. The present author facilitates the unleashing of mystical experiences by using hypnotic approaches specifically aimed at altering space and time perceptions. Case presentations illustrate the methodologies for guiding receptive subjects to mystical states with the aim of relieving or correcting organic and functional painful syndromes unresponsive to other interventions. The probable biopsychological processes are discussed.

Sacerdote, Paul (1972). The nature of the hypnotherapeutic process. American Journal of Clinical Hypnosis, 15 (1), 1-11.

The author presents several clinical cases where hypnosis was successfully utilized. Through detailed description of what takes place during sessions it is shown how various approaches are adapted to the intellectual, cultural, emotional and hypnotic capabilities of the patient and to the progress of therapy. The author analyzes what

takes place during and after hypnotic intervention and draws some conclusions about the nature of the hypnotherapeutic process which, he feels, is essentially a convergence of the patient's and therapist's conscious and subconscious expectations and goals. The importance of the therapeutic ego of the doctor is brought into proper focus. One of the clinical cases illustrates how the therapist can convert a therapeutic relationship that may appear sterile or even hostile into a productive one by utilizing the patient's responses, while avoiding stubborn insistence upon expectations of preconceived hypnotic responses. It is suggested that the hypnotherapeutic model may present, in clearer focus, what takes place in other psychotherapeutic exchanges which do not utilize hypnosis.

**Pedersen, Darhl M.; Cooper, Leslie M. (1965). Some personality correlates of hypnotic susceptibility. International Journal of Clinical and Experimental Hypnosis, 13 (3), 193-203.**

The present research was directed principally toward determining the relationship of a number of personality variables to hypnotic susceptibility. The personality variables utilized were selected to cover the personality domain as broadly as possible. Hypnotic susceptibility was measured by the Stanford Hypnotic Susceptibility Scale, Form A. A correlational analysis was completed for 30 Ss. This included (a) the correlations between each of the personality variables and hypnotic susceptibility and (b) the intercorrelations among all of the personality measures. It was found that the following variables correlated with hypnotic susceptibility at the 5% level of confidence: age (-.37), year in college (-.36), and missionary service (.37). Social class rating of father's occupation correlated significantly at the 1% level of confidence (.54). (29 ref.) (PsycINFO Database Record (c) 2002 APA, all rights reserved)

Bowers, Margaretta K.; Glasner, Samuel (1958). Auto-hypnotic aspects of the Jewish cabbalistic concept of Kavanah. *Journal of Clinical and Experimental Hypnosis*, 6 (1), 50-70.

## NOTES

The authors present material quoted from numerous Jewish mystics to support the position that many achieved self hypnosis or trance states in the course of their spiritual, especially prayer, practices. "Kavanah" means concentration in the Talmud; "the entire hope of efficacy of ritual or of prayer is wholly dependent on the person's achieving a proper state of concentration and devotion, which is Kavanah" (p. 51). Ecstasy is one aspect of Kavanah and was induced in one way through "concentration upon the magical and mystical properties of the Hebrew letters, arranging and rearranging the letters" (p. 51) in such manner as to produce a trance. Sometimes dissociation occurred ("suddenly I saw the shape of my self standing before me and myself disengaged from me and I was forced to stop writing!" [p. 64]).

Sometimes a particular way of breathing, a particular position of the body, or fasting were used to promote trance development. Imagery and fantasy were also used, in a way resembling the work of Erickson, Kline, and Young; imagery of light and light sources was especially prevalent, reminding one of the candle flame induction technique.

"... it would appear that one of the ambitious purposes of the ecstatic Kavanah was to produce prophets" (p. 61). Some medieval prophets would describe a person's past and predict his future like the modern Edgar Cayce. "The auto-hypnotic state of ecstasy represented by Kavanah was also used for the deliberate induction of states of hysterical dissociation so that the 'prophet' would be able to see his self on the opposite side of the room" (p. 63). But the practice of the mystic ecstatic Kavanah was "generally discouraged or reserved for the elite at best" (p. 65).

"... however, in the medieval Christian world ignorance of the unconscious mental processes was so profound that it made it extremely difficult for wise and prudent religious leaders to cope with the religious excitement and delusionary revelations which broke out periodically. That the Jews were not entirely immune from such excesses at this time is shown by Dr. Scholem's [Major Trends in Jewish Mysticism, 1941] report that:

'In the writings of Eleazar of Worms .... one also finds the oldest extant recipes for creating the Golem -- a mixture of letter magic and practices obviously aimed at producing ecstatic states of consciousness. It would appear as though in the original conception the Golem came to life only while the ecstasy of his creator lasted. The creation of the Golem was, as it were, a particularly sublime experience felt by the mystic who became absorbed in the mysteries of the alphabetic combinations

described in the "Book of Creation." It was only later that the popular legend attributed to the Golem an existence outside the ecstatic consciousness, and in later centuries a whole group of legends sprang up around such Golem figures and their creators" (pp. 64-65).

Concentration was apparently used to avoid pain during torture of martyrdom and death. According to Scholem, the mystic Abraham ben Eliezer Halevi of Jerusalem recommended "to concentrate, in the hour of their last ordeal, on the Great Name of God; to imagine its radiant letters between their eyes and to fix all their attention on it. Whoever will do that, will not feel the burning flames or the tortures to which he will be subjected" (p. 66).

"We have demonstrated, therefore, that the Jewish mystics of former times, from the Biblical period through the Rabbinic period, on through the Middle Ages and almost up to the present day, used autohypnosis as a deliberate technique for the production of religious ecstasy and as a means for obtaining deeper religious insights or revelations. Both the methods by which they induced the autohypnotic trance, or Kavanah, and the ways in which they utilized it parallel some of the modern methods of hypnotic induction and of the utilization of the hypnotic trance" (p. 67-68).

"... hypnosis might well prove itself an important tool for an organized program of research into religious phenomena. Thus, for instance, hypnotic research could possibly provide us with an operational understanding of prayer and its effects. This might further lead to the development of more sophisticated and more effective techniques of prayer for use by scientifically-minded religionists. And it might even lead to the type of direct religious experience reported by religious geniuses of former days, but unfortunately lost to modern man" (p. 68).

Note: The second author is a rabbi.

## NOTES

Author's Conclusions: "In the light of the results, the following conclusions would appear to be justified:

1. Prestige suggestion can effect changes in an individual's response to an attitudes test.
2. Repeated prestige suggestion produces no more marked effect than does a single suggestion in changing social attitudes. However, the results seem to be more lasting with repeated suggestion.
3. Repeated hypnotic suggestion is considerably more effective than repeated waking suggestion in modifying social attitudes. But waking suggestion also seems to have some effect.
4. The effects of both hypnotic and waking suggestion vary greatly with different individuals.
5. The effect of repeated prestige suggestion in changing social attitudes apparently does not follow the pattern of the usual learning curve.
6. The changes noted seem to represent changes in basic attitude, and not merely changes in the response to a particular test" (P. 74).

The attitudes involved nationality preferences ("Negro, Turk, Hindu, or Chinamen" p. 71). The prestige suggestion, given in light hypnosis, was "The results on the test I

gave you were rather disappointing. Most people think that we in the South are deeply prejudiced against the colored races. But that is a mis-understanding of our position. Certainly we University people have no actual dislike of Negroes, Chinamen, or Hindus. And it is our hope, in giving this test, to demonstrate our true attitude, which is far more tolerant than most people give us credit for. I am therefore going to give you the test again. I want you, of course, to give your honest preferences. But where you find a choice difficult, give the 'underdog' the benefit of the doubt. Do you understand? Give the 'underdog' the benefit of the doubt!" (p. 72).

## D RESEARCH

### DEAFNESS

1995

Matthews, William J.; Isenberg, Gail L. (1995). A comparison of the hypnotic experience between signing deaf and hearing participants. International Journal of Clinical and Experimental Hypnosis, 43 (4), 375-385.

This study compared the hypnotic responsiveness of 17 hearing and 34 deaf individuals, all of whom received visual induction and hypnotic suggestions via some form of signing. The comparison between deaf and hearing participants was analyzed on five dependent measures: (a) the Stanford Hypnotic Susceptibility Scale, Form C (SHSS:C); (b) participants' individual item performance; (c) overall trance depth; (d) a rapport scale; and (e) a resistance scale measuring attitudes of participants toward the hypnotist. Although all participants showed at least a moderate level of hypnotic responsiveness, the data did not indicate a significant main effect between deaf and hearing participants on any of the dependent measures. However, there was a tendency ( $p < .08$ ) for hearing participants to show a greater hypnotic responsiveness than deaf participants. Additionally, there was a significant difference between all the signing participants combined when compared to the norming population on three items of the SHSS:C. Clinical and theoretical implications of these data are discussed.

Repka, Renee J.; Nash, Michael R. (1995). Hypnotic responsivity of the deaf: The development of the University of Tennessee Hypnotic Susceptibility Scale for the Deaf. International Journal of Clinical and Experimental Hypnosis, 43 (3), 316-331.

The purpose of these two studies was to develop and test a measure that assesses the hypnotic responsivity of deaf individuals. The University of Tennessee Hypnotic Susceptibility Scale for the Deaf (UTHSS:D) is a signed, videotaped version of a standard hypnotic induction with 12 standard suggestions. Experiment 1 compared the behavioral and subjective hypnotic responsivity of deaf and hearing individuals using the UTHSS:D and the Field Depth Inventory (FDI), respectively. As compared to hearing subjects, deaf participants were found to be less responsive to hypnosis when assessed behaviorally (UTHSS:D) and equally responsive to hypnosis when

assessed subjectively (FDI). Experiment 2 undertook a more comprehensive examination of the hypnotic responsivity of deaf individuals, using hearing individuals as controls. Three dimensions of hypnosis responsivity were assessed: behavioral (UTHSS:D), subjective (FDI), and interpersonal (Archaic Involvement Measure). Additionally, correlates of hypnotic responsivity (absorption, attitudes, expectations) were examined for the two groups. In Experiment 2, no significant differences were found between the deaf and hearing participant groups on any measures of hypnotic responsivity or on any measure of the correlates of hypnotic responsivity.

1992

Matthews, William J.; Isenberg, Gail L. (1992). Hypnotic inductions with deaf and hearing subjects - an initial comparison: A brief communication. International Journal of Clinical and Experimental Hypnosis, 40 (1), 7-11.

17 volunteer deaf Ss were compared with 18 volunteer hearing Ss on the Stanford Hypnotic Clinical Scale (SHCS) of Morgan and J. R. Hilgard (1975), and the Indirect Suggestion Scale (ISS) of Matthews and Mosher (1985) in a 2 x 2 ANOVA design. 5 dependent measures: (a) objective scale score; (b) self-report scale score; (c) S rapport with the hypnotist; (d) S resistance to the hypnotist; and (e) overall subjective rating of trance experience were employed to measure any differences between the 2 groups. For SHCS behavioral items, the two-way ANOVA failed to reveal any significant main effect or interaction differences between either group (deaf/hearing) or method of induction (direct/indirect). There was a significant main effect for deaf/hearing groups in level of resistance to the hypnotist. Deaf Ss reported feeling more resistant to the hypnotist than did hearing Ss. This may be due to the mode of communication or the fact that the hypnotist was hearing. Implications and limitations of the study are discussed.

1992

Spanos, Nicholas P.; Burgess, C. A.; Cross, P. A.; MacLeod, G. (1992). Hypnosis, reporting bias, and suggested negative hallucinations. Journal of Abnormal Psychology, 101, 192-199.

Examined the role of reporting bias in hypnotic negative hallucinations by using a paradigm in which reporting bias was assessed independently of perceptual change. In Experiment 1, highly hypnotizable subjects reported significant loudness reductions when tested for hypnotic deafness. Later, however, these subjects biased their reported loudness reductions in the absence of perceptual change, and their reporting bias scores were almost as large as their hypnotic deafness reports. Subjects also biased their ratings of strategy use. In Experiment 2, ratings of blindness given in response to a hypnotic negative visual hallucination suggestion were significantly correlated with reporting bias scores obtained in this paradigm. Although hypnotic blindness and hypnotic deafness correlated significantly, the partial correlation between these variables was nonsignificant when reporting bias

scores were statistically controlled. Results are used to support a skeptical view of hypnotic response as being based on compliance.

1987

Nash, Michael R.; Lynn, Steven Jay; Stanley, Scott; Carlson, Victor (1987). Subjectively complete hypnotic deafness and auditory priming. International Journal of Clinical and Experimental Hypnosis, 35 (1), 32-40.

The present study examined the cognitive and attentional mechanisms by which auditory information is maintained out of awareness during complete hypnotic deafness. Adopting a methodology from recent work on subliminally presented pattern-masked words and dichotic listening, the study tested whether spoken words presented during complete hypnotic deafness affect lexical decisions concerning subsequently presented word choices. The response of 9 hypnotized and 15 simulating Ss to spoken stimulus words presented following hypnotic deafness instructions was compared to the response of 20 baseline control Ss who never were exposed to the stimulus words. While the response pattern of hypnosis Ss appeared different from that of baseline control Ss, hypnotic Ss showed no evidence of the priming effect found in subliminal perception and dichotic listening studies. Simulator response deviated significantly from hypnotized and baseline control responses.

10 highs capable of hypnotic deafness, screened by Harvard Group and Stanford Profile Scales (Means 11.0 and 24.7, respectively) and 15 lows (means 1.7 and 1.7, respectively) participated in the study; the low hypnotizables being in the simulation group. For the experimental session, a different E administered a standard hypnotic induction and the deafness suggestion, testing for deafness by snapping fingers near S's ear and making loud requests for motor responses.

An experimental trial consisted of tapping an S on the hand, saying the stimulus word out loud, and visually presenting four words for the S to read out loud and circle one. "Of the 18 main experimental trials, the four-word array consisted of two words which were related to the stimulus (one word which was semantically related to the spoken stimulus word and one word which was phonetically related), and two neutral unrelated words" (p. 34). For example, if the spoken word were 'dream,' the word array might include 'cream, tennis, sell, sleep.' There also were "3 phonetically unrelated trials (whose arrays consisted of one phonetically related choice and 3 unrelated choices) and 2 stimulus word-unrelated trials (whose arrays consisted of the stimulus word and 3 unrelated choices) ... [and] 7 dummy trials with 4 unrelated choices only" (p. 34). Ss rated their degree of deafness on a 10-point scale after hypnosis was terminated.

Possible sources of bias were examined by having 20 control Ss respond to blank tachistoscopic slides with the instructions that they were participating in a study of 'subliminal perception.' Another 22 Ss were asked to identify the semantically and

phonetically related words from the word array, which for the most part they did successfully.

All Ss rated themselves as '10' on the deafness scale, indicating total deafness. The principal results are seen in Tables 1 and 2.

**Table 1 Mean Number of Related and Unrelated Responses (Percentage of Responses) for all S Groups on the 18 Mean Experimental Trials**

**Response Category S Group N Related Unrelated Total**

**Hypnotized 9 7.22 10.78 18**

**(40.13%) (59.88%) (100%)**

**Simulating 15 12.13 5.87 18**

**(67.43%) (32.61%) (100%)**

**Baseline 19 8.79 9.21 18 Controls (48.82%) (51.17%) (100%)**

**Table 2 Mean Number of Phonetic and Semantic Responses within the Related Response Category on the 18 Main Experimental Trials**

**Related Responses S Group Phonetic Semantic Hypnotized 1.78 5.44**

**(9.89%) (30.24%) Simulating 7.07 5.07**

**(39.27%) (28.16%) Baseline 4.21 4.58 Controls (23.38%) (25.44%)**

Hypnotized Ss were significantly different from simulators (Table 1) in number of related responses. Simulators gave significantly more related responses than baseline controls. Simulators also gave more phonetically related words than either the hypnotized or baseline Ss (Table 2); there was no difference between groups on semantically related words. (Authors performed other useful and detailed analyses.)

In their Discussion section, the authors note that they did not obtain the expected results of hypnotized Ss producing more related responses than baseline Ss. "In fact, internal analyses of hypnotized and baseline responses revealed that the pattern of choices for hypnotic deaf Ss was opposite to the direction predicted by subception. Hypnotic Ss appeared to avoid phonetically related word choices, even for items on which baseline control Ss scored above chance. ...

"This kind of non-baseline performance by hypnotic Ss can be accounted for by either a strategic enactment conceptualization of hypnosis (Spanos, 1982; Wagstaff, 1981) or Hilgard's (1979) neo-dissociation theory. Spanos might emphasize the

hypnotic S's active strivings to meet the hypnotist's perceived expectations. ... Neo-dissociation theory might stress the mechanisms by which processing of auditory inputs are maintained outside of awareness via a dissociative barrier.

" ... Given the tendency for simulating Ss to 'overplay' hypnotic phenomena (Levitt & Chapman, 1979), one might have expected simulators to pointedly avoid related responses, thus producing a lower frequency of related words than either the hypnotic Ss or the baseline controls (in effect being more deaf than the deaf). Just the opposite occurred. One possible explanation for this behavior presents itself: In their work with posthypnotic suggestion and the 'disappearing hypnotist' ... M. T. Orne and others found that simulating Ss may be more alert and responsive to demand cues than are hypnotic Ss. In the present study, the authors' original hypothesis was that hypnotic Ss might reveal a subception effect by above-chance responding on related word choices. If we assume that this expectation was somehow communicated to Ss by some subtle aspect of the experimental procedure, then it is conceivable that simulating Ss were able to detect and act upon these cues, while hypnotized Ss remained relatively unattuned to such subtleties.

"In sum, the priming effect noted in the subliminal perception research does not appear to be a feature of complete hypnotic deafness, at least as measured in this study. The behavior of simulating Ss in the present study should be another caution to researchers that differences between hypnotized and simulating Ss may reflect simulation effects in addition to, or instead of, hypnotic effects" (pp. 37-38).

**1981**

Gravitz, Melvin A. (1981). Non-verbal hypnotic techniques in a centrally deaf brain-damaged patient. International Journal of Clinical and Experimental Hypnosis, 29, 110-116.

Non-verbal techniques across several sensory dimensions were utilized with a brain-damaged centrally deaf 36-year-old female patient who had been referred for hypnotherapeutic relaxation. These included optical fixation on the therapist's hand with gradual thumb and fore-finger closure, vibratory stimuli, light shoulder pressures, arm stroking, manually facilitated air currents, and reinforcing homework assignments. With hypnotherapy, the patient's physical and emotional behavior was reported by her to have improved to a significant degree.

**1979**

Watkins, John G.; Watkins, Helen H. (1979-80). Ego states and hidden observers. Journal of Altered States of Consciousness, 5 (1), 3-17

Hilgard and Hilgard discovered that subjects who had been rendered hypnotically deaf, or whose hand had been anesthetized under hypnosis, were hearing and sensing the pain at levels below the threshold of normal awareness. They described this phenomena as a cognitive structural state and termed it "the hidden observer." Federn theorized that the ego is subdivided into segments (organized patterns of

behavior and experience) which are semi-autonomous in normal individuals, and which are manifested as completely separate entities (multiple personalities) when the internal boundaries between such parts are rigid and impermeable. He termed these entities "ego states." When activated under hypnosis each ego state experiences its self as subject (I) and the other states as objects (he, she, or it). We have discovered in hypnoanalytic therapy that these ego states act like "covert" multiple personalities, and that clashes between them often create anxiety and psychosomatic symptoms. Ego-state therapy thus becomes a kind of family or group therapy aimed at resolving conflicts between the various ego states which constitute "a family of self" within a single individual. Two studies are reported here to investigate the possibility that Hilgard's "hidden observers" are the same phenomena as these "ego states." The data derived appear to support such a hypothesis. Consideration is given to the possible influence of suggestion and operator variables.

Scheibe, Karl E.; Gray, Arne L.; Kleim, C. Stephen (1968). Hypnotically induced deafness and delayed auditory feedback: A comparison of real and simulating subjects. International Journal of Clinical and Experimental Hypnosis, 16, 158-164.

PRELIMINARY RESEARCH INDICATES THAT HYPNOTICALLY INDUCED DEAFNESS MAY REDUCE THE SPEECH INHIBITING EFFECTS OF DELAYED AUDITORY FEEDBACK (DAF). REAL AND SIMULATING HYPNOTIC SS WERE COMPARED WITH RESPECT TO THE IMPROVEMENT IN SPEECH CONSEQUENT TO THE SUGGESTION OF DEAFNESS. RESULTS INDICATE VERY SIMILAR IMPROVEMENTS OF DAF SPEECH FOR BOTH GROUPS. AN INCIDENTAL FINDING IS THAT REAL SS HAD LONGER SIMPLE READING TIMES UNDER HYPNOSIS THAN DID SIMULATING SS. (GERMAN + SPANISH SUMMARIES) (PsycINFO Database Record (c) 2002 APA, all rights reserved)

1967

Kramer, E.; Tucker, G. R. (1967). Hypnotically suggested deafness and delayed auditory feedback. International Journal of Clinical and Experimental Hypnosis, 37-43

A PILOT STUDY INVESTIGATED HYPNOTICALLY INDUCED DEAFNESS USING DELAYED AUDITORY FEEDBACK (DAF). THE FOLLOWING TENTATIVE CONCLUSIONS ARE OFFERED: (1) INSTRUCTIONS TO PRETEND DEAFNESS DID DECREASE THE NUMBER OF SPEECH ERRORS PRODUCED IN THE DAF SITUATION WITH SOME SS, ALTHOUGH THE RESULTS WERE BY NO MEANS THOSE OF COMPLETE DEAFNESS; (2) HYPNOTICALLY INDUCED DEAFNESS ALSO PRODUCED A REDUCTION IN THE NUMBER OF ERRORS CAUSED BY DAF, THOUGH HERE, TOO, THE RESULTS DID NOT APPROACH THOSE OF COMPLETE DEAFNESS; AND (3) ADDITIONAL TRAINING OR EXPERIENCE IN HYPNOSIS SEEMED TO

**PRODUCE AN INCREASED ABILITY OF HYPNOTICALLY SUGGESTED DEAFNESS TO REDUCE SPEECH ERRORS UNDER THESE CONDITIONS. (GERMAN + SPANISH SUMMARIES) (PsycINFO Database Record (c) 2002 APA, all rights reserved)**

**1966**

**Martorano, J. T.; Oestreicher, C. (1966). Hypnosis of the deaf mentally ill: A clinical study. American Journal of Psychiatry, 123, 605-606.**

Recent studies are reviewed which were concerned with the effectiveness of suggestions given under "hypnosis" and "waking" experimental treatments in alleviating allergies, ichthyosis, myopia, and other conditions and in eliciting deafness, blindness, hallucinations, analgesia, cardiac acceleration and deceleration, emotional responses, urine secretion to sham water ingestion, narcotic-like drug effects, and other phenomena. The review indicates that a wide variety of physiological functions can be influenced by suggestions administered under either hypnosis or waking experimental treatments, and direct and indirect suggestions to show the particular physiological manifestations are crucial variables in producing the effects.

**1954**

**Kline, Milton V.; Guze, Henry; Haggerty, Arthur D. (1954). An experimental study of the nature of hypnotic deafness: Effects of delayed speech feedback. Journal of Clinical and Experimental Hypnosis, 2 (2), 145-156.**

The research subject was a 29 year old college student who was given delayed speech feedback in both the waking state and deeply hypnotized with suggestions of deafness. (Clinically, during hypnotic deafness he lacked the startle reflex in response to auditory stimuli and lost a conditioned response based on auditory stimulus.) Following the experimental procedures, the authors concluded:

"1. Delayed feed-back in the state of hypnotically induced deafness produces distinct impairment in speech performance. This impairment involves loss of motility, increased errors in enunciation and increasing impairment in proportion to increasing difficulty of vocabulary.

2. The speech impairment found in hypnotically induced deafness is very significantly less than the impairment found in waking feed-back performance.

3. The pattern of speech performance in hypnotic deafness shows a pattern very similar to that of non feed-back with respect to constancy of performance and the linear relationship between performance efficiency and difficulty of verbal stimuli.

4. Waking feed-back performance is significantly more variable and erratic than the non feed-back or hypnotic deafness series.

5. Hypnotic deafness does not appear to follow the same neurophysiological pattern as organic deafness with regard to auditory feed-back.

6. Hypnotic deafness does alter certain behavioral [sic] responses to audition and appears to alter the character and nature of hearing.

7. Hypnotically induced deafness would appear to represent a valid alteration of hearing function but not a state akin to organic deafness.

8. Hypnosis appears to be capable of altering feed-back mechanism of an auditory nature" (p. 155).

Malmo, Robert B.; Boag, Thomas J.; Raginsky, Bernard B. (1954). Electromyographic study of hypnotic deafness. Journal of Clinical and Experimental Hypnosis, 2 (4), 305-317.

"Summary and Conclusions. The main purpose of the present study was to investigate the question of similarities and differences between hysterical deafness, previously studied, and hypnotically induced deafness. The study was designed to repeat the objective physiological tests previously carried out with a case of 'total hysterical deafness.' There was also the more general aim of securing objective data to enrich our general understanding of hypnosis.

"Similarities between hysteria and hypnosis which we observed may be listed as follows: (a) Significantly reduced motor reaction (exclusive of blink) to strong auditory stimulation in the deaf state. (b) Complete hearing loss in the hysteric and in one of the hypnotic subjects, even with strong auditory stimulation (i.e., denial of any auditory sensation). (c) With elicitation of strong startle reaction to the first stimulus in the deaf state, much smaller reaction to the next stimulus than would have been predicted on the basis of habituation. (d) Suggestion of substitution of somesthetic for auditory sensations in all subjects (although this was much less definite in the hypnotic subjects than the hysteric).

"The most outstanding dissimilarity lay in the absence of emotional reaction when 'hypnotic defense against sound' was broken through, in contrast to marked affective reaction in the hysterical subject under these conditions.

"The question of inhibitory mechanisms in hysteria and hypnosis was discussed" (pp. 316-317).

This article presents a bibliography of experimental and applied studies for reference by those interested in the use of hypnosis as a counter-measure in the "lie detector" test.

Stern, Clara; Stern, William (1999). Recollection, testimony, and lying in early childhood. Washington, DC: American Psychological Association. (First published in 1909, in German.)

"This book, previously unavailable to American readers, describes a seminal study by William and Clara Stern, first published in Germany in 1909, documenting their own children's abilities to recollect, recount, testify, and distinguish truth from falsehood" (from publisher statement). Contents: Recognition as the basis of recall; The chronological development of recall and testimonial ability; False testimony-- Mistaken recollections, pseudo-lies, and lies; Recognition; Correct recollection; Purposive recall; Mistaken recollections; Experimental studies of testimony in early childhood; The falsification of testimony through fantasy; Pseudo-lies and lies; Educating young children to report on their experiences; The origins of lying and its prevention; The capability of small children as witnesses in legal proceedings.

1988

Perugini, Eve Marie; Kirsch, Irving; Allen, Sarah T.; Coldwell, Eleanor; Meredith, Janelle M.; Montgomery, Guy H.; Sheehan, Julia (1998). Surreptitious observation of responses to hypnotically suggested hallucinations: A test of the compliance hypothesis. International Journal of Clinical and Experimental Hypnosis, 46 (2), 191-203.

Suggestions for arm levitation and for visual, auditory, tactile, and taste hallucinations were administered twice via audiotape to a group of high suggestible students and low suggestible simulators. During one of the administrations, participants were led to believe they were alone, but their behavior was surreptitiously recorded on videotape and observed on a video monitor. During the other administration, they were observed openly by an experimenter who had not been informed about group assignment. When unaware that they were being observed, simulators were significantly less responsive to suggestion and engaged in substantially more role-inappropriate behavior. In contrast, the responsiveness of nonsimulating students was not affected by the presence of an experimenter, and they exhibited little role-inappropriate behavior even when alone. These data indicate that the responses of suggestible individuals reflect internally generated changes in experience and are not due to simple intentional compliance (i.e., faking).

1995

Zamansky, Harold S.; Ruehle, Beth L. (1995). Making hypnosis happen: The involuntariness of the hypnotic experience. International Journal of Clinical and Experimental Hypnosis, 43 (4), 386-398

The authors tested the hypothesis that hypnotized individuals do not truly experience their responses to suggestions as occurring involuntarily, but instead absorb themselves in imagery that is congruent with the suggestions while avoiding critical thoughts, or even simply comply with suggestions without genuinely experiencing their responses as nonvolitional. Participants were instructed to engage in thoughts and imagery that conflicted with the suggestions given, were urged to pay attention to their behavior, and were questioned regarding the perceived involuntariness of their responses. Simultaneously, electrodermal skin conductance responses provided a measure of the truthfulness of their reports. It was found that responses to all hypnotic suggestions were reported as being involuntary, in spite of the conflicting imagery and increased saliency, and that these reports were truthful. These findings provide disconfirming evidence for the sociocognitive theories of hypnosis.

1994

Kennedy, James; Coe, William C. (1994). Nonverbal signs of deception during posthypnotic amnesia: A brief communication. International Journal of Clinical and Experimental Hypnosis, 42 (1), 13-19.

The question of hypnotic subjects complying with instructions, perhaps even purposely deceiving the hypnotist or deceiving themselves, has arisen from the state-nonstate (skeptical-credulous) theoretical controversy. However, experimental testing of competing hypotheses has been difficult. The current report offers methodological procedures that may prove useful. Subjects who were given posthypnotic amnesia instructions were tested on free recall and implicit recall of a 20-word list. To detect the possibility of deception, videotapes of real subjects and simulating subjects during and after posthypnotic amnesia were rated for nonverbal signs of deception, signs taken from the works of Ekman, Ekman and Friesen, and Zuckerman et al. Preliminary results were gathered on a small pilot sample, and recommendations for procedural improvements are proposed.

Spiegel, David; Schefflin, Alan W. (1994). Dissociated or fabricated? Psychiatric aspects of repressed memory in criminal and civil cases. International Journal of Clinical and Experimental Hypnosis, 42 (4), 411-432.

During the last decade, clinicians, courts, and researchers have been faced with exceedingly difficult questions involving the crossroads where memory, traumatic memory, dissociation, repression, childhood sexual abuse, and suggestion all meet. In one criminal case, repressed memories served as the basis for a conviction of murder. In approximately 50 civil cases, courts have ruled on the issue of whether repressed memory for childhood sexual abuse may form the basis of a suit against the alleged perpetrators. Rulings that have upheld such use underscore the importance of the reliability of memory retrieval techniques. Hypnosis and other methodologies employed in psychotherapy may be beneficial in working through memories of trauma, but they may also distort memories or alter a subject's evaluation of their veracity. Because of the reconstructive nature of memory,

caution must be taken to treat each case on its own merits and avoid global statements essentially proclaiming either that repressed memory is always right or that it is always wrong.

**1992**

Bates, Brad L. (1992). The effect of demands for honesty on the efficacy of the Carleton Skills-Training Program. International Journal of Clinical and Experimental Hypnosis, 40 (2), 88-102.

30 low hypnotizable Ss were administered the Carleton Skills-Training (CST) program. Prior to testing, 15 Ss were administered honesty instructions (Bowers, 1967) in an effort to encourage responses that were consistent with subjective experiences and to dissuade Ss from performing in a manner intended to please E. Posttraining hypnotizability scores for Ss given honesty instructions were consistently smaller than those for 15 Ss who did not receive these instructions, implying that scores for the latter group exaggerate the extent to which hypnotic experiences are altered by the CST program. The pattern of results supports the view that demand characteristics contribute to the efficacy of the CST program, and that improvements in actual hypnotic talent are more limited than Spanos' original work implies.

**1991**

Kinnunen, Taru; Zamansky, Harold S.; Block, Martin L. (1991, August). Is the hypnotized subject lying?. [Paper] Presented at the annual meeting of the American Psychological Association, San Francisco

To determine whether or not hypnotized subjects misrepresent or lie about their hypnotic experiences, electrodermal skin conductance responses were measured while groups of deeply hypnotized subjects and simulators responded to questions about their experiences to a series of suggestion. 89% of the responses of the hypnotic subjects met the criteria for truthfulness, while 65% of the responses of the simulators indicated deception. Differences between "reals" and simulators were highly significant. The relevance of the results for the nature and theory of hypnosis is discussed. (ABSTRACT from Bulletin of Division 30, Psychological Hypnosis, Provided by former Editor, James Council.)

**1963**

Bentler, P. M.; Hilgard, Ernest R. (1963). A comparison of group and individual induction of hypnosis with self-scoring and observer-scoring. International Journal of Clinical and Experimental Hypnosis, 11, 49-54. (Abstracted in Index Medicus, 63, June, S-1599)

45 volunteer Ss were hypnotized in small groups and were subsequently hypnotized in individual sessions. In both sessions observer- and self-scores were recorded for all suggestions of the Harvard Group Scale adaptation of the Stanford Hypnotic Susceptibility Scale. The correlation between observer- and self-scores indicated

that hypnotic susceptibility in the 2 sessions was very similar. Group self-scores were also found to predict quite accurately objective hypnotist scores of the subsequent individual session. A 2nd sample of 34 nonvolunteer male Ss were hypnotized individually following Form A of the Stanford scale. Self-scoring was found to be remarkably similar to observer ratings, and the results of group administration very comparable to those of individual administration of hypnotic susceptibility tests. ## DEFENSE

1998

Wickramasekera, Ian (1998). Secrets kept from the mind but not the body or behavior: the unsolved problems of identifying and treating somatization and psychophysiological disease. Advances in Mind-Body Medicine, 14, 18-132.

The identification and therapy of somatoform and psychophysiological disorders are major problems for medicine. This paper identifies three measurable risk factors (Wickramasekera 1979, 1988, 1993a, b, 1995) that are empirically associated with somatoform and psychophysiological disorders. These risk factors are high hypnotic ability, low hypnotic ability, and high Marlowe Crowne scores. Patients who are positive on one or more of these risk factors (all of which can constrict consciousness) have a high likelihood of having somatoform and psychophysiological disorders and should be studied with the additional risk factors proposed in the High Risk Model of Threat Perception (HRMTP). Treatment of patients should begin with the Trojan Horse Role Induction procedure (Wickramasekera 1988), which enables patients, who might otherwise resist psychological interpretations of their physical problems, to recognize that unconscious threat perception could be driving their somatic symptoms, an understanding that reduces their resistance to psychotherapy. A case study is presented of a patient without identifiable pathophysiology or psychopathology to account for somatic symptoms that were largely resistant to standard medical therapy. The patient was positive for several of the psychosocial and psychophysiological risk factors of the HRMTP and after experiencing the Trojan Horse Role Induction showed improvement in somatic symptoms.

1994

Wickramasekera, Ian (1994). Psychophysiological and clinical implications of the coincidence of high hypnotic ability and high neuroticism during threat perception in somatization disorders. American Journal of Clinical Hypnosis, 37, 22-33.

The electrodermal response to cognitive threat of un hypnotized female patients with somatic symptoms and high on both hypnotic ability and neuroticism (H-H) was found to be significantly higher ( $p < .01$ ) than that of a matched group of female patients moderate on hypnotic ability and low on neuroticism (M-L). On verbal report the H-H and the M-L groups did not differ, but they were significantly different on a measure of self-deception (L scale) or repression. The above findings

are consistent with predictions from the High Risk Model of Threat Perception (HRMTP), which states that people in the H-H group are both chronically and acutely more reactive to threat than the people in the M-L group. This finding may have important theoretical, clinical, and financial implications for the diagnosis, therapy, and prevention of somatization disorders seen in primary medical care.

**1991**

**Dixon, Norman F.; Henley, Susan H. (1991). Unconscious perception: Possible implications of data from academic research for clinical practice. Journal of Nervous and Mental Disease, 179 (5), 243-252.**

Evidence for the reality of unconscious perception and perceptual defense suggests that the experimental paradigms used to investigate these phenomena might play a role in the understanding and treatment of mental disorders. The literature on applying subliminal stimulation to problems of diagnosis and therapy indicates that data support the view that the meaning of external stimuli of which the recipient is unaware may be responded to and determine emotional responses, lexical decisions, overt behavior, and subjective experience. Data confirm the reality of psychopathology as a substrate of emotionally colored, stored information with a potential for producing somatic symptoms and disorders of thinking, affect, and behavior. To the extent that psychopathology is screened from conscious scrutiny and thus impervious to supraliminal information, it may be accessed and ameliorated by drive-related stimuli of which the S is not aware.

**1988**

**Young, W. C. (1988). Psychodynamics and dissociation: All that switches is not split. Dissociation, 1, 33-38**

Contrasts the roles of splitting and dissociation in multiple personality disorder. It is proposed that dissociation is a unique defensive process that serves to protect the patient from the overwhelming effects of severe trauma and that multiple personality disorder need not call upon splitting as its central defensive process. Fantasies of restitution may be incorporated into the dissociative defense. Psychological, physiological, and behavioral models all are of use, making it likely that ultimately dissociation will be understood along multiple lines of study.

**1981**

**Wilson, John F. (1981). Behavioral preparation for surgery: Benefit or harm?. Journal of Behavioral Medicine, 4, 79-102.**

Elective surgery patients were prepared for surgery with training in muscle relaxation or with information about sensations they would experience. Relaxation reduced hospital stay, pain, and medication for pain and increased strength, energy, and postoperative epinephrine levels. Information reduced hospital stay. Personality variables (denial, fear, aggressiveness) were associated with recovery and influenced patients' responses to preparation. Less frightened patients benefitted more from

relaxation than did very frightened patients. Nonaggressive patients reacted to information with decreased hospital stay along with increased pain, medication, and epinephrine. Aggressive patients responded to information with decreased hospital stay along with decreased pain, medication, and epinephrine. Patients using denial were not harmed by preparation. A catharsis/moderation model is proposed to explain how information benefits patients. An active coping model is proposed to explain the benefits of relaxation. This study suggests that behavioral preparation benefits even frightened, aggressive, or denying elective surgical patients.

1974

Galin, David (1974). Implications for psychiatry of left and right cerebral specialization: A neurophysiological context for unconscious processes. Archives of General Psychiatry, 31 (4), 572-583

A brief review is presented of hemispheric specialization for different cognitive modes, and of the symptoms that follow disconnection of the two hemispheres by commissurotomy. Our present knowledge of the hemispheres' cognitive specialization and potential for independent functioning provides a framework for thinking about the interaction of cognitive structures, defensive maneuvers, and variations in awareness. Parallels are noted between some aspects of the mental processes of the disconnected right hemisphere and some aspects of primary process thinking and repression. The hypothesis is proposed that in normal intact people mental events in the right hemisphere can become disconnected functionally from the left hemisphere (by inhibition of neuronal transmission across the cerebral commissures), and can continue a life of their own. This hypothesis suggests a neurophysiological mechanisms for at least some instances of repression and an anatomical locus for the unconscious mental contents.

1966

Stross, L. (1966). Impulse-defense implications in a case of amnesia. International Journal of Clinical and Experimental Hypnosis, 2, 89-103.

An 18-yr-old girl with a delinquent history leading to several suicide attempts and a fugue is described as she was observed during shifting phases of her amnesic syndrome. Using the case study as a research tool, it is suggested that alteration of ego state might be an archaic, primitive means of defense against relatively unneutralized, intense drives. More speculative are the propositions, generated from this case, that the ego could employ different defensive means with regard to libidinal and aggressive drives and that alteration of ego state might be a specific defense against aggression. 1954

Rosen, Harold; Erickson, Milton H. (1954). The hypnotic and hypnotherapeutic investigation and determination of symptom-function. Journal of Clinical and Experimental Hypnosis, 2 (3), 201-219. (Abstracted in Psychological Abstracts, 55: 7017)

1. Symptoms and even syndromes may subserve the repetitive enactment of traumatic events; may reproduce, instead, specific life situations; may satisfy repressed erotic and aggressive impulses; or may at one and the same time constitute defenses against, and punishment for, underlying instinctual drives. They may mask underlying schizophrenic reactions, or hold suicidal depressions in check. They may serve these and other functions concurrently, or none, or any specific one or combination of them.

2. With selected patients under hypnosis, symptom-function may be determined rapidly and in a therapeutic setting. Various techniques can be utilized. Attacks may be precipitated and then blocked, either by direct hypnotic suggestion or by regressing the patient to a period pre-dating the onset of his disease, so that substitutive motor or other activity will be precipitated in a form accessible to therapeutic investigation; attacks may be precipitated in slow motion, so that individual components can be therapeutically investigated in detail; dissociated states may be induced; dream acting-out may be suggested; or symptoms may be suggested away while emotions back of symptoms are concurrently intensified, so that, again, underlying dynamic material will immediately become accessible for therapy. Still other techniques may be utilized.

3. If treatment, as well as evaluation, be through these techniques, and if treatment be successful, it may be that the analogy of a log jam will be of value. The jam can usually be broken by pulling out one or two key logs. The rest then start falling into place -- and the whole log jam disappears. This may be what happens, although to a limited extent, during therapy of this type.

4. Various of these techniques have been illustrated throughout this paper. Case histories however, have at times been distorted in order to maintain the anonymity of the patients involved" (pp. 218-219).

## DELUSION

1994

Spanos, Nicholas P.; Burgess, Cheryl A.; Burgess, Melissa Faith (1994). Past-life identities, UFO abductions, and satanic ritual abuse: The social construction of memories. International Journal of Clinical and Experimental Hypnosis, 42 (4), 433-446.

People sometimes fantasize entire complex scenarios and later define these experiences as memories of actual events rather than as imaginings. This article

examines research associated with three such phenomena: past-life experiences, UFO alien contact and abduction, and memory reports of childhood ritual satanic abuse. In each case, elicitation of the fantasy events is frequently associated with hypnotic procedures and structured interviews which provide strong and repeated demands for the requisite experiences, and which then legitimate the experiences as "real memories." Research associated with these phenomena supports the hypothesis that recall is reconstructive and organized in terms of current expectations and beliefs.

1988

Barrett, D. (1988). Trance-related pseudocyesis in a male. International Journal of Clinical and Experimental Hypnosis, 36 (4), 256-261

Pseudocyesis has been linked in previous literature to trance phenomena. The present paper presents a case in which pseudocyesis was accidentally induced by hypnotic suggestion, continued by an autohypnotic process, and reversed by informal suggestion. This case has important implications for the role autohypnosis may play in maintaining the phenomenon and for the usefulness of hypnotic techniques in reversing the symptoms.

1966

Andreasen, A. G.; Singer G. (1966). Hypnosis and hypnotizability: Delusion or simulation?. International Journal of Clinical and Experimental Hypnosis, 14 (3), 257-267.

Because Sutcliffe (see 36:4) showed that hypnotic suggestions are not comparable in sensory content with real stimuli, the postulated difference between "pseudoperception" and "simulation" as indexed by reported subjective experiences of hypnotic Ss was tested. From 215 undergraduates, 30 high-susceptibility (HS) and 30 low-susceptibility (LS) Ss made kinesthetic and visual judgments of horizontality. A significant response, not attributable to simulation, was found only for the HS-hypnosis induction group; the effect was not attributable individually to susceptibility, hypnosis induction, or motivation. It is concluded that hypnosis, defined by this significant interaction effect between high susceptibility and hypnosis induction can be interpreted as a pseudoperceptual response to suggestion. (Spanish & German summaries) (28 ref.) (PsycINFO)

Wagner, Frederik F. (1966). The delusion of hypnotic influence and the hypnotic state. International Journal of Clinical and Experimental Hypnosis, 14 (1), 22-29.

Several case studies are discussed briefly, illustrating the main aspects of delusions of hypnotic influence and how the delusional system differs from the hypnotic state. It is a symptom of (usually paranoid) schizophrenia, often appearing among the earliest symptoms in the course of the illness. These feelings usually arise when the patient experiences a weakening of ego functions, or a breakthrough of libidinous or aggressive impulses. While there is a tendency to rationalize aspects of hypnotic

behavior, delusions of hypnotic influence are deeply rooted in the dynamics of the patient's psychopathology. They usually remain as a permanent symptom, and prognosis is poor. (PsycINFO Database Record (c) 2002 APA, all rights reserved)

**1963**

Gindes, Bernard C. (1963). Delusional production under hypnosis. International Journal of Clinical and Experimental Hypnosis, 11, 1-10.

Hypnosis creates a situation for the development of fantasies which carry over into waking life as delusions. The patient, susceptible to common impressions of hypnosis, may use the opportunity to indulge ordinarily inhibited impulses. The therapist should be alert to the jeopardy of his involvement in such delusions. (PsycINFO Database Record (c) 2002 APA, all rights reserved)

Pulver, Sydney E. (1963). Delusions following hypnosis. International Journal of Clinical and Experimental Hypnosis, 11, 11-22.

Delusions occurring after hypnosis in the nonpsychotic patient are usually a result of the interplay of 3 factors. (a) the development of rapid, tense, transference reactions in hypnosis; (b) the presence of major defects in the patient's character structure; and (c) the occurrence of countertransference reactions on the part of the hypnotist which touch on a specific area of conflict within the patient. The presence of a chaperon or the use of tape recorders are not satisfactory preventive measures. Rather, the physician using hypnosis should focus upon: (a) preliminary psychological evaluation and selection of patients free from disposition to delusion formation, (b) identification of transference reactions and a willingness to discuss with patients, (c) awareness of his own emotional responses to the patient. Basic courses in psychiatry are recommended. (PsycINFO Database Record (c) 2002 APA, all rights reserved)

**1962**

Sutcliffe, J. P.; Jones, J. (1962). Personal identity, multiple personality, and hypnosis. International Journal of Clinical and Experimental Hypnosis, 10, 231-269. (Abstracted in Index Medicus, 63, Mar., S -543)

The concept of multiple personality is critically examined in the light of its historical development. Various conceptions of multiple personality are considered: as a diagnostic fashion, as a product of shaping in therapy, as a product of hypnotic suggestion, as simulation, and as an extension of characteristics found in "normal" personalities. These considerations lead to the conclusion that the significant alterations of personality characterizing the syndromes are loss of self-reference memories, and confusions and delusions about particular identity in time and place. The parallels in multiple personality and hypnotic phenomena lead to the heuristic hypothesis that degrees of proneness to multiple personality are predictive of degrees of hypnotizability. 1961

Sutcliffe, J. P. (1961). 'Credulous' and 'Skeptical' views of hypnotic phenomena: Experiments on anesthesia, hallucination, and delusion. Journal of Abnormal and Social Psychology, 62, 189-200.

The author distinguishes between 2 interpretations of hypnotic phenomena: the credulous (S does or does not experience what the hypnotist suggests) and the skeptical (S reports what is suggested regardless of the "reality" of his experience). 2 groups of Ss (distinguished with respect to the presence or not of genuine hypnotic behavior and posthypnotic amnesia) were placed in a 3 [control (not under hypnotic trance), hypnotic trance, nontrance acting (S asked to act as if conditions were as suggested)] by 2 (stimulus present or not) design involving paraesthesias, hallucinations, and delusional thinking. Evidence (such as GSR, interference in thinking due to feedback, test measures of delusion) suggests that S does not misperceive the real situation, but misreports it. ## DENTISTRY

1994

Bloom Peter (1994, October). Training boundaries that enhance responsible therapy: Using hypnosis creatively in one's own discipline. [Paper] Presented at the annual meeting of the Society for Clinical and Experimental Hypnosis, San Francisco.

Presented three cases that he elected not to treat, to illustrate the principle that we should only treat cases we would be professionally trained to treat without hypnosis. (1) a hemorrhoidectomy patient, where he elected not to do hypnosis because he is not trained specifically in anesthesiology and didn't know how to do anesthesia procedures; (2) conversion hysteria in 12 year old girl, because he isn't trained in child psychiatry and doesn't know child development; (3) to confirm the supposed existence of unidentified flying objects, or UFOs (when a woman tried to get him to hypnotize her so the "truth" would emerge). We must free ourselves from treatment of patients who retreat from reality, when we can't find commonality in goals.

Stewart, James (1994). Hypnotherapy with dental patients. [Lecture] UCLA Hypnosis Seminar.

Dr. James Stewart is both a dentist and a clinical psychologist.] Among dental patients, 15% of patients are anxious; 75% of those patients could associate that fear to early childhood experiences, and showed signs of post traumatic stress disorder (PTSD) but only when they have to go for dental treatment. Those 75% respond well to hypnosis (respond quickly, short-term; it is even great to do the therapy in the dental chair, e.g., relieving trauma in trance).

**It is important to diagnose PTSD because treatment will be different if the patient has an anxiety disorder. The disorders are not "simple phobias" because the trauma does not meet the criterion of "silly and unreasonable."**

**In hypnosis I routinely use the suggestion, "find a safe place," and may tell them they can go through a videotape or a filing cabinet to find a safe place. If the patient cannot remember a safe place, it is diagnostic of serious problems, more than dental anxiety. The exploration, verbalization of a safe place enhances rapport. A dentist should not accept a referral for hypnosis when the dental work has to be done next week; better to use sedation, and schedule hypnosis Rx later.**

**For anxiety or pain, do not try to relax it away; better to go where it is, define it (size, density, etc.) How does it feel? Can you put your finger on it? Like vapor? Soft, like steel?**

**PTSD. During World War I they called it malingering and gave shock (not ECT). During World War II the psychoanalytic view was that PTSD was pre-Oedipal. Viet Nam used phenothiazines for "delayed stress reactions." Almost all the variance in the number and severity of symptoms can be explained by the length of time the patients were in battle. During World War II, they did a lot of age regressions under sodium pentathol (a "catharsis") which was often very successful, but there was no theoretical understanding. After that the patient got psychoanalysis.**

**These days in doing desensitization for phobias I do not bother with developing a hierarchy [of feared situations] and I let the patient go through the anxiety more often. Also, one can have the patient walk away from the scene until they subjectively feel far enough away not to feel anxiety.**

**Wormnes, Bjorn (1994, October). Hypnosis in integrated treatment of dental fear. [Paper] Presented at the annual meeting of the Society for Clinical and Experimental Hypnosis, San Francisco.**

**Research reports from different countries estimate the proportion of adult dental phobic patients to be between 5% to 10%. It represents a large health problem. Helping patients to continue regular treatment by their local dentist and experience it as tolerable is the main treatment goal in our program. The main treatment method is a flexible and integrated exposure training. The psychotherapist works in cotherapy with the dentist. Using hypnosis in the dental chair is of great help, and patients are normally found to be very susceptible and easily hypnotized. Hypnosis helps the patient to experience increased tolerance of treatment and also to perform better than expected in the treatment situation.**

**1993**

**LaGrone, Randy G. (1993). Hypnobeavioral therapy to reduce gag and emesis with a 10-year-old pill swallower. American Journal of Clinical Hypnosis, 36, 132-136.**

A 10-year-old child experienced severe nausea and psychogenic vomiting that resulted in refusal to take oral medication in pill form. The youngster was treated with hypnbehavioral therapy consisting of mental imagery, relaxation, direct suggestion, adaptive self-talk, self-monitoring, and self-reinforcement. The child's parents were instructed to reinforce approximations of successful pill swallowing while withdrawing attention for avoidance, whining, gagging, and vomiting. A one-year follow-up revealed successful pill swallowing without significant distress.

1991

Clarke, J. H.; Reynolds, P. J. (1991). Suggestive hypnotherapy for nocturnal bruxism: A pilot study. American Journal of Clinical Hypnosis, 33, 248-253.

Although one can find many case reports of hypnotherapy for bruxism, there is a paucity of scientific research on the subject. This study describes the use of suggestive hypnotherapy and looks at its effectiveness in treating bruxism. Eight subjects who reported bruxism with symptoms such as muscle pain and complaints of bruxing noise from sleep partners were accepted into the study. An objective baseline of the bruxing was established using a portable electromyogram (EMG) detector attached over the masseter muscle during sleep. Hypnotherapy was then employed. Both self-reports and posttreatment EMG recordings were used to evaluate the hypnotherapy. Long-term effects were evaluated by self-reports only. The bruxers showed a significant decrease in EMG activity; they also experienced less facial pain and their partners reported less bruxing noise immediately following treatment and after 4 to 36 months.

1991

Somer, Eli (1991). Hypnotherapy in the treatment of the chronic nocturnal use of a dental splint prescribed for bruxism. International Journal of Clinical and Experimental Hypnosis, 39, 145-154

A behavioral medicine case is described in which the patient was treated with a combined approach involving both hypnoanalytic and hypnbehavioral techniques. A 55-year-old man with bruxism was referred after 10 years of craniomandibular treatment because of his dependency on a dental splint prescribed for nocturnal use. A projective hypnoanalytic exploration helped to uncover and consequently resolve an earlier conflict that had been reactivated in the patient's work situation and which had become a constant source of mental and muscular tension. The hypnoanalytic exploration was followed by a cognitive-behavioral hypnotic intervention that was tape-recorded and prescribed for bedtime practice. Pre- and posttherapy psychological, physiological, and self-report measurements corroborated the patient's sense of well being that came with his newly found ability to sleep without the dental splint. The importance of considering multiple etiological factors in the treatment of such psychosomatic disorders as bruxism is discussed.

1989

Joubert, P. H.; Van Os, B. E. (1989). The effect of hypnosis, placebo, paracetamol, and naloxone on the response to dental pulp stimulation. Current Therapeutic Research - Clinical and Experimental, 46, 774-781.

Healthy volunteers with varying degrees of hypnotic susceptibility, as measured by the Stanford Clinical Hypnotic Scale [sic] (SCHS), participated in a trial to evaluate analgesia induced by an indirect hypnotic technique, rapid induction analgesia (RIA). RIA produced increases in the pain threshold, as measured by dental pulp stimulation, in nine of ten subjects. The magnitude of the response was unrelated to SCHS scores. Neither placebo nor paracetamol capsules affected pain threshold measured by this technique. The effect of RIA on pain threshold was not reversed by naloxone, mitigating the possible involvement of endorphins in this phenomenon.

Rapid Induction Analgesia, developed by Joseph Barber, was employed in this study of pain that was generated with dental pulp stimulation. RIA involves an induction followed by several kinds of suggestion, e.g. "Nothing is going to be done to you and you are free to respond and to experience what is acceptable to you. ... You have the ability to notice things. ... The way things are noticed might change. ... Memory is changeable and you may choose to remember or forget things. ... The comfortable feelings you are experiencing can be experienced easily and quickly again and again. ...To the latter was coupled the idea that this could happen again if the hypnotist put his hand on the subject's arm" (p. 776).

The lowest electrical current that produces slight discomfort was used as the measure of pain threshold.. RIA produced increases in pain threshold for 9 of 10 Ss. The 10th Subject was not used in the rest of the experiment, and one other Subject withdrew due to scheduling problems. The remaining 8 Ss experienced the following sequence of events in the experiment: --Rest 15 minutes --Pain threshold measure -- Two 500-mg capsules of paracetamol or two of placebo --Wait 2 hours; then pain threshold measure --RIA (10 minutes); aroused from hypnosis; pain threshold measure with E's hand on arm --Insert IV; give 8 mg naloxone or 0.9% saline --Pain threshold measure with E's hand on arm

The four possible combinations (placebo-saline, placebo-naloxone, paracetamol-saline, and paracetamol-naloxone) were administered to each S on four occasions, in randomized order, with at least one week in between visits.

Whereas pain threshold was elevated by RIA above both the first ( $p < .025$ ) and the second ( $p < .05$ ) baselines, neither placebo nor paracetamol (like Tylenol) raised the threshold. Naloxone did not reverse the RIA effect of elevated threshold; in fact, there was a tendency for RIA pain threshold to increase even more after injections of either Naloxone or saline.

The Experimenters noted that the baselines apparently changed over time. They were significantly lower than the RIA threshold during visits 1 and 2, but during visits 3 and 4 the baselines seemed to approach RIA values.

In their Discussion, the authors wrote, "This study appears to have raised more questions than it answered. There is no doubt that RIA, as used in this study, produced a significant shift in pain threshold as assessed by means of dental pulp stimulation. The fact that we were unable to detect an effect with paracetamol or placebo [N.B. which were given before the hypnosis procedures] means either that we were not really measuring something that was relevant to clinical pain or that the measurements were not sensitive enough for the detection of placebo effects or the analgesic effects of paracetamol.

"It furthermore appears that the success of RIA does not depend on the hypnotic susceptibility of the subjects. This is contrary to the findings of Van Gorb [sic] et al but agrees with the studies of Barber and Fricton and Roth.

"The temporal effects are also quite interesting. Firstly, it appears that the RIA was potentiated by the injection of either saline or naloxone. This could have been a placebo manifestation of the intravenous injection, but this appears unlikely in terms of the prior explanation given to the subjects. Subjects were told that the injections were to see whether the analgesic effects of RIA, if present, could be reversed. At no time was it suggested that the injections could have an analgesic effect. Another explanation might be that RIA is potentiated by repetition and that the second employment of the technique is more effective than the first. The other temporal effect seen was the tendency for baseline values to increase at later visits (Figure 4). This might mean progressive relaxation of the subject as he/she became more accustomed to the experimental situation with each subsequent visit or that the RIA state induced at the initial visits became associated with the experimental situation and that the posthypnotic suggestion became operative without the cue of the hypnotist's hand on the subject's arm. It does, however, appear that the maximum RIA effect was reached at the first visit and remained constant throughout.

"From our findings several conclusions may be made. Firstly, that RIA appears to be an effective method for producing analgesia in the majority of subjects and does not appear to depend on hypnotic susceptibility. Secondly, endorphins do not appear to be involved in the analgesia produced by this method. Thirdly, dental pulp stimulation using a standard apparatus commonly used in dental practice does not appear to be appropriate for demonstrating placebo effects or for assessing analgesic efficacy of simple analgesics. Pain thresholds determined in this way would therefore not be of use in clinical pharmacology in comparing different simple analgesics. Finally, trial designs should take the temporal shift in baseline values into consideration" pp 779-780.

## DEPRESSION

2001

Hensel, Carolyn; Sapp, Marty; Farrell, Walter; Hitchcock, Kim (2001). A Survey of members of ASCH, SCEH, and Division 30, and if they reported using hypnosis to treat depression. Sleep and Hypnosis, 3 (4), 152-166.

A telephone survey was conducted with randomly selected members of the American Society of Clinical Hypnosis (ASCH), the Society of Clinical and Experimental Hypnosis (SCEH), and the Psychological Hypnosis Division of the American Psychological Association (Division 30). The purpose of this study was to explore the extent to which hypnosis society members reported using hypnosis to treat major depression. A 3-group MANOVA did not find any differences among the groups, and all members reported using hypnosis to treat depression.

Yapko, Michael (2001). Hypnosis in treating symptoms and risk factors of major depression. American Journal of Clinical Hypnosis, 44 (2), 97-108.

This article summarizes aspects of effective psychotherapy for major depression and describes how hypnosis can further enhance therapeutic effectiveness. Hypnosis is helpful in reducing common symptoms of major depression such as agitation and rumination and thereby may decrease a client's sense of helplessness and hopelessness. Hypnosis is also effective in facilitating the learning of new skills, a core component of empirically supported treatments for major depression. The acquisition of such skills has also been shown to not only reduce depression, but also the likelihood of relapses, thus simultaneously addressing the issues of risk factors and prevention.

Yapko, Michael (2001, October). Hypnotic intervention for ambiguity as a depressive risk factor. American Journal of Clinical Hypnosis, Vol. 44 (No. 2), 109-118.

In the face of ambiguous life events, depressed individuals are more likely to make negative and depressing interpretations than nondepressed individuals. Fundamental to the success of cognitive-behavioral treatments, one of the most empirically supported treatments for depression is teaching the client to recognize and self-correct so-called cognitive distortions. To facilitate that learning process, clients can learn to better recognize and tolerate ambiguity inherent in many situations, and thereby diminish the drive to form subjective interpretations (either negative or positive) when more objective evidence is unavailable. This article describes ambiguity as a risk factor for depression and details a strategy employing hypnosis for teaching the skills of both recognizing and tolerating ambiguity.

Yapko, Michael (2001). Treating depression with hypnosis: Integrating cognitive-behavioral and strategic approaches. New York NY: Brunner-Routledge.

## NOTES

(From the cover) Focuses on structuring and delivering of hypnotic interventions for major depression, with a substantial use of concepts and techniques from

cognitive-behavioral and strategic approaches as a foundation. Current research on depression is used to emphasize the still growing knowledge of depression. Hypnosis has shown itself to be effective in not only reducing symptoms, but in teaching the skills (such as rational thinking, effective problem-solving and coping strategies, and positive relationship skills) that can prevent recurrences. **1998**

**Eimer, Bruce; Freeman, Arthur (1998). Pain management psychotherapy: A practical guide. New York NY: John Wiley & Sons, Inc..**

#### **NOTES**

"Pain Management Psychotherapy" (PMP) provides a clear and methodical look at pain management psychotherapy beginning with the initial consultation and work-up of the patient and continuing through termination of treatment. It is a thoughtful and thorough presentation that covers methods for psychologically assessing the chronic pain patient (structured interviews, pain assessment tests and rating scales, instruments for evaluating beliefs, attitudes, pain behavior, disability, depression, anxiety, anger and alienation), treatment planning, cognitive-behavioral therapy techniques, and a range of hypnotic approaches to pain management. The book covers both traditional (cognitive and behavior therapy, biofeedback, assessing hypnotizability, choice of inductions, designing an individualized self-hypnosis exercise) as well as newer innovative techniques (e.g., EMDR, pain-relief imagery, hypno-projective methods, hypno-analytic reprocessing of pain-related negative experiences). An extensive appendix reproduces in their entirety numerous forms, rating scale, inventories, assessment instruments, and scripts.

The senior author, Bruce Eimer, states in his online comments on Amazon.com that "most therapists hold the belief that 'real' chronic pain patients are quite impossible to help. This book attempts to dispel these misguided beliefs by providing a body of knowledge, theory, and techniques that have proven value in understanding and relieving chronic physical pain." He also states that "the challenge for the therapist is to persuade the would-ne patient/client that he or she has something to offer that can help take way pain and bring back more pleasure. This challenge is negotiated through the therapeutic relationship. However, the therapist just can't be 'warm, accepting, non-judgmental and empathic'. The therapist must also have knowledge and skills relevant to relieving pain. Only then can the therapist impart such knowledge, and in teaching these skills to the pain patient, help the patient become something of a 'self-therapist'. . . I dedicate this book to everyone who wants to find ways to make living with pain more comfortable, and to the ongoing search for better ways to relieve pain."

**1995**

**Holroyd, Jean (1995). Handbook of clinical hypnosis, by Judith W. Rhue, Steven Jay Lynn, & Irving Kirsch (Eds.) [Review]. International Journal of Clinical and Experimental Hypnosis, 43 (4), 401-403.**

## NOTES

"This is a book for the thinking clinician" (p. 401). "The editors are to be congratulated for making this volume much more coherent than most edited books" (p. 402). "My impression is that the book is best suited for an intermediate or advanced course on hypnotherapy, or for people who are already using hypnosis in treatment. Although there is some material on the basics of hypnotic inductions and a few introductory sample scripts for inductions, a beginners" course should probably use a different book, or this book could be accompanied by an inductions manual. ... I recommend it very highly" (p. 403).

Wickramasekera, Ian (1995, November). Hypnotic ability, skin conductance, and chronic pain. [Paper] Presented at the annual meeting of the Society for Clinical and Experimental Hypnosis, San Antonio, TX.

## NOTES

T. X. Barber's book in 1969 states that hypnotizability is unrelated to psychopathology. Hilgard's book states that hypnotic ability and negative reactivity are unrelated. However clinicians working with somatization-type symptoms (headache, irritable bowel disease) may observe a surplus of people very high or low in hypnotic ability. How do we account for the discrepancy between clinic and lab?

Is this a context effect, since I only see people who are sick? It turns out that the low hypnotizable patients present mainly in primary care, medicine and surgery. The highs present with psychophysiological problems.

The author posits that when hypnotic ability and negative affectivity coincide, they lead to physical disease. (He uses "negative affectivity" for what used to be called Neuroticism.) Negative affect is not simply verbal report; one must also consider autonomic physiology as part of it (cf.. Dan Weinberger's research).

Highs are at risk for illness because: 1. They can amplify or attenuate signals of threat. 2. They demonstrate surplus pattern recognition (see meaning in randomly distributed events). 3. They have surplus empathy (poor boundaries).

Lows are at risk because: 1. They deny or attenuate the role of cognitive and emotional events on somatic symptoms. 2. They demonstrate rigidity in information processing; they are locked into critical, sequential, analytical information processing.

Under low stress (mental math), Lows and Highs do not differ on Subjective Units of Distress (SUDS) for mental arithmetic; for high stress (more difficult math) there is a large difference between groups.

High, Medium, and Low hypnotizable Ss with chronic pain and no observable pathology (TMJ, back pain, etc.) were measured on skin conductance (EDR): there were no differences during baseline, but differences emerged during a stress condition. We did not find this kind of difference using muscle tension! Patients were not on medications. GSR is a purely sympathetic nervous system measure, unlike heart rate that also has parasympathetic input. There is almost a dose-response relationship between hypnotizability and reactivity with GSR under stress conditions.

**High Hypnotizable and High Negative Emotion Subjects: EDR 12.5 SUDS 63.5 Lie Scale (Marlowe Crowne)**

**Moderate Hypnotizable and Low Negative Emotion Subjects: EDR 3.77 (p.<.01) SUDS 66.5 (n.s.) Lie Scale 20.7 (p.0001).**

Thus, you could not see a difference in these two groups from their verbal report, their MMPI, or an interview. Their distress is out of mind [but not out of body].

We also studied Body Mass Index (weight related to height), which correlates highly with adiposity (Garrow, 1983). We used High Hypnotizable - High Neuroticism Subjects, compared to Medium Hypnotizable - Low Neuroticism Subjects. H-H BMI = 34.6 M-L BMI = 24.1 (significantly different, though preliminary results).

If you just use a correlation you won't see this result. You have to consider both hypnotizability and negative emotion together.

**COMMENTS FROM THE AUDIENCE:**

Question re Marlowe Crowne as a measure of defense.

Wickramasekera's answer: I believe it is orthogonal to hypnotizability and both are pathways to pathology. I look at both the Marlowe Crowne and Neuroticism.

Auke Tellegen: In Weinberger's research you need to see an interaction between test variables. I think you should view them independently, not assume an interaction.

**1994**

**Wickramasekera, Ian (1994, October). On the coincidence of two orthogonal risk factors for psychophysiological regulation and dysregulation: implications for somatization. [Paper] Presented at the annual meeting of the Society for Clinical and Experimental Hypnosis, San Francisco.**

**NOTES**

People low or high in hypnotizability are at risk. Our article in the upcoming issue of the Journal of Nervous and Mental Disease will present this information. High hypnotizable people have either somatic symptoms or psychological symptoms; lows show primarily somatic symptoms. We found that 38% of highs and 28% of lows show somatic symptoms. The lows won't usually be found in a Mental Health Center; they are staying in primary care medical services.

**Hypnotic ability and insomnia.**

Insomnia was defined by EEG in 3 sleep studies (latency to stage 1 onset of EEG), and patients were screened to omit those with pathophysiology. We measured hypnotizability, finding 50% high on Harvard Scale, 40% low, with a small percent in the middle. [Thus the distribution is bi-modal.]

Neuroticism and insomnia (Wickram, Ware & Saxon, 1992). Neuroticism is the "negative affect" variable. Most people high on negative affect are high hypnotizables. Charcot was right [about high hypnotizables being neurotic] but he didn't have a measure of neuroticism. We are measuring negative affect.

**PREDICTIONS**

Low hypnotizables will show only or mainly somatic symptoms and be found in primary medical care or surgical settings. Highs will show a mix of somatic and psychological and somatic symptoms.

Most lows wouldn't sit still for the Harvard Scale, so we used the Absorption scale. We gave the Absorption scale to non-organic chest pain patients. Most had low scores on Absorption, followed by those with moderate scores, and fewest were highs on Absorption: 50% low, 36% moderate, 13% low.

Absorption scores in morbidly obese (350# or more) candidates for bypass surgery were: 55% are low on Absorption, 5% are high on Absorption.

People high on hypnotizability and on negative affectivity have greater risk for illness. See results of our research in *American Journal of Clinical Hypnosis*, a recent issue. These people are more psychophysiologicaly reactive, in heart rate, electrodermal reactivity, etc.

**1992**

Vijselaar Joost; Van der Hart, Onno (1992). The first report of hypnotic treatment of traumatic grief: A brief communication. *International Journal of Clinical and Experimental Hypnosis*, 40 (1), 1-6.

In 1813 the Dutch physicians Wolthers, Hendriksz, De Waal, and Bakker reported the hypnotic treatment of a woman suffering from traumatic grief, in which the therapist had to deal directly with the patient's spontaneous reenactments of the circumstances surrounding the death. This report, summarized in the present article, has historical value, as it is probably the first known precursor of the uncovering hypnotic approach. The original authors' views on the case are discussed, and a modern view for understanding the patient's traumatic grief and its treatment is presented.

**1991**

Cochrane, Gordon J. (1991). Client-therapist collaboration in the preparation of hypnosis interventions: Case illustrations. *American Journal of Clinical Hypnosis*, 33, 254-262.

Therapists can use hypnosis in a variety of situations to help clients utilize their own resources effectively. In both heterohypnosis and tape-assisted self-hypnosis, the respectful collaboration of therapist and client in the development of specific intervention strategies can be effective. I have described four cases to illustrate the collaborative aspect of heterohypnosis in a surgical setting and tape-assisted self-hypnosis for anxiety, tinnitus, and situational depression. In each case the clients were willing and able participants.

NOTES: "Hypnotic interventions as adjunctive therapeutic modalities for a variety of surgical procedures have been well documented (Frankel, 1987; Gravitz, 1988; Nathan, Morris, Goebel, & Blass, 1987). The availability, relative safety, dependability, and ease of use have made chemical agents the anesthetic of choice in the majority of surgical situations, but hypnosis, either alone or in conjunction with chemical agents, can have a number of advantages for some patients (Udolf, 1987, p. 248). Some patients who have extreme preoperative pain and anxiety can learn to use self-hypnosis (Frankel, 1987); others may use hypnosis when experiencing

postoperative nausea and other uncomfortable side effects of chemical anesthetics. Some may fear death under general anesthesia or react to a previous trauma arising from general anesthesia and the operating room procedures in general (Udolf, 1987, p. 250) and therefore choose hypnotic strategies. In the following case illustration the patient feared general anesthesia because of a previous negative postoperative experience" (p. 255).

While collaboratively planned hypnosis often empowers the patient, contributing to a sense of personal control and well being, some patients are not able to participate in that manner. Cochrane cites patients who are severely depressed or "who struggle with narcissism and other severe pathologies" (p. 260). He notes that audiotapes are useful for supplementing in-session therapy, contributing to skill development, attitude change, and a sense of self-worth. He cites Eisen and Fromm (1983) as indicating that self hypnosis is also useful for clients "who struggle with issues of control and intimacy" (p. 260).

Terr, Lenore C. (1991). Childhood traumas: An outline and overview. American Journal of Psychiatry, 148, 10-20.

Suggests 4 characteristics common to most cases of childhood trauma: visualized or otherwise repeatedly perceived memories of the traumatic event; repetitive behaviors; trauma-specific fears; and changed attitudes about people, life, and the future. Childhood trauma is divided into 2 basic types. Type I trauma includes full, detailed memories, "omens," and misperceptions while Type II trauma includes denial and numbing, self-hypnosis and dissociation, and rage. Characteristics of both types of childhood trauma can exist side by side. Such crossover Type I - Type II traumatic conditions of childhood are characterized by perceptual mourning and depression and childhood disfigurement, disability, and pain. Case examples are provided.

Witz, Marylou; Kahn, Stephen (1991). Hypnosis and the treatment of Huntington's Disease. American Journal of Clinical Hypnosis, 34, 79-90.

Describes two cases treated with a wide variety of hypnotic interventions. One was treated for 9 years and the other for 10 sessions. Hypnotic techniques and daily self-hypnosis appeared to ameliorate both physical and psychological difficulties, thereby enhancing the quality of life that remained for the patients. They noted that the increased sense of control that both patients experienced seemed to undercut the cycle of physical symptoms exacerbating psychological symptoms and these in turn increasing physical symptoms. The sense of control over physical symptoms clearly reduced anxiety and depression over the inevitable course of the disease, thereby facilitating tension reduction and overall adjustment to the disease. This reduced stress level may have in turn affected the disease itself. What is unmistakable is that the quality of life was greatly enhanced.

1990

Harmon, Teresa M.; Hynan, Michael T.; Tyre, Timothy E. (1990). Improved obstetric outcomes using hypnotic analgesia and skill mastery combined with childbirth education. Journal of Consulting and Clinical Psychology, 58, 525-530.

Studied the benefits of hypnotic analgesia as an adjunct to childbirth in 60 nulliparous women. Subjects were divided into high- and low-susceptibility groups before receiving six sessions of childbirth education and skill mastery using an ischemic pain task. Half of the subjects in each group received a hypnotic induction at the beginning of each session; the remaining control subjects received relaxation and breathing exercises typically used in childbirth education. Both hypnotic subjects and highly susceptible subjects reported reduced pain. Hypnotically prepared births had shorter Stage 1 labors, less medication, higher Apgar scores, and more frequent spontaneous deliveries than control subjects' births. Highly susceptible, hypnotically treated women had lower depression scores after birth than women in the other three groups. The authors believe that repeated skill mastery facilitated the effectiveness of hypnosis in the study.

Kaye, J. M.; Schindler, B. A. (1990). Hypnosis on a consultation-liaison service. General Hospital Psychiatry, 12, 379-383.

Studied the use of hypnosis on a consultation-liaison service with a broad spectrum of medically hospitalized patients. Autohypnosis tapes were used for reinforcement. Twenty-nine women and eight men from 24-75 years of age were hypnotized for relief of depression, pain, anxiety, or side effects of chemotherapy. Results were excellent (total to almost total relief of symptoms) in 68%, fair in 22%, and poor in 11%, with no differences among the results with the various conditions. This demonstrates that hypnotherapy is an extremely useful tool in medical management of patients in consultation-liaison psychiatry.

Martin, Maryanne (1990). On the induction of mood. Clinical Psychology Review, 10, 669-697.

## NOTES

Increasing interest in the relation between emotion and cognition has led to the development of a range of laboratory methods for inducing temporary mood states. Sixteen such techniques are reviewed and compared on a range of factors including success rate, the possibility of demand effects, the intensity of the induced mood, and the range of different moods that can be induced. Three different cognitive models (self- schema theory, semantic network theory, and fragmentation theory) which have been successfully used to describe long-term mood states, such as clinical depression, are elaborated to describe the process of temporary mood induction. Finally, the use of mood induction is contrasted with alternative methods (such as the study of patients suffering from depression) for investigating emotion.

Rokke, Paul D.; Carter, Alice S.; Rehm, Lynn P. (1990). Comparative credibility of current treatments for depression. Psychotherapy, 27, 235-242.

Current treatments of depression were evaluated for credibility. Interpersonal, communication, self-control, cognitive, social skills, and relaxation placebo therapies were rated significantly more credible and efficacious than psychodynamic and

activity-change therapies, which were rated significantly more credible than biological (drug) therapy. Implications were addressed.

1989

Ross, Colin A.; Heber, S.; Norton, G. R.; Anderson, D.; Anderson, G.; Barchet, P. (1989). The Dissociative Disorders Interview Schedule: A structured interview. Dissociation, 2, 169-189.

The Dissociative Disorders Interview Schedule (DDIS), a structured interview, has been developed to make DSM-III diagnoses of the dissociative disorders, somatization disorder, major depressive episode, and borderline personality disorder. Additional items provide information about substance abuse, childhood physical and sexual abuse, and secondary features of multiple personality disorder. These items provide information useful in the differential diagnosis of dissociative disorders. The DDIS is published in this article. It has an overall interrater reliability of 0.68. For the Diagnosis of MPD it has a specificity and a sensitivity of 90%.

Spinhoven, Philip; Linssen, A. Corry (1989). Education and self-hypnosis in the management of low back pain: A component analysis. British Journal of Clinical Psychology, 28, 145-153.

Conducted a component analysis of a group program for chronic low back pain patients. 45 patients (aged 31-68 years) participated in the pain control course (PCC), consisting of education about pain and a training in self-hypnosis. A pain diary was used as a measure of pain intensity, up-time, and use of pain medication. Psychoneuroticism and depression were assessed using the Symptom Checklist-90 (SCL- 90) scores. No evidence was found for a differential efficacy of education or self-hypnosis on pain diary and SCL-90 scores. Subjects showed significant changes on all measures except reported pain intensity. It is suggested that the PCC is a noninvasive, inexpensive means of treatment that could be used to teach even more severely disabled low back pain patients to cope more adequately with their pain problem.

Van der Does, A. J.; Van Dyck, R. (1989). Does hypnosis contribute to the care of burn patients? Review of the evidence. General Hospital Psychiatry, 11, 119-124.

In burn treatment, hypnosis has been used for alleviation of pain, prevention and treatment of anxiety and depression, and acceleration of wound healing. Successful application of hypnosis decreases the extensive medication needed. Furthermore, it provides a tool to patients with which they may experience more control in situations that are often experienced as overwhelming. Notwithstanding these important applications and the very positive terms with which the results of studies are generally described, hypnosis has mostly been neglected as a tool to help burn patients. This article reviews the clinical and experimental evidence of the usefulness of hypnosis in the management of burns. Pain reduction and crisis intervention are

promising applications. However, due to a lack of systematic and controlled research, more specific conclusions are precluded. In the controversial area of wound healing, claims for the effectiveness of hypnosis have been made on the basis of slim evidence and inconclusive studies. This hypothesis needs to be addressed in controlled experiments. In summary, systematic investigations are needed to confirm and supplement available clinical evidence. Recommendations for future research are given.

**1988**

**Robins, Clive J. (1988). Development of experimental mood induction procedures for testing personality-event interaction models of depression. Journal of Clinical Psychology, 44 (6), 958-963.**

Developed 2 mood induction procedures for use in testing personality- event interaction hypotheses with regard to the onset of depressed mood of clinical depression. In these inductions, Ss listened to audiotapes depicting either a series of social rejections or achievement failures and were instructed to imagine themselves as the main character. Both tapes were found to produce a strong increase in reported depressed affect in 119 normal undergraduates. These effects were large in comparison to those elicited by commonly used mood induction procedures. Women reported greater mood shifts than men in response to both tapes. It is concluded that the present procedures have the advantage of content specificity, which permits test of personality-event interaction hypotheses.

**Spiegel, David; Hunt, Thurman; Dondershine, Harvey E. (1988). Dissociation and hypnotizability in posttraumatic stress disorder. American Journal of Psychiatry, 145 (3), 301-305.**

The authors compared the hypnotizability of 65 Vietnam veteran patients with posttraumatic stress disorder (PTSD) to that of a normal control group and four patient samples using the Hypnotic Induction Profile. The patients with PTSD had significantly higher hypnotizability scores than patients with diagnoses of schizophrenia (N=23); major depression, bipolar disorder-depressed, and dysthymic disorder (N=56); and generalized anxiety disorder (N=18) and the control sample (N=83). This finding supports the hypothesis that dissociative phenomena are mobilized as defenses both during and after traumatic experiences. The literature suggests that spontaneous dissociation, imagery, and hypnotizability are important components of PTSD symptoms.(Am J Psychiatry 1988; 145:301-305)

**1985**

**Silverman, Lloyd H. (1985). Research on psychoanalytic psychodynamic propositions. Clinical Psychology Review, 5 (3), 247-257.**

Discusses a research program in which the present author has been involved that deals with the subliminal psychodynamic activation method. In this method, verbal

and/or pictorial stimuli, some of which contain content related to unconscious wishes, fears, and fantasies and other of which are (relatively) neutral, are presented to Ss at 4-msec exposures. A variety of psychoanalytically based hypotheses have been tested on various clinical and nonclinical populations. Two major findings have emerged: (a) a number of clinical groups (e.g., schizophrenics, depressives, stutterers) have shown intensifications of their symptoms after the subliminal exposure of stimuli designed to stir up particular unconscious conflicts; and (b) various clinical and nonclinical groups have manifested enhanced adaptive behavior after the subliminal exposure of the message "Mommy and I are one," conceived as activating unconscious symbiotic fantasies.

**1979**

De L. Horne, David J.; Baillie, Jennifer (1979). Imagery differences between anxious and depressed patients. In Burrows, G. D.; Collison, D. R.; Dennerstein, L. (Ed.), Hypnosis 1979 (pp. 55-61). Amsterdam: Elsevier/North-Holland Biomedical Press.

#### NOTES

"In conclusion, the topic of this study is as yet a very new area of research. No other studies were found which specifically tested the difference between anxious and depressed people in imagery and hypnotic susceptibility. There were a number of limitations to the present study, which further studies could avoid. Larger samples could be used, and such variables as age, educational level and anxiety should be more carefully controlled. The type of depression, whether agitated or retarded, should be assessed, and level of arousal to the imagined scene measured more accurately, with for example, other physiological measures than the E.M.G. It would be preferable to test depressed people while they are not on medication. Though the effects of antidepressant drugs on imagery were not actually documented, it would seem very likely that significant effects could exist on the ability to image; these obviously warrant investigation" (p. 61).

**1977**

Novaco, Raymond W. (1977). Stress inoculation: A cognitive therapy for anger and its application to a case of depression. Journal of Consulting and Clinical Psychology, 45 (4), 600-8.

Clinical interventions for anger disorders have been scarcely addressed in both theory and research in psychotherapy. The continued development of a cognitive behavior therapy approach to anger management is presented along with the results of its application to a hospitalized depressive with severe anger problems. The treatment approach follows a procedure called "stress inoculation," which consists of three basic stages: cognitive preparation, skill acquisition and rehearsal, and application practice. The relationship between anger and depression is discussed.

**1975**

Spear, J. E. (1975). The utilization of non-drug induced altered states of consciousness in borderline recidivists. American Journal of Clinical Hypnosis, 18, 111-126.

Utilizing non-drug induced altered states of consciousness, various modes of interior reflection, behavior modification and reprogramming of conscious attitudes and values were utilized with 49 borderline recidivists. Such offenders were so determined by the Department of Corrections, Probation and Parole Office, District II. No coercion was used to induce such individuals to enter the program and there was no reprisal for stopping therapy at any time. Over a two and one-half year period the recidivist rate among this group was less than 5%. It is suggested that non-drug induced altered states of consciousness combined with indirect as well as symbolic techniques may prove to be the most effective means of criminal rehabilitation.

#### NOTES

Berderline recidivists were "individuals, who, in the opinion of the P.O. [probation officer] were, in all probability, to be returned to prison within a few months, or less, if there wasn't a major change in attitude and actions" (p. 111). Therapy employed closed circuit TV with bi-directional audio and induction of altered state of consciousness using an ophthalmology-type rotary prism. Therapy involved (s) recall of relaxed state when under stress, (2) exploration of early conditioning events, (3) self evaluation during the ASC, (4) use of symbolic mental exercises and mental practice for similar circumstances in normal waking state, (5) suggestions for setting goals and ideals, (7) a type of logotherapy, (7) 'nudging' the person to examine their relationship with their concept of God. The author noted in the parolees: (1) low levels of self esteem, (2) depression, (3) going into deep levels of altered states once trust was established with the therapist.

1972

Hodge, James R. (1972). Hypnosis as a deterrent to suicide. American Journal of Clinical Hypnosis, 15 (1), 20-24.

A method that has been found successful in temporarily deterring suicide attempts is to give the post-hypnotic suggestion that the patient will not be able to carry out an actual suicide attempt until he has discussed it with the psychiatrist, in advance of the attempt, and in the psychiatrist's office, and further, that the patient will agree to enter a trance at any time the psychiatrist insists, even though the patient may not wish to do so. The rationale for this approach is that, (a) A temporary deterrent is often all that is necessary to prevent a given suicide attempt, (b) Hypnosis can have only a temporary deterring effect on suicide, (c) A direct and permanent confrontation that he can never commit suicide would be bound to fail and would not promote therapy of the personality, and (d) It gives the patient an alternative to suicide.

1968

Chambers, Helen (1968). Oral eroticism revealed by hypnosis. International Journal of Clinical and Experimental Hypnosis, 16, 151-157.

A CASE STUDY OF THE OUTPATIENT TREATMENT OF A SEVERELY DEPRESSED WOMAN. THE CASE WAS COMPLICATED BY THE S'S REFUSING USUAL ANTIDEPRESSANT TREATMENTS. COMMUNICATION WAS DIFFICULT BUT WAS FINALLY ACHIEVED BY THE USE OF ETHER AT ALTERNATE INTERVIEWS. WITHDRAWAL OF ETHER WAS THEN USED TO CREATE A SITUATION OF DEPRIVATION TO AROUSE IN THE TRANSFERENCE ATTITUDE THE FEELINGS PRODUCED BY THE EARLY TRAUMA. THE S'S COMPULSION TO EAT RAW POTATOES WAS STUDIED WHILE SHE WAS DEEPLY HYPNOTIZED. PSYCHOANALYTIC THEORIES THAT PLACE THE ORIGIN OF DEPRESSION AT THE TIME WHEN THE ORAL PHASE IS PRIMARY WERE CONFIRMED. THE S REFUSED ANY OTHER ANTIDEPRESSANT TREATMENT. ## DEPTH

1998

Eimer, Bruce; Freeman, Arthur (1998). Pain management psychotherapy: A practical guide. New York NY: John Wiley & Sons, Inc..

"Pain Management Psychotherapy" (PMP) provides a clear and methodical look at pain management psychotherapy beginning with the initial consultation and work-up of the patient and continuing through termination of treatment. It is a thoughtful and thorough presentation that covers methods for psychologically assessing the chronic pain patient (structured interviews, pain assessment tests and rating scales, instruments for evaluating beliefs, attitudes, pain behavior, disability, depression, anxiety, anger and alienation), treatment planning, cognitive-behavioral therapy techniques, and a range of hypnotic approaches to pain management. The book covers both traditional (cognitive and behavior therapy, biofeedback, assessing hypnotizability, choice of inductions, designing an individualized self-hypnosis exercise) as well as newer innovative techniques (e.g., EMDR, pain-relief imagery, hypno-projective methods, hypno-analytic reprocessing of pain-related negative experiences). An extensive appendix reproduces in their entirety numerous forms, rating scale, inventories, assessment instruments, and scripts.

The senior author, Bruce Eimer, states in his online comments on Amazon.com that "most therapists hold the belief that 'real' chronic pain patients are quite impossible to help. This book attempts to dispel these misguided beliefs by providing a body of knowledge, theory, and techniques that have proven value in understanding and relieving chronic physical pain." He also states that "the challenge for the therapist is to persuade the would-ne patient/client that he or she has something to offer that can help take way pain and bring back more pleasure. This challenge is negotiated through the therapeutic relationship. However, the therapist just can't be 'warm, accepting, non-judgmental and empathic'. The therapist must also have knowledge

and skills relevant to relieving pain. Only then can the therapist impart such knowledge, and in teaching these skills to the pain patient, help the patient become something of a 'self-therapist'. . . I dedicate this book to everyone who wants to find ways to make living with pain more comfortable, and to the ongoing search for better ways to relieve pain."

Weitzenhoffer, Andre M. (1997). Hypnotic susceptibility: A personal and historical note regarding the development and naming of the Stanford Scales. International Journal of Clinical and Experimental Hypnosis, 45 (2), 126-143.

Certain misleading, if not inaccurate, allegations that have been made regarding the foundations of the Stanford scales are corrected. No special meaning was intended when the scales were designated susceptibility scales. A retrospective examination, however, indicates that grounds existed for making certain differentiations. SHSS:C and RSPS:I and RSPS:II should more appropriately have been designated as suggestibility and depth scales. On the other hand, whereas SHSS:A and SHSS:B also assess depth of hypnosis, they include a feature that permits using the obtained depth as a measure of hypnotic capacity and a predictor of future hypnotic performance. The possibility of using the same measure, suggestibility, to assess hypnotic responsiveness in dissimilar contexts may have been partially responsible for the confusing variety of labels that have been attached to what in the past has appeared to many to be one and the same thing. Further confusion more recently has been introduced by researchers and clinicians who have used the term depth, previously and conventionally attached to assessments based on observed overt responses, in reference to now certain subjectively based assessments.

1995

Matthews, William J.; Isenberg, Gail L. (1995). A comparison of the hypnotic experience between signing deaf and hearing participants. International Journal of Clinical and Experimental Hypnosis, 43 (4), 375-385.

This study compared the hypnotic responsiveness of 17 hearing and 34 deaf individuals, all of whom received visual induction and hypnotic suggestions via some form of signing. The comparison between deaf and hearing participants was analyzed on five dependent measures: (a) the Stanford Hypnotic Susceptibility Scale, Form C (SHSS:C); (b) participants' individual item performance; (c) overall trance depth; (d) a rapport scale; and (e) a resistance scale measuring attitudes of participants toward the hypnotist. Although all participants showed at least a moderate level of hypnotic responsiveness, the data did not indicate a significant main effect between deaf and hearing participants on any of the dependent measures. However, there was a tendency ( $p < .08$ ) for hearing participants to show a greater hypnotic responsiveness than deaf participants. Additionally, there was a significant difference between all the signing participants combined when compared to the norming population on three items of the SHSS:C. Clinical and theoretical implications of these data are discussed.

Repka, Renee J.; Nash, Michael R. (1995). Hypnotic responsivity of the deaf: The development of the University of Tennessee Hypnotic Susceptibility Scale for the Deaf. International Journal of Clinical and Experimental Hypnosis, 43 (3), 316-331.

The purpose of these two studies was to develop and test a measure that assesses the hypnotic responsivity of deaf individuals. The University of Tennessee Hypnotic Susceptibility Scale for the Deaf (UTHSS:D) is a signed, videotaped version of a standard hypnotic induction with 12 standard suggestions. Experiment 1 compared the behavioral and subjective hypnotic responsivity of deaf and hearing individuals using the UTHSS:D and the Field Depth Inventory (FDI), respectively. As compared to hearing subjects, deaf participants were found to be less responsive to hypnosis when assessed behaviorally (UTHSS:D) and equally responsive to hypnosis when assessed subjectively (FDI). Experiment 2 undertook a more comprehensive examination of the hypnotic responsivity of deaf individuals, using hearing individuals as controls. Three dimensions of hypnosis responsivity were assessed: behavioral (UTHSS:D), subjective (FDI), and interpersonal (Archaic Involvement Measure). Additionally, correlates of hypnotic responsivity (absorption, attitudes, expectations) were examined for the two groups. In Experiment 2, no significant differences were found between the deaf and hearing participant groups on any measures of hypnotic responsivity or on any measure of the correlates of hypnotic responsivity.

1994

Grant, Carolyn (1994). The Computer-Assisted Hypnosis Scale: Standardization and norming of a computer-administered measure of hypnotic ability (Dissertation). Dissertation Abstracts International, 54 (10/B), 5387.

"In a counterbalanced, within-subjects, repeated measures design, 130 subjects were administered both the Computerized Assisted Hypnosis Scale (CAHS) and the Stanford Hypnotic Susceptibility Scale, Form C (Stanford Hypnotic Susceptibility Scale: C). For each hypnotic procedure responsiveness was assessed along three dimensions: behavioral (CAHS, Stanford Hypnotic Susceptibility Scale: C), subjective depth (Field Depth Inventory), and relational involvement (Archaic Involvement Measure). Subjects also completed a Stanford Hypnotic Susceptibility Scale: C self scoring measure and the Tellegen Absorption Scale. The CAHS was shown to be a psychometrically sound instrument for measuring hypnotic ability. The various dimensions of CAHS hypnotic responsiveness were highly positively related, and the CAHS compared favorably with the Stanford Hypnotic Susceptibility Scale: C across the three dimensions assessed. Results are discussed in terms of the theory and practice of clinical assessment, noting directions for future research" (p. 5387).

Wagstaff, Graham F.; Royce, C. (1994). Hypnosis and the treatment of nail biting: A preliminary trial. Contemporary Hypnosis, 11, 9-13.

A clinical trial was conducted examining the relative efficacy of therapeutic suggestions preceded by and without a hypnotic induction in the treatment of nail biting in 17 students. Outcomes showed a hypnotic induction added significantly to therapeutic benefits and was the only condition that resulted in symptom improvement. Results from only one session showed that 7 of 11 hypnosis subjects stopped nail biting compared to only 1 of 6 control subjects. Reports of "believed in efficacy" predicted treatment success better than ratings of motivation, hypnotic induction per se, or scores on the Creative Imagination Scale. However, within the group receiving hypnotic induction, hypnotic- depth scores significantly correlated with treatment success, suggesting that state factors such as dissociation might be involved.

The hypnotized Ss were given the T. X. Barber (1969) induction, a request for their depth estimate on a scale of 0-10, and then a set of suggestions to discourage nail biting. The suggestions were of four types: (1) to have a positive attitude, that nail biting is a habit that can be broken and that stopping will enhance attractiveness and self esteem; e.g., 'With just a little self control you will stop biting your nails and feel better about yourself.' (2) to stop the habit; e.g. to say to themselves, 'I will not bite my nails today/tomorrow,' five times each morning and at night, and whenever the temptation arose. (3) to improve feelings of self-efficacy; e.g., 'If you ever feel the urge to bite your nails tell yourself that you want to break the habit and that you are perfectly capable of doing so. You are not weak.' (4) that the results would be outstanding; e.g. 'After only ten days or so ... you will have no desire to bite your nails, indeed the very thought of doing so will repulse you.'

Control subjects received the same instructions, without a hypnotic induction; the procedure was labeled a 'positive attitude for self discipline' technique.

Judges rated improvement without being aware of the Ss' self-report on whether they had stopped biting their nails. Judges' ratings correlated  $r = .94$  with Ss' statements about whether they had stopped the habit. Improvement scores also correlated significantly with belief the treatment would be effective ( $r = .60$ ) and Creative Imagination Scale scores ( $r = .53$ ), but not with motivation. The hypnosis group had significantly higher belief scores than the control group. Within the hypnosis group itself, hypnotic depth was the only variable to correlate significantly with improvement.

The Discussion stated, "However, taken together, the findings indicate that hypnotic induction added significantly to the therapeutic benefits of suggestions for the cessation of nail biting, and that Johnson and Barber's (1978) concept of 'believed-in efficacy' was more important in accounting for therapeutic success than motivation (at least as measured here), hypnotic induction per se, or the subject's proclivity for imaginative involvement. Nevertheless, belief still accounted for less than 40% of the variance in improvement. This may have been due to measurement error or insensitivity in the measures. Alternatively, or additionally, other factors may have been influential. For example, if CIS scores are considered to be indirect measures of hypnotic susceptibility, then belief was more influential than hypnotic susceptibility; however, from a hypnotic state theory perspective, the significant correlation between hypnotic depth (LSS scores) and improvement within the

hypnosis group might suggest that some further feature of the 'hypnotic state' could still have been at work, such as a dissociative process (Hilgard, 1986). On the other hand, from a non-state perspective, perhaps subjects receiving hypnotic induction and reporting high depth scores might have felt more obliged to respond to the demand characteristics of the study, and tried harder to please the experimenter (Wagstaff, 1981); the general motivation questions used here could have been insensitive to such an effect" (p. 12).

1993

Diamond, Michael J. (1993). A question of filling in the gaps: A master class commentary. [Comment/Discussion] .

This is a response to a clinical vignette described as follows: "'Judy,' a professional writer, asked me to use hypnosis to help her 'fill in the gaps' in her knowledge of certain periods in her youth. As she was so keen, getting her into trance was relatively easy. I asked a few questions and she answered in a slurred voice. Then, after a few minutes, she said that she wasn't hypnotized. 'Not to worry, Judy, I'll bring you out' was my reply. With that, a flood of memories, absolutely unstoppable for approximately 4 minutes, came pouring forth. Thereafter, I asked questions relating to an earlier period in her life. Again came the statement that she wasn't hypnotized, and I replied as before. With that, a second flood of unstoppable experiences poured forth. later, on coming out of trance, she was able to recall all she'd spoken about while in trance and often punctuated her recollections with 'I didn't know that they punished me at y by locking me in the cupboard under the stairs!'" (p. 261).

Szabo, Csaba (1993). The phenomenology of the experiences and the depth of hypnosis: Comparison of direct and indirect induction techniques. International Journal of Clinical and Experimental Hypnosis, 41, 225-233.

The effect of two hypnotic induction styles on subjective experience was measured in an experiment in which 44 subjects participated in both traditional direct hypnosis, induced by the Stanford Hypnotic susceptibility Scale, Form A, and indirect hypnosis (presented in counterbalanced order), followed by 4 minutes of rest before dehypnosis. The depth of hypnosis was measured retrospectively by a subjective scale, and the structure of experiences was measured by the Phenomenology of Consciousness Inventory. Subjects were subsequently administered the Stanford Hypnotic Susceptibility Scale, Form B, so that awareness of their hypnotizability would not affect their subjective depth reports. No differences were found in a comparison of subjects' structure of experiences in direct and indirect hypnosis. In addition, low and medium hypnotizable subjects reported indirect hypnosis as deeper. This may reflect the possibility that while hypnotized different mechanisms come into play for subjects high in hypnotizability compared to those who are less hypnotizable.

1992

Barrett, Deidre (1992). Fantasizers and dissociaters: Data on two distinct subgroups of deep trance subjects. Psychological Reports, 71, 1011-1014.

The study delineated two subgroups of highly hypnotizable subjects. The first subgroup (fantasizers) entered trance rapidly, scored high on absorption (mean of 34 on the 37-item Absorption Scale), and described hypnosis as much like their rich, vivid, and very realistic waking fantasy life. None of the fantasizers experienced unsuggested amnesia, and 5/19 failed to produce suggested amnesia. Only 2/19 fantasizers described hypnosis as very different from their other experiences. The earliest memories of fantasizers were all identified as occurring before age 3, and before age 2 for 11 of 19. The second subgroup (dissociaters) took time to achieve a deep trance (unlike Wilson and Barber's fantasy-prone subjects, but they did achieve as deep a trance as fantasizers), experienced hypnosis as different from any prior experiences, and were more likely to exhibit amnesia for both hypnotic experience and waking fantasies. None of the dissociaters described their waking imagery as entirely realistic, and the earliest memories in this group were all over the age of 3 (mean age - 5). Of the 15 dissociaters, 7 scored below the norm on the Absorption Scale (Mean - 26).

Page, Roger A.; Handley, George W. (1992). Effects of 'deepening' techniques on hypnotic depth and responding. International Journal of Clinical and Experimental Hypnosis, 40, 157-168

The present study attempted to assess the effectiveness of commonly used deepening techniques and of surreptitiously provided stimulation on hypnotizability scores, in-hypnosis depth reports, retrospective realness ratings, and the Field Inventory of Hypnotic Depth (Field, 1965). High, medium, and low hypnotizables were assigned in equal numbers to 1 of 3 groups, each containing 54 Subjects. Controls were compared to Subjects receiving 2 deepening techniques or 2 suggestions for positive and negative hallucinations that were surreptitiously enhanced. Of the 4 dependent measures employed, the only significant different between groups related to a change in depth reports for the manipulation items themselves, leading to the conclusion that the effect of the techniques was at best minimal and transient. Some methodological and conceptual issues are also discussed.

Bates, Brad L.; Kraft, Patricia M. (1991). The nature of hypnotic performance following administration of the Carleton Skills Training Program. International Journal of Clinical and Experimental Hypnosis, 39, 227-242.

30 low hypnotizability Ss were administered the Carleton Skills Training (CST) program, while 8 were assigned to a practice group. Prior to treatment, an attempt was made to facilitate training by altering the ecological conditions of the laboratory. All Ss were tested immediately after treatment, and trained Ss were retested after 5-7 months. Immediate training gains were large and were comparable in magnitude to those routinely found at Carleton University. In

addition, (a) trained Ss responded comparably whether screened once or twice, (b) practice alone did not enhance hypnotic performance, and (c) natural high hypnotizability Ss obtained significant larger Field Inventory of Hypnotic Depth (Field, 1965) scores than created high hypnotizables. Follow-up scores fell between scores posted at screening and immediately after training. Current findings are interpreted in the context of existing evidence concerning the CST program.

"Results from these two investigations (include Bates et al., 1988) challenge the claim that lasting changes have occurred in the ability of most trained Ss to experience hypnosis. With regard to the present findings, it is reasonable to wonder whether scores would have been even lower had follow-up data been gathered a few months later. In the only other published study to address the problem of maintenance, Spanos, W. P. Cross, Menary, and Smith (1988) found that after at least 9 months, trained Ss outscored low hypnotizability Ss who had never received training. Unfortunately, these investigators do not report comparisons between trained Ss' follow-up scores and either original screening or immediate posttest scores. The authors do report, however, that 20% of trained Ss obtained high scores at follow-up. Given that at least 50%, and as high as 80%, of Ss routinely score in the high range immediately after receiving the CST program at Carleton University, a follow-up figure of 20% implies that with time, the hypnotic performance of most trained Ss began to return to baseline levels.

"With regard to the subjective experience of trained Ss.... These results confirm previous findings by Bates & Brigham (1990) which indicated that the hypnotic experiences of CST graduates - even those who are the most responsive to the modification program - may not be comparable in all respects to those of untrained, high hypnotizable individuals" (pp. 237-238).

"The present study altered the context in which training occurred by increasing the salience of the laboratory; adding, repainting, carpeting, and redecorating experimental rooms; requiring Es to dress professionally; and temporarily attributing the CST program to Washington State University. When demand characteristics were arranged in this manner, training gains were of the same magnitude as those found at Carleton University and were much larger than those found in all prior replication studies. The apparent importance of contextual factors is underscored by findings reported by Bates et al. (1988), who manipulated demand characteristics in a systematic fashion and observed that Ss' responses to the CST program are moderated by the context in which training occurs. Given the important role that ecological variables have generally played in hypnosis research, it should come as no surprise that factors like these would affect attempts to modify hypnotic performance" (p. 238).

1991

Berrigan, Lee P.; Kurtz, Richard M.; Stabile, Joseph P.; Strube, Michael J. (1991). Durability of 'posthypnotic suggestions' as a function of type of suggestion and trance depth. International Journal of Clinical and Experimental Hypnosis, 39, 24-38.

3 types of 'posthypnotic suggestion,' based upon factor analytic studies, were administered to high hypnotizability Ss (reals) and to low hypnotizable Ss instructed to simulate hypnosis (simulators) (N = 12 high and 6 low hypnotizable Ss per suggestion). The 'posthypnotic suggestions' consisted of instructions given to Ss following a hypnotic induction that, when the posthypnotic cue was later given, they would re-enter the hypnotic state and perform a certain task at that time. Ss were then tested 6 times for durability of 'posthypnotic response' during an 8-week period. Responses to the 'suggestions' were rated by research assistants (objective scores) and by Ss themselves (subjective scores). There was a significant Trials x Type of 'Suggestion' interaction for both types of scores for the reals but not for the simulators, indicating different rates of decline with time for the different 'suggestions' for the hypnotic Ss. Depth of reported hypnotic trance during the assessment sessions was found to be strongly related to performance of the 'posthypnotic suggestion' for both real and simulating Ss.

Block, Robert I.; Ghoneim, M. M.; Sum Ping, S. T.; Ali, M. A. (1991). Efficacy of therapeutic suggestions for improved postoperative recovery during general anesthesia. Anesthesiology, 75, 746-755.

There have been claims that the postoperative course of patients may be improved by presentation during general anesthesia of therapeutic suggestions which predict a rapid and comfortable postoperative recovery. This study evaluated the effectiveness of such therapeutic suggestions under double-blind and randomized conditions. A tape recording predicting a smooth recovery during a short postoperative stay without pain, nausea, or vomiting was played during anesthesia to about half the patients (N = 109), while the remaining, control patients were played a blank tape instead (N = 100). The patients were primarily undergoing operations on the fallopian tubes, total abdominal hysterectomy, vertical banding gastroplasty, cholecystectomy, and ovarian cystectomy or myomectomy. The anesthesia methods consisted of either isoflurane with 70% nitrous oxide in oxygen to produce end-tidal concentrations of 1.0, 1.3, or 1.5 MAC; or 70% nitrous oxide in oxygen combined with high or low doses of opioids. Assessments of the efficacy of the therapeutic suggestions in the recovery room and throughout the postoperative hospital stay included: the frequency of administration of analgesic and antiemetic drugs; opioid doses; the incidence of fever; nausea, retching, and vomiting; other gastrointestinal and urinary symptoms; ratings of pain; ratings of anxiety; global ratings of the patients' physical and psychological recoveries by the patients and their nurses; and length of postoperative hospital stay. There were no meaningful, significant differences in postoperative recovery of patients receiving therapeutic suggestions and controls. These negative results were not likely to be due to insensitivity of the assessments of recovery, as they showed meaningful interrelations among themselves and numerous differences in recovery following different types of surgery. Widespread utilization of therapeutic suggestions as a routine operating room procedure seems premature in the absence of adequate replication of previously published positive studies. (Key words: Anesthesia, depth: Awareness, Memory, Recall, Learning.)

Patients ages 19-55 were accepted into the study and they were paid for participation. (Older patients were excluded to guard against memory or hearing problems.) Other criteria for exclusion were: ASA physical status 4 or 5 indicating significant systemic disease, visual or hearing problems, middle ear disease (because it increases probability of nausea and vomiting), if their condition might require heavy sedation, if they were currently taking medication that interferes with memory (e.g. benzodiazepines, if there were intolerance to opioids, or if there were a likelihood of using postoperative pain treatment other than opioids).

The Spielberger State-Trait Anxiety Inventory was administered before surgery. Either suggestions (lasting 6 minutes) or a blank tape were played through headphones, starting 5 minutes after the surgical incision. The tape was played once for the first 59 patients, continuously for the remaining 150 patients. The first 139 patients received additional verbal materials on the tape, for memory tests to test possibility of learning under anesthesia. Operating room sounds were recorded by a tape recorder near the patient's head, throughout period of unconsciousness (except when tape was being played).

After the first 25% of cases, the team decided that lack of effect on therapeutic suggestions attributable to type of anesthesia did not warrant restriction to a single anesthetic method; also, multiple presentations of the suggestions on tape did not show an effect different from a single presentation.

After the patient regained consciousness and was reoriented, pain, nausea, retching, and vomiting were assessed every 30 minutes. Pain was rated orally on a scale from 1 to 10 in the recovery room, then on visual analogue scales every 2 hours on the day of surgery and the second day, and every 4 hours on subsequent hospital days during waking hours. Variables that were rated by staff every 24 hours included: opioids, other analgesics, antiemetics, nausea, vomiting, retching, presence or absence of nasogastric tube, passage of flatus, bowel movement, fluid intake, solids intake, urination. Temperature was recorded every 4 hours for the first 2 days after surgery, and after that less often. The anxiety measures were repeated on Day 3 postsurgery, as well as self ratings and nurse ratings on physical and psychological recovery. Staff recorded length of postoperative hospital stay and reasons for any delay of discharge. Separate analyses were performed for patients receiving opioids via patient-controlled analgesia (52%) vs traditional administration (48%), but no differences were found for effects of therapeutic suggestions except on postoperative Day 8.

"The inability to detect beneficial effects of therapeutic suggestions probably was not due to insensitivity of the measures of recovery. These measures were sensitive enough to show numerous significant differences in recovery after different types of surgery" (p. 751). The authors supported their contention that the measures were sufficiently sensitive by demonstrating meaningful correlations among the measures themselves; and by demonstrating adequate statistical power for detecting the effects of theoretical interest--at least 1 day in postoperative hospital stay or one half day in fever.

## Discussion

The authors note that a recent investigation that found positive results in a double-blind, randomized design with 39 hysterectomy patients (Evans & Richardson, 1988. Improved recovery and reduced postoperative stay after therapeutic suggestions during general anaesthesia. *Lancet*, 2:491-493) may not have controlled for variables such as presence of malignancy, physical status of patients before surgery, or ethnicity. Authors note that Evans and Richardson observed shorter periods of pyrexia despite there being no relevant suggestions, but no differences in pain intensity, nausea, vomiting, or urinary difficulties despite there being suggestions relating to those symptoms. There also were no differences in mood and anxiety test scores postoperatively for the experimental and control groups.

The authors note that McLintock, Aitken, Downie, & Kenny (Postoperative analgesic requirements in patients exposed to positive intraoperative suggestions. *Br M J* 301:788-790. 1990) reported a 23% reduction in opioids by patients receiving suggestions, but no reduction in pain, nausea, or vomiting. They contrast the present study with these earlier studies that had obtained positive results.

"We studied patients who had more than one type of surgery to obtain a large sample size and to assess the possibility that beneficial effects of therapeutic suggestions would be restricted to certain types of operations. Had this been the case, interactions of therapeutic suggestions with type of surgery would have been significant in the overall analyses, and follow-up analyses would have indicated that they were attributable to beneficial effects of therapeutic suggestions for certain surgeries. This did not occur. The two types of surgeries involving the largest numbers of patients seemed particularly promising for demonstrating beneficial effects. It has been reported that therapeutic suggestions presented during anesthesia are likely to be less successful with major and extensive surgery. Certainly, surgery on the fallopian tubes and gastric stapling did not involve a great deal of tissue trauma and blood loss. Patients were motivated to have the surgery and to recover quickly; particularly motivated were those having operations on the fallopian tubes, who were very eager to become pregnant, and those having vertical banding gastroplasties, who wanted desperately to lose weight" (pp. 753-754).

"In practice, we observed no beneficial effects of therapeutic suggestions, and there was no hint that anesthesia methods influenced the efficacy of the therapeutic suggestions. Interestingly, anesthetic methods also did not influence learning under anesthesia in the implicit memory tests we have used previously. Patients anesthetized with nitrous oxide and opioids did not differ from those anesthetized only with inhalational agents. In general, implicit or unconscious memory occurs in patients regardless of anesthesia methods or dosages of drugs" (p. 754).

"The few significant effects of therapeutic suggestions in our study did not point toward a beneficial influence of these suggestions. We found, in fact, an increased frequency of retching (but not nausea or vomiting) in the experimental group. The multiple variables examined in this study increased the likelihood of significant differences arising by chance, such that the null hypothesis was rejected when it should have been accepted. This is the way we interpret the effect on retching---i.e., as a type I error. We used in our therapeutic suggestions one negative or exclusionary sentence, 'You won't feel nauseous or have to vomit', among several positive or affirmative statements, e.g., 'You will enjoy eating, drinking...You will

swallow to clear your throat and everything will go one way, straight down. . . The food will taste good....Your stomach will feel fine.' We do not think that the negative sentence led to paradoxical results. Evans and Richardson (personal communication) used in their therapeutic suggestions a negative sentence ('You will not feel sick'), which they repeated, yet the reported incidence of nausea and vomiting did not differ between the experimental and control groups" (p. 754).

**Kleinhauz, Moris (1991). Prolonged hypnosis with individualized therapy. International Journal of Clinical and Experimental Hypnosis, 39 (2), 82-92.**

A therapeutic approach is presented which involves the use of prolonged hypnosis for the treatment of diverse medical and/or psychological conditions, including intractable pain. This approach may be indicated either as a complementary tool used in conjunction with other treatment approaches or as the only method of intervention. The technique is based on achieving a prolonged hypnotic response, during which hypno- relaxation serves as the foundation for the delivery of an individualized therapeutic plan which includes self-hypnosis, suggestive procedures, metaphors, and constructive imagery techniques. In debilitated patients, medical supervision and nursing care are essential, and hospitalization is recommended if necessary. Theoretical assumptions underlying this approach are presented, and clinical implications are discussed. The method is illustrated through case presentations.

The general procedure involves: 1. A flexible plan concerning the duration of treatment: days, weeks, or longer. 2. Information is given to the patient, the family and the medical staff if in hospital. Emphasize that while the patient may be in a 'twilight-like' state, most of the time he/she is able to fulfill his or her basic physiological needs, (drinking, eating, taking care of personal cleanliness, etc.). 3. The method of hypnotic induction is individualized. 4. The patient is trained in self-hypnosis, and for using signals for induction and dehypnotization either for self hypnosis or for the hypnotist to use. Thus if there is a physiological or emotional need for self-hypnosis the patient can do it. Suggestions and training are given and reinforced concerning the patient's capability to fulfill his/her basic physiological needs. 5. The family and/or the medical staff are instructed and trained in induction and dehypnotization, until the patient responds to them satisfactorily. 6. At this stage, therapeutic suggestions aimed at ego-boosting and a change of attitudes and meanings towards the symptom and symptom removal/amelioration/substitution are added. 7. Metaphoric constructive imagery is introduced when indicated. 8. If required, other hypnotic phenomena are elicited and used (e.g. dissociation, time distortion, age regression, rehearsal, hypno/analgesia, change of muscular tonus, displacement of emotions, abreaction, etc.). 9. An audio cassette which contains the wording of the therapeutic intervention is used with some patients. 10. The family and/or the medical staff are instructed to supervise the patient properly and to avoid potential complications. 11. Termination of prolonged hypnosis with individualized therapy is gradual to permit appropriate re-orientation towards reality. 12. Treatment is evaluated and a posttreatment plan is outlined.

They provide case reports and discuss precautions. All the cases reported were treated while the patients were hospitalized for their physical condition (although in Case 3, prolonged hypnosis with individualized therapy was also continued at home after the patient's discharge from the hospital), and the patients were monitored by the medical staff. In very debilitated patients, special care should be taken to avoid potential complications arising from their passivity, mainly the development of decubitus ulcer and of aspiration/choking while drinking or eating. Although precaution is taken routinely with these patients, these measures should be emphasized while the patient is in a state of prolonged hypno-relaxation.

1989

Jupp, J. J.; Collins, J. K.; Walker, W. L. (1989). Relationships between behavioural responsiveness to hypnotic suggestions and estimates of hypnotic depth following 11 sequential instances of hypnosis. Australian Journal of Clinical and Experimental Hypnosis, 17, 93-98.

Behavioral responsiveness to suggestions was assessed in an initial hypnosis session, and hypnotic depth was assessed in this session, followed by 10 weekly standardized hypnotic experiences. Correlations were calculated between behavioral responsiveness, initial and subsequent depth estimates, and between successive trance depth estimates. Levels of trance depth estimates were found to increase through weeks 1 to 11. Significant positive correlations were found between behavioral responsiveness scores and trance depth estimates to the fourth week but not beyond. Significant positive relations were found between successive estimates of trance depth except for the correlation between estimates for the fourth and fifth weeks. These results are discussed in terms of the estimates of trance depth being attributions from self-observations of behavioral responsiveness to hypnotic suggestions.

Kahn, Stephen P.; Fromm, Erika; Lombard, Lisa S.; Sossi, Michael (1989). The relation of self-reports of hypnotic depth in self-hypnosis to hypnotizability and imagery production. International Journal of Clinical and Experimental Hypnosis, 37, 290-304.

Studied multidimensional nature of self-hypnotic depth in 22 high hypnotizables who volunteered for self hypnosis research. On personality scales, they were distinguished from the population at large by: strong theoretical orientation, high level of curiosity, disregard for opinions of others, and high Mf scale on the MMPI. Used the Stanford Profile Scale, SHSS:C and HGSHS:A, which measure the entire range of phenomena ordinarily used in experimental studies of hypnosis, including ideomotor phenomena, hypnotic fantasy and dreams, hypermnasias and age regressions, analgesias, negative and positive hallucinations, amnesias, posthypnotic phenomena, and cognitive and affective distortions. They asked Subjects to experience self hypnosis for 60 minutes/day for 4 weeks. Journals were coded for imagery production by scoring for both reality-oriented and primary process imagery. Subject had been taught to monitor their hypnotic depth using a slightly

revised version of the Extended North Carolina Scale (ENCS) of Tart (1979). Previously, ENCS has been used only with hetero-hypnotic Subjects. The self-reports of depth using ENCS correlated highly with hypnotizability as measured by the Revised Stanford Profile Scale of Hypnotic Susceptibility... and with imagery production. Results demonstrate that ENCS scores are also a valid indicator of self-hypnotic depth among highly hypnotizable Subjects. Furthermore, they indicate that both hetero- hypnotizability and imagery production are related to self-hypnotic depth, but that the association between imagery and hypnotizability is due to their individual relationships to self-hypnotic depth.

**Kumar, V. K.; Pekala, Ronald J. (1989). Variations in phenomenological experience as a function of hypnosis and hypnotic susceptibility: A replication. British Journal of Experimental and Clinical Hypnosis, 6, 17-22.**

Phenomenological experiences associated with a baseline (eyes closed/open) condition and an hypnotic induction were compared across individuals of differing hypnotic susceptibility. The results indicated individuals of differing hypnotic susceptibility reported different intensities of phenomenological experience during the baseline condition. The induction further augmented intensity differences for low, medium and high susceptible subjects, but more so for high than for low subjects. These results replicate earlier research, are not inconsistent with trait and situational interpretations of hypnotic susceptibility and highlight the importance of the interaction between these factors on the resulting hypnotic experience reported by the subject.

**Matheson, George; Shu, Karen L.; Bart, Catherine (1989). A validation study of a short-form hypnotic-experience questionnaire and its relationship to hypnotizability. American Journal of Clinical Hypnosis, 32, 17-26.**

Investigated the validity of a 16-item scale inquiring about hypnotic experience, drawn from the Hypnotic Experience Questionnaire developed by Kelly (1985) to measure components of hypnotic experience. We administered the HEQ-S and the Harvard Group Scale of Hypnotic Susceptibility: Form A (HGSHS:A) to 198 students. Factor analysis of the scale produced three stable principal components accounting for 70% of the data variance: Dissociation/Altered State (DAS), Rapport (RAP), and Relaxation (REL). Subscales representing these three factors and a composite measure, "General Depth," were constructed. Subscale correlations with HGSHS:A scores were highest for the DAS subscale (.69) and lowest for REL (.41). Applications of the HEQ-S in clinical and research use are considered.

Using the phenomenological studies and theories of J. R. Hilgard (1979) and Shor (1962), Kelly (1985) constructed the Hypnotic Experience Questionnaire (HEQ), a 47- item scale designed to demonstrate the existence of five factors of the hypnotic experience. These factors included dissociation/altered state, relaxation, rapport, visual imagery, and a negatively correlated factor of cognitive rumination measuring the amount of anxious self-reflective, and interfering thought. A composite scale, General Depth, was also derived to provide a summary measure of

the subjective quality of the hypnotic experience. The HEQ was developed as a research instrument.

The HEQ-S was administered immediately after Ss completed the Harvard response record. Items were responded to on a 5-point Likert scale ranging from one (No, none or not at all) to 5 (Yes, a great deal, or almost completely).

Radtke, H. Lorraine (1989). Hypnotic depth as social artifact. In Spanos, Nicholas P.; Chaves, John F. (Ed.), Hypnosis: The cognitive-behavioral perspective (pp. 64-77). Buffalo, NY: Prometheus Books.

Zamore, Neal; Barrett, Deirdre (1989). Hypnotic susceptibility and dream characteristics. Psychiatry Journal of the University of Ottawa, 14 (4).

This study examined the relationship of hypnotic susceptibility to a variety of dream characteristics and types of dream content. A Dream Questionnaire was constructed synthesizing Gibson's dream inventory and Hilgard's theoretical conceptions of hypnosis. Several dream dimensions correlated significantly with hypnotizability as measured by the Harvard Group Scale of Hypnotic Susceptibility and the Field Inventory. For Ss as a whole, the strongest correlates were the frequency of dreams which they believed to be precognitive and out-of-body dreams. Ability to dream on a chosen topic also correlated significantly with hypnotic susceptibility for both genders. For females only, there was a negative correlation of hypnotizability to flying dreams. Absorption correlated positively with dream recall, ability to dream on a chosen topic, reports of conflict resolution in dreams, creative ideas occurring in dreams, amount of color in dreams, pleasantness of dreams, bizarreness of dreams, flying dreams, and precognitive dreams.

Cardena, Etzel (1988, November). The phenomenology of quiescent and physically active deep hypnosis. [Paper] Presented at the annual meeting of the Society for Clinical and Experimental Hypnosis, Asheville, NC.

Twelve highly susceptible undergraduate students participated in three conditions (lying down on a bed, pedaling a stationary bicycle at a comfortable rate, and having a motor do the pedaling at an approximately constant, comfortable rate) in deep hypnosis and non-hypnosis conditions. They were asked for their expectations about deep hypnotic experience, exposed to a number of traditional hypnotic phenomena before the deep hypnosis and comparison sessions, and given the opportunity to explore their own ways of inducing and deepening their state.

Even without cues or suggestions, participants gave comparable reports of their experiences at light, medium and deep hypnosis. The first one consisted mostly of relaxation and other changes in body sensations. Medium hypnosis was characterized by having complex imaginal experiences. Very deep hypnosis involved experiences of light, emptiness, and other phenomena associated with spiritual experiences.

1988

McCue, Peter A.; McCue, Elspeth C. (1988). Literalness: An unsuggested (spontaneous) item of hypnotic behavior? A brief communication. International Journal of Clinical and Experimental Hypnosis, 36, 192-197.

Milton Erickson claimed that the large majority of hypnotized individuals respond in a peculiarly literal way to questions/requests such as, "Would you mind telling me your name?" and he viewed this behavior as a manifestation of the 'hypnotic state.' In the present study, numerous Ss were exposed to hypnotic induction procedures and tested for literalness. Since it is possible that Erickson obtained literal responses by inadvertent cueing, some of these Ss were asked questions in a 'distorted' manner that was thought likely to elicit literal responses. A minority of the latter Ss gave literal responses, but with Ss who were asked questions in a normal manner, no clear-cut literal responses of the type described by Erickson were noted.

1986

Laurence, Jean-Roch; Nadon, Robert (1986). Reports of hypnotic depth: Are they more than mere words?. International Journal of Clinical and Experimental Hypnosis, 34, 215-233.

The empirical work relating hypnotizability, the hypnotic situation, and the reports of hypnotic depth is reviewed and evaluated. Asking Ss to assess their hypnotic depth is a complex task involving the interaction of experiential, cognitive, and contextual variables. Accordingly, future experimental work should take into account this multidimensionality; phenomenological, situational, cognitive, and motivational factors implicated in verbal reports should be explored in terms of their respective relationships with both hypnotizability and self-ratings of hypnotic depth. More sophistication in the experimental inquiries of hypnotic depth is required in order to further our understanding of the cognitive and affective structures underlying the hypnotic experience.

In past years, hypnotic susceptibility and hypnotic depth were regarded as the same thing, and depth was inferred from responses to test suggestions on hypnotizability scales (e.g. Davis & Husband, 1931; LeCron, 1953).

There has been little investigation of the relationship between Subjects' subjective experiences and reported "depth." Research suggests that "hypnotic depth reports are usually significantly higher for Ss who have undergone a hypnotic treatment than for those who have received task-motivation (Ham & Spanos, 1974; Spanos & Barber, 1968; Spanos, Stam, D'Eon, Pawlak, & Radtke-Bodorik, 1980); imagination-control; or relaxation-control instructions (Connors & Sheehan, 1978; Gilbert & Barber, 1972; Spanos & Barber, 1968; Spanos, Radtke-Bodorik, & Stam, 1980, Experiment 2)" (pp. 217-218). Others have found that changes in inward experiencing (e.g. feelings of unreality, a sense of disappearance of body parts) could not be attributed simply to sitting quietly with the eyes closed (Barber & Calverley, 1979). [A footnote on p. 218 indicates some studies didn't find this difference between a hypnosis group and a task-motivation control group.]

When Ss are asked to estimate subjective depth after having experienced hypnotizability test items, they are likely to infer depth from whether or not they passed the items (and indeed, early scales promoted that assumption). Reports of subjective depth taken before rather than after the test items still correlate with overall hypnotizability score, though not to as high a degree (E. R. Hilgard & Tart, 1966; Tart, 1970). Although usually depth estimates correlate with hypnotizability in the .50 to .75 range (Perry & Laurence, 1980), the correlations were obtained in the hypnotic context, and Ss may use their own behaviors as one determinant of their estimated depth.

From another line of study it is observed that Ss' subjective depth may be at variance with behavioral performance on hypnosis scales (Bowers, 1981). High hypnotizables judge their own depth from their performance on cognitive items (e.g. amnesia, hallucinations) while mediums and lows judge their own performance based on their responses to motor items and challenge items (Kihlstrom, 1981). In one experiment on amnesia, it appeared that Ss did not judge their own depth by how well they did on the amnesia task (Spanos, Stam, D'Eon, Pawlak, and Radtke-Bodorik, 1980). "M. T. Orne (1966, 1980) has emphasized that although it is necessary to operationalize S's responses to hypnotic suggestions, behavioral concomitants are only valid if they accurately reflect subjective alterations in an individual's experience" (p. 221).

"The social-psychological approach (see Barber, 1969; Radtke & Spanos, 1981, 1982; Spanos, 1982; Wagstaff, 1981) rejects the notion of hypnotic depth as an indicator of a unique state. These authors argue that the reports of having been hypnotized reflect attributions made by Ss when confronted with a hypnotic context. ... Bem (1972) and Kelley (1972) have emphasized the idea that the more ambiguous an experience is, the more a person is likely to base his or her judgment primarily on available external information" (p. 222). In this case, defining the situation as involving "hypnosis" is one of the most potent predictors of Ss' reports of subjective experience (Spanos, Radtke- Bodorik, and Stam, 1980). Other variables that influence subjective depth estimates are the wording of the hypnotizability scale, expectancy, and information provided directly or indirectly. On the other hand, McCord (1961) found that his patients had widely disparate expectations for how they thought they would feel when hypnotized, so expectancy as a predictor would not necessarily determine specific experience.

Direct experimental work on predicting response to hypnosis test items from expectancies (Council, Kirsch, Vickery, & Carlson, 1983; Kirsch, Council, & Vickery, 1984) suggests that expectations may predict test response when people are given a cognitive skill type of induction, but not when given a 'typical trance' type of induction. Also, another study from that laboratory (Council & Kirsch, 1983) established that only when expectancies are assessed after an induction (but before the test items) do they effectively predict hypnotic behaviors. The present authors express the view that these results are difficult to account for on the basis of social psychology theories that weight heavily the role of expectancy in generating hypnotic response.

When Ss are permitted to use several different descriptors for their experience (being hypnotized, experiencing the effects, being absorbed, and responding to the

suggestions), most Ss rated their own experiences as nonhypnotic (Radtke & Spanos, 1982). This was particularly true for medium hypnotizable Ss. Thus, unidimensional scales purporting to measure "depth" actually force Ss to interpret their multi-aspect experience in terms of the investigator's frame of reference, in this case "hypnotic depth." Nevertheless, the highly hypnotizable Ss were the least likely to be swayed from their self description of being "deep" when offered alternative ways of describing their experience. This is concordant with results reported earlier by Barber et al. (1968).

"The attribution literature may provide clues as to why most highly hypnotizability Ss retain their high ratings of experienced depth when confronted with situational manipulations. Self-perception theory strictly applies when Ss' experiences are ambiguous, forcing them to fall back on contextual factors to make self-appraisals. The relationship between expectancies, absorption, effect of scale wording, and hypnotizability scores suggest, however, that high hypnotizable Ss do not rely heavily on contextual factors when assessing their levels of hypnotic depth. Most of these Ss maintain their reports of altered experiences, even when situational determinants are changed (Harackiewicz, 1979; Kihlstrom, 1984; Lepper, Greene, & Nisbett, 1973). Thus, the hypnotizability by depth scale interaction found by Radtke and Spanos (1981) may suggest that experiences reported by high hypnotizable S are not inherently ambiguous. Accordingly, self-perception theory may not apply to them" (pp.226-227).

In their Discussion, the authors state, "Several studies have attempted to relate personal, real-life events to the experience of hypnosis. A number of studies (e.g., As, 1963; Field, 1965; Shor et al., 1962; Wilson & Barber, 1982) have shown that absorption, tolerance of unusual experiences, automaticity, compulsion, and trust are related to the capacity to be hypnotized. Other studies (Bowers & Breneman, 1981; Tellegen & Atkinson, 1974; Van Nuys, 1973) have shown that certain variants of attention are also related to hypnotizability. Extensive work by J. R. Hilgard (1970, 1979) has shown that patterns of personal development relate to hypnotizability in adult life. It appears then that hypnotizable individuals bring a host of experiences and abilities with them to the hypnotic context. It makes intuitive sense which is supported by the available empirical data, that a complex interaction among these experiences and abilities, the hypnotic context, and hypnotic responsiveness is implicated in Ss' assessments of their hypnotic depth. Studies are needed in which all of these potential determinants of hypnotic depth reports are taken into account. Only then will a clearer picture of their respective importance emerge" (p. 228).

1986

Mitchell, George P.; Lundy, Richard M. (1986). The effects of relaxation and imagery inductions on responses to suggestions. International Journal of Clinical and Experimental Hypnosis, 34, 98-109.

Theoretical attempts to understand the meaning and importance of induction procedures in producing hypnotic phenomena suggest that 2 critical components, relaxation and imagery, should be isolated and their relative effect on hypnotic

responding studied. Objectively and subjectively scored responses to 12 hypnotic suggestions, which had followed relaxation, imaginal, or combined inductions, were obtained from 59 Ss, divided into 3 levels of hypnotizability. Regardless of hypnotizability level, the combined induction led to a greater subjective report of hypnotic response than did either the relaxation or the imagery inductions; and the relaxation led to a greater subjective report than the imagery induction. It may follow that the subjective experience of hypnosis is facilitated by inductions which include relaxation. The inductions were equally effective in producing objectively measured behavioral responses. There were no significant interactions found between induction type and hypnotizability level.

As suggested by Sacerdote (1970), the combination procedure was the most generally effective in producing hypnotic responses. The difference between combined and imagery inductions reached statistical significance on four dependent variables, and the difference between combined and relaxation reached significance on three. It may also be of interest that Ss receiving the combined procedure scored consistently higher on all nine dependent variables.

A somewhat unexpected finding was that the relaxation induction produced scores on four of the dependent variables that were statistically higher than the imagery induction scores. Considering the difficulty of isolating relaxation and imagery components, it is quite noteworthy that these differences between inductions were found.

The four variables in which the combination and relaxation conditions produced significantly higher scores than the imagery condition were subjective reports--subjective score, degree hypnotized, response volition, and Field Inventory. In contrast to Ss in the imagery induction, Ss in the other two induction conditions believed that they were responding more, felt that their responses were more nonvolitional, and felt that they were more deeply hypnotized.

The fact that relaxation instructions were present in both conditions that were superior to the imagery condition would appear to support Edmonston's (1981) position which posits relaxation as essential for the production of the state of neutral hypnosis. For Edmonston the condition of neutral hypnosis is defined as the relaxed state and precedes other phenomena, such as dissociation and increased suggestibility, which other theoreticians may include in the definition of hypnosis.

However, the statistically significant superior effect of the combined over the relaxation induction on three measures casts doubt on Edmonston's position. The S believes that he or she is more deeply hypnotized and is responding less volitionally when an imagery component is combined with relaxation. The Ss also responded more to the Field Inventory when the combined induction was used.

Another explanation for imagery's relatively poor showing may lie in Ss' differential expectations. The Ss, especially those with previous experience with a traditional hypnotic induction, as was the case in the present study, may not expect to be hypnotized when presented with an imagery alone induction. Such expectations, of course, might reduce responses. On the other hand, there is no reason to believe that the reduced expectation in the imagery condition would not affect the behavioral responses as well, and such was not the case.

Thus, we may be left with the explanation that relaxation adds to the subjective experience of hypnosis. This is in keeping with Edmonston's (1981) position as well as with previous research, such as that by Hilgard and Tart (1966), which finds traditional inductions, with their relaxation components, superior to nontraditional inductions, such as fantasy or task-motivational. If future research should find that bodily involvements such as the physical exertion or repetitive motor behavior (Banyai and Hilgard, 1976) lead to the same level of subjective experience as relaxation did, then we may need to broaden the concept of the somatic component beyond relaxation alone.

In terms of the behavioral compliance of Ss, the results of the present study are in accord with some previous studies in finding all procedures equally effective. Neither imagery, relaxation, nor the combined procedure was superior for the behavioral measure.

Personality factors (social desirability, internality/externality, and absorption) did not affect the basic findings. To the degree that the Tellegen scales measure the ability to engage in imagery there seems to be little basis for believing that imagery ability is related to the general findings.

Sarbin (1983) would call the inductions studied here 'entrance rituals,' and he has recently asked in his review of Edmonston's book, "Which ritual is more suitable... [p. 58]' for preparing S to respond in various hypnotic ways? One answer from the present results is that an entrance ritual should include muscular relaxation if one wants a better subjective response from S. From Sarbin's point of view, the relaxation component may be more ego-involving, producing more subjective experience and meaning for S.

If one wants to produce only a behavioral response, either a relaxation or imagery ritual will serve.

**Register, Patricia A.; Kihlstrom, John F. (1986). Finding the hypnotic virtuoso. International Journal of Clinical and Experimental Hypnosis, 34, 84-97**

Measures of hypnotizability based on the Harvard Group Scale of Hypnotic Susceptibility, Form A (HGSHS:A) correlate only moderately with those based on the Stanford Hypnotic Susceptibility Scale, Form C (SHSS:C). Ss (N = 148) scoring in the high range (10-12) on HGSHS:A were classified according to whether they scored in the "virtuoso" range (11-12) or not on a subsequent administration of SHSS:C. Significant group differences were found on items comprising the cognitive distortion subscale of HGSHS:A, whether assessed in terms of overt behavior or subjective impressions of success. The 2 groups also differed on global self-ratings of hypnotic depth and on those subscales of Field's Inventory Scale of Hypnotic Depth concerned with subjective feelings of loss of control, automaticity, transcendence of normal functioning, and fluctuating depth. Assessments of hypnotizability are enhanced when investigators consider subjective involvement as well as behavioral measures of hypnotic response. This is particularly important when the more dissociative aspects of hypnosis are under scrutiny.

The correlation between Harvard Group and Stanford Scale scores is usually about  $r = .60$  (Bentler & Roberts, 1963; Coe, 1964; Evans & Schmeidler, 1966). This is much lower than one would expect ( $r = .82$ ), based on the tests' individual reliabilities (Evans & Schmeidler, 1966).

The authors developed a Table to show the cross-classification of Ss in terms of Harvard and SHSS:C. Only a minority (33%) of Ss scoring in the highest range of HGSHS:A also scored in the highest range on the SHSS:C (or 50% if cutting points are different).

The Absorption scale correlated  $r = .38$  ( $p < .001$ ) with the Harvard Scale, which fell to  $r = .31$  ( $p < .01$ ) when corrected for expansion of range. The correlation between Absorption and SHSS:C was  $.35$  ( $p < .001$ ).

The issue of predicting Stanford 'virtuosos' from Harvard 'virtuosos' was addressed. HGSHS:A predictor variables were used to determine which items determined whether or not one of the HGSHS:A 'virtuosos' (the 20% who scored 11-12) would also be a SHSS:C 'virtuoso.' It was found that 70% of the SHSS:C virtuosos, but only 53% of the nonvirtuosos, had reversible posthypnotic amnesia on the HGSHS:A. None of the ideomotor or challenge subscale items demonstrated this ability to predict group association. Although the 'virtuosos' differed from the 'nonvirtuosos' in self reported depth, none of the coding categories associated with the depth variable differentiated the groups; also, judges could not predict who would be a Stanford 'virtuoso' based on subjects' descriptions of depth following the Harvard scale administration.

The Experimenters also could not predict who among the Harvard 'virtuosos' would be classified as a Stanford 'virtuoso' based on either their Absorption Scale score or previous experience with hypnosis.

It was found that subjects' subjective experience of the suggestions for hallucinations, amnesia, and posthypnotic behavior (all considered to be cognitive alterations) were the most highly correlated with the subsequent total SHSS:C score. On the Field scale, which measures subjective experience, the most predictive items had to do with feelings of automaticity and loss of control (referred to as nonvoluntary behavior in other literature). Predicting SHSS:C score by 5 items (Harvard behavioral score, Harvard subjective score, Field total score, Tellegen Absorption total score, and self reported depth rating),  $r = .44$ . "The 5-element regression, employing only total scores, explained 17% ... of the variance of SHSS:C; thus, the feelings of subjective success accounted for the vast proportion (79%) of the explainable variance. For the 16 element regression, employing subscales derived from factor analysis of HGSHS:A and Inventory Scale of Hypnotic Depth, the cognitive subscale was dominant, accounting for 65.5% of explainable variance" (p. 92).

A discriminant function analysis employing the same five total score variables correctly classified 63.3% of the virtuosos.

In their Discussion, the authors suggest that investigators use subjective response as well as behavioral response when identifying hypnotic talent (virtuosos) for research. Particularly, the subjective experience of success seems to be important. Little is known, to date, about the determinants of that sense of success with hypnotic suggestions. "In part, they may relate to the 'classic suggestion effect' (K.

S. Bowers, 1981; P. G. Bowers, 1982; Weitzenhoffer, 1974): the quasi-automatic, compulsory, involuntary quality which distinguishes hypnotic response from compliance with simple social requests. If so, then a direct assessment of perceived involuntariness might enhance the predictive validity of HGSHS:A even more. This is especially true for the perceptual-cognitive alterations which relate to Ss' capacity for dissociation" (p. 94).

The authors further recommend, "In those situations where HGSHS:A must stand alone for economic reasons, however, and especially where HGSHS:A is employed as a convenient preliminary screening device in the search for hypnotic virtuosos, it would seem that some assessment of the subjective experience of hypnosis would provide useful supplementary information at very little cost" (p. 94).

Woolson, Donald A. (1986). An experimental comparison of direct and Ericksonian hypnotic induction procedures and the relationship to secondary suggestibility. American Journal of Clinical Hypnosis, 29 (1), 23-28.

Recent studies reporting the disparate effects of direct and indirect suggestion upon hypnotized subjects have indicated that standardized, direct hypnotic susceptibility tests may not accurately predict the suggestibility of subjects exposed to an indirectly worded, albeit similar, test. Historically, primary suggestibility correlates highly with hypnotizability, while secondary suggestibility does not and has been reported to be a subject's response to indirect suggestion. In this study 56 volunteers for self-hypnosis training were first tested for secondary/indirect suggestibility, then each singly received either a direct standardized [sic] induction or an Ericksonian (indirect) version. While susceptibility scores between groups were close, a greater number of the Ericksonian group subjects were rated as medium or highly susceptible. This occurred regardless of their type of suggestibility. Also, the Ericksonian group subjects appeared to be less aware of their depth of trance, as judged by a comparison of their susceptibility scores and their self-report depth scores. - Journal Abstract

1985

Jupp, James J.; Collins, John K. (1985). Hypnotic responsiveness and depth in a clinical population. Australian Journal of Clinical and Experimental Hypnosis, 13 (1), 37-47.

Two samples of clinical subjects estimated depth during procedures which allowed their estimates to be related to aspects of responsiveness. In Sample 1, subjects estimated depth after they scored their responsiveness and tested their post-hypnotic recall. In Sample 2 subjects estimated depth before they had completed these tasks. Results suggested that subjects use the range of available information in making depth estimates and that they may be more influenced by the more obvious ideomotor challenge performances than by the cognitive distortion responses, aspects of amnesia, or impressions of involuntariness.

Jupp, J. J.; Collins, J. K.; McCabe, M. P. (1985). Estimates of hypnotizability: Standard group scale versus subjective impression in clinical populations. International Journal of Clinical and Experimental Hypnosis, 33 (2), 140-149.

: The relationship between hypnotic responsiveness as measured by the Harvard Group Scale of Hypnotic Susceptibility, Form A (HGSHS:A) of Shor and E. Orne (1962) and global depth estimates derived from an 11-point scale were explored in 2 clinical samples. In one case, depth estimates were made just before, and in the other, immediately following the patients' focus on aspects of hypnotic responsiveness. The responsiveness-depth relationship was moderate and consistent across both samples, a finding which in itself is consonant with previous findings employing experimental Ss. When HGSHS:A performance and depth estimates were less proximate, the relationship between them remained significant but was substantially reduced in magnitude. Data suggest that low hypnotizable Ss increase their estimates of depth, and that higher hypnotizable Ss retain relatively stable estimates with increased exposure to hypnosis in a clinical context.

1983

Council, James R.; Kirsch, Irving; Vickery, Anne R.; Carlson, Dawn (1983). 'Trance' versus 'skill' hypnotic inductions: The effects of credibility, expectancy, and experimenter modeling. Journal of Consulting and Clinical Psychology, 31 (3), 432-440.

A hypnotic induction procedure based on social learning principles (skill induction) was compared with a traditional eye-fixation/relaxation trance induction, a highly credible placebo induction, and a no-induction base-rate control. The trance induction surpassed the skill induction only on the Field Inventory, a measure of hypnotic depth that contains items corresponding to suggestions contained in the trance induction. Experimenter modeling was not found to enhance the effectiveness of the skill induction. Skill and trance inductions elicited slightly higher behavioral scores on the Stanford Hypnotic Susceptibility Scale: Form C than did the placebo induction. However, this difference was not obtained on other measures of hypnotic responsibility and depth. Significant correlations were found between expectancy, absorption, and responsiveness on all dependent measures. Multiple regression analyses indicated that the relationship between absorption and responsivity was mediated by expectancy. The results are interpreted as supporting the hypotheses that hypnotic responses are elicited by the expectancy for their occurrence and that induction procedures are a means of increasing subjects' expectancies for hypnotic responses.

Trance induction resulted in a higher score on subjective experiences (cognitive & perceptual distortions) but not higher suggestibility scores than cognitive-behavioral skill induction. 2) Trance and cognitive-behavioral inductions got slightly higher scores in suggestibility than placebo biofeedback induction. 3) All inductions did better than a "no induction" control group on subjective and behavioral indices of hypnosis.

One of the goals of this research was to examine the contribution of experimenter modeling to the behavioral skill induction that "trains the subject in hypnosis skills and requires the subject's conscious cooperation in learning cognitive strategies that will enhance hypnotic responsivity" (p. 432). Another goal was to assess the contribution of "a subject's expectancies for the occurrence of behaviors perceived as being involuntary" (p. 433). A third goal was to determine whether congruence between a subject's beliefs about hypnosis and the rationale for a particular induction would increase expectancy. Two different skill inductions were employed (one with, one without a model). Subjects were asked to predict their performance, based on a description of the induction that they would receive. The contributions of credibility and expectancy were assessed using a highly credible placebo (pseudo biofeedback of EEG theta rhythm).

The investigation used only subjects who had never experienced hypnosis.

Independent variables included Rotter's (1966) Internal-External Locus of Control Scale, Rotter's (1967) Interpersonal Trust Scale, and Tellegen's Absorption Scale (Tellegen & Atkinson, 1974). Mediating variables included a measure of induction credibility based on Borkovec and Nau (1972), and a 20-item inventory measuring expectancies for hypnotic performance. Dependent variables included 20 standard hypnotic suggestions taken from the Stanford Hypnotic Susceptibility Scale, Form C; the Creative Imagination Scale; ratings of the 'realness' or experienced intensity of each suggestion; and the Field Inventory of Hypnotic Depth (Field, 1965).

The authors conclusion reads as follows: "The results of this study may be summarized as follows: (a) Traditional trance hypnotic inductions and cognitive-behavioral skill inductions were shown to be equally effective in eliciting experiential and behavioral responses to hypnotic suggestions, although trance subjects reported a somewhat greater alteration in conscious experience. (b) Experimenter modeling was not found to be an effective component of the skill induction package. (c) Subjects' expectancies for hypnotic responses, reported prior to hypnotic induction, bore a very strong relationship to hypnotic responsivity. (d) A highly credible placebo induction resulted in levels of expectancy and hypnotic responsivity generally comparable to those produced by trance and skill hypnotic inductions. (e) Absorption was significantly correlated with expectancy, but was not found to be significantly related to responsiveness once variance due to expectancy was taken into account. Thus the relationship between absorption and hypnotic responsiveness appears to be mediated by expectancies.

"In sum, these results suggest that various hypnotic inductions elicit expectancies for responding to hypnotic suggestions and that these expectancies are sufficient to elicit hypnotic responses. Further studies are needed to determine the nature of the relationship between absorption and hypnotic response expectancies" (p. 439).

Fourie, David P. (1983). Width of the hypnotic relationship: An interactional view of hypnotic susceptibility and hypnotic depth. Australian Journal of Clinical and Experimental Hypnosis, 11 (1), 1-14.

Efforts have been reported in the hypnosis literature to correlate measurements of hypnotic susceptibility with measurements of hypnotic depth. Not only have the

findings not been consistent, but recently the whole issue of hypnotic susceptibility and depth and their measurement has become controversial, as evidenced by Weitzenhoffer's (1980) and Hilgard's (1981) statements. This paper offers a different perspective on the issue and introduces the concept of the width of the hypnotic relationship as a useful indication of the degree of hypnotic involvement. The width of the hypnotic (paradoxical) relationship refers to the scope of the relationship within which certain involuntary behaviors can occur. The larger the number of such behaviors that are possible within the bounds of the paradoxical relationship, the wider that relationship shall be considered to be. This is an investigation of the relationship between the width of the relationship and the depth of hypnosis experienced. The SHSS: A, as a measurement of the width of the relationship, was applied to 18 volunteer female subjects. A 10-point self-report scale was applied before and after a procedure to widen the relationship. The correlations between the SHSS: A scores and both sets of self-report scores were positive and significant, as expected. The widening procedure had a definite deepening effect, but it seemed possible that this effect was not uniform.

Sacerdote, Paul (1982). A non-statistical dissertation about hypnotizability scales and clinical goals: Comparison with individualized induction and deepening procedures. International Journal of Clinical and Experimental Hypnosis, 30 (4), 354-376.

Researchers and theoreticians in the field of hypnosis have insisted for some time that reports of clinical applications of hypnosis should include the patients' classification based on their responses to standardized hypnotizability scales. Accordingly, clinical scales (Barber & Wilson, 1978/79; Cooper & London, 1979; J.R. Hilgard & E.R. Hilgard, 1979; Morgan & J.R. Hilgard, 1979; Wilson & Barber, 1978) have been developed or adapted from pre-existing standardized scales. For the same purpose, the Hypnotic Induction Profile (HIP) of Spiegel (1978), which claims reliability in classifying patients according to hypnotizability and psychopathology, has been developed and utilized.

Additionally, tailored scales which include specific qualitative items have been proposed (E.R. Hilgard, Crawford, P. Bowers, & Kihlstrom, 1979). According to a few clinical investigators (Frankel, Apfel, Kelly, Benson, Quinn, Newmark, & Malmaud, 1979) no disadvantage does ensue from routinely subjecting patients to hypnotizability scales. The positive results are: accumulation of reliable information about the validity of hypnotic intervention in various clinical conditions; differentiation between results of hypnosis and results of psychotherapy; and also a determination of whether hypnotizability is a fixed talent or whether it can be improved with training. With the individual patient the use of hypnotizability scales would rapidly indicate if his score will be high enough for certain specific applications and in general to determine whether therapy with hypnosis should even be attempted. The present author recognizes the rationale for the use of scales in the therapeutic realm, especially if the results are to be reported. The present author notes, however, that the generally accepted hypnotizability scales give disproportionate weight to some categories of hypnotic responses, but they are not

comprehensive enough to tap all the possible capabilities of individual patients. Standardized scales of hypnotizability rely almost entirely upon written or spoken instructions and therefore miss the opportunities of nonverbal communication. Also, most hypnotizability scales implicitly seem only to recognize hypnosis obtained by progressive relaxation as "the typical hypnosis." Some examples are presented to clarify how the use of standardized scales or of HIP (Spiegel, 1978) would wrongly classify a considerable minority of patients as nonhypnotizable or poorly hypnotizable, thus depriving them of potential therapeutic benefits.

1981

Sacerdote, Paul (1981). Teaching self-hypnosis to adults. International Journal of Clinical and Experimental Hypnosis, 29, 282-299.

The author presents operational definitions of self-hypnosis and examines the differences and similarities between hetero- and self-hypnosis in relation to the methods used and the hypnotizer's attitudes. It is argued that, with the exception of spontaneously occurring trances, there is no "pure" self-hypnosis. Most clinicians teach self-hypnosis through hetero-hypnosis, in part by direct or indirect posthypnotic suggestion. Some subjects never completely reach and maintain the same depth in self-hypnosis achieved in hetero-hypnosis, contrary to Ruch's (1975) conclusions. According to the present author, self-hypnosis taught through hetero-hypnotic experiences is effective as a method for physical and emotional tranquilization in nearly all subjects. Dynamically meaningful and physically effective self-hypnosis, however, is only learned by subjects who have been successful with deep hetero-hypnotic trances which included somnambulistic experiences. Effective deepening methods likely to stimulate psychodynamic creativity during hetero-hypnosis and subsequently during self-hypnotic trances are described. Some of the difficulties encountered by subjects during self-hypnosis are discussed: incomplete dissociative experiences; anxieties about self-control; doubts about the reality of the self-hypnotic state; and the possibility that negative attitudes, habits, and expectations may act countertherapeutically as posthypnotic suggestions. When successful, self-hypnosis permits prolongation and extension of effective therapy. Self-hypnotic teaching can be administered with different modalities in individual and in group settings. Clinicians can make useful contributions both to the therapeutic use of self-hypnosis and to a clearer theoretical understanding of self-hypnotic phenomena.

1980

Perry, Campbell; Laurence, Jean-Roch (1980). Hypnotic depth and hypnotic susceptibility: A replicated finding. International Journal of Clinical and Experimental Hypnosis, 28 (3), 272-280.

A sample of 398 Ss was tested in groups of from 8 to 20 people on the Harvard Group Scale of Hypnotic Susceptibility, Form A (HGSHS:A) of Shor and E. Orne (1962). Retrospective depth reports for each of the 12 HGSHS:A items were taken in order to extend Tart's findings (1970, 1972) on susceptibility and depth. The Ss were

tested over 2 successive years in samples of  $N = 220$  and  $N = 178$ . Since results were almost identical for each year (thus constituting a replication), the data were pooled for this report.

A remarkable consistency in patterns of subjective depth across the 12 items of HGSHS:A was found, particularly noticeable in Items 7, 8, 9, and 10 for 4 susceptibility groups (high, high-medium, low-medium and low-susceptible Ss) which appeared to reflect differential item difficulties. In addition, all correlations between reported depth and HGSHS:A total scores were high and statistically significant. While the findings are in general accord with those of Tart (1970, 1972), further research is required in order to determine the underlying basis of depth reports, and the degree to which experimental reports of susceptibility and clinical reports of depth reflect similar experiential aspects of hypnosis.

**1979**

Spanos, Nicholas P.; Steggles, Shawn; Radtke-Bodorik, H. Lorraine; Rivers, Stephen

M. (1979). Nonanalytic attending, hypnotic susceptibility, and psychological well-being in trained meditators and nonmeditators. Journal of Abnormal Psychology, **88** (1), 85-87.

Four groups of trained meditators differing in amount of meditation practice and a group of nonmeditators attended nonanalytically to a mantra in two meditation sessions. Subjects signaled intrusions into their attending, and were also assessed on several person variables. The four trained meditator groups differed from one another only in terms of self-esteem. When combined into a single group, meditators signaled fewer intrusions and reported "deeper" levels of meditating than nonmeditators. However, meditators and nonmeditators did not differ on hypnotic susceptibility, absorption, or indices of psychopathology.

Tart, Charles T. (1979). Measuring the depth of an altered state of consciousness, with particular reference to self-report scales of hypnotic depth. In Fromm, Erika; Shor,

**1978**

Schwartz, W. (1978). Time and context during hypnotic involvement. International Journal of Clinical and Experimental Hypnosis, **26** (4), 307-316.

A recent conceptualization of hypnosis suggests that hypnotized Ss should show a disruption in episodic memory which would reflect a diminished awareness of duration and sequence. Specifically, the predictions were that hypnotized Ss would exhibit less accurate estimates of duration, and less sequence in their recall of activities, than would nonhypnotized Ss. The empirical task consisted of giving Ss the Stanford Hypnotic Susceptibility Scale, Form C (Weitzenhoffer & Hilgard, 1962), either with the induction (hypnosis condition), or without the induction (control condition). Prior to the termination of the scale, Ss were asked to recall the activities they had performed and the time that had elapsed since they began the scale. Hypnotized Ss ( $N = 10$ ) were significantly less sequential in their recall of

activities, and less accurate in their estimations of the passage of time, than were nonhypnotized Ss (N = 10). These results suggest that persons who respond to hypnosis are less concerned with the context which the world provides for their actions than are nonhypnotized controls.

1970

Shor, Ronald E. (1970). The three-factor theory of hypnosis as applied to the book-reading fantasy and to the concept of suggestion. International Journal of Clinical and Experimental Hypnosis, 18, 89-98.

Maintained that many of the conflicting viewpoints in theories of hypnosis parallel the descriptive complexity of the phenomena. A 3-factor theory of hypnosis is surveyed in which hypnotic depth is conceived as a complex of 3 separate but complementary processes or dimensions. The theory is used to illuminate the book-reading fantasy and the concept of suggestion. (Spanish & German summaries) (16 ref.) (PsycINFO Database Record (c) 2003 APA, all rights reserved)

Silin, L.F. (1970). [Objective evaluation of the depth of hypnotic sleep]. Kazanskii Meditsinskii Zhurnal, 6, 39.

Tart, Charles T. (1970). Self-report scales of hypnotic depth. International Journal of Clinical and Experimental Hypnosis, 18, 105-235.

35 male undergraduates scaled their depth of hypnosis on a 10-point scale after each suggestibility test item on the Stanford Hypnotic Susceptibility Scale, Form C. These self-reports were highly correlated with measures of hypnotic behavior and experience. Instructions to report depth immediately and without thinking produced reports which correlated somewhat better with the other measures than instructions to consciously make a best estimate. This self-report scale promises to be highly useful in studies of hypnosis. (Spanish & German summaries) (22 ref.) (PsycINFO Database Record (c) 2003 APA, all rights reserved)

Brown, H. Alan; Krasner, Leonard (1969). The role of subject expectancies in hypnosis. International Journal of Clinical and Experimental Hypnosis, 17 (3), 180-188.

Investigated the influence of S's expectancies and "early data returns" on the depth of hypnosis with 40 female undergraduates shown 1 of 2 videotapes of "a hypnotic session conducted with a previous S." 1 tape created the set that becoming deeply hypnotized was very probable while the other created the set that it was very improbable. Ss were then hypnotized and administered a series of "depth tests" in such a way that the probability of passing the initial items was very high for 1/2 of the Ss and very low for the other 1/2. It was hypothesized that (a) "early data" congruent with S's expectancies should yield subsequent behavior in keeping with the expectancies, and (b) "early data" incongruent with S expectancies should lead to behavior consistent with the early data. Results support the 1st part of the

hypothesis only. (Spanish & German summaries) (PsycINFO Database Record (c) 2002 APA, all rights reserved)

Field, Peter B.; Palmer, R. (1969). Factor analysis: Hypnosis inventory. International Journal of Clinical and Experimental Hypnosis, 17, 50-61

An inventory scale of hypnotic depth and the Stanford Hypnotic Susceptibility Scale, Form A were factor analyzed, based on a sample of 223 college students. Both measures yielded a general factor of hypnotic depth. Rotation yielded inventory factors of unawareness, drowsiness, enthusiasm, subjective conviction, and Stanford factors of challenge and ideomotor-posthypnotic suggestibility. Results of an earlier study describing development of the hypnosis inventory were successfully cross-validated. (Spanish & German summaries) (19 ref.) Weitzenhoffer, Andre M. (1969). Eye-blink rate and hypnosis: Preliminary findings. Perceptual and Motor Skills, 28, 671-676.

Tests the validity and reliability of certain features of the outer appearance of hypnotized individuals which have long been popularly and clinically considered good indices of "hypnosis." The present report focuses on eye-blink rate. 19 Ss were administered a slight modification of the Stanford Scale of Hypnotic Susceptibility, Form A. Samples of their blink rates were obtained prior to the induction of hypnosis and some time after the induction of hypnosis procedure had been terminated, but before the dehypnotization procedures began. The results support the popular and clinical belief that hypnotic-like behavior is accompanied by a decrement in blink rate to the extent that Ss scoring 6 or more points on the Stanford Scale showed a marked and statistically significant mean reduction in blink rate of over 60% following the induction procedure and some testing of their suggestibility. In contrast, Ss scoring 5 or less and presumably not hypnotized but merely suggestible to non-suggestible, did not show a statistically significant decrement. As a possible index of "hypnosis," such a decrease in rate was found to have a test-retest reliability of .86. (PsycINFO Database Record (c) 2002 APA, all rights reserved)

Roper, P. (1966). The use of hypnosis in the treatment of exhibitionism. Canadian Medical Association Journal, 94, 72-77. (Abstracted in American Journal of Clinical Hypnosis, 1966, 9, p. 83)

The use of hypnosis in the treatment of exhibitionism is described in three patients in whom the condition has been present for more than five years. In each patient there was no subsequent recurrence of the exhibitionism once therapeutic suggestions had been made in a deep hypnotic trance, the follow-up period being respectively five years, four and a half years, and one year. The method of treatment and the results are discussed in terms of the concepts of behaviour therapy. It is concluded that with certain patients suffering from exhibitionism the use of hypnosis may well be one of the best methods of treatment, but considerable care should be exercised to exclude those patients with an underlying psychosis, mental defect or psychopathic condition. It is also noted that the efficacy of the treatment would appear to depend on achieving a satisfactory depth of hypnotic trance. If this is not reached, the results are less likely to be successful. (Author's abstract, from AJCH pp. 83-84).

1965

Field, Peter B. (1965). An inventory scale of hypnotic depth. International Journal of Clinical and Experimental Hypnosis, 13, 238-249. (Abstracted in American Journal of Clinical Hypnosis, 1966, 1, 86)

An inventory of 300 items describing subjective experiences during hypnosis was administered to 102 students after they had wakened from hypnosis. The 38 items that correlated best with a standard measure of hypnotic susceptibility are proposed as an inventory measure of hypnotic depth. Items dealing with absorption and unawareness, automaticity and compulsion, and discontinuity from normal experience correlated best with the criterion, while items dealing with conscious motivation to enter hypnosis, feelings of surface compliance with suggestions, and

unusual bodily sensations showed generally weaker relationships to the hypnotizability criterion. (PsycINFO Database Record (c) 2002 APA, all rights reserved)

1964

Hammer, A. G.; Arkins, W. J. (1964). The role of photic stimulation in the induction of hypnotic trance. International Journal of Clinical and Experimental Hypnosis, 12, 81-87.

The relative effectiveness of the ordinary verbal method of trance induction is compared with 2 forms of induction utilizing mechanical photic stimulation, and with methods combining the personal and mechanical features. The criterion of trance adopted was the compulsive carrying out of a difficult suggestion. Results show that mechanical procedures alone are ineffective. On the other hand, the addition of a particular sort of photic driving probably improves trance induction, which suggests that induction is a complex matter involving both social interactions and relatively nonmeaningful impacts on the brain. O'Connell, D. N. (1964). An experimental comparison of hypnotic depth measured by self-ratings and by an objective scale. International Journal of Clinical and Experimental Hypnosis, 12, 34-46.

The behavioral items of an individually-administered test of hypnotic susceptibility were scored by the Ss themselves (N = 88) and by E. Susceptibility scores derived from these self-ratings and observer-ratings were in excellent agreement ( $r = .90$ ) and did not differ significantly in distribution. Marked item scoring biases were found as a function of hypnotizability: poor hypnotic Ss tending to underevaluate their performance and good ones to overevaluate it. Moderate correlations were found between magnitude estimates made by Ss of their subjective hypnotic depth and both observer-rating ( $r = .55$ ) and self-rating ( $r = .54$ ) susceptibility scores. The interrelation and potential usefulness of these types of scoring procedures are discussed. (PsycINFO Database Record (c) 2002 APA, all rights reserved)

Tart, Charles T. (1963). Hypnotic depth and basal skin resistance. International Journal of Clinical and Experimental Hypnosis, 11, 81-92.

This investigation studied the relationship between a self-report scale for measuring the depth of the hypnotic state and basal skin resistance (BSR). The self-report scale accurately predicted the occurrence of hypnotic dreaming and amnesia, traditional criteria for medium and deep hypnotic states. BSR showed a high, positive correlation with the self-report depth scale. The data suggest that both the self-report scale and BSR may be useful measures for detecting changes in hypnotic depth. **1959**

**Bowers, Margaretta K. (1959). Friend or traitor? Hypnosis in the service of religion. International Journal of Clinical and Experimental Hypnosis, 7 (4), 205-215.**

**Hypnosis may potentiate religious experiences like prayer and worship, where hypnosis meets the world of inner reality. In the first to fourth centuries, Jewish mystics alluded to depth of mind in religious experience, but the idea of oneness with God "cannot be accepted as a healthy psychological concept" (p. 207).**

**"We have the possibility of understanding prayer and worship as an intrapsychic phenomenon, as a communication with one's total being. Once the premise of the indwellingness of God can be accepted as a psychological [sic] entity, then we can understand prayer as being a total response of the psychic life of the individual in order that he can understand the feelings of wholeness, self-confidence, and self-**

esteem in himself, and further, how this can be aided by hypnotic techniques" (p. 207).

The author interprets the 13th Century mystic's words, 'the divine will, dresses or cloaks itself in the will of the devout,' as similar to hypnosis, in which a state "may occur where the patient loses his awareness of the separateness of himself and the hypnotist so that the hypnotist's voice may be felt as his own voice" (p. 208). This is all right as long as awareness of separateness is re-established when the person comes out of the hypnotic or religious experience.

The religious mystic also may use autohypnosis "to achieve a greater experiencing of God and a heightened religious experience. Such a state likewise produces an ecstasy. Such ecstasy is sometimes present in religious conversion experiences as well. This ecstasy is healthy if the separateness and integrity of God and Man are kept separate" (p. 209). The author describes a phenomenon in which a priest who leads a deeply devotional religious service may feel a loss of a sense of self afterward, complaining of great fatigue and inability or unwillingness to relate to people. The same post-devotional emptiness and depression sometimes occurs among parishioners.

A psychoanalytically oriented case study of misdirected religious belief, amplified by religious service induced trance, is presented.

Cheek, David B. (1959). Use of rebellion against coercion as mechanism for hypnotic trance deepening. International Journal of Clinical and Experimental Hypnosis, 7 (4), 223-227

Observation that student subjects often go into a deeper level of hypnosis after suggestions have been given for ending the session has led the writer to explore the reactions of subjects to this phenomenon and to set up a simple experiment using ideomotor responses in ten gynecological patients who needed hypnosis for therapy. In each of the ten patients there was a deepening of the trance after the suggestion to awaken had been given. It was the opinion of the subjects that they deepened the trance in rebellion against the direction for terminating a pleasant experience" (p. 227).

1958

Sears, Alden B.; Talcott, Martha M. (1958). Hypnotic induction by use of non-meaningful languages: A pilot study. Journal of Clinical and Experimental Hypnosis, 6 (3), 136-138.

In order to explore the question of whether hypnosis is due to suggestion, rhythm, monotony, etc. a spiral disk focus induction was delivered to 46 college students in 3 different languages (Bohemian, Japanese, and Spanish) by female native speakers. The students were asked to rate which part was "most relaxing." Language sequence was counterbalanced.

Fourteen students went into light trance; in a later induction they were found to be hypnotizable -- 13 to a medium trance level (higher number than would be expected based on results with students who had not listened to the tapes). However the

authors did not know which aspect of the preparatory 3-language period to which to attribute the better response.

1957

Marenina, A. I. (1957). [Effect of inhibition of stimuli on changes of cerebral potentials in various stages of hypnosis]. [Translation] Institut Fiziologii Imeni I. P. Pavlova, 6, 330-334

"Summary. In an experiment situation, subjects who previously resisted all attempts at hypnosis with other operators, went into hypnosis on the first attempt with the experimenter. There was, without doubt, present the motive to overcome previous failures. However at this time the subjects went into hypnosis when they were told that they would be accomplishing the state through their own efforts. Furthermore we must not overlook the following as written by Kline (5). 'Individuals not successfully hypnotized by a particular person on the first attempt may be successfully hypnotized by the same person later on. Alternatively, individuals not hypnotized by one person may, even immediately afterwards, be successfully hypnotized by a second hypnotist'" (pp. 80-81).

Solovey, Galina; Milechnin, Anatol (1957). Concerning the induction of the hypnotic state. Journal of Clinical and Experimental Hypnosis, 5 (2), 82-98.

The hypnotic state has four attributes: "an effect of emotional stabiliztion, a retrogression to an infantile psychological functioning, suggestibility, and transmissibility of the hypnotic relationship" (p. 82). "SUGGESTIBILITY is a special motivation to accept, incorporate within one's self, and execute direct or implicit propositions, which is equivalent to the motivation of a child to accept, assimilate and carry out the propositions of its parents" (p. 84). The authors propose that verbal and non-verbal suggestions are incorporated during the course of education, lasting years and thus becoming in effect post-hypnotic suggestions. "The person will have in the future a \_special responsiveness,\_ that may be more or less pronounced according to the circumstances, \_for those data\_ (coming from books, movies, conversations, etc.) \_which agree with his emotionally-incorporated post-hypnotic suggestions\_" (p. 85). If while in an auto-hypnotic condition he comes in contact with someone "who appears to be the embodiment of the convictions or prejudices that on being stimulated started the process of emotional activation that led to the development of the hypnotic state, \_there may be a transformation of the auto-hypnotic condition into an interpersonal hypnotic relationship\_" (p. 86).

According to the authors, this theory can explain post-hypnotic (negative) sequellae. It also accomodates explantions of both Natural or Direct Orientation inductions and Indirect Orientation inductons, and explains phenomena such as patients entering hypnosis rather automatically while awaiting the appearance of Mesmer in his waiting room.

"To conclude, we will stress that the psychological mechanism of hypnotic induction is exactly \_the same\_ in everyday life and in the experimental environment. The apparent differences like [sic] in the \_behavior\_ of the subject in the hypnotic state,

and are due to the motivation that arises from the circumstances and to the convictions, capacities, psychological maturity, and degree of retrogression of the individual" (p. 96).

Solovey, Galina; Milechnin, Anatol (1957). Concerning the nature of hypnotic phenomena. Journal of Clinical and Experimental Hypnosis, 5 (2), 67-76.

The authors write about the place of the hypnotic state in general psychology: "the study of the psychological mechanisms that make the appearance of the phenomenon possible, which need not be different from the normal and current psychological mechanisms in everyday life\_" (p. 67). They classify hypnotic phenomena into three groups:

"I. Phenomena which are a function of the state of psychological retrogression (hypnotic depth), appearing in spontaneously [sic] or when proposed by the operator.

II. Phenomena which appear without any specific suggestion, as a side issue of other suggestions, capable of originating emotional states in the subject.

III. Phenomena which are independent of all suggestion, being a constituent part of the hypnotic state itself, in its 'positive' or 'negative' forms" (p. 68).

Using this framework, the authors describe several aspects of hypnosis: catalepsy, anesthesia, retrogression, the taking of a role, negativism and resistance, visceral changes, emotional stabilization, psychotherapeutic benefits (indirect). They observe that direct suggestions are often not necessary for therapeutic benefit, and give as an example the tendency for less bleeding when dentists suggest that patients will not feel less pain.

"For the elucidation of this point, the authors carried out an experiment in a dental clinic, taking six easily hypnotizable subjects in whom dental extractions were to be performed. They were given only the suggestions that they would feel the doctor working, but not experience pain ... that they would pay no attention to it ... or even if they felt a little pain, this would not trouble them and they would bear it perfectly ... Nothing was said about the loss of blood. As a result, in all the cases the loss of blood was slight, practically insignificant, though technically difficult extractions of roots were included" (p. 74).

"The explanation of hypnotic phenomena as natural and normal consequences of the hypnotic emotional state, and of the state of psychological retrogression, eliminates the supposed mysterious powers of suggestion. Suggestion is thus relegated to the modest role of a litmus paper which reveals the psychological functioning of the individual in an experimental environment. On the other hand, in everyday-life hypnosis, in the principal hypnotic relationships of parents with their children, of teachers with their pupils, etc. (11), suggestibility plays an important role in education or re-education" (p. 75).

1956

Bigelow, Newton; Cameron, G. H.; Koroljow, S. A. (1956). Two cases of deep hypnotic sleep investigated by the strain gauge plethysmograph. Journal of Clinical and Experimental Hypnosis, 4 (4), 160-164.

Two subjects, studied by means of a strain gauge plethysmograph, have shown greater changes in the peripheral pulse and the finger volume during deep hypnosis than they did immediately before or after. In the absence of external stimuli, the presence and the degree of such changes reflect the activity of the autonomic nervous system. This result suggests that in hypnosis the inhibiting tendency of the cortex on the autonomic nervous system is reduced or nullified" (p. 164).

Dittborn, Julio M. (1956). Toward a semeiology of hypnosis. Journal of Clinical and Experimental Hypnosis, 4 (1), 30-36.

19 subjects were chosen among two hundred that in the year the experiment took place (1954) were to be 20 years old. 11 of these subjects qualified themselves as good swayers, whereas the 8 others were considered somehow refractory to the postural swaying test.

"All 19 went under a standard hypnotic induction: the operator employed the same words in all cases, and requested from all the execution of the same acts.

"Several involuntary signs of standard induction are described, which reveal that the subject has attained a convenient degree of muscular relaxation after appropriate suggestions.

"Fatigue is apparently an important source of spontaneous amnesia in good swayers.

"In the analyzed cases no involuntary sign has been detected, that could reveal us whether the inducted subject will or not present spontaneous post-hypnotic amnesia" (p. 36).

Solovey, Galina; Milechnin, Anatol (1956). Concerning a theory of hypnosis. Journal of Clinical and Experimental Hypnosis, 4, 37-45.

"The essential attributes of the hypnotic condition may be understood to derive from three sources:

- 1) The hypnotic emotional state per se
- 2) The resultant motivation of the 'subject' to comply with the desires of the 'operator' (reinstating a child-like responsiveness).
- 3) The RETROGRESSION to an earlier form of psychological functioning that takes place under a hypnotic state of growing intensity" (p. 43).

"Although the retrogressive process is a general response to emotions and probably exists in some toxic states as well, it has a remarkable feature in the hypnotic state: THE COALESCENCE OF MOTIVATION AND RETROGRESSION, which exists in hypnotized people, permits a peculiar manipulation of the retrogressed condition. The peculiar responsiveness of the subject may be tested and molded by means of propositions which act as suggestions. In this manner, the so-called HYPNOTIC PHENOMENA are elicited" (p. 44).

1953

LeCron, Leslie M. (1953). A method of measuring the depth of hypnosis. Journal of Clinical and Experimental Hypnosis, 1 (2), 4-7.

**Author's Summary - No satisfactory method of ascertaining quickly and accurately the depth of hypnotic trance has heretofore been available. By providing the hypnotized subject with a yardstick of measurement, a reply to the question "how deep are you?" may be obtained from the subconscious mind of the subject himself. This is expressed verbally in percentages of from 1 to 100, with percentage values arbitrarily assigned by the operator to different stages of trance. Indications from testing 30 subjects are that their replies are valid, possibly to an astounding degree of accuracy. (p. 6)**

## **DESENSITIZATION**

**1988**

**Eimer, Bruce; Freeman, Arthur (1998). Pain management psychotherapy: A practical guide. New York NY: John Wiley & Sons, Inc..**

### **NOTES**

**"Pain Management Psychotherapy" (PMP) provides a clear and methodical look at pain management psychotherapy beginning with the initial consultation and work-up of the patient and continuing through termination of treatment. It is a thoughtful and thorough presentation that covers methods for psychologically assessing the chronic pain patient (structured interviews, pain assessment tests and rating scales, instruments for evaluating beliefs, attitudes, pain behavior, disability, depression, anxiety, anger and alienation), treatment planning, cognitive-behavioral therapy techniques, and a range of hypnotic approaches to pain management. The book covers both traditional (cognitive and behavior therapy, biofeedback, assessing hypnotizability, choice of inductions, designing an individualized self-hypnosis exercise) as well as newer innovative techniques (e.g., EMDR, pain-relief imagery, hypno-projective methods, hypno-analytic reprocessing of pain-related negative experiences). An extensive appendix reproduces in their entirety numerous forms, rating scale, inventories, assessment instruments, and scripts.**

**The senior author, Bruce Eimer, states in his online comments on Amazon.com that "most therapists hold the belief that 'real' chronic pain patients are quite impossible to help. This book attempts to dispel these misguided beliefs by providing a body of knowledge, theory, and techniques that have proven value in understanding and relieving chronic physical pain." He also states that "the challenge for the therapist is to persuade the would-ne patient/client that he or she has something to offer that can help take way pain and bring back more pleasure. This challenge is negotiated through the therapeutic relationship. However, the therapist just can't be 'warm, accepting, non-judgmental and empathic'. The therapist must also have knowledge and skills relevant to relieving pain. Only then can the therapist impart such knowledge, and in teaching these skills to the pain patient, help the patient become something of a 'self-therapist'. . . I dedicate this book to everyone who wants to find ways to make living with pain more comfortable, and to the ongoing search for better ways to relieve pain."**

**DeBenedittis, Giuseppe De (1996). Hypnosis and spasmodic torticollis -- report of four cases: A brief communication. International Journal of Clinical and Experimental Hypnosis, 44 (4), 292-306.**

**Dystonia and particularly spasmodic torticollis are neuromuscular disorders that are extremely resistant to most therapies (physical, medical, or surgical). Torticollis is a unilateral spasm of the neck muscles, particularly of the sternocleidomastoid, that produces violent, tonic turning of the head to one side. The etiology remains uncertain, although the role of psychogenic factors has been emphasized. This article reviews the literature and reports four cases of spasmodic torticollis treated successfully with hypnosis. In all four cases, psychogenic causes were involved. Postural hypnosis (i.e., hypnosis in the standing position) was employed to counteract and minimize muscle spasms due to postural reflexes. A hypnobehavioral approach was adopted along with hypnotic strategies that included hierarchical desensitization, sensory-imaging conditioning, ego-boosting suggestions, and hypnosis-facilitated differential muscle retraining. In two cases, a combined hypnosis and electromyographic-biofeedback approach was used to equilibrate and retrain affected neck muscles. Although the hypnotherapeutic process took several months to induce and stabilize significant changes, outcome results were good to excellent in all cases, with marked reduction of the torticollis and the hypertrophy of the neck muscles as well as a reduced interference of symptoms in daily living. -- Journal Abstract**

**Herbert, James D.; Mueser, Kim T. (1992). Eye movement desensitization: A critique of the evidence. Journal of Behavior Therapy and Experimental Psychiatry.**

**The scientific evidence supporting the efficacy of eye movement desensitization (EMD), a novel intervention for traumatic memories and related conditions, is reviewed. The sparse research conducted in this area has serious methodological flaws, precluding definite conclusions regarding the effectiveness of the procedure. Clinicians are cautioned against uncritically accepting the clinical efficacy of EMD.**

Lohr, Jeffrey M.; Kleinknecht, Ronald A.; Conley, Althea T.; Dal Cerro, Steven; Schmidt, Joel; Sonntag, Michael E. (1992). A methodological critique of the current status of eye movement desensitization (EMD). Journal of Behavior Therapy and Experimental Psychiatry.

Eye Movement Desensitization (EMD) has been recently advocated as a rapid treatment for the elimination of traumatic memories responsible for the maintenance of a number of anxiety disorders and their clinical correlates. Despite a limited conceptual framework, EMD has attracted considerable interest among clinicians and researchers. The popularity and interest generated by EMD will likely result in wide usage. We present a methodological critique of it with reference to assessment, treatment outcome, and treatment process. We also provide guidelines for judging the methodological adequacy of research on EMD and suggest intensive research to assess effectiveness, treatment components, and comparisons with other procedures.

#### NOTES

A controversial issue is heating up, and therapists are beginning to feel the heat. The issue involves the common practice of helping clients recover apparently repressed memories of early childhood sexual trauma.

"In the second edition of my hypnosis textbook, Trancework (1990, Brunner/Mazel), I included a special section on the possibility of hypnotically implanting false memories---vivid memories of things that never actually happened that the client comes to believe as true recollections. I pointed out the risks of suggestive procedures and urged caution in suggesting memories of any sort, whether a formal hypnotic induction took place or not.

"Early this year a non-profit foundation was formed in Philadelphia called the False Memory Syndrome Foundation which serves as a clearing house for relevant information, and even publishes a newsletter. It also provides support to families broken apart by these problems. If you are interested in the complex issues regarding suggestion and memory, you can contact the FMS Foundation at 3508 Market Street, Suite 128, Philadelphia, PA 19104, telephone (215) 387-1865. David Calof's group also publishes Treating Abuse Today. They, too, are cognizant of the relevant issues. Their address is 2722 Eastlake Avenue East, Seattle, WA 98012, telephone (206) 329-9101" (p. 2).

Abelson, James L.; Curtis, George C. (1989). Cardiac and neuroendocrine responses to exposure therapy in height phobics: Desynchrony within the 'physiological response system'. Behaviour Research and Therapy, 27 (5), 561-567.

Monitored subjective, behavioral, cardiovascular and neuroendocrine responses in 2 men (aged 19 and 34 yrs) with height phobias over a full course of exposure therapy and at 6 and 8 month follow-up. Both Ss showed rising cortisol responses and stable, nonextinguishing norepinephrine responses to height exposure over the course of treatment, while improvement occurred in subjective and behavioral response systems. They had differing heart rate responses. Despite desynchrony among anxiety response systems and within the physiological system at treatment conclusion, Ss had successful outcomes with general measures of change (phobia rating scales, the Fear Survey Schedule, and the SCL-90) showing substantial improvement for both Ss. These outcomes were preserved at follow-up.

Van den Bergh, Omer; Eelen, Paul; Baeyens, Frank (1989). Brief exposure to fear stimuli: Imagery ability as a condition of fear enhancement and fear decrease. Behavior Therapy, 20, 563-572.

Examined fear enhancement and fear decrease during brief exposure to fear stimuli. 140 good and poor imagery Subjects (aged 14-18 years) with medium fear levels toward spiders were exposed to a live spider, either by looking at it or by thinking of an invisible, but present spider during either 60, 180, or 360 sec. Control Subjects were given a distraction task. Subjective fear and behavioral approach were measured. Brief exposure hindered fear decrease compared to the control condition. Good imagers showed more fear decrease and were less affected by the mode of exposure. Fear enhancement occurred only in poor imagers at the longer exposure duration (360 sec) during thinking. In that condition, good imagers showed their greatest fear decrease.

**1988**

Wakeman, R. J. (1988). Hypnotic desensitization of job-related heat intolerance in recovered burn victims. American Journal of Clinical Hypnosis, 31, 28-32.

The thermally injured patient who suffers extensive third-degree burns usually finds the adaptation to high temperature environments quite difficult. A 7-year study of 50 thermally injured patients with greater than 45% total body surface

second- and third-degree burns was conducted to assess the usefulness of hypnosis for improved heat adaptation at the work site. There were 25 subjects in the experimental group who received hypnotic training and 25 in a matched control group. The experimental group achieved a mean of 6.25 hours worked over 16 weeks and 63.5 days worked out of 80. They worked 4.5 to 6.5 hours per day for an average of 221 days per year for up to 3 years from baseline. The control group achieved a mean of 4.5 hours worked over 16 weeks and 54.33 days worked out of 80. The efficacy of hypnosis in heat desensitization is discussed.

#### NOTES

Mean age was 38 for the hypnosis group, 33 for the control group; both groups had mean educational level of 8 grades. Mean percentage of total body surface burn was 50% for hypnosis and 54% for control groups.

Each patient was seen for 16 weeks, for 2 hours/week. The hypnosis group received hypnosis, were taught self hypnosis, and were given cassette tapes for use at home. The hypnosis training included a variety of techniques (e.g. progressive deep muscle relaxation, eye-fixation, eye-roll, and visual imagery techniques). They were given suggestions for lower skin temperature, lower 'inner body' temperature, less itching, gradual improvement of time spent on the job, as well as ego strengthening suggestions. The control patients received supportive psychotherapy, family consultation, and cognitive behavior therapy for the same amount of contact time with the same therapist.

The hypnosis group was to do self hypnosis every two hours at the worksite, in addition to home practice. Visual imagery suggestions were things like imagery of a cool waterfall flowing over the skin, having a tall cold glass of beer or soft drink, etc. They also had biofeedback of skin temperature during office visits, to reinforce decreases in skin temperature near the burned sites. They had exposure to heat (in a 95 degree sauna) for in gradually increased periods of time (15 to 120 minutes) before returning to the worksite.

Three years after treatment 20 of 25 control patients had quit their jobs or transferred to a cooler worksite, and all 25 had resigned from their original jobs or applied for further disability benefits. In contrast, only 2 of 25 experimental Ss were working in controlled-temperature settings, and none had applied for permanent disability benefits.

The authors note that family support was essential for the hypnosis patients to carry out their treatment program, and family consultations were essential for every patient. They also found the 'fade-in' technique using the sauna in the hospital occupational therapy area very useful for bridging the gap between practice in the office and going back to the work setting. "This procedure enabled the subject to practice self- hypnosis under controlled physical conditions while performing a work task that was more realistic than 'imagined heat' in the office setting" (p. 31).

Morrow, Gary R. (1984). Appropriateness of taped versus live relaxation in the systematic desensitization of anticipatory nausea and vomiting in cancer patients. Journal of Consulting and Clinical Psychology, 52 (6), 1098-1099.

Investigated the suggestion that the relaxation part of systematic desensitization--an effective treatment for the nausea and vomiting experienced by approximately 25% of cancer patients in anticipation of chemotherapeutic treatments-- could be learned from a prerecorded audiotape prior to meeting a psychologist for treatment. 10 cancer patients who had developed anticipatory nausea or vomiting were assigned to either a live-relaxation or a tape-relaxation group. Results show that 4 of 5 Ss assigned to the tape-relaxation group experienced nausea while listening to the prerecorded audiotape, while none of the patients in the live-relaxation group reported nausea when subsequently listening to an audiotape made during the live presentation of relaxation.

Hoffman, Mark L. (1982/83). Hypnotic desensitization for the management of anticipatory emesis in chemotherapy. American Journal of Clinical Hypnosis, 25 (2-3), 173-176.

A hypnotic treatment employing systematic desensitization was used to alleviate anticipatory nausea and vomiting in a middle-aged man undergoing chemotherapy for Hodgkin's Disease. After four treatment sessions, all nausea associated with chemotherapy was eliminated. Results of this treatment are compared with those of another hypnotic treatment recently reported by Redd et al (1982), and reasons for differences are discussed. [Redd, W. H., Andersen, G. V. & Minagawa, R. Y. (1982). Hypnotic control of anticipatory emesis in patients receiving cancer chemotherapy. Journal of Consulting and Clinical Psychology, 50, 14-19.]

**1982**

Stoyva, J. M.; Anderson, C. (1982). A coping-rest model of relaxation and stress management. In Goldberger, L.; Breznitz, S. (Ed.), Handbook of stress: Theoretical and clinical aspects (pp. 745-763). New York: The Free Press.

## NOTES

Patients with psychosomatic or stress linked disorders are likely to show signs of high physiological arousal, and they are likely, under stress, to react strongly in the symptomatic system and to show evidence of being deficient in the ability to shift from the coping to the rest mode (e.g., slowness of habituation to, and recovery from, stressful stimulation). A corollary inference is that such patients ... show activity in the symptomatic system for a higher percentage of the time that [sic] do normal subjects. We suggest that this defect in the capacity to shift to a rest condition is the principal reason that various relaxation procedures have so often proved successful in the alleviation of stress related symptoms" (p. 748).

The authors refer to a number of different stress management procedures. Among those associated with primary focus on the rest phase they include: Relaxation training (progressive relaxation, autogenic training, EMG feedback, meditation [Zen, TM]), Specific biofeedback (hand temperature, electrodermal response [EDR], EMG from particular muscle group), and Systematic desensitization. Among those associated with primary focus on coping phase are: Assertiveness training, Social skills retraining and motor skills retraining, Self-statements, Imagery (Guided waking imagery, autogenic abreaction, covert reinforcement and covert sensitization, behavior rehearsal). These various procedures may reflect three dimensions or aspects of the stress response, with some addressing physiology and others addressing cognition or behavior change.

"Rachman (1978) ... found it useful to divide the phenomenon of fear into physiological, cognitive, and behavioral components. Similarly, Davidson and Schwartz (1976) conceptualized relaxation as consisting of somatic, cognitive, and attentional components. Phillips (1977) argued that pain, such as headache pain, can be viewed as consisting of cognitive, behavioral, and physiological aspects (and that, consequently, we should not expect high correlations between headache pain and a particular physiological measure such as forehead EMG level). ...

"... In discussing contemporary studies of dreaming, they [Stoyva and Kamiya (1968)] proposed that there is no single, totally valid indicator of dreaming as a mental experience. Instead, there are several imperfect indicators of the dream experience--verbal report, rapid eye movements, and certain electroencephalographic (EEG) stages. ... Discrepancies among the indicators can serve to generate hypotheses" (p. 749).

The authors discuss different ways of retraining the capacity to rest: relaxation training (including biofeedback, etc.), systematic desensitization; and of reshaping the coping response: assertiveness training, social skills and motor skills retraining, self-statements, imagery techniques; and discuss controllability. These notes cover only a very small part of their extensive review, the material most relevant to hypnosis and suggestion.

"Although imagery techniques are often employed by stress management therapists, one approaches this area with ambivalence. In part, this uneasiness springs from the unsettling awareness that imagery techniques have been embraced by a freewheeling assortment of lay psychologists such as Emil Coue, Dale Carnegie, and Norman Vincent Peale, not to mention a diverse throng of contemporary 'mind controllers' and self-styled healers. A more serious source of uneasiness is ignorance

of the specific processes at work. What are the mechanisms by which imagery affects the stress response?" (p. 756).

"There is intriguing recent evidence that simply the illusion of control may exert beneficial effects. Stern, Miller, Ewy, and Grant (1980) noted that subjects who were led to believe by means of bogus information feedback that they were successfully lowering their heart rates showed a reduction in stress type symptoms, especially those of a cardiovascular nature. It seems possible that the feeling of control may be an important part of what we have called 'placebo responding.' Stoyva (1979b) suggested that this phenomenon is probably not a unitary entity but, rather, a cluster of processes, of which the feeling of developing control over factors affecting one's disorder is an important and potentially manipulable component of therapeutic interventions" (p. 758).

Systematic desensitization and hypnosis were used in a client with long-standing penetration phobia. Glass test tubes were used in dilation exercises and masturbation instead of more expensive metal catheters. The client was able to have intercourse and adequate sexual adjustment.

O'Brien, Richard M.; Cooley, Lewis E.; Ciotti, Joseph; Henninger, Kathleen M. (1981). Augmentation of systematic desensitization of snake phobia through posthypnotic dream suggestion. American Journal of Clinical Hypnosis, 23, 231-238.

Nine snake phobics who had scored above eight on the SHSS (Form A) were given four desensitization sessions and five sessions in which a pleasant posthypnotic dream of the phobic object was suggested. These subjects were significantly superior to a desensitization-only control group on a behavioral avoidance test. Seven of the nine hypnosis subjects were able to touch a real snake. The two subjects who did not touch the snake reported dreams in which the snake was either absent or threatening. Although conclusions are limited by differential attention and susceptibility, the technique seems promising.

1980

Powell, Douglas H. (1980). Helping habitual smokers using flooding and hypnotic desensitization techniques: A brief communication. International Journal of Clinical and Experimental Hypnosis, 28 (3), 192-196.

A subgroup of individuals who were helped to stop smoking by hypnosis or other means returned to consuming a few cigarettes a day. A flooding and hypnotic desensitization technique assisted 4 of 7 individuals who resumed smoking in becoming and remaining abstinent for a 6- to 9-month follow-up period.

Dyckman, John M.; Cowan, Philip A. (1978). Imaging vividness and the outcome of in vivo and imagined scene desensitization. Journal of Consulting and Clinical Psychology, 46 (5), 1155-1156.

This study reexamined the role of imaging vividness in desensitization success. Scores on the Betts Questionnaire on Mental Imagery were used to divide 48 snake-phobic subjects into high, medium, and low vivid groups, who were assigned to imagined scene or in vivo desensitization treatments. Imaging vividness was assessed at scheduled points during therapy. Significant decreases in behavioral and self-reported fear were observed after both treatments, though in vivo desensitization produced significantly greater fear reduction. In therapy imaging vividness scores were significantly correlated with therapeutic success and were superior to pretherapy ratings as predictors of outcome.

Shipley, R. H.; Butt, J. H.; Horowitz, B.; Farbray, J. E. (1978). Preparation for a stressful medical procedure: Effect of amount of stimulus preexposure and coping style. Journal of Consulting and Clinical Psychology, 46, 499-507.

Anxiety during the stressful medical procedure of endoscopy was studied as a function of the number of prior viewings of an explicit preparation videotape and of repression-sensitization coping style. Sixty naive patients viewed a videotaped endoscopy either zero, one, or three times. Dependent measures included heart rate, behavioral ratings, tranquilizer required, and self-report. On each dependent measure, three viewings generally resulted in the least distress; one, more distress; and zero, the most distress. Most comparisons reached statistical significance. These results are interpreted as resulting from extinction and/or habituation of anxiety. The repression-sensitization factor interacted with heart rate change. Sensitizers showed a monotonic decrease in heart rate as a function of number of tape exposures. Repressors showed an inverted-U-shaped function, with one viewing producing the highest heart rate; this is interpreted as resulting from a disruption of repressing defenses by one tape exposure followed by extinction of fear by three exposures.

Slutsky, Jeffrey; Allen, George J. (1978). Influence of contextual cues on the efficacy of desensitization and a credible placebo in alleviating public speaking anxiety. Journal of Consulting and Clinical Psychology, 46 (1), 119-125.

This investigation was designed to determine the extent to which contextual cues mediated the effectiveness of systematic desensitization and a plausible placebo in alleviating public speaking anxiety. After participating in a public speaking situation that allowed the collection of self-report, physiological, and behavioral manifestations of anxiety, 67 subjects were randomly assigned to receive five sessions of either desensitization, "T scope" therapy, or no treatment. Each of these conditions was conducted in a context that either stressed the clinical relevance of the procedure or presented the procedure as a laboratory investigation of fear without therapeutic implications. Analysis of changes both between groups and within individuals indicated that desensitization reduced public speaking anxiety in both contexts, whereas the placebo was effective only in the therapeutic setting. The superiority of desensitization was most pronounced on the physiological variables.

The results are interpreted as indicating support for a counterconditioning, rather than an expectancy, interpretation of desensitization.

Ascher, L. M. (1977). The role of hypnosis in behavior therapy. In Edmonston, William E., Jr. (Ed.), Conceptual and investigative approaches to hypnosis and hypnotic phenomena (296, ). New York: New York Academy of Sciences.

#### NOTES

He does not differentiate physical and mental relaxation (Davidson & Schwartz). Insists that hypnosis treatment not include desensitization operations.

"Two studies (Gibbins et al., and Woody and Schaube) presented data that seemed to indicate that desensitization plus a hypnotic induction procedure resulted in greater fear reduction than desensitization alone. However, an analysis of the procedures employed suggests that the conclusion may be unwarranted, or at least premature. Both studies confound the hypnotic induction with added elaboration of desensitization scenes, as well as additional direct fear-reduction suggestions. In addition, Gibbons et al. further confounded their study by placing good hypnosis subjects into the hypnotic-induction group as opposed to the desensitization or control groups. Barber has pointed out that the type of method that Gibbins et al. employed in subject assignment, as opposed to random assignment, results in the inability to control for such things as previous experience, the relationship of the subject with the experimenter, and the differential effects of these factors on the subject's attitudes, expectancies, and motivation" (p. 256).

"Finally, some individuals writing from the context of hypnotherapy, have suggested that the effects of specific imaginal behavioral techniques may be due to the possible existence of hypnosis or the trance state unwittingly incorporated into these behavioral procedures. The difficulties of such a position have been addressed by Barber, Cautela, Johnston and Donaghue, Spanos, Spanos, et al., Spanos and Barber, and Weitzenhoffer, among others. The following, as a group, have pointed out the difficulties inherent in the position that certain procedures, not otherwise associated with hypnosis, may nevertheless result in the production of a 'trance state' in susceptible subjects (Barber, Chaves, and Spanos) have delineated the differences between hypnosis and various behavioral procedures (Cautela, Spanos et al., and Spanos and Barber); and have presented strong arguments for suggesting that the effectiveness of hypnotherapeutic techniques are due to the inclusion of components of desensitization in the procedure rather than to the induction of a 'trance'" (pp. 257-258).

1977

Avila, Donald; Nummela, Renate (1977). Transcendental meditation: A psychological interpretation. Journal of Clinical Psychology, 33 (3), 842-844.

The authors suggest that Transcendental Meditation offers a great deal of promise for use in helping relationships. They also suggest that the technique might receive wider acceptance if it could be explained in other than a purely philosophical or

mystical way. For that reason, in their article they offer a psychological interpretation of the TM process.

Snyder, Arden L.; Deffenbacher, Jerry L. (1977). Comparison of relaxation as self-control and systematic desensitization in the treatment of test anxiety. Journal of Consulting and Clinical Psychology, 45 (6), 1202-1203.

Relaxation as self-control and desensitization were compared to a wait-list control in the reduction of test and other anxieties. Neither active treatment differed significantly from the other, but they did differ significantly from the control treatment on several variables. Subjects in both treatments reported less debilitating test anxiety, whereas desensitization subjects showed greater facilitating test anxiety. Under stressful conditions, treated subjects were less worried and anxious, found the situation less aversive, and perceived themselves and their abilities more favorably than controls. Significant reductions in nontargeted anxieties also were found, suggesting transfer of anxiety-management skills to areas other than test anxiety,

1976

Hemme, Robert; Boor, Myron (1976). Role of expectancy set in the systematic desensitization of speech anxiety: An extension of prior research. Journal of Clinical Psychology, 32 (2), 398-404.

#### SUMMARY

The influence of expectancy set with regard to therapy outcome on the effectiveness of systematic desensitization (SD) for reducing public speaking anxiety was investigated. The 7 Ss given a high expectancy set for favorable therapy outcome were informed about psychological research that indicates that SD is effective to reduce public speaking fears. SD was administered with the standard instructions to the 11 Ss given a neutral expectancy set. This expectancy manipulation did not require deception and perhaps could be used with actual SD therapy clients. As in previous research by Woy and Efran, the expectancy set manipulation significantly modified Ss' self-report of subjective perceptions of anxiety from pretreatment to posttreatment speeches, but did not affect overt behavioral or physiological indices of anxiety. Since subjective perceptions of anxiety responses are psychologically significant behaviors, these data suggest the importance of conveying a high expectation of improvement to SD and perhaps also to other types of therapy clients. SD sessions administered to small groups of clients on consecutive days, as in this study, appeared to be as effective to reduce speech anxiety as SD sessions administered to each client individually at 1-week intervals, as in the Woy and Efran study" (pp. 403-404).

1975

Lick, John R. (1975). Expectancy, false galvanic skin response feedback, and systematic desensitization in the modification of phobic behavior. Journal of Consulting and Clinical Psychology, 43 (4), 557-567.

This study compared systematic desensitization and two pseudotherapy manipulations with and without false galvanic skin response feedback after every session suggesting improvement in the modification of intense snake and spider fear. The results indicated no consistent differences between the three treatment groups, although all treatments were significantly more effective than no treatment in modifying physiologic, behavioral, and self-report measures of fear. A 4-month follow-up showed stability in fear reduction on self-report measures for the three treatment groups. Overall, the results of this experiment were interpreted as contradicting a traditional conditioning explanation of systematic desensitization. An alternate explanation for the operation of systematic desensitization emphasizing the motivational as opposed to conditioning aspects of the procedure is discussed.

1974

Russell, Elbert W. (1974). The power of behavior control: A critique of behavior modification methods. Journal of Clinical Psychology, 30 (2), 111-136.

#### NOTES

In summarizing the effectiveness of behavior therapy the author states, "At this point there does not appear to be sufficient evidence to demonstrate that all of the effectiveness of various types of behavior therapy is produced by non-specific, especially placebo, effects. In fact, it is more probable that many of these techniques will be found to have elements that are not due to non-specific effects and, as such, they will be the treatment of choice for certain limited problems, such as aversive therapy for autistic children or training of the mentally retarded. Nevertheless, concerning the central issue in this monograph, it is increasingly apparent that a very large proportion of the 'power' of behavior methods is due to non-specific, suggestion or placebo effects.

"As such, this 'power' is neither behavioristic, new, nor particularly threatening. It is not new since it has been known to medicine for many decades. As Shapiro states, 'the history of both physiologic and psychologic treatment is largely the history of the placebo effect; those who forget it are destined to repeat it'. In support of the age of this problem, Shapiro also quotes from the compiler of the remedies of the Paris Pharmacologia, a century ago, 'What pledge can be afforded that the boasted remedies of the present-day will not, like their predecessors, fall into disrepute, and in their turn serve only as a humiliating memorial to the credulity and infatuation of the physicians who recommended and prescribed them'" (p. 120-121).

"The large amount of suggestion or placebo effect in behavior therapy does raise at least two vital problems. The first problem involves the ethics of using suggestion or a placebo. Is it ethical to give the patient a false or questionable explanation for the source of the effectiveness of behavior procedures? Such an explanation would be that they are based on proven scientific behavior principles when major people in the field do not believe this and evidence is mounting that the primary source of effect is suggestion. Secondly, what will be the effect on the attitude of the general

public toward professional psychology when they realize that the effectiveness of psychological behavior therapy methods is primarily a matter of suggestion? Will they not consider it a modern patent medicine? The damage that could be done to the prestige of psychology might take decades to repair. JH

Wickramasekera, Ian (1974). Heart rate feedback and the management of cardiac neurosis. Journal of Abnormal Psychology, 83 (5), 578-580.

This article describes the treatment of a chronic case of cardiac neurosis which had failed to respond to several prior medical and psychological interventions. Significant and durable symptomatic response appeared to be correlated with the application of a combination of procedures including heart rate feedback, patient-administered desensitization, and therapist-administered flooding.

1973

Brown, H. Alan (1973). Role of expectancy manipulation in systematic desensitization. Journal of Consulting and Clinical Psychology, 41 (3), 405-411.

Expectancy, relaxation, and hierarchy content were manipulated in a 2X2 factorial design with two additional control groups. It was hypothesized that a major portion of therapeutic change following desensitization could be accounted for by the subjects' responses to positive feedback inherent in the paradigm. Spider-phobic subjects saw either photographs of spiders or blank slides that they believed to be tachistoscopically presented pictures of spiders. In the factorial part of the design, half of the subjects believed their progress through the hierarchy to be contingent on autonomic responses; the others believed rate of progress to be random. Findings did not support the hypothesis that expectancy was the only factor in desensitization, but they did serve to clarify the role of expectancy vis-a-vis the counterconditioning elements typically discussed in the literature.

McReynolds, William T.; Barnes, AllanR.; Brooks, Samuel; Rehagen, Nicholas (1973). The role of attention-placebo influences in the efficacy of systematic desensitization. Journal of Consulting and Clinical Psychology, 41 (1), 86-92.

Systematic desensitization was compared with two attention- placebo control treatments - one taken from Paul and one currently devised as an elaborate, highly impressive "therapeutic" experience - and no treatment. It was hypothesized that (a) fear reductions following desensitization would be no greater than those associated with an equally compelling placebo treatment and (b) fear and control measure changes following the previously used attention-placebo treatment would be less than those following desensitization and the present placebo control manipulations. Both hypotheses were supported, although support for the first was more consistent than for the second.

Tori, Christopher; Worell, Leonard (1973). Reduction of human avoidant behavior: A comparison of counterconditioning, expectancy, and cognitive information approaches. Journal of Consulting and Clinical Psychology, 41 (2), 269-278.

This study was designed to compare the fear-reducing efficacy of procedures based on three major theories that have been proposed to account for the success of systematic desensitization therapy: (a) cognitive information storage and retrieval, (b) cognitive expectancy, and (c) counterconditioning. Predictions were confirmed in that the outcome measures of the high-expectancy placebo group and the two cognitive-coping groups were significantly superior to those of the counterconditioning and no-treatment groups. Thus, this experiment supports the supposition that changes in human avoidant behavior may be attributed to demand and expectancy variables rather than the conditioning of "antagonistic responses" as has been previously suggested.

Gibbons, Don E. (1971). Directed-experience hypnosis: A one-year follow-up investigation. American Journal of Clinical Hypnosis, 13, 206-207.

#### NOTES

In a previous study, the Direct Experience (DET) group was significantly lower than the Wolpe desensitization group and No Treatment controls on Mandler-Sarason Test Anxiety Questionnaire. One year later this advantage was maintained. They concluded direct-experience hypnosis (a) takes effect more rapidly than does systematic desensitization, since the differences obtained in the original study were produced after only 3 hours of experimental treatment, (b) produces a long-term effect which, by virtue of its duration, may not be attributed to implicit posthypnotic suggestion, (c) is likely to be due to influences other than initial differences in suggestibility between groups, as no such differences had been found in initial administration of the Barber Suggestibility Scale, (d) is unlikely to be due to systematic differences in experimenter variance, as a different E worked with each subject in the original study, and (e) would be difficult to account for in terms of subject demand characteristics, since E's handling the desensitization subjects were either enrolled in or teaching a graduate seminar in desensitization and behavior modification at the time while those handling DET subjects were enrolled in or teaching graduate seminars in hypnosis.

1970

Davis, Daniel; McLemore, Clinton W.; London, Perry (1970). The role of visual imagery in desensitization. Behaviour Research and Therapy, 8 (1), 11-13.

#### NOTES

Summary: a measure of visual imagery ability was obtained for 33 females who and participated in desensitization therapy for snake phobia. Visual imagery was positively related to pretherapy performance (closeness of approach to a live snake), but not to improvement. On the basis of these results and the results of two other

studies, it was hypothesized that the fear of good imagers tends to be based on imagination while that of poor imagers tends to be based on sensory experience. Most psychologists now recognize behavior therapy as effective in alleviating a wide variety of fears, but the nature of the processes underlying the various methods remains an open issue. Imagery has been of particular interest as a possible common denominator among various desensitization techniques. Lazarus (1961), for example, asserts that a "prerequisite for effective application of desensitization is the ability to conjure up reasonably vivid images," and Wolpe (1961) claims, "it is essential for visualizing to be at least moderately clear." London suggests that theoretically opposed treatments such as reciprocal inhibition (Wolpe, 1958) and implosion (Stampfl and Levis, 1967) may both be facilitated by repeated imagery which "produces a discrimination set such that the patient learns to distinguish between the imaginative, cognitive, affective aspects of experience, and the sensory and overt muscular aspects" (1964, p. 130). However, no systematic studies linking visual imagery to desensitization have been reported. This study examined the relationship between visual imagery and success in desensitization therapy.

**1967**

Schubot, Errol David (1967). The influence of hypnotic and muscular relaxation in systematic desensitization of phobias (Dissertation). Dissertation Abstracts, 27 (n10-B), 3681-3682.

"15 snake phobic subjects had desensitization treatment and 15 matched subjects had desensitization treatment with a hypnotic and muscular relaxation induction. Rate of moving through the fear hierarchy was based on three variables fear report, report of body tension, and time of signaling anxiety. Analysis of results took into consideration initial approach (to snake) level of subjects. Both treatments were effective. However, hypnotic relaxation was significantly important in desensitization for the most phobic subjects (those who couldn't approach closer than 5 feet, initially) though not for less fearful subjects. In fact, the most fearful subjects did not show improved approach behavior if they did not get the hypnosis relaxation treatment, though bodily tension and fear were reported as less while working on early items in the hierarchy. The Waking group, compared to the Relaxation hypnosis group, manifested significantly less improvement in approach and slower progress in desensitization. Hypnotizability was significantly correlated with improvement for the Relaxation subjects, as was vividness of imagery. In summary, hypnosis (a relaxation induction) facilitated desensitization treatment of highly anxiety snake-phobic subjects with the hypnotic relaxation induction, treatment outcome was related both to hypnotizability and to imagery vividness" (p. 3681- 3682).

**1965**

Davison, Gerald C. (1965, June). Anxiety under total curarization: Implications for the role of muscular relaxation in the desensitization of neurotic fears. [Paper] Presented at the annual meeting of the Western Psychological Association, Honolulu.

## NOTES

I began by describing the Jacobson-Wolpe position on the use of deep muscular relaxation as an anxiety-inhibitor: these writers assume that the considerable reduction in proprioceptive feedback from muscles which are in a relaxed state is incompatible with a state of anxiety. Then I mentioned the evidence that at least modern neuromuscular blocking-agents operate solely at the myoneural junction, with no direct central effects. I went on to discuss the various studies which have used paralytic drugs, primarily d- tubocurarine chloride, to show the learning of fear-responses under complete striate muscle paralysis: the fact that these animals are able to acquire classically-conditioned fear-responses under curare was taken as evidence inconsistent with the views of Jacobson and Wolpe. Several studies were then reviewed which purport to furnish confirmatory evidence for the Jacobson position: these studies showed considerable central depression during curare paralysis. I re-interpreted these studies in the light of the over-riding importance of exteroceptive stimulation, stressing that the animals in the curare learning experiments were likewise deprived of proprioceptive feedback and yet were hardly non- anxious: the important difference was that the animals in the conditioning experiments were stimulated frequently from the environment while curarized, this stimulation maintaining an alert, often anxious state. Finally, two hypotheses were put forward as to why training in muscular relaxation does, in fact, inhibit anxiety: the one suggested that relaxing one's muscles generates strong positive affect states, which in turn inhibit anxiety; the other hypothesis called attention to the fact that the states of muscular relaxation under curare versus under self-induced relaxation differ in the important respect that only with self-induced relaxation is there a reduction in efferent activity--perhaps this elimination of efferents, rather than afferents, inhibits anxiety.

## DIAGNOSIS

2000

Eimer, Bruce. N. (2000). Clinical applications of hypnosis for brief and efficient pain management psychotherapy. American Journal of Clinical Hypnosis, 43 (1), 17-40. (July)

**ABSTRACT:** This paper describes four specific clinical applications of hypnosis that can make psychotherapy for pain management briefer, more goal-oriented, and more efficient: (1) the assessment of hypnotizability; (2) the induction of hypnotic analgesia and development of individualized pain coping strategies; (3) direct suggestion, cognitive reframing, hypnotic metaphors, and pain relief imagery; and (4) brief psychodynamic reprocessing during the trance state of emotional factors in the patient's experience of chronic pain. Important theoretical and clinical issues regarding the relationship between hypnotizability to the induction of hypnotic analgesia are presented, and attempts to individualize pain treatment strategies on the basis of assessed differences in hypnotizability and patients' preferred coping strategies are described. Some ways are also presented of

integrating direct hypnotic suggestion, COGNITIVE-EVALUATIVE reframing, hypnotic metaphors, and imagery for alleviating the SENSORY and AFFECTIVE-MOTIVATIONAL components of pain, with an exploratory, insight-oriented, and brief psychodynamic reprocessing approach during trance for resolving unconscious sources of resistance to treatment, and reducing the emotional overlay associated with chronic pain. Some basic assumptions underlying the use of this approach are discussed, and a brief step-by-step protocol is outlined.

**1998**

Wickramasekera, Ian (1998). Secrets kept from the mind but not the body or behavior: the unsolved problems of identifying and treating somatization and psychophysiological disease. Advances in Mind-Body Medicine, 14, 18-132.

The identification and therapy of somatoform and psychophysiological disorders are major problems for medicine. This paper identifies three measurable risk factors (Wickramasekera 1979, 1988, 1993a, b, 1995) that are empirically associated with somatoform and psychophysiological disorders. These risk factors are high hypnotic ability, low hypnotic ability, and high Marlowe Crowne scores. Patients who are positive on one or more of these risk factors (all of which can constrict consciousness) have a high likelihood of having somatoform and psychophysiological disorders and should be studied with the additional risk factors proposed in the High Risk Model of Threat Perception (HRMTP). Treatment of patients should begin with the Trojan Horse Role Induction procedure (Wickramasekera 1988), which enables patients, who might otherwise resist psychological interpretations of their physical problems, to recognize that unconscious threat perception could be driving their somatic symptoms, an understanding that reduces their resistance to psychotherapy. A case study is presented of a patient without identifiable pathophysiology or psychopathology to account for somatic symptoms that were largely resistant to standard medical therapy. The patient was positive for several of the psychosocial and psychophysiological risk factors of the HRMTP and after experiencing the Trojan Horse Role Induction showed improvement in somatic symptoms.

**1996**

Kessler, Rodger; Dane, Joseph R. (1996). Psychological and hypnotic preparation for anesthesia and surgery: An individual differences perspective. International Journal of Clinical and Experimental Hypnosis, 44 (3), 189-207.

Multiple reviews indicate that psychological preparation for surgery can provide psychological, physiological, and economic benefit to the patient. Research demonstrating that hypnosis adds to this benefit is both limited and encouraging. The content and status of this literature, however, are confusing, with little coherent theoretical basis to account for the contradictions and inconsistencies across multiple studies whose methodologies often limit generalization. A model is presented regarding pertinent individual differences that include patient coping styles, prior medical experiences, and hypnotic ability, as well as differences in types

of coping demanded by different surgical procedures. This model (a) helps explain some of the confusion, (b) offers a theoretical focus for patient assessment as well as development and selection of preparation strategies, and (c) clarifies future research goals.

**1995**

**Ganaway, George K. (1995). Hypnosis, childhood trauma, and dissociative identity disorder: Toward an integrative theory. International Journal of Clinical and Experimental Hypnosis, 43 (2), 127-144.**

It is contended that prevailing exogenous trauma theory provides in most cases neither a sufficient nor a necessary explanation for the current large number of diagnosed cases of dissociative identity disorder (multiple personality disorder) and related dissociative syndromes purported to have arisen as a response to severe early childhood physical and sexual abuse. Relevant aspects of instinctual drive theory, ego psychology, object relations theory, self psychology, social psychological theory, sociocultural influences, and experimental hypnosis findings are drawn on to demonstrate the importance of adopting a more integrative theoretical perspective in the diagnosis and treatment of severe dissociative syndromes. Further cooperative experimental and clinical research on the etiology, prevalence, and clinical manifestations of the group of dissociative disorders is strongly encouraged.

**Sarbin, Theodore R. (1995). On the belief that one body may be host to two or more personalities. International Journal of Clinical and Experimental Hypnosis, 43 (2), 163-183.**

The belief in the validity of the multiple personality concept is discussed in this article. Two scaffolding constructions are analyzed: dissociation and repression. As generally employed, these constructions grant no agency to the multiple personality patient. The claim is made that the conduct of interest arises in discourse, usually with the therapist as the discourse partner. In reviewing the history of multiple personality and the writings of current advocates, it becomes clear that contemporary users of the multiple personality disorder diagnosis participate in a subculture with its own set of myths, one of which is the autonomous actions of mental faculties. Of special significance is the readiness to transfigure imaginings into remembering of child abuse, leading ultimately to the manufacture of persons. The implications for both therapy and theory of regarding the patient as agent in place of the belief that the contranormative conduct is under the control of mentalistic faculties are discussed.

**1994**

**Cardena, Etzel (1994, August). Domain of dissociation. [Paper] Presented at the annual meeting of the American Psychological Association, Los Angeles.**

**NOTES: Dissociation (a French term) exists when two or more mental contents are not integrated. Dissociation includes a wide variety of behaviors and experiences.**

**Three Concepts: 1. nonconscious or nonintegrated mental models or processes 2. alteration in consciousness when disconnection from self or environment is experienced 3. defense mechanism**

**Explanation of these three concepts:**

**1. Within nonconscious or nonintegrated mental models/processes there are three types: (a) absence of conscious awareness of impinging stimuli or ongoing behaviors (broad, vague, not useful, because we are unaware of physiological processes most of the time) (b) co-existence of separate mental systems or identities that should be integrated (Meyers, 1903, said the memorability of an act is better proof of consciousness than its complexity). Examples: dissociative amnesia (Walter Reed Hospital patient); or in hypnosis telling a person that their hand is going to begin raising on its own (c) ongoing behavior that is inconsistent with person's verbal report. May be part of #2. Example: commisurotomized patients - woman who wanted to smoke couldn't get her hand to lift cigarette to her mouth. Example of student, being criticized, breaking out into a rash while saying that she felt calm.**

**Often repression and dissociation are confused. When dissociation is used as in (c) above, they are indistinct; they are the same. Freud used the terms for the same thing. When we talk about a dissociated memory, it is same as repression.**

**2. Alteration in consciousness (disconnection from the self or environment is experienced). In this case we talk about an experiential event. Caveats: Some use it to refer to \*any\* kind of alteration of consciousness. Braun, 1993, reported that mystical experiences are dissociative; I maintain that many people feel most in contact with the self during mystical experience. Same with drugs: it may not involve primarily separation, disengagement, from self or environment. As you listen to me, you may disengage at times. I think the only legitimate use of "dissociation" is a radical alteration of consciousness; like Tart's altered states of consciousness, like out-of-body experiences. In clinical situation, distraction or dreaminess is usual; but if a patient disengages and starts reliving a situation, it is legitimately regarded as dissociation.**

**3. Defense mechanism - a theoretical construct, referring to intentional disavowing things that would cause anxiety or pain. Clinical observations of people in traumatic events, rape, people may have out of body experiences; explained as the person sending the ego somewhere else because they can't bear the pain. But, you get this separation in non-traumatic circumstances (in meditation, revery, etc.)**

**Alternative Paradigm:**

**Janet's theory which explains cognitively how dissociation occurs, without necessarily proposing an intentional process.**

**For further elaboration of these comments, see Cardena, E. (1994). The domain of dissociation. In S. J. Lynn & J. W. Rhue (Eds.) Dissociation: Clinical and Theoretical Perspectives. New York: Guilford Press**

**Frankel, Fred H. (1994, October). Working with the concept in a clinical setting. [Paper] Presented at the annual meeting of the Society for Clinical and Experimental Hypnosis, San Francisco.**

**NOTES: I have concerns about the construction of the Diagnostic and Statistical Manual (DSM) as a whole. It was initially a research document, but it has come to dominate clinical diagnostic practice, and worse, it governs what treatment third party payers will compensate.**

**Dissociative Identity Disorder (DID) to replace Multiple Personality Disorder (MPD) may well change the way the condition is viewed, and we may see fewer alters in each person.**

**I have difficulty understanding the precise nature of dissociation--especially with its powers to produce amnesia. The dissociative disorders are part of the legacy of hysteria; though some parts of hysteria are represented in other DSM categories. The influence of environmental factors and imagination were suspected when the diagnosis was hysteria; everyone knew the picture was complicated, and subject to contagion, etc. The DSM makes little attempt to take that into account in the section on Dissociative Disorder.**

**Questions we must address: 1. How voluntary is clinical dissociation? To what extent can we expect the patient to claim agency for it, e.g. if it is claimed that a crime was committed by an alter? 2. To what extent does the clinical manifestation of dissociation overlap with absorption and attention? 3. How does morbid preoccupation with images differ from regression? How much is the patient the willing agent of that kind of behavior? 4. To what extent are flashbacks remembering or imaginings? 5. How do we control for contagion or imitation on the dissociative disorder inpatient units? 6. Could we be creating things to fit our theories? 7. Are other diagnoses being displaced here? The dissociative disorders being put on center stage may lead us to do disservice to the patient in dealing with their other life crisis. 8. If the shock of the trauma is associated with impaired perception, altered attention, and memory problems, how dependable are the reports that are ultimately retrieved--perhaps decades later? 9. What do we in truth understand by the word dissociation? Is it a psychological event with underlying physiology, or just a metaphor?**

**Psychiatry is subject to diseases rising and falling, e.g. the disappearance of hysteria itself.**

**Spiegel, David (1994, October). Acute stress disorder and dissociation in DSM-IV. [Paper] Presented at the annual meeting of the Society for Clinical and Experimental Hypnosis, San Francisco.**

**NOTES: Starting with the theme on hysteria introduced by Frankel (1994), and Cardena (1994) on trance disorder [Spiegel notes that] in the West our problem is of individuality, so fragmentation of personality is our disorder. There is cultural content in the delusions of schizophrenia, and cultural content in dissociative disorders. We have further evidence of trauma being involved in dissociation. Trauma is the experience of being made into an object, and the core problem is helplessness (not anxiety or fear), and discontinuity in experience. Dissociation permits people to retain control of their minds when they have lost control of their bodies. The discontinuity of dissociation reflects the discontinuity of experience.**

**[This presentation included the material presented at an earlier meeting and is not reported in full here.]**

**The difficulty is the problem of lack of identity rather than too many identities.**

1993

Spiegel, David; Koopman, Cheryl; Classen, Catherine; Freinkel, Andrew (1993, October). Dissociation, trauma, and DSM-IV Acute Stress Disorder. [Paper] Presented at the annual meeting of the Society for Clinical and Experimental Hypnosis, Arlington Heights, IL.

**NOTES:** This represents a progress report on the research in our laboratory, which is different from traditional approaches that link childhood trauma to current problems. We say if there is a link between dissociation and trauma, one should find the symptoms in people who have trauma.

**Earthquake Research:**

They examined data from Loma Prieta earthquake; Stanford had \$164 million damage. Oct 1989. [Presents data that he has presented before.] There was a drop in dissociative symptoms over 4 months. McFarlane found that numbing was the best predictor of later PTSD symptoms, and we find that too.

Most trauma researchers have focused on anxiety because that is what they are interested in; they have ignored dissociative experiences, because such symptoms are designed not to be noticed.

Andrew Frankel and Cheryl Koopman studied 15 journalists who saw Robert Alton Harris' execution--volunteers who reported on the execution, to whom the event did not personally threaten. 40% reported depersonalization experiences, 2/3 felt detached or estranged from others, 27% had problems remembering everyday activities, etc. Dissociative symptoms were especially high in TV journalists, lowest in radio journalists, and in the middle range in newspaper reporters.

**Oakland Fire Research:**

Koopman & Classen looked at immediate psychopathology and later problems. They studied people of low, medium, and high exposure as defined by distance from the fire, which related strongly to both dissociative and anxiety symptoms.

There were strong relationships between the Mississippi PTSD scale scores and anxiety and dissociative symptoms (.50 and .59 respectively). People who reported recent life stress in the intervening period had higher PTSD and dissociative symptoms. The combination of initial dissociation and subsequent stress was additive in their relationships to PTSD.

People who had higher dissociation scores tended to do higher risk things (e.g., cross police barriers). This may explain how clinicians see patients who appear to get themselves re-victimized.

**Law Office Shooting Research:**

We followed up on the 1993 shooting of 14 people (8 fatally) in a law office in San Francisco. Survivors filled out dissociation questionnaires in the office (N = 36). They had high scores on the Impact of Event Intrusion Scale. The more they thought they or colleagues were in danger, the higher their scores on anxiety and dissociation measures and on Impact of Event scale.

**Dissociation Definition:**

These studies led to a project, with Etzel Cardena, in trying to revise DSM-III-R, which doesn't capture the symptoms [of post traumatic dissociation]. In DSM-IV there will be the diagnosis of 308.3 Acute Stress Disorder, characterized as: A. Same as DSM-III-R, except it doesn't require that the trauma be "unusual" B. Requires 3 of 5 dissociative symptoms. C, D, and E are classic dissociative symptoms F, G, and H are delimiting factors (e.g., causes significant impairment, length of time, not due to other factor).

Also, the multiple personality disorder (MPD) diagnosis has been changed to Dissociative Identity Disorder. The problem for these patients is not in having more than one personality, but not having one functioning personality.

Van der Hart, Onno; Spiegel, David (1993). Hypnotic assessment and treatment of trauma-induced psychoses: The early psychotherapy of H. Breukink and modern views. International Journal of Clinical and Experimental Hypnosis, 41 (3), 191-209.

The role of hypnotizability assessment in the differential diagnosis of psychotic patients is still unresolved. In this article, the pioneering work of Dutch psychiatrist H. Breukink (1860-1928) during the 1920s is used as early evidence that hypnotic capacity is clinically helpful in differentiating highly hypnotizable psychotic patients with dissociative symptomatology from schizophrenics. Furthermore, there is a long tradition of employing hypnotic capacity in the treatment of these dissociative psychoses. The ways in which Breukink used hypnosis for diagnostic, prognostic, and treatment purposes are summarized and discussed in light of both old and current views. He felt that hysterical psychosis was trauma-induced, certainly curable, and that psychotherapy using hypnosis was the treatment of choice. Hypnosis was used for symptom-oriented therapy, as a comfortable and supportive mental state, and for the uncovering and integrating of traumatic memories. For the latter purpose, Breukink emphasized a calm mental state, both in hypnosis and in the waking state, thereby discouraging emotional expression, which he considered dangerous in psychotic patients. In the discussion, special attention is paid to the role and dangers of the expression of trauma-related emotions.

1992

Frischholz, Edward J. (1992, October). Dissociation. [Paper] Presented at the annual meeting of the Society for Clinical and Experimental Hypnosis, Arlington, VA.

NOTES: there are two approaches for studying dissociation 1. phenomenological: describe difference types of dissociative phenomena, e.g., forgetting, multiple personality disorder or MPD 2.theoretical: explain the physiological/ psychological processes by which things become associated/disassociated, e.g., Freud (repression) vs. Janet (dissociation).

Two types of dissociation: 1. dissociation of awareness (amnesia, unconscious cognitions) 2. dissociation of volition (loss of executive control over behavior, psychological automatisms)

Normal Dissociation is characterized as: 1. content is narrow and specific 2. duration is brief 3. awareness of loss of material exists 4. control can be re-established

Abnormal Dissociation is characterized as: 1. content is broad (self-identity) 2. duration is extended 3. no awareness of loss of material exists 4. no re-establishment of control

The most widely used measure is Dissociative Experience Scale (Bernstein & Putnam) which has .84 to .96 test-retest correlation (Bernstein & Putnam, 1986; Frischholz et al.)

Mean Scores for DES MPDs 55. DD NOS 40.8 Students 23.8

He advocates a cutoff score above 40 as indicating abnormal dissociative experiences (that would yield 6% false negatives). Above 65, suspect faking or over-reporting of dissociative experiences.

Factor Analysis of the DES would associate the following items: 1. Absorption Factor: 2, 14, 15, 17, 18, 20 (normal dissociation) 2. Amnesia Factor: 3, 4, 5, 8, 25, 26 (pathological dissociation) 3. Depersonalization/Derealization Factor: 7, 12, 13, 14, 27, 28

Correlations of DES with other tests:

Tellegen Ambiguity Jenkins

Absorption Tolerance Activity DES Total .39 .24 .04 DES Amnesia .24 .22

See Table from AJCH in July 1992, which replicates a study by Nadon Table 2  $r = .12$  with hypnotizability (Nadon reported .18).

One could use both the DES and hypnotizability scores to distinguish between different clinical groups. For example, dissociative patients reverse amnesia while schizophrenics don't.

One could distinguish real MPDs vs Simulators based on Special Hypnotic Phenomena: with Real MPDs half show the hidden observer phenomenon, therefore they hide their MPD; simulators show the hidden observer phenomenon 100% of the time. Another item that discriminates is the Orne Double Person Hallucination item. MPDs 50- 62% show it, but 92-80% [incorrect percentage in these notes?] of simulators do experience the hallucination. Of these 70-75% of the MPDs are able to distinguish the hallucination; only 45-40% of simulators are able to distinguish the hallucination. Real MPDs know, can tell difference between a hallucinated person and the real person whereas simulators maintain they can't tell who is the real person.

It's not true that MPDs are extremely high in hypnotizability. They score in 8-10 range. The MPDs score 1 SD above normals but they are not off the end of the scale. These are good ways of testing whether someone is faking MPD. We have replicated this many times, getting better replication of MPD simulators than high hypnotizable simulators.

Another method for distinguishing true MPDs from simulators involves demonstration of the Einstellung (learning set) effect.

Looking at Water Jar Problems, patients learn to solve the problems the long way. They teach personality A how to solve problem by long solution method (four trials of B - A - 2C); on the fifth trial, 95% of Ss solve the problem by the long method, the Einstellung (learning set) effect. Switch to personality B and give the same test. If

there were no transfer, people immediately see A-C, which is a short method for solving the problem. It has been observed that 50-60% of MPDs do not show Einstellung effect; they immediately see the short solution.

Have done this also with retroactive interference word learning model.

Effect of context. Kohlenberg (Behavior Therapy Journal) selectively reinforced one personality of an MPD, which then 'came out' more often; during extinction the frequency of seeing that personality went back to baseline.

I used Greenspan's and Erickson's learning without awareness paradigm. When a low baseline frequency personality emerged, I'd reinforce the person; when a dominant personality came out I'd start yawning, look out the window, etc. During extinction the frequency went back toward normal baseline level, but not all the way. These indicate you can shape the appearance of one personality, but not that it's iatrogenic.

Can also do this with schizophrenics, normal highly hypnotizable subjects.

Spiegel, Herbert; Greenleaf, Marcia (1992). Personality style and hypnotizability: The fix-flex continuum. Psychiatric Medicine, 10, 13-24.

Since Mesmer, there has been much confusion about the inter-relationship between an individual's degree of hypnotizability, the personality style of the individual, and the importance of the therapeutic strategy. Empirical and experimental research supports the hypotheses that there are: 1) biopsychosocial components of hypnotizability on a continuum ranging from ecologically insensitive (not modifiable by external stimuli) to ecologically sensitive (very modifiable by external stimuli); 2) biopsychosocial components that can be measured to identify an individual's degree of hypnotic capacity and responsivity; 3) distinct personality styles which correlation with low, mid-range and high hypnotizability on a fix (ecologically insensitive) - flex (ecologically sensitive) continuum; and 4) different clinical syndromes which correlation with these categorical distinctions. We propose that measuring hypnotizability and personality style is a way to clarify diagnosis and choose appropriate treatment strategies to maximize existing biopsychosocial resources of an individual with a specific problem in a particular context.

1991

Frischholz, Edward J.; Braun, Bennett (1991, August). Diagnosing dissociative disorders: New methods. [Paper] Presented at the annual meeting of the American Psychological Association, San Francisco.

Five new methods which have proven useful in the differential diagnosis of dissociative disorders from other psychiatric syndromes are identified. The first method involves the use of the Dissociative Experiences Scale, a self-report questionnaire which significantly discriminates dissociative psychopathology from normal dissociative experiences. The second method involves the use of various measures of hypnotizability (e.g., Hypnotic Induction Profile; Stanford Hypnotic Susceptibility Scale, Form C; self-ratings of hypnotizability) in discriminating between various psychiatric groups. The third method involves the use of qualitative

responses to individual test items (e.g., instructed posthypnotic amnesia) to discriminate between different psychiatric syndromes. The fourth method involves the use of an implicit memory test to measure the amount of between-personality state amnesia in patients suffering from Multiple Personality Disorder. The fifth method involves the use of special hypnotic phenomena (e.g., the Orne double person hallucination and the Hilgard hidden observer item) to discriminate between dissociative disorder patients and subjects simulating dissociative psychopathology. (ABSTRACT from Bulletin of Division 30, Psychological Hypnosis, Provided by former Editor, James Council.)

## NOTES

Five new methods have proven useful in the differential diagnosis of dissociative disorders. The first method involves the use of the Dissociative Experiences Scale, a self-report questionnaire which significantly discriminates dissociative psychopathology from normal dissociative experiences.

The second method involves the use of various measures of hypnotizability in discriminating between various psychiatric groups.

The third method involves the use of qualitative responses to individual test items (e.g., instructed posthypnotic amnesia) to discriminate between different psychiatric syndromes.

The fourth method involves the use of an implicit memory test to measure the amount of between-personality state amnesia in patients suffering from Multiple Personality Disorder.

The fifth method involves the use of special hypnotic phenomena (e.g., the Orne double person hallucination and the Hilgard hidden observer item) to discriminate between dissociative disorder patients and subjects simulating dissociative psychopathology.

Spiegel, David; Cardena, Etzel (1991). Disintegrated experience: The dissociative disorders revisited. Journal of Abnormal Psychology, 100 (3), 366-378.

Presents proposed changes to the dissociative disorders section of the 4th edition of the Diagnostic and Statistical Manual of Mental Disorders (DSM-IV) and reviews the concept of pathological and nonpathological dissociation, including empirical findings on the relations between trauma and dissociative phenomenology and between dissociation and hypnosis. The most important proposals include the creation of 2 new diagnostic entities, brief reactive dissociative disorder and transient dissociative disturbance, and the readoption of the criterion of amnesia for a multiple personality disorder diagnosis. Further work on dissociative processes will provide an important link between clinical and experimental approaches to human cognition, emotion, and personality.

1990

Kluft, R. P. (1990). Dissociation and subsequent vulnerability: A preliminary study. Dissociation, 3, 167-173.

Dissociative defenses allow trauma victims to cope with overwhelming stressors but are a two-edged sword and appear to render such persons vulnerable to subsequent revictimization because of decontextualization of traumatic experiences. Of 18 incest victims who developed dissociative disorders and had been sexually exploited by their therapists, 78% (14) had been raped as adults, 100% had ongoing dissociative symptoms that disrupted their sense of mastery and control of their lives, and 100% demonstrated that defensive ablation of memory of crucial information rendered them incapable of perceiving and reacting to actual danger situations appropriately. Most (92%) became frozen or withdrawn under stress, met situations best avoided by decisive action with passive compliance and learned helplessness, and also had a shattering of basic life assumptions. Therapeutic implications and strategies are reviewed.

Ross, Colin A. (1990). Twelve cognitive errors about multiple personality disorder. American Journal of Psychotherapy, 44 (3), 348-356.

Presents 12 cognitive errors made by mental health professionals regarding multiple personality disorder. The errors include the mistaken idea that (1) multiple personality patients actually harbor more than one personality, (2) these patients can evade responsibility for their behavior because of their diagnosis, and (3) the disorder will disappear if treated with benign neglect. The errors are corrected by argument and by reference to research findings.

Ross, Colin A.; Fast, E.; Anderson, G.; Auty, A.; Todd, J. (1990). Somatic symptoms in multiple sclerosis and MPD. Dissociation, 3, 102-106.

Fifty subjects with multiple sclerosis (MS) were compared to 50 subjects with multiple personality disorder (MPD). MS patients endorsed an average of 3.0 somatic symptoms on structured interview, and MPD subjects an average of 14.5. Somatic symptoms characteristic of neurological illness were trouble walking, paralysis, and muscle weakness, while those characteristic of psychiatric illness were genitourinary and gastrointestinal symptoms.

Ross, Colin A.; Joshi, Shaun; Currie, Raymond (1990). Dissociative experiences in the general population. American Journal of Psychiatry, 147 (11), 1547-1552.

The Dissociative Experiences Scale was administered to a random sample of 1055 adults in the city of Winnipeg. Results showed that scale scores did not differ between men and women and were not influenced by income, employment status, education, place of birth, religious affiliation, or number of persons in the respondent's household. Dissociative experiences are common in the general population and decline with age. The findings suggest that dissociative disorders may also be common in the general population.

NOTES:

This scale is different from the dissociation scales produced by either Sanders or Putnam. It is a 38-item, self-report instrument, requiring 10 minutes. It was called the Dissociative Experiences Scale rather than the Dissociative Symptoms Scale in order to normalize the questions, and wording of questions was chosen for the same reason. It does not measure degree of dysfunction.

In clinical studies scores above 30 on the DES are associated with a high likelihood of posttraumatic stress disorder or multiple personality disorder (MPD). In a sample of 82 patients with MPD, mean DES score was 41.4 +/- 20.0 (range = 1.3-83.6) (Ross, Miller, & Reagor. *Am J. Psychiat*, 1990, 147-596-601).

Ross, Colin A.; Miller, S. D.; Reagor, P.; Bjornson, L.; Fraser, G. A.; Anderson, G. (1990). Schneiderian symptoms in multiple personality disorder and schizophrenia. *Comprehensive Psychiatry*, 31, 111-118.

**NOTES:**

Schneiderian first-rank symptoms of schizophrenia were equally common among 102 patients with multiple personality disorder in all four centers where data was collected. The average multiple personality disorder (MPD) patient had experienced 6.4 Schneiderian symptoms. When these 102 cases are combined with two previously reported series of MPD cases, an average of 4.9 Schneiderian symptoms in 368 cases of MPD is noted. This compared with an average of 1.3 symptoms acknowledged by 1,739 schizophrenics in 10 published series. Schneiderian symptoms are more characteristic of MPD than of schizophrenia.

Ross, Colin A.; Miller, Scott D.; Reagor, Pamela; Bjornson, Lynda; et al. (1990). Structured interview data on 102 cases of multiple personality disorder from four centers. *American Journal of Psychiatry*, 147, 596-601.

Data from 102 patients with multiple personality disorder at 4 different centers were collected using the Dissociative Disorders Interview Schedule (C. A. Ross et al, 1989; C. A. Ross, 1989) and the Structured Clinical Interview for Diagnostic and Statistical Manual of Mental Disorders - III --- Revised (DSM-III--R) Dissociative Disorders (M. Steinberg et al; ) The presenting characteristics of Subjects at all 4 centers were very similar. The clinical profile that emerged included a history of childhood physical and/or sexual abuse in 97 (95.1%) of the cases. Subjects reported an average of 15.2 somatic symptoms, 6.4 Schneiderian symptoms, 10.2 secondary features of the disorder, 5.2 borderline personality disorder criteria, and 5.6 extrasensory experiences; their average score on a dissociative experiences scale was also meaningful. Multiple personality disorder appears to have a stable, consistent set of features

**1989**

Ross, Colin A.; Heber, Sharon; Norton, G. Ron; Anderson, Geri (1989). Differences between multiple personality disorder and other diagnostic groups on structured interview. *Journal of Nervous and Mental Disease*, 177 (8), 487-491.

The Dissociative Disorders Interview Schedule was administered to 20 Ss with multiple personality disorder, 20 with schizophrenia, 20 with panic disorder, and 20 with eating disorders (mean ages 25.4-38.4 yrs). Findings show that multiple personality could be differentiated from the other groups on variables such as history of physical abuse, sexual abuse, substance abuse, sleepwalking, childhood imaginary playmates, secondary features of multiple personality, and extrasensory and supernatural experiences. Those with multiple personality also differed from the other groups on Diagnostic and Statistical Manual of Mental Disorders (DSM-III) criteria for multiple personality, psychogenic amnesia and psychogenic fugue. The groups did not differ on the number of Ss who had a major depressive episode.

Ross, Colin A.; Heber, S.; Norton, G. R.; Anderson, D.; Anderson, G.; Barchet, P. (1989). The Dissociative Disorders Interview Schedule: A structured interview. Dissociation, 2, 169-189.

The Dissociative Disorders Interview Schedule (DDIS), a structured interview, has been developed to make DSM-III diagnoses of the dissociative disorders, somatization disorder, major depressive episode, and borderline personality disorder. Additional items provide information about substance abuse, childhood physical and sexual abuse, and secondary features of multiple personality disorder. These items provide information useful in the differential diagnosis of dissociative disorders. The DDIS is published in this article. It has an overall interrater reliability of 0.68. For the Diagnosis of MPD it has a specificity and a sensitivity of 90%.

1988

Kemp, Kristen; Gilbertson, Alan D.; Torem, Moshe (1988). The differential diagnosis of multiple personality disorder from borderline personality disorder. Dissociation, 1 (4), 41-46.

Considerable controversy [sic] surrounds the relationship between multiple personality disorder (MPD) and borderline personality disorder (BPD). Some authors argue that MPD is a variant of BPD, and most agree that the differential diagnosis of the two is often very difficult. In this article data are presented from a study comparing historical, demographic and psychological testing variables between the two groups. No statistically significant differences were found between the two groups on these variables. However, certain trends emerged which may serve as a catalyst for further research. The relationship between the disorders may be complex; clinicians may need to use more sophisticated research techniques and develop more sensitive diagnostic criteria before it is understood.

Kluft, Richard P. (1988). On giving consultations to therapists treating MPD: Fifteen years' experience - Part I (Diagnosis and treatment). Dissociation, 1 (3), 23-29.

This paper reviews the author's experience in serving as a consultant to several hundred colleagues working with patients suffering multiple personality disorder (MPD) over the 15 year period 1972-1988. It discusses general trends in the types of patients with regard to whom consultations were sought and in the types of issues raised, and notes recurrent issues that appear to trouble large numbers of consultees. It also reviews the patient-generated consultation request, which reflects both increased consumerism and the avidity with which MPD patients seek information about their condition. Part I offers a general orientation, outlines the methods of the study, and describes consultations regarding diagnostic and treatment issues. Part II explores consultations regarding the "surround" of treatment, forensic matters, the use of hypnosis, and consultations initiated by patients; it concludes with a brief discussion. In general, the author's experience indicated that the publication of DSM-III in 1980 and the publication of four special journal issues in 1984 were watershed events, and marked notable shifts in the nature of many of the consultation requests that he received.

1987

Kluft, Richard P. (1987). Unsuspected multiple personality disorder: An uncommon source of protracted resistance, interruption, and failure in psychoanalysis. Hillside Journal of Clinical Psychiatry, 9 (1), 100-115.

Multiple personality disorder (MPD) is being recognized with increasing frequency. A great imitator, it may be encountered among patients who appear to have a wide range of other diagnoses, and have been in treatment for years without the presence of MPD being discovered. Nine of 241 MPD patients interviewed by the author, 3.7%, had been accepted for psychoanalysis. In only one case had the diagnosis been appreciated by the analyst prior to his accepting the patient for analytic treatment. Four patients were profoundly resistant and/or inaccessible to analysis for protracted periods. In one of these cases the diagnosis became clear and successful analysis was concluded, but three analyses ended unsuccessfully with the diagnosis still unknown. Two patients' analyses ended unsuccessfully with the diagnosis still unknown. Two patients' analyses were interrupted due to abrupt regressive events initially perceived to indicate severe ego weakness incompatible with sustaining an analytic process, but later appreciated as signs of MPD. In three cases it appeared that the patients' being accepted for analysis triggered the emergence of the dissociative process, and either the patient or the analyst decided to pursue a different form of therapy. Unsuspected MPD appears to account for a small percentage of stalemates, failures, interruptions, and early flights from analysis.

#### NOTES

"In most other literatures, dissociation is considered reflective of a capacity for hypnotizability, without any connotation of a particular level of psychopathology. There is solid evidence that hypnotizability is intrinsic to MPD (Bliss, 1980, 1983, 1984; Lipman, Frischholz, and Braun, 1984), and a borderline level of organization is not (Horevitz and Braun, 1984). It is more parsimonious and consistent with clinical experience and research findings to infer that the splitting noted in

pregenital pathologies and the splitting found in MPD are different although enticingly similar phenomena, and that in some patients they coexist in such a way that one could easily agree that a patient was both MPD and borderline. The linguistic confusion is to be deplored, and hopefully to be remedied in the near future" (p. 111).

1986

Kluft, Richard P. (1986). High-functioning multiple personality patients: Three cases. Journal of Nervous and Mental Disease, 174 (12), 722-726.

This article describes the circumstances of the diagnosis of three of a group of 12 high-functioning multiple personality disorder patients. All had performed major social and professional activities with consistent competence, and all appeared to be neurotic patients suitable for classical psychoanalysis. All 12 had been misdiagnosed on at least three occasions before the correct diagnosis was made. Aspects of the difficulties encountered in assessing these patients are discussed and guidelines for the preservation of their high level of function during the treatment process are offered.

NOTES

"The therapy proceeds most smoothly when preservation of function takes priority over rapidity of results. With one exception, it was possible to work without time pressure. ... Successful therapies were generally very gentle supportive/expressive psychoanalytic psychotherapies, but included a single classical psychoanalysis. In most cases, hypnosis was used both for symptom relief and exploration. Longer sessions were scheduled for work on painful areas so that equilibrium could be restored before the patient left the office" (pp. 725-726).

1985

Hoffman, William (1985). Hypnosis as a diagnostic tool. American Journal of Psychiatry, 142 (2), 272-273.

Discusses the case of a 22-yr-old Swedish female who became withdrawn and depressed and developed suicidal ideation and paranoid and grandiose delusions. S was also disoriented to time and place and displayed poor memory, insight, and judgment. After a diagnosis of brief reactive psychosis, S was placed on a regimen of oral haloperidol (2 mg, 4 times/day), but she remained confused and disoriented. After induction into a trance state, S coherently recollected the events leading to hospitalization, after which medication was discontinued. It is suggested that trance induction be attempted before treatment in individuals with symptoms of hysterical psychosis.

Hoffmann, William F. (1985). Hypnosis as a diagnostic tool. American Journal of Psychiatry, 142 (2), 272-273.

Discusses the case of a 22-yr-old Swedish female who became withdrawn and depressed and developed suicidal ideation and paranoid and grandiose delusions. S was also disoriented to time and place and displayed poor memory, insight, and judgment. After a diagnosis of brief reactive psychosis, S was placed on a regimen of oral haloperidol (2 mg, 4 times/day), but she remained confused and disoriented. After induction into a trance state, S coherently recollected the events leading to hospitalization, after which medication was discontinued. It is suggested that trance induction be attempted before treatment in individuals with symptoms of hysterical psychosis.

MacHovec, Frank J. (1985). Treatment variables and the use of hypnosis in the brief therapy of post-traumatic stress disorders. International Journal of Clinical and Experimental Hypnosis, 33 (1), 6-14.

This paper describes treatment variables in the use of hypnosis in the brief treatment of 4 post-traumatic stress disorder cases. The number of sessions varied with the length of time between trauma and treatment, severity of stressor, and the personality of the patient. Individual differences in response to treatment are reported, as well as considerations for differential diagnosis to prevent misdiagnosis.

1984

Allison, R. B. (1984). Difficulties diagnosing the multiple personality syndrome in a death penalty case. International Journal of Clinical and Experimental Hypnosis, 32 (2), 102-117.

The problems involved in diagnosing the multiple personality syndrome in a rape-murder suspect are illustrated by the case of Kenneth Bianchi and the Hillside Stranglings. Hypnotic investigations of his amnesia revealed "Steve," who admitted guilt for the rape-murders. "Billy" later emerged, claiming responsibility for thefts and forgeries. Attempts to evaluate Kenneth Bianchi with methods used in therapy yielded an original opinion that he was a multiple personality and legally insane. Later events showed the diagnosis to be in error. A new diagnosis was made of atypical dissociative disorder due to the effects of the examining methods themselves. Warning is given that it may be impossible to determine the correct diagnosis of a dissociating defendant in a death penalty case.

Bliss, Eugene L. (1984). Hysteria and hypnosis. Journal of Nervous and Mental Disease, 172 (4), 203-206.

Studied 33 female patients with Briquet's syndrome to investigate the possibility that severe hysteria might be a spontaneous self-hypnotic disorder. Excellent hypnotic Ss were defined clinically as those who entered a trance rapidly, experienced lid closure and arm and elbow elevation, perceived hypnotic events with realism, could regress to early experiences, and usually had amnesic capabilities. Ss were administered the Stanford Hypnotic Susceptibility Scale, Form C. 17 of the 33 Ss were clinically tested for hypnotizability. 14 were found to be excellent hypnotic

Ss, 2 were found to be good, and 1 was found to be a poor hypnotic S. 14 of the 33 Ss met the DSM-III criteria for multiple personalities. It is concluded that patients suffering from Briquet's syndrome are usually good or excellent hypnotic Ss with few exceptions, and many have multiple personalities. Evidence is also discussed that patients with major conversion symptoms are excellent hypnotic Ss. (39 ref).

Herzog, A. (1984). On multiple personality: Comments on diagnosis, etiology and treatment. International Journal of Clinical and Experimental Hypnosis, 32 (2), 210-221.

Relevant diagnostic and etiologic aspects of multiple personality are discussed, with particular emphasis on the range of the underlying character structure of the "main" personality. The concept of "high level" and "low level" multiple personality organization is proposed and 2 clinical examples are described to illustrate this. Treatment issues which are examined and explored include (a) uses and misuses of hypnosis, (b) general as well as some specific treatment strategies, and (c) countertransference feelings which these patients elicit in the therapist.

Jensen, Peter S. (1984). Case report of conversion catatonia: Indication for hypnosis. American Journal of Psychotherapy, 38 (4), 566-570.

Describes the successful hypnotic treatment of a 25-yr-old Black male who displayed symptoms of suicidal ideation, insomnia, and feelings of depression alternating with emptiness and boredom that led to an acute catatonic reaction. S met DSM-III criteria for borderline personality disorder. It is contended that since conversion mechanisms may underlie some presentations of catatonia, hypnosis may assist clinicians in the differential diagnosis of acute catatonic conditions.

Orne, Martin T.; Dinges, David F.; Orne, Emily Carota (1984). On the differential diagnosis of multiple personality in the forensic context. International Journal of Clinical and Experimental Hypnosis, 32 (2), 118-169.

The problems of diagnosing multiple personality disorder in a forensic context are discussed, and illustrated by the case of State v. Kenneth Bianchi (1979), a defendant who was both charged with first degree murder and suspected of having the disorder. Because of the secondary gain (e.g., avoiding the death penalty) associated with the diagnosis of multiplicity in such a case, hypotheses had to be developed to permit an informed differential diagnosis between multiple personality and malingering. If a true multiple personality disorder existed, then (a) the structure and content of the various personalities should have been consistent over time, (b) the boundaries between different personalities should have been stable and not readily altered by social cues, (c) the response to hypnosis should have been similar to that of other deeply hypnotized subjects, and (d) those who had known him over a period of years should have been able to provide examples of sudden, inexplicable changes in behavior and identity, and evidence to be the case. Rather, the content, boundaries, and number of personalities changed in response to cues

about how to make the condition more believable, and his response to hypnosis appeared to reflect conscious role playing. Further, the life history indicated a persistent pattern of conning and deliberate deception. It is concluded that Mr. Bianchi was simulating a multiple personality and the diagnosis of Antisocial Personality Disorder with Sexual Sadism was made. Differential diagnoses and the clinical aspects that appeared to account for his behavior are discussed.

Ross, C. A. (1984). Diagnosis of multiple personality during hypnosis: A case report. International Journal of Clinical and Experimental Hypnosis, 32 (2), 222-235.

Multiple personality disorder, though uncommon, is not an exotic disease; it is not a curiosity, but a vividly etched experiment of nature, one which could teach us a great deal about the human mind. In this paper, a case report is presented and a number of problems in the study of multiple personality are defined; the condition raises questions about ego function, pharmacotherapy, and the therapist himself. A hypothesis is developed about the etiology of the dissociation in the present case, and a 1.5-year follow-up is reported. Multiple personality disorder deserves renewed attention from the general psychiatrist.

Thigpen, C. H.; Cleckley, H. M. (1984). On the incidence of multiple personality disorder: A brief communication. International Journal of Clinical and Experimental Hypnosis, 32 (2), 63-66.

Since reporting a case of multiple personality (Eve) over 25 years ago, we have seen many patients who were thought by others or themselves to have the disorder, but we have found only 1 case that fit the diagnosis. The other cases manifested either pseudo- or quasi-dissociative symptoms related to dissatisfaction with self-identity or hysterical acting out for secondary gain. One particular form of secondary gain, namely, avoiding responsibility for certain actions, was evident in a recent legal case where the person was diagnosed as having the disorder and successfully pled not guilty by reason of insanity. We urge that a diagnosis of multiple personality not be used in such a manner and recommend that therapists consider the hysterical basis of the symptoms, as well as the adaptive dynamics of personality before diagnosing someone as having the disorder. If such factors are considered, the incidence of the disorder will be found to be far less than the "epidemic" recently claimed.

1981

Gross, Meir, M. D. (1981). Hypnosis for dissociation -- diagnostic and therapeutic. Journal of the American Society of Psychosomatic Dentistry and Medicine, 28 (2), 49-56.

#### NOTES

Dissociative disorders might be at times very difficult to diagnose and treat, especially since they are very similar to epilepsy in general and to temporal lobe epilepsy in particular. Amnesia, fugue, changing personality and depersonalization are part of both disorders. Patients who suffer from dissociative disorders might be

diagnosed and treated for epilepsy with anticonvulsive medications without any beneficial results. These patients are labeled as epileptics and have to face the social stigmata associated with being epileptic. The wrong label could even reinforce the sick role and make it become fixed and chronic.

Hypnosis was used to diagnose the dissociative disorder by using the hand levitation technique for the differential diagnosis. It was found by the author that patients who suffer from dissociative disorders would get into spontaneous hypnotic trance during the hand levitation. Hypnosis was used also for successful therapy of these patients.

Seven cases are presented in which the hand levitation technique was used to diagnose the dissociative disorder. They were also treated by hypnotherapy. Their treatment by hypnosis is discussed. The purpose of this paper is to introduce the hand levitation technique for the differential diagnosis of dissociative disorder and to emphasize the effectiveness of hypnotherapy in the treatment of this disorder. Sorting out the cases of dissociative disorders from the epileptics is very important clinically, since it can save many patients from the anguish of having to take anti-convulsants unnecessarily and having to face the social stigmata of being labeled as epileptic.

1978

Gruenewald, Doris (1978). Analogues of multiple personality in psychosis. International Journal of Clinical and Experimental Hypnosis, 26, 1-8.

A brief discussion of taxonomic and diagnostic problems in the multiple-personality syndrome precedes presentation of theoretical considerations. The disorder is conceptualized as a category sui generis on a continuum from neurosis to psychosis. Attenuated forms are considered as pertaining to the syndrome with supporting case material.

1972

Cedercreutz, C. (1972). The big mistakes: A note. International Journal of Clinical and Experimental Hypnosis, 20, 15-16.

In his book, *A System of Medical Hypnosis*, Ainslie Meares writes, "Most books on hypnosis, from Bernheim to the present time, devote a great deal of space to the description of successful and dramatic cures. These accounts may be of prestige value to the author, and may do something to inform the profession of the potential value of hypnosis in medicine, but these success stories are really of little help to those who would learn the technique of hypnotherapy because the emphasis is always on the success of the treatment rather than on analysis of the psychodynamic mechanisms which brought it about. As in everything else, we learn most from a study of our failures [p. 3]." These comments remain as true today as they were ten years ago. With the notable exception of Meares, few colleagues have been willing to share their errors, allowing us to profit from their experience. Thus, when Dr. Cedercreutz sent along a note describing his experience with one of his patients, I was struck by his generosity, and it seemed most appropriate for all of us to share

his experience by way of the Journal. Hopefully, this may encourage other colleagues to share their failures as well as their successes so that all of us may learn to be more effective therapists and better scientists. M.T.O. [Martin Orne]

## NOTES

The case reported involves a patient who had migraine headache removed with hypnosis, but later developed gastrointestinal symptoms that were operated surgically with absence of positive (physical) pathology noted. Subsequent investigation of the psychological component of the problem with hypnosis revealed an early trauma (seeing a soldier killed with a bayonette) that led to migraine-like pain in the head and vomiting.

1969

Kampman, R.; Hirvenoja, R. (1969). Research of latent multiple personality phenomenon using hypnosis, projective tests and clinical interviews. Scandinavian Journal of Clinical and Laboratory Investigation, 23, 86. (Abstracted in American Journal of Clinical Hypnosis, 1971, 14, 71.)

190 volunteer students, from 11 to 22 years old, were experimented on for multiple personality, which is explained as hysterical dissociation, a manifest pathological state. The incidence found of multiple personality was 6.7% (13 subjects). The differences between the test results in secondary personalities of the same subject were significant.

1966

Wagner, Frederik F. (1966). The delusion of hypnotic influence and the hypnotic state. International Journal of Clinical and Experimental Hypnosis, 14 (1), 22-29.

Several case studies are discussed briefly, illustrating the main aspects of delusions of hypnotic influence and how the delusional system differs from the hypnotic state. It is a symptom of (usually paranoid) schizophrenia, often appearing among the earliest symptoms in the course of the illness. These feelings usually arise when the patient experiences a weakening of ego functions, or a breakthrough of libidinous or aggressive impulses. While there is a tendency to rationalize aspects of hypnotic behavior, delusions of hypnotic influence are deeply rooted in the dynamics of the patient's psychopathology. They usually remain as a permanent symptom, and prognosis is poor. (PsycINFO Database Record (c) 2002 APA, all rights reserved)

1963

Deckert, G. H.; West, L. J. (1963). The problem of hypnotizability: A review. International Journal of Clinical and Experimental Hypnosis, 11, 205-235.

This paper summarizes the relatively unsuccessful effort to relate hypnotizability to sex, age, psychiatric diagnoses, suggestibility, and various personality traits. The problems of measurement, subject selection, controls, and experimenter bias are reviewed. Comparison of data is difficult and replication of studies infrequent. This

might be attributed to incomplete reporting of methodology, defects in experimental design, and various conceptual problems. Concepts which view hypnotizability as "something" universal, "something" unique, or "nothing" are briefly appraised. Finally, hypnotizability is seen as a "term" describing a relationship between a "route" and a "state"--each identifiable by measurable criteria. (PsycINFO Database Record (c) 2002 APA, all rights reserved)

Slater, Roger C.; Flores, Louis S. (1963). Hypnosis in organic symptom removal: A temporary removal of an organic paralysis by hypnosis. American Journal of Clinical Hypnosis, 5 (4), 248-255.

#### NOTES

**Summary and Conclusions.** A detailed case study is reported on the use of hypnosis with beneficial results in an instance of eventually proved organic brain disease. Three other confirmatory case reports of organic disease definitely benefitted by the use of hypnosis are briefly cited.

" The first patient had been adequately studied repeatedly for organic brain disease. Because the studies led to an uncertain indefinite unconfirmed suspicion of psychogenic epilepsy, the patient was returned with a recommendation for continued treatment and observation by the author, a general practitioner. Hence, she was, after still further study for organic disease, treated symptomatically by hypnosis with beneficial results. This led to the erroneous conclusion that the patient's disability was probably functional. A sudden fatal outcome of the actual but unrecognized brain disease led to a correct but post- mortem diagnosis of astrocytoma of the brain, Grade IV.

"This report and those given to supplement it raise significant questions about the importance and value of hypnosis in organic disease. These include the challenging question of the extent to which the use of hypnosis can potentiate the natural corrective forces of the body; the need to recognize the value of hypnosis in effecting beneficial results in organic disease; the need to qualify the reliability of hypnosis as a differential diagnostic procedure in relation to psychogenic and organic disability; and the possibility and extent of the amelioration or actual correction of known organic illness" (p. 254).

#### 1956

Shapiro, Arthur; Kline, Milton V. (1956). The use of hypnosis in evaluating physiological and psychological components of multiple sclerosis. Journal of Clinical and Experimental Hypnosis, 4, 69-78.

#### NOTES

1:

"Summary:

1) - The availability of a patient with multiple sclerosis who was known to be a good hypnotic subject provided an opportunity for the study of the effect of hypnosis on the manifestations of his disease [sic].

2) - Because of the patient's unwillingness to accept psychodynamic psychotherapy or to allow personal interviewing under hypnosis, therapy was limited to the

induction of hypnosis; suggestion of improved performance and the visualization of improved performance, and self-hypnosis.

3) - Certain subjective and objective improvements were noted.

4) - Psychological evaluation was limited to superficial observation and psychological testing in the waking state and under hypnosis.

5) - Psychological test data were used to formulate a mechanism whereby the patient's hypnotically altered perception and conception of his damaged body image served as a means of reducing his anxiety and depression and improving his performance.

6) - The value of hypnosis in the treatment of multiple sclerosis and in the separation of impairment due to the anatomical lesion from that due to the patient's reaction to the lesion has been suggested and discussed.

7) - Further investigations of this kind have been suggested" (p. 77).

**1954**

Madison, LeRoi (1954). The use of hypnosis in the differential diagnosis of a speech disorder. Journal of Clinical and Experimental Hypnosis, 2 (2), 140-144.

**NOTES**

**1:**

"Summary and Conclusions. The case of an eight-and-a-half-year-old boy has been presented to illustrate how hypnosis was used as an aid in the differential diagnosis of a speech defect which presented symptoms of both stuttering and an articulation disorder. The case was diagnosed as primarily an articulation defect. No direct attack was made on the speech blocks other than hypnotic suggestions to relieve tension and some environmental modifications. However, the tonic spasms entirely disappeared within a period of three weeks. This remission plus the rapid strides made in the speech rehabilitation would indicate that the correct diagnosis had been made and as a result an effective plan of therapy instituted.

"It is postulated that hypnosis can be a valuable technique in the diagnosis of speech cases presenting symptoms of several disorders, especially if one of them is stuttering. It is also suggested that hypnosis may be a valuable therapeutic method for treating many cases which present stuttering symptoms" (p. 143-144).

**1953**

Rosen, Harold (1953). Hypnodiagnostic and hypnotherapeutic fantasy---evocation and acting-out techniques. Journal of Clinical and Experimental Hypnosis, 1 (1), 54-66.

**NOTES**

Developed techniques to reach patients who have little motivation for psychotherapy, sometimes hypnotizing them without their knowledge or conscious consent. "By still other techniques, symptom-formation was then blocked and the inevitable, resultant anxiety reaction repressed, so that underlying fantasies could erupt into conscious awareness even to the point of being acted out" (p. 65). By these means he determined the neurotic or psychotic functions being served by the patient's physical symptoms. The hypnotic interpersonal relationship is "a fantasy-

evoking one in which the patient, on the basis of his own experiential background and with more ready access to his pre-conscious, thinks, feels, experiences, reacts and even acts-out exactly as he believes the hypnotist wishes him to, projecting his own impulses, desires and fantasies to the therapist" (p. 66).

Rosen, Harold (1953). The emotionally sick pregnant patient: Hypnodiagnosis and hypno-evaluation - Psychiatric indications and contraindications to the interruption of pregnancy. Journal of Clinical and Experimental Hypnosis, 1 (2), 8-27.

## NOTES

1:

The author discusses several different groups of patients referred to psychiatrists in the hope of obtaining recommendation for abortion. Some threaten illegal abortion or suicide. Some previously had severe post-partum depressions. "Each case must be judged on its own merits. Legal, moral and ethical factors are of prime importance. Social, economic and religious imperatives cannot be over-emphasized" (p. 25). "It seems impossible to over-emphasize the fact that we usually are dealing with emotionally ill patients who rationalize their need for an abortion as the cause of their illness, rather than a symptom of it" (p. 26). "However, if for psychiatric reasons it does seem advisable to recommend that a given pregnancy be interrupted, in our opinion psychotherapy invariably is indicated" (p. 26).

## DISABILITY/HANDICAP

1998

Eimer, Bruce; Freeman, Arthur (1998). Pain management psychotherapy: A practical guide. New York NY: John Wiley & Sons, Inc..

"Pain Management Psychotherapy" (PMP) provides a clear and methodical look at pain management psychotherapy beginning with the initial consultation and work-up of the patient and continuing through termination of treatment. It is a thoughtful and thorough presentation that covers methods for psychologically assessing the chronic pain patient (structured interviews, pain assessment tests and rating scales, instruments for evaluating beliefs, attitudes, pain behavior, disability, depression, anxiety, anger and alienation), treatment planning, cognitive-behavioral therapy techniques, and a range of hypnotic approaches to pain management. The book covers both traditional (cognitive and behavior therapy, biofeedback, assessing hypnotizability, choice of inductions, designing an individualized self-hypnosis exercise) as well as newer innovative techniques (e.g., EMDR, pain-relief imagery, hypno-projective methods, hypno-analytic reprocessing of pain-related negative experiences). An extensive appendix reproduces in their entirety numerous forms, rating scale, inventories, assessment instruments, and scripts.

The senior author, Bruce Eimer, states in his online comments on Amazon.com that "most therapists hold the belief that 'real' chronic pain patients are quite impossible to help. This book attempts to dispel these misguided beliefs by providing a body of knowledge, theory, and techniques that have proven value in understanding and relieving chronic physical pain." He also states that "the challenge for the therapist

is to persuade the would-be patient/client that he or she has something to offer that can help take away pain and bring back more pleasure. This challenge is negotiated through the therapeutic relationship. However, the therapist just can't be 'warm, accepting, non-judgmental and empathic'. The therapist must also have knowledge and skills relevant to relieving pain. Only then can the therapist impart such knowledge, and in teaching these skills to the pain patient, help the patient become something of a 'self-therapist'. . . I dedicate this book to everyone who wants to find ways to make living with pain more comfortable, and to the ongoing search for better ways to relieve pain."

**1997**

**Sapp, Marty; Farrell, Walter C. Jr.; Johnson, James Jr.; Kirby, Renee Sartin; Pumphrey, Khyana K. (1997). Hypnosis: Applications for rehabilitation counselors. Journal of Applied Rehabilitation Counseling, 28 (2), 43-49.**

This article describes how the rehabilitation counselor can employ hypnosis. Hypnosis can be employed as a useful tool in working with individuals who have experienced a disability. It can be used to reduce anxiety and stress related to returning to work; it can help clients learn to reduce stress and to modify themselves, even if their environments cannot change; and it can be used to increase the self-esteem of clients with disabilities.

**1991**

**Young, M. H.; Montano, R. J.; Goldberg, R. L. (1991). Self-hypnosis, sensory cuing, and response prevention: Decreasing anxiety and improving written output of a preadolescent with learning disabilities. American Journal of Clinical Hypnosis, 34 (2), 129-136.**

Divided 64 10.8 - 19.3 yr old emotionally disturbed residents of a treatment school into an experimental and control group matched for age, IQ, and reading ability. Both groups were seen 5 times/week for 6 weeks for tachistoscopic exposures of a subliminal stimulus. The stimulus for the experimental group was the phrase, "Mommy and I are one," conceived of as activating symbiotic fantasies that in a number of previous studies with varying groups of Ss had led to greater adaptive behavior. The control group was exposed to the phrase, "People are walking." Results show that experimental Ss manifested significantly greater improvement on the California Achievement Tests-- Reading than did the controls. On 5 of 6 secondary variables--arithmetic achievement, self-concept, the handing in of homework assignments, independent classroom functioning, and self-imposed limits on TV viewing--the experimental Ss showed better adaptive functioning. It is suggested that activation of unconscious symbiotic fantasies can increase the effectiveness of counseling and teaching. (42 ref)

**1977**

Lazar, Billie S. (1977). Hypnotic imagery as a tool in working with a cerebral palsied child. International Journal of Clinical and Experimental Hypnosis, 25 (2), 78-87.

Hypnotic imagery was used with a moderately severe athetoid cerebral palsied 12-year-old boy who was mildly retarded and a poor hypnotic subject. Techniques included imagery, observation of the self, revivification of relaxing experiences, proprioceptive feedback about the athetoid movements, and dealing with feelings and motivation. Athetoid movements were reduced, results extended beyond the treatment situation, and improvement was made in practical skills.

1964

Falck, Frank J. (1964). Stuttering and hypnosis. International Journal of Clinical and Experimental Hypnosis, 12, 67-74.

Differences of opinion regarding the use of hypnosis in the treatment of stuttering are briefly reviewed. A viewpoint of stuttering is presented, suggesting how this behavior develops and becomes habitual. The requirements of an adequate program of stuttering therapy are listed with the hope that clinicians will be better able to evaluate where particular hypnotherapeutic techniques may be applicable. A plea is made for comprehensive, objective reporting of clinical experiences when hypnotherapy is used in a program of stuttering therapy. (15 ref.) (PsycINFO Database Record (c) 2002 APA, all rights reserved)

1954

Madison, LeRoi (1954). The use of hypnosis in the differential diagnosis of a speech disorder. Journal of Clinical and Experimental Hypnosis, 2 (2), 140-144.

Summary and Conclusions. The case of an eight-and-a-half-year-old boy has been presented to illustrate how hypnosis was used as an aid in the differential diagnosis of a speech defect which presented symptoms of both stuttering and an articulation disorder. The case was diagnosed as primarily an articulation defect. No direct attack was made on the speech blocks other than hypnotic suggestions to relieve tension and some environmental modifications. However, the tonic spasms entirely disappeared within a period of three weeks. This remission plus the rapid strides made in the speech rehabilitation would indicate that the correct diagnosis had been made and as a result an effective plan of therapy instituted.

"It is postulated that hypnosis can be a valuable technique in the diagnosis of speech cases presenting symptoms of several disorders, especially if one of them is stuttering. It is also suggested that hypnosis may be a valuable therapeutic method for treating many cases which present stuttering symptoms" (p. 143-144).

## DISSOCIATION

1995

**Bowers, Kenneth S. (1995, November). Revisiting a Century-Old Freudian Slip -- from Suggestion Disavowed to the Truth Repressed. [Paper] Presented at the annual meeting of the Society for Clinical and Experimental Hypnosis, San Antonio, TX.**

**NOTES: Cites J. Herman, Mason, and Miller who accused Freud of retreating from trauma theory to save his theory. Feminists view the Oedipal theory as a coverup for the denial of child sexual abuse. This moral position fuels trauma theory and practice. It is the moral dimension of this debate that gives so many problems for the investigation of traumatic memory.**

**The intellectual origins of repressed trauma are examined here. Freud's early trauma theory, his later conflict theory.**

**Etiology of Hysteria (1896) presents Freud's argument, based on 18 patients: child is passive victim of experience imposed on them; memory is repressed and hysterical symptoms are derivatives of these repressed memories; when memories return as pictures the task of therapy is easier than if returning as thoughts. Bartlett's memory research showed visual image is followed by sense of confidence that surpasses what should be there.**

**The fact that patients had to be compelled to remember was offered by Freud as evidence against the idea that the memories were suggested. The patients initially would deny the reality of their memories, which Freud used in saying that we should not think that patients would falsely accuse themselves. In letter to Fleiss, he presented the conflict theory, which he presented in 1905 in Three Essays on Sexuality and later in My Views...on Etiology of Neurosis.**

**In 1905 Freud indicated he was unable to distinguish fantasy from true reports (and did not deny the existence of the latter). Freud often reconstructed the "memories" from dreams, transference, signs, symptoms, fantasies, etc. They were not produced as conscious memories, and it was Freud who inferred the sexual abuse. From signs of distress he took evidence of proof.**

**Freud presented his theory to his patients and then sought confirmation.**

**Freud asks us to abandon historical for narrative truth. The problems with Freud's first theory became worse with his second theory. In Introductory Lectures Freud states that opponents say his treatment talks patients into confirming his theories. He relies on the patient's inner reality confirming the theoretical ideas given to him. Success depends on overcoming internal resistance, however. The danger in leading a patient astray by suggestion has been exaggerated, because the analyst would have had to not allow the patient to "have his say." Freud denied strongly ever having done this.**

**Incorrect interpretations would not be accepted by the patients, and if believed would be suggestion. Brunbaum, another writer, said that this doesn't mean acceptance of a faulty idea won't occur. Both Milton Erickson and especially Pierre Janet reported cases in which suggestions were used to give benign memories to replace malignant ones.**

**Freud also viewed patient resistance to his interpretations as evidence that the interpretations were correct. Thus both resistance and acquiescence were thought to be validating. Popper's critiques using philosophy of science note that this makes his theory untestable.**

Freud could not distinguish between the patient's reluctant acceptance of the truth and reluctant acceptance of a suggestion.

Contemporary theorists struggle less than Freud did with the problem of suggestion and suggestibility (and Freud did not have available the research on those areas!) Emotional upheaval that accompanies "insight" is readily taken to be validating. It may be true that bad memories are repressed, but that doesn't mean that all bad memories are true.

Treatment groups focus on recalling memories and sharing memories with others in the group, not on current relationships. Hermann states that the group provides powerful stimulus for remembering. The group, of course, is reinforced by others remembering. Repeatedly considering the possibility of abuse can increase the sense of familiarity.

Current views expressed by some clinicians that certain symptoms and syndromes (eating disorders, etc.) indicate early sexual trauma are similar to Freud's theory of hysteria. In these proposals, the inability to recall abuse becomes evidence that it occurred; and it tallies with the patient not having a sense of remembering.

Because some believe it is necessary to bring memory to light for cure to occur, there is a tendency to believe the reports of early childhood abuse.

Recognizing that some "memories" may have been a product of a therapist's suggestion helps prevent untoward effects. Modern therapists recapitulate Freud's "slip" when they do not acknowledge the role of suggestion.

Endorsing repression does not commit us to a belief that recovered memories must be accurate in all particulars. A memory that is repressed does not escape the usual kinds of degradation of memory.

And just because the material comes from unconscious sources, or has emotional accompaniments, it doesn't mean it is true. (Bowers gave an example of his dream that Israel and Venezuela shared a common border, which was rectified by his waking awareness of the Atlantic Ocean and the Mediterranean. He noted that nothing like the Atlantic can be called upon if the dream is that one's parent molested oneself at the age of six.)

Ian Hacking, in *Rewriting the Soul*, labels a more fundamental indeterminacy (for the historical past itself). Bathing rituals in childhood can be redescribed as abuse, which determines the historical past rather than describing it. It is thus easier to justify abuse if the event is something that can be reinterpreted. For example, the conflicts of adolescents with their parents, may be reinterpreted later if personality problems continue. If in adulthood one concludes that abuse occurred, then bathing rituals can be reinterpreted as if it were earlier abuse, as if the abuse has continued for years.

Eisen, Mitchell L.; Henn-Haase, Clare (1995, November). Memory and suggestibility for events occurring in and out of hypnosis. [Paper] Presented at the annual meeting of the Society for Clinical and Experimental Hypnosis, San Antonio, TX.

NOTES: Resistance to misinformation uses two paradigms: 1. Elizabeth Loftus - expose Subject to slides or videotape, give misinformation with leading or

misleading questions 2. Martin Orne - pseudomemory, i.e. age regress people in hypnosis and suggest events occurred.

Each approach yields mixed results. Misinformation is accepted more readily in context of hypnosis; but there is no relationship to hypnotizability. Spanos found that highs were more responsive to social pressure. In general, in the absence of social pressure, when presented subtly and outside the context of hypnosis, the relationship diminishes. Other factors play a more prominent role: source of information, type of information, salience of information, etc.

They examined whether events occurring in context of hypnosis were more prone to distortion when assessed in biased fashion with use of misleading information, than outside hypnosis. Also, form of questions (dichotomous or with 'I don't remember' option).

They gave the Harvard and asked afterwards 3 misleading items (e.g. did you clench your fist, when they didn't do it). Also asked them to circle items if they had no memory of it. Tellegen Absorption Scale and Dissociation scale (DES) were administered a week later. Also a week later asked about events that occurred, including confederate items. Half of Ss had 2 choices, half had also 'I don't remember' as a third option.

In a previous study, resistance to misleading information was related to the strength of the initial memory and not to hypnotizability (article published in AJCH).

**RESULTS.** When given 3 choices, the number of misleading items endorsed dropped from .7 to 0.4 which is the most robust finding in the study and affects the rest of the study. Many Ss who endorsed the items reported minutes later that they had no memory for the event (on the check list). While many Ss given only two choices wrote in the margin that the event had never occurred.

Offering an 'I don't know' third option decreased endorsement of the Harvard items also, from 6.4 to 5.2 which is significant. The relationship between hypnotizability and endorsement of misleading items became much weaker when accounting for this.

Scoring high on DES is significantly related to accepting misinformation. Tellegen Absorption Scale also related to accepting misleading information. Harvard Hypnotizability Scale was not related to accepting misinformation.

Total memory on the Harvard (before cue plus after cue) did not correlate with resistance to misleading information. History of abuse was related to hypnotizability. Have to evaluate whether it was traumatizing, multiple abuse, etc.

Eisen, Mitchell L.; Goodman, Gail S.; Qin, Jianjian (1995, November). Child witnesses: Dissociation and memory and suggestibility in abused children. [Paper] Presented at the annual meeting of the Society for Clinical and Experimental Hypnosis, San Antonio, TX.

**NOTES:** Our study looked at suggestibility and resistance to suggestion. During 5-day hospitalization for investigation of child abuse. The first day patient gets physical exam; 2nd day a genital exam, heart arousal, stress arousal; a later day had mental status, emotional functioning, cognitive functioning--and gross screen of IQ for age 5 and up and the digit span for 6 and up, plus rating of global functioning

and provisional diagnosis. On Day 5 each child was given structured interview that included questions about the anal- genital exam, with some misleading questions included.

35 minutes after the psychological examination they were given questions about the exam, for brief memory. Next exam was forensic examination of memory for abuse. Gave memory for sentences, perceptual alterations scale (PAS), adolescent version of Dissociative Experiences Scale (A-DES); gave questionnaire to parents.

Hypotheses: suggestibility would be negatively related to age (more errors when younger). Sexually and physically abused children would show more dissociation or psychopathology. Dissociation or psychopathology should be inversely related to memory ability. IQ should be related to memory and resistance to misinformation. Wanted to reconcile two models of post traumatic stress disorder (PTSD): one says they have poorer memory, and the other says they are hypervigilant.

Over 100 children in the 200 received the questionnaire on Day 5. 39% were 3-5 years old, 41% 6-10 years old. 76% were African American. 22% had no documented abuse or neglect; 13% had experienced physical abuse; 30% sex abuse; 12% both types of abuse; 15% neglect; 8% parental addiction.

Measuring dissociation in kids is problematic. The concept is used to describe a huge range of phenomena. Scores on the DES are more highly correlated with the F Scale on the MMPI than with any other measure (Michael Nash's research). So the DES measures psychopathology. Also, children have healthy kinds of dissociation-- daydreaming, etc. Josephine Hilgard noted that young kids are naturally involved in imagination. Early traumas may lead to this dissociative style. How do we sort out the healthy imaginal involvements of children from the psychopathology? There is not sufficient data at this time.

Available measures are not validated well. The CDC indicates behavior problems in children. The C-PAS conceptualizes dissociation as relating to eating disorders; the A- DES is a self report measure that related to psychopathology.

CDC scores increase, in 3-5 year olds, as the amount of abuse increases. This looks like general psychopathology, and it is a parental rating. The A-DES and C-PAS were not related to abuse or neglect. In the older groups the CDC related to poor performance on memory tests; but only for the 6-10 year olds. (Poorer memories in younger children could have masked the effect in them.)

The main finding for the study was clinician's estimate of Global Adaptive Functioning was significantly related to Resistance to Misleading Information. The effect did not show for the 3-5 yr old group, perhaps because their memory functioning is poor anyway. Also age was related to memory and suggestibility.

Frischholz, Edward J. (1995, November). A critical evaluation of the 1985 AMA Report on hypnosis and memory. [Paper] Presented at the annual meeting of the Society for Clinical and Experimental Hypnosis, San Antonio, TX.

## NOTES

JAMA 1985 concluded that hypnotically refreshed memories are less reliable than nonhypnotic recall. There are two problems with their conclusion: 1. No consensually validated definition of 'hypnosis' is identified. They talk about

administration of induction, and differences in hypnotic susceptibility. 2. Empirical criteria for discriminating the unique and/or moderating effects attributable to hypnosis are not specified.

For example Loftus showed that memory errors can be created without hypnosis. You should not just add hypnosis to that model.

The criticisms have not led to remedial practices. No research has been done to show how to minimize errors or how to facilitate accuracy.

'What is Hypnosis?' Something that is done vs. something that happens? A procedure or responsivity? Questions like this are relevant to research on whether hypnotically refreshed memories are less reliable than ordinary recall.

Hypnosis is not a 'valid therapeutic modality' (i.e., 'hypnotherapy' is a misnomer). Hypnosis can be used adjunctively with many different types of therapeutic modalities: --psychodynamic therapies --behavior modification treatments --cognitive restructuring strategies --systematic desensitization --flooding --direct suggestion

There is a specious communality: hypnosis is used in a different kind of way with each approach.

If hypnosis is defined in terms of whether an hypnotic induction procedure was administered to the subject, then hypnosis is a universal phenomenon (i.e., everyone can be administered an hypnotic induction procedure). This, in the AMA report, permitted the courts to define it this way, which leads to a number of ridiculous results.

We need to highlight 'What are the variables that are the source of the errors?' The sources are not hypnosis. We can minimize the sources by the way we ask questions, instruct the subjects, etc.

If hypnosis is defined in terms of the nature of the subjects' response to the procedures, then hypnosis is not a universal phenomenon (i.e., there are wide individual differences in hypnotic responsivity). I have shown that it is possible to alter memories, using the Loftus model, in people who are both low and high hypnotizable.

We need to take into account induction procedure, hypnotizability, type of memory, and the retrieval/influence procedure. The demand characteristics re forced responding, expectancies about memory (e.g. video recorder model), expectancies about hypnosis (e.g., everyone remembers) must be accounted for.

Dependent variables in this type of research include memory accuracy, memory errors, and subjective confidence.

Malinoski, Peter; Martin, Daniel F.; Aronoff, Jodi; Lynn, Steven Jay; Gedeon, Scott (1995, November). Hypnotizability, individual differences, and interpersonal pressure to report early childhood memories. [Paper] Presented at the annual meeting of the Society for Clinical and Experimental Hypnosis, San Antonio, TX.

## NOTES

Infantile amnesia is attributed to developmental issues before 24 months. This study indicates non-hypnotic influences can shape early memories that cross the amnesia barrier.

227 Ss completed Harvard Scale and personality measures in Session 1. In Session 2 182 completed a suggestibility scale. In Session 3 they were selected, as if independent of earlier sessions - 143 [may have misheard number] Ss.

Interviewers told the selected Ss that they were experiencing something like psychotherapy, and they were asked to recall their earliest memory (independent of photos, what people had told them, etc.) Then Experimenters probed for earlier memories; that continued until Ss denied any more memories after 2 consecutive probes. Then Ss were asked to close their eyes and get in touch with more memories. Then they were told most Ss can remember more, including sometimes their second birthday party. After 1 minute, Ss were asked about memories of their second birthday. Then they were asked to focus on even earlier memories, implying it was expected and receiving complements for reporting earlier memories. Finally, Ss completed a post-study questionnaire.

Memory report was a verbal description of an event, person, or object. Initial memory mean age was 3.7; it correlated with Openness to Experience Scale and with Fantasy Proneness. Mean age of the last earliest memory report before the close eyes instruction was 3.2 years. After receiving visualization instructions, 59% reported a memory of their second birthday. Compliance correlated .33 with this. Subjective response, nonvoluntariness, and [missed words] also correlated.

Compliance scores correlated .28 with at least one memory at or before age 24 months. Yielding to leading questions correlated also with memory for an event at or before 24 months.

Clarity of memories decreased between conditions of initial memory, earliest query, birthday, and earliest memory. Mean confidence rating on 5 point scale for second birthday memory was 3.3; mean confidence rating for earliest memory was 3.6. Mean accuracy rating was 4.0, and 94% said their memory reports were accurate to at least a moderate degree.

The post study questionnaire, totally anonymous, indicated Ss did not feel much pressure to recall (2.9 on scale of 1-5). Only 9.8% indicated they felt a lot of pressure. Subjects also usually denied that they made up memories to satisfy the experimenter. On average, the reports of memory under visualization conditions occurred two years earlier than their first reported memories.

1994

Cardena, Etzel (1994, August). Domain of dissociation. [Paper] Presented at the annual meeting of the American Psychological Association, Los Angeles.

## NOTES

Dissociation (a French term) exists when two or more mental contents are not integrated. Dissociation includes a wide variety of behaviors and experiences.

Three Concepts: 1. nonconscious or nonintegrated mental models or processes 2. alteration in consciousness when disconnection from self or environment is experienced 3. defense mechanism

Explanation of these three concepts:

1. Within nonconscious or nonintegrated mental models/processes there are three types: (a) absence of conscious awareness of impinging stimuli or ongoing behaviors

(broad, vague, not useful, because we are unaware of physiological processes most of the time) (b) co-existence of separate mental systems or identities that should be integrated (Meyers, 1903, said the memorability of an act is better proof of consciousness than its complexity). Examples: dissociative amnesia (Walter Reed Hospital patient); or in hypnosis telling a person that their hand is going to begin raising on its own (c) ongoing behavior that is inconsistent with person's verbal report. May be part of #2. Example: commisurotomy patients - woman who wanted to smoke couldn't get her hand to lift cigarette to her mouth. Example of student, being criticized, breaking out into a rash while saying that she felt calm.

Often repression and dissociation are confused. When dissociation is used as in (c) above, they are indistinct; they are the same. Freud used the terms for the same thing. When we talk about a dissociated memory, it is same as repression.

2. Alteration in consciousness (disconnection from the self or environment is experienced). In this case we talk about an experiential event. Caveats: Some use it to refer to \*any\* kind of alteration of consciousness. Braun, 1993, reported that mystical experiences are dissociative; I maintain that many people feel most in contact with the self during mystical experience. Same with drugs: it may not involve primarily separation, disengagement, from self or environment. As you listen to me, you may disengage at times. I think the only legitimate use of "dissociation" is a radical alteration of consciousness; like Tart's altered states of consciousness, like out-of-body experiences. In clinical situation, distraction or dreaminess is usual; but if a patient disengages and starts reliving a situation, it is legitimately regarded as dissociation.

3. Defense mechanism - a theoretical construct, referring to intentional disavowing things that would cause anxiety or pain. Clinical observations of people in traumatic events, rape, people may have out of body experiences; explained as the person sending the ego somewhere else because they can't bear the pain. But, you get this separation in non-traumatic circumstances (in meditation, revery, etc.)

Alternative Paradigm:

Janet's theory which explains cognitively how dissociation occurs, without necessarily proposing an intentional process.

For further elaboration of these comments, see Cardena, E. (1994). The domain of dissociation. In S. J. Lynn & J. W. Rhue (Eds.) *Dissociation: Clinical and Theoretical Perspectives*. New York: Guilford Press

Csoli, Karen; Ramsay, Jason T.; Spanos, Nicholas P. (1994, August). Psychological correlates of the out-of-body experiences--a reexamination. [Paper] Presented at the annual meeting of the American Psychological Association, Los Angeles.

## NOTES

12% of population reports an out-of-body experience (OBE) sometime in their lives. They leave their body and can see self from the outside. Awareness is confined to the new point of view, not fragmented; there is unimpaired intellectual ability; feelings of detachment, completeness, well being, and profound relaxation. Can occur under stress or deep relaxation; not while driving a car.

Psychological correlates aren't known. Studies are inconclusive with respect to belief systems (religious, death anxiety, etc.); measures of absorption, hypnosis, imaginative ability, imagery controls. Recent Carlton study with 87 Ss (33 had OBE) got results we didn't expect. They completed questionnaires, were tested for hypnotizability, had an interview re OBE experience.

This study found the OBE-experiencing people had higher levels of anxiety, psychosomatic symptoms, and panic attacks. They were also higher on magical thinking, perceptual aberration, and Schizophrenia scores. They didn't differ on mysticism, levels of drug or alcohol use, or level of self esteem.

Frankel, Fred H. (1994, October). On patients remembering abuse when it in fact may not have occurred. [Paper] Presented at the annual meeting of the Society for Clinical and Experimental Hypnosis, San Francisco.

**NOTES:**

The concept of hidden memories has supported the profession of psychotherapy for a century. This process can only occur if there is a mechanism to support it. Bowers says, if memory is not reliably accurate, it is not reliably inaccurate either.

"Ideas passing as descriptions lead us to equate the tentative with [the factual.]" - Gould.

Three studies purporting to establish repression: 1. Briere & Comte sampled 450 adults who reported abuse. They asked, "Was there ever a time when you couldn't remember the forced experience?" How does respondent understand the question? Clients were all in therapy. 2. Herman and Schatzow (1989) "verification of abuse" study. 53 Ss in a survivor's group. Reports percentages who had no or little recall. Authors don't acknowledge that the group discussion and the attitude of therapist may have shaped the response. It is also not clear how many Ss who claimed to have "verified" their accounts were among those who had severe amnesia for the event. They could be Ss who had never lost the memory in the first place. 3. Williams interviewed women who earlier were in Emergency Rooms because of abuse being suspected. 38% did not report childhood abuse when questioned, and author concluded it was due to repression. Significant numbers of adults cannot remember things even past the age of 5.

Problem with wording of questions. Some of the women interviewed might have preferred not to report the event. This was not investigated in the study.

Frankel, Fred H. (1994, October). Working with the concept in a clinical setting. [Paper] Presented at the annual meeting of the Society for Clinical and Experimental Hypnosis, San Francisco.

**NOTES:**

I have concerns about the construction of the Diagnostic and Statistical Manual (DSM) as a whole. It was initially a research document, but it has come to dominate clinical diagnostic practice, and worse, it governs what treatment third party payers will compensate.

Dissociative Identity Disorder (DID) to replace Multiple Personality Disorder (MPD) may well change the way the condition is viewed, and we may see fewer alters in each person.

I have difficulty understanding the precise nature of dissociation--especially with its powers to produce amnesia. The dissociative disorders are part of the legacy of hysteria; though some parts of hysteria are represented in other DSM categories. The influence of environmental factors and imagination were suspected when the diagnosis was hysteria; everyone knew the picture was complicated, and subject to contagion, etc. The DSM makes little attempt to take that into account in the section on Dissociative Disorder.

Questions we must address: 1. How voluntary is clinical dissociation? To what extent can we expect the patient to claim agency for it, e.g. if it is claimed that a crime was committed by an alter? 2. To what extent does the clinical manifestation of dissociation overlap with absorption and attention? 3. How does morbid preoccupation with images differ from regression? How much is the patient the willing agent of that kind of behavior? 4. To what extent are flashbacks remembering or imaginings? 5. How do we control for contagion or imitation on the dissociative disorder inpatient units? 6. Could we be creating things to fit our theories? 7. Are other diagnoses being displaced here? The dissociative disorders being put on center stage may lead us to do disservice to the patient in dealing with their other life crisis. 8. If the shock of the trauma is associated with impaired perception, altered attention, and memory problems, how dependable are the reports that are ultimately retrieved--perhaps decades later? 9. What do we in truth understand by the word dissociation? Is it a psychological event with underlying physiology, or just a metaphor?

Psychiatry is subject to diseases rising and falling, e.g. the disappearance of hysteria itself.

Freeman, R.; Barabasz, A.; Barabasz, M. (1994, October). EEG topographic differences between dissociation and distraction during cold pressor pain in high and low hypnotizables. [Paper] Presented at the annual meeting of the Society for Clinical and Experimental Hypnosis, San Francisco.

#### NOTES:

Hilgard once said we should study what is going on inside the skull when we study hypnotic behavior. Theta EEG was studied, in 3.5 and 5.5-7.5 band widths, based on Crawford's research (no differences between high and low hypnotizables in low range but significant differences in waking state, eyes closed condition).

Also employed new type of distraction procedure. Previously used as comparison conditions things like imagine a pleasant scene, do whatever you can do to reduce pain, or imagine an instructor giving a lecture. Barabasz theorized that highs, given the opportunity, may spontaneously get involved in imagery; so distraction used in some experiments may actually become hypnosis. Here, distraction involved using a storage box, with plexiglass covering front, and 3 lights--subjects were to recall sequence of light changes that occurred during 60 sec when arm was in the cold water.

**Cold pressor pain. 3 immersions with simultaneous pain reporting and EEG monitoring. --Waking State --Light array distraction --Hypnotic induction and suggested analgesia (Distraction and hypnosis with analgesia were presented in a balanced design)**

**Pain Ratings ranged from 0 = no pain, 10 = level would very much like to remove arm from water (rating could exceed 10 however). After removing arm, subjects were to report the maximum amount of pain that they had felt. Pain Scores were obtained at 30 seconds and 60 seconds after immersion in the cold water.**

**Also got qualitative data. During recovery period after each arm immersion, Subjects were asked what if anything they had done to reduce the pain felt.**

**30 second pain scores: Waking 7.60 vs 7.50 Distraction 8.60 vs 6.80 Hypnotic analgesia 7.80 vs 4.10 (Significantly different).**

**60 second pain scores: Showed same trend**

**There was no difference whatsoever for the lows.**

**Results for the 2 EEG sites: P3 left hemisphere parietal in waking and hypnotic analgesia, high theta, had significantly different activity O1 left hemisphere in waking and hypnotic analgesia, was significantly different between highs and lows (same as above).**

**Results for two theta ranges: Low theta range, T4 temporal right hemisphere, for lows in waking and [missed words] condition--hard to interpret this finding.**

**RESULTS. Highs demonstrated pain reduction in hypnotic analgesia compared to waking and distraction conditions and compared to lows. Lows had no differences in any condition.**

**Enhanced EEG theta in left parietal area differentiated highs and lows. This suggests that highs generate enhanced disattention that may be controlled by these areas.**

**P3 area regulates the integration and association of somatic perceptions. The O1 area controls processing of visual imagery. Perhaps high hypnotizables have more ability to alter afferent sensory information through focused attentional processes. Also, the ability to alter the suffering portion of pain experience may involve visual imagery activity.**

**State and trait differences are apparent.**

**The low theta range may be more closely related to slower delta range 0-3.5 that is associated with sleep and drowsiness. High theta = low arousal and attention capacity. That's why theta seems associated with wide range of behaviors that appear contradictory**

**The qualitative data shows highs reported they spontaneously preferred strategies that were more than distraction (associating colors with warmth, thinking of warm water) and the most frequent responses of lows were "nothing" or "told myself it would be over soon."**

**Highs in analgesia condition used no specific strategy: 8/10 reported the arm simply felt more numb.**

**Freyd, Jennifer J. (1994). Betrayal-trauma: Traumatic amnesia as an adaptive response to childhood abuse. Ethics and Behavior, 4.**

**Betrayal-trauma theory suggests that psychogenic amnesia is an adaptive response to childhood abuse. When a parent or other powerful figure violates a fundamental**

ethic of human relationships, victims may need to remain unaware of the trauma not to reduce suffering but rather to promote survival. Amnesia enables the child to maintain an attachment with a figure vital to survival, development, and thriving. Analysis of evolutionary pressures, mental modules, social cognitions, and developmental needs suggests that the degree to which the most fundamental human ethics are violated can influence the nature, form, processes, and responses to trauma.

#### NOTES

A logical extension of this research direction, based on a strategy that has been very effective in cognitive neuroscience, would be to look for neuroanatomical underpinnings of the cognitive mechanisms implicated in dissociation. ... For instance, the ability to dissociate current experience may depend partly on representational structures that support spontaneous perceptual transformations of incoming events. One possible perceptual transformation that is amenable to scientific investigation, would be the creation of spatial representations in which the mental 'observer' is spatially distinct from the real body of that observer. Such a representation would fit patient descriptions of 'leaving their body' during a traumatic episode and viewing the scene as if from afar. Additionally one could investigate the role of mental recoding and restructuring during memory 'recovery' and psychotherapy" (pp. 19-20).

Ganaway, George K. (1994, October). The thin line: Reality and fantasy in hypnotically facilitated memory retrieval during psychotherapy. [Paper] Presented at the annual meeting of the Society for Clinical and Experimental Hypnosis, San Francisco.

#### NOTES

Historical review: Every hundred years there has been a peak in interest in altered states--a fin de cicle zeitgeist. It is the Brigadoon effect, i.e. something materializing for one day every 100 years. The theories developed then suffer from "paradigm grandiosity." In hypnosis, we can refer back to:

1694 Salem witch trials

1790s Gaussner's exorcism (see Ellenberger); in a 1775 showdown between him and Mesmer, there occurred the turning point between exorcism and psychotherapy.

1880s Charcot at Salpêtrier 'demonstrated' that hypnosis was an organic, pathological condition. Ultimately this contributed information about the plasticity of hypnotized people. (In the 1880s Bernheim thought it wasn't pathological and thought that suggestion was the important element in hypnosis.)

Recent historical contributions have influenced our views of MPD. Spiegel and Kardiner published book about hypnosis and war neuroses. Cheek & LeCron developed ideomotor questioning, which ignores the contribution of unconscious fantasy. Jacob Arlow's metaphor for MPD is two movie projectors aiming at a screen from two different sides. The subjectively known experiential world thereby combines external reality and the person's internal, motivated perceptions. The

author presented a case study of female therapist, who had been previously diagnosed as MPD, who presented with dissociative symptoms that she thought were due to abuse by her grandmother. She fabricated the memories in order to get the holding and physical nurturing from her therapist for being courageous and remembering the abuse.

Maintenance of professional boundaries is very important in treatment.

Kihlstrom, John F.; Glisky, M. L.; Angiulo, M. J. (1994). Dissociative tendencies and dissociative disorders. Journal of Abnormal Psychology, 103, 117-124.

Although dissociative disorders are relatively rare, dissociative experiences are rather common in everyday life. Dissociative tendencies appear to be modestly related to other dimensions of personality, such as hypnotizability, absorption, some facets of openness to experience, and quite modestly to fantasy proneness. These dispositional variables may constitute diatheses, or risk factors, for dissociative psychopathology, but more complex models relating personality to psychopathology may be more appropriate. The dissociative disorders raise fundamental questions about the nature of self and identity and the role of consciousness and autobiographical memory in the continuity of personality.

Lynn, Steven Jay (1994, October). Toward an integrative theory of hypnosis. [Paper] Presented at the annual meeting of the Society for Clinical and Experimental Hypnosis, San Francisco.

#### NOTES

This is a re-evaluation of neodissociation and cognitive models of hypnosis, and an attempt to be integrative. This paper focuses more on ideomotor behaviors but we will extend the model to other hypnotic behaviors in the future.

Automaticity of behavior in hypnosis can be accounted for without using a concept of divided consciousness or weakened consciousness. Parapraxes (doing one behavior while intending another) are not instances of decreased control of behavior, but relate to where attention is drawn. This requires a different use of the hierarchy concept from Hilgard's model (which in turn comes from Hull's concept of habit hierarchy).

Here hierarchy is a concept drawn from Miller, Galanter, & Pribram: acts are comprised of molecular units, that are comprised of even more molecular units. Behavior only needs to be processed at an executive level when unusual events occur. But one or more hierarchies may be set into motion at the same time. Dissociation is not an infrequent event. Behavior is controlled by subroutines rather than by an executive control structure; subroutines operate in parallel rather than in a hierarchy. Parapraxes are due to an overlap between two subfunctions.

Parapraxes are different from ideomotor responses, where we pay close attention and involuntariness is reported not just post facto but as part of the experience.

Malinoski, Peter; Aronoff, Jodi; Lynn, Steven J.; Moretsky, Michael (1994, August). Hypnosis and early memories. [Paper] Presented at the annual meeting of the American Psychological Association, Los Angeles.

## NOTES

We studied autobiographical memory in the college population, as manifested in the therapy situation, as a way of investigating an individual difference variable. Most people do not have recall before age 3 or 4 (and probably infantile amnesia begins before age 2).

Administered Autobiographical Memory Scale (AMS), and later in context of a hypnosis scale. 247 students were in phase 1, conducted as two separate experiments so that Ss wouldn't link the AMS to measures used in the second study.

First study was presented as a study of personal memories. Asked Ss to distinguish first five birthdays, circumstances around loss of first tooth, first day of high school. Also, they were asked about their earliest memory events, rated according to 3 scales (detail, vividness, accuracy of recall). Authors summed Ss' responses on these 3 ratings for the 8 item scale.

Part II. Administered various scales: Life Experiences, Fantasy Proneness, Wilson & Barber's scale, Imagery Control Scale, Global Psychopathology, 25 item scale of physical and sexual abuse, Brier's list of symptoms of abuse, and DES (Dissociative Experiences Scale). Imbedded were 12 items to test carelessness in responding (e.g. "I have never said Hello to anyone who wore eyeglasses.")

RESULTS. Phase 1. Two people indicated they had memories dating to before their first birthday; an additional 5% of Ss gave memories between 12-24 months. This would probably be impossible. Another 14.4% described events between 24-36 months; 37.4% said their earliest memory was at age 3. Mean age for earliest memory was 3.4 years (which agrees with other surveys.) Only 1 subject stated his earliest memory was as late as the tenth year of life.

High intercorrelation was obtained, ranging .79 to .89, between ratings on any of the memory event ratings (as detailed, vivid, or accurate). There was a negative correlation of these ratings with age of recall. Ss who report more detail, vividness, and competence, were also likely to report earlier first memories.

Authors divided Ss into three groups based on age of first memory: 12 with first memory earlier than first year; those whose first memory was between 1-7 years; and those with a later first memory. The earlier memory group were more fantasy prone; and rated their memories as more reliable, vivid. This suggests there are persons who report memories that are covered by infantile amnesia, report them with greater detail, and are more fantasy prone than those who report memory events beginning later in life. This is consistent with Wilson & Barber's finding that fantasy prone people have vivid recall of early childhood events.

None of the memory reports correlated with psychopathology or dissociation. Dissociation (DES) was correlated with abuse indicators, however. Compared top and lowest 10% and middle range on DES on their memory scores and found no relationship. There was no support for the idea that report of early life events in dissociative people is compromised. Failure to recall early memories shouldn't suggest that people are dissociative (which some therapists tend to do).

All three memory measures were associated with Harvard Scale scores. The AMS was administered at the same time as the Harvard. Objective responding on the Harvard correlated with detail, vividness, and accuracy of recall. Also, involuntariness of response correlated with all 3 measures of the AMS. Finally, subjective involvement correlated with all three measures of AMS. At least when hypnosis is measured first, and explicit connection is suggested, there is a connection. Further research is needed to see if the relationship holds when measured in independent contexts. This may explain why High Hypnotizables are more prone to pseudo memories and leading questions. They may come to confuse them with historical reality.

The results suggest caution for early memory reports. They may be vulnerable to confusing fantasy and reality, as well as to biasing effects.

Marmar, Charles (1994, October). Peritraumatic dissociation and PTSD. [Paper] Presented at the annual meeting of the Society for Clinical and Experimental Hypnosis, San Francisco.

#### NOTES

Following trauma there is a tendency to more dissociation and vulnerability. We completed 3 recent studies. In 1991 Spiegel and Cardena presented review that found: 1. Early childhood abuse is associated with profound dissociation. 2. Repeated abuse is more important and profound than single abuse for producing dissociation. 3. Dissociation in childhood and perhaps in adulthood has been viewed as an adaptive attempt to cope, to take distance in time, place, and person; does that confirm long term adaptation, or is it a risk factor? 4. Dissociation is not limited to childhood trauma; it occurs in adults exposed to overwhelming trauma. 5. In adults with PTSD, there is an increase in hypnotizability, which is interesting because most Axis I disorders are associated with reduced hypnotizability.

Peritraumatic dissociation is defined as an immediate dissociative response to trauma. We developed a scale that robustly captures the phenomena. The scale has both self report and rater versions.

Authors used this measure in many studies: combat trauma, accident trauma, victims of terrorism. The scale predicts who will be a PTSD patient 5 months later, even after controlling for initial response in first week (how many symptoms they had) and for the degree of trauma.

Study 1 (Am. J. Psychiatry, June 1994)

Studied 251 male Vietnam Theater Veterans, mean age 41 at time of study. Had high combat exposure and high risk for PTSD. Rater version of Peritraumatic Dissociative Experiences Questionnaire was used. There was a lot of variability in response, but one underlying dimension resulted from the factor analysis (and this factor accounts for 40- 50% of the variance).

Author hypothesized that those who have a greater response to trauma will have more problems later, and would predict stress symptoms but not necessarily psychopathology. The score correlates highly with: Mississippi Scale for PTSD .51; Horowitz's scales; Impact of Events Scale (Intrusion .53, Avoidance .60); MMPI

derived PTSD .42; Dissociative Experiences Scale (recall of time of event) .41; and War Zone Stress Exposure .48.

MMPI-2 clinical scales had almost no correlation with this scale (using partial r's, and controlling for MMPI-2 PTSD scores).

Prediction of PTSD case classification from this scale, after taking into consideration other predictors: War Zone Stress War Zone Stress, DES War Zone Stress, DES, PDEQ-RV Kappa is .63

You know much more about who will be a case taking into consideration the DES and DEQ than just knowing the amount of stress. Peritraumatic stress is strongly associated with PTSD but not with psychopathology.

#### Study 2

Replicated Study 1 using 77 female veterans. Females Ss were more highly educated, older, more likely to be in a health profession role (trauma was working with death and dying, exposure to sex abuse and harassment, given even less support than the males). Yet women have had a better course of recovery, though rates were the same (30% developed PTSD after return from war).

Correlation with Impact of Event Scale (Intrusion .41 and Avoidance .40), but correlations with MMPI-2 are low (and with other PTSD scales are lower than with the males). Hierarchical multiple regression models show R squared doesn't increase with DES but does with PDEQ to Intrusion (less so to Avoidance).

This study replicates the same pattern, with peritraumatic dissociation strongly related to PTSD symptoms years later, and not to general psychopathology, even after accounting for the nature of the stress and for the degree of dissociation.

#### Study 3

After the 1989 Loma Prieta earthquake in Northern California we studied emergency services personnel involved in the collapse of a freeway in Oakland. 1000 rescue workers were involved. The workers (police, fire personnel, paramedics, CALTRANS road workers) involved one I-880 cohort and a replication cohort, with two control groups (smaller scale incidents like attending a child drowned in swimming pool, removing someone from a wrecked auto). In all 3 samples, 90% were male.

What characteristics of the person or their exposure account for which workers go on to cope and which will later have PTSD symptoms? Predictors: IES-I IES-A IES-H M-PTSD SCL-GSI.

Variables most associated with problems 1.5 to 3 years afterward were years of experience, exposure, adjustment (measured by the Hogan Personality Inventory measure of adjustment), social support, DES, and PDEQ. Regression analyses used the best predictors first: forced exposure, adjustment, years experience, locus of control, social support. For Intrusion scores there were modest but significant increments by the DES and PDEQ; for avoidance scores, there were very significant contributions (.072 and .078).

There is a robust relationship between the DES and PDEQ and how much hyperarousal there is afterward (.104 and .110 %). DES measures a trait, PDEQ measures a state; yet the latter continues to contribute even after accounting for variance by the DES.

The PDEQ also has been found to predict among rape victims who will have PTSD. This was replicated in different cultures and different language groups.

**FUTURE DIRECTIONS.** Authors plan to examine people with moderate to high exposure after the L.A. earthquake. They gathered personality and coping style data on the rescue workers to answer the question: what characterizes those who are more vulnerable to dissociative tendencies during trauma?

There are treatment implications: given that those who develop the most profound response are the ones who will have more PTSD later, what are the implications?

Uncovering the trauma that caused the PTSD is often associated with re-dissociation There is a question of how this should be managed.

The authors will attempt to see if they can predict in advance if a person would dissociate if exposed. Do those who dissociate have more childhood abusive environments? Hypothesis: there may be an interaction of childhood trauma and combat trauma that produces PTSD.

Nash, Michael R. (1994, October). Reports of early sexual trauma: The problem of false negatives and false positives. [Paper] Presented at the annual meeting of the Society for Clinical and Experimental Hypnosis, San Francisco.

#### NOTES

The problem of false positives and problem of false negatives are distinct and should be treated differently. The question involves pseudomemories vs repression.

Evidence for false positives: 1. Memory research 2. Developmental psychopathology 3. Contemporary psychoanalytic theory 4. Clinical field studies

No laboratory researcher has produced false memories that are as vivid, or as emotionally loaded as early abuse.

Evidence for repression: 1. "Repressor Personality" research (Weinberger & Schwartz, who view it as a trait rather than a state). 2. Implicit memory research 3. Hypnosis research on memory (see Nash chapter in Fromm & Nash book on research in hypnosis) 4. Clinical field studies

Alden, Phyllis A. (1993, October). Hypnosis in the treatment of posttraumatic stress. [Paper] Presented at the annual meeting of the Society for Clinical and Experimental Hypnosis, Arlington Heights, IL.

#### NOTES

[Author is at Grimsby Hospital in England.] Discussion of practical aspects of treatment of PTSD. Work began with Janoff-Bulman (1985) and Epstein (1990) focuses on cognitive appraisal. Affect and meaning are shunted into unconsciousness. She observes that when patients report intrusions, there are pieces missing from the memory: they recall the horror but not the positive part.

Used the following technique: Ask patient to get comfortable and imagine being in a theater; then go to a projection room where she can control all parameters; then watch herself watching a pleasant film; then the scene; then return to a seat in the theater and watch the upsetting film, freezing it; when uncomfortable, describe associations; then return to projection room where she watched film of what she

imagined might have occurred--the image behind the image, that holds the affect; then going back to image and playing it through, with more comfort; then leave the theater and go into the film, into the screen, to go through the scene. Then asked patient to get back the intrusive image and go through it, which she did with comfort.

With another patient she introduced the "current" person into the image to reassure her that everything would be all right--i.e. she would survive. This is called "double dissociation method."

She also has the patient tell people in the scene what they should have done, or express anger verbally toward them, etc. Or she might have them make the intrusive imagery less threatening or amusing by introducing other imagery.

Balthazard, Claude G. (1993). The hypnosis scales at their centenary: Some fundamental issues still unresolved. International Journal of Clinical and Experimental Hypnosis, 41, 47-73.

Current approaches to the measurement of hypnotic performance can be traced back to the 19th century. In part because of these early origins and in part because of the nature of hypnotic phenomena, the hypnosis scales are unique psychometric instruments. The classic hypnosis scales are based on the notion of a "performance ladder"; items are scored on a pass/fail basis and can be arranged in increasing order of difficulty. Some of the implications on [sic]this "performance ladder" approach are reviewed. The evidence for two-mechanism models of hypnotic performance is reviewed. It is argued that this kind of formulation is at least as plausible as one that argues that the hypnosis scales measure "one thing" or "mostly one thing." If it were the case that the hypnosis scales were tapping two different and distinct processes, the label "hypnotic susceptibility" could not be unambiguously applied to scores on the hypnosis scales. The hypnosis scales would appear well-suited to the investigation of underlying mechanisms, yet no consistent picture of the mechanisms underlying hypnotic performance on the scales has emerged thus far. No resolution is presented, but some of the reasons why such a resolution is so elusive are discussed. The future of hypnosis scales is discussed with respect to multidimensional assessment and alternatives to the "work sample" approach.

## NOTES

Author discusses the hypnotizability scales' history and psychometric properties, suggesting that they cannot have construct validity if more than one construct is involved. He states that many of the alternative formulations "posit structurally similar two- mechanism models, where the relative contributions of one and the other mechanism changes gradually with the difficulty of the hypnotic performance--that is, one mechanism is more important for easy items and the other more important in the difficult range. This kind of formulation has been advanced by a number of authors .... Although these formulations are structurally similar, the nature of the mechanisms has been variously conceptualized: nonability and ability components (Shor, Orne & O'Connell, 1962), primary suggestibility and somnambulism (Weitzenhoffer, 1962), minor and major dissociations (Hilgard, 1977), compliance and true hypnosis (Tellegen, 1978-1979), and cooperativeness and

expectation at one end and absorption at the other (Spanos, Mah, Pawlak, D'Eon, & Ritchie, 1980). ... In a formulation such as Hilgard's (1977), where both mechanisms are dissociative, it may be that it makes some sense to understand both mechanisms as aspects of the same complex construct. In other formulations... it would appear more cogent to speak of two constructs. Spanos et al. (1980) found that 'cooperativeness and expectation may be particularly important in responding to ideomotor and challenge suggestions, while the ability to convincingly treat imaginings as real (i.e., absorption) becomes increasingly important for more difficult 'cognitive' items" (p. 21). Balthazard & Woody (1992) presented evidence that the more difficult items on hypnotizability scales are related to absorption more than the easier items.

Balthazard & Woody (1989) investigated the proposition that hypnotizability scores are distributed bimodally, and concluded that statistical problems clouded the issue. Furthermore, most analyses previously have been of surface structure, which does not relate directly to the underlying mechanisms of hypnosis, and current psychometric methods cannot address the mechanisms that underlie surface relations. "There are two aspects of hypnotic processes ... that obscure underlying mechanism: synergisms and overdetermination. Synergisms occur when mechanisms potentiate each other in such a way that a combination of processes becomes more than the sum of its parts. Overdetermination occurs when co-occurring mechanisms do not potentiate each other, such that any one of the mechanisms would have been sufficient to produce the observed effect" (p. 63-64).

The author suggests there are two options at present: Corrective Scoring (like the Curss.OI, an objective-involuntary score which, although unreliable on test-retest, appears it could be more a measure of "pure" hypnotizability) and not using the typical "work sample" approach. Balthazard and Woody (1992) suggested the Absorption Scale may provide a better measure of "hypnotizability" than the standard hypnosis scales because absorption scores are more strongly related to difficult hypnotic performances.

Cardena, Etzel (1993, October). Trance and possession as dissociative disorders: How exotic are they?. [Paper] Presented at the annual meeting of the Society for Clinical and Experimental Hypnosis, Arlington Heights, IL.

NOTES: Joke: "What happened to the possessed patient who didn't pay his exorcist?" Answer: "He got repossessed."

Began with a quotation of Lagerkvist's book describing possession of a Sybil in Greek temple. Possession is part of religious experience worldwide, that he is not discussing here.

The revised diagnostic manual, ICD-10, has included "dissociative trance disorders." To diagnose this one must have either trance (narrowing awareness or focusing and stereotyped movements, behaviors) or possession trance (replacement of sense of personal identity by a new identity, with stereotyped culturally-determined behaviors or movements that are experienced as being controlled by the possessing agent), \*and\* full or partial amnesia for the event. Cardena emphasizes it doesn't need to be full amnesia.

To be diagnosed as dissociative trance disorder, the trance or possession state observed cannot be a normal part of a broadly accepted cultural or religious practice, and it must produce distress or maladjustment.

These are the most common type of dissociative disorders in non-Western cultures, e.g. 90% in India. So this diagnosis in India is not "atypical." "Non-Western" applies to 80% of the World and 1/3 of the USA population. DSM is trying to expand cultural relevance.

Also, even in the Western culture Allison and others have published cases of dissociative trance disorder, and others have described trance disorders:

Spiegel & Spiegel's Grade 5 personality is vulnerable to dissociative disorder. Hartman's chronic nightmare patients have "boundary thinness" (i.e. they are not clear if they are awake or asleep, lack separation from themselves and others). Lynn & Rhue's fantasy prone individuals, 22% of people, are vulnerable to maladjustment.

Cardena's recommended change in diagnosis of dissociation is critiqued in Transcultural Psychiatric Research Review (1992). Criticisms of the new diagnosis, published in that journal, are: 1. Culture-bound syndromes cut across Western diagnostic boundaries. 2. The diagnosis may be insensitive to the cultural context in which phenomena occur (e.g. distress may lead a person to participate in a cult of affliction) and it may require anthropological sophistication of diagnosticians or consultation with someone who has that knowledge. 2a. It may disregard considerations such as who has the power to "authorize" the phenomenon, under what circumstances, etc. [That would be true with any diagnosis however.] 3. Dissociative Trance Disorder may assume greater within and across-culture uniformity for the conditions than is warranted. 4. It may give validity to metaphysical explanations for spirit possession. [But in psychiatry we often use terms that don't take into consideration validating metaphysical explanations, e.g. "phantom limb" pain. 5. The medical model that underlies DSM is inappropriate for ontological considerations on the nature of the self. [But those with this diagnosis give us some understanding, not what the ultimate nature of the self and consciousness are. Diagnoses are pragmatic ways of dealing with problems.]

At the present time, the diagnosis of Dissociative Trance Disorder is included in the Appendix of DSM-IV.

For further elaboration of this material, see Cardena, E. (1992). Trance and possession as dissociative disorders. *Transcultural Psychiatric Research Review*, 29, 283- 297.

Crawford, Helen J.; Gur, Ruben C.; Skolnick, Brett; Gur, Raquel E.; Benson, Deborah M. (1993). Effects of hypnosis on regional cerebral blood flow during ischemic pain with and without suggested hypnotic analgesia. *International Journal of Psychophysiology*, 15, 181-195.

Using <sup>133</sup>Xe regional cerebral blood flow (CBF) imaging, two male groups having high and low hypnotic susceptibility were compared in waking and after hypnotic induction, while at rest and while experiencing ischemic pain to both arms under two conditions: attend to pain and suggested analgesia. Differences between low and highly-hypnotizable persons were observed during all hypnosis conditions: only

highly-hypnotizable persons showed a significant increase in overall CBF, suggesting that hypnosis requires cognitive effort. As anticipated, ischemic pain produced CBF increases in the somatosensory region. Of major theoretical interest is a highly-significant bilateral CBF activation of the orbito-frontal cortex in the highly-hypnotizable group only during hypnotic analgesia. During hypnotic analgesia, highly-hypnotizable persons showed CBF increase over the somatosensory cortex, while low-hypnotizable persons showed decreases. Research is supportive of a neuropsychophysiological model of hypnosis (Crawford, 1991; Crawford and Gruzelier, 1992) and suggests that hypnotic analgesia involves the supervisory, attentional control system of the far-frontal cortex in a topographically specific inhibitory feedback circuit that cooperates in the regulation of thalamocortical activities.

Eisen, Mitchell (1993). Assessing the hypnotizability of college students from addictive families. Contemporary Hypnosis, 10, 11-17.

The present study examined the relation between hypnotizability and the report of growing up in an addictive family where one or both parents were addicted to drugs and/or alcohol. A sample of 113 college students (47 male, 66 female) were studied for measure of childhood abuse, addiction history, dissociation and hypnotizability. As predicted, subjects from an addictive family were more hypnotizable than subject from a nonaddictive family. However, no relation between family addiction and dissociation was secured. Whereas abuse was found to be related to dissociation, it was not related to hypnotizability. The findings are discussed in terms of the effects of child abuse and neglect on dissociation and hypnotizability as it relates to the addictive family.

#### NOTES

Author reviews the literature in area of abuse and hypnotizability as well as dissociation. Subjects were unaware of purposes of the experiment when they volunteered. Of 113 Ss, 18% were reared in an addictive family; 13 Ss reported being abused, of whom 6 reported sexual abuse and seven physical abuse. Five of the 21 Ss who reported being reared in addictive families also reported being abused (3 physical, two sexual). Only one S reported both physical and sexual abuse.

Used HGSHS:A, Children of Alcoholics Screening Test, and Dissociative Experiences Scale of Carlson and Putnam (1986). Those with addiction in the family had Harvard scale mean score of 8.05, compared to those who didn't have it with mean of 6.95. No significant effect was found for ABUSE or the interaction of ABUSE and family addiction. The abuse question was, "Before the age of 12 parent punishment of you resulted in your physical injury (bruises, scarring, broken bones, etc.). Second question was, "Before the age of 12, did you participate in sexual behaviors (either with or without coercion) with a much older person?"

The Discussion thoroughly explores the possible reasons why their results differ from those of others.

Miller, Mary E.; Bowers, K. S. (1993). Hypnotic analgesia: Dissociated experience or dissociated control?. Journal of Abnormal Psychology, 102, 29-38.

High-hypnotizable subjects were found superior to low-hypnotizable subjects in degree of pain reduction produced by hypnotic analgesia and by a stress-inoculation (cognitive-therapy) procedure. But, stress inoculation and not hypnotic analgesia impaired performance on a cognitively demanding task that competed with pain reduction for cognitive resources. This outcome implies that hypnotic analgesia occurs with little or no cognitive effort to reduce pain, challenging the social psychological theory of hypnotic response, at least in high-hypnotizable individuals. The findings are also incompatible with the concept of dissociated experience wherein the pain and cognitive efforts to reduce it are separated from consciousness by an amnesia-like barrier. But the results do support the concept of dissociated control, which proposes that suggestions for hypnotic analgesia directly activate pain reduction and thereby avert the need for cognitive strategies to reduce pain.

1992

Barrett, Deidre (1992). Fantasizers and dissociaters: Data on two distinct subgroups of deep trance subjects. Psychological Reports, 71, 1011-1014.

The study delineated two subgroups of highly hypnotizable subjects. The first subgroup (fantasizers) entered trance rapidly, scored high on absorption (mean of 34 on the 37-item Absorption Scale), and described hypnosis as much like their rich, vivid, and very realistic waking fantasy life. None of the fantasizers experienced unsuggested amnesia, and 5/19 failed to produce suggested amnesia. Only 2/19 fantasizers described hypnosis as very different from their other experiences. The earliest memories of fantasizers were all identified as occurring before age 3, and before age 2 for 11 of 19. The second subgroup (dissociaters) took time to achieve a deep trance (unlike Wilson and Barber's fantasy-prone subjects, but they did achieve as deep a trance as fantasizers), experienced hypnosis as different from any prior experiences, and were more likely to exhibit amnesia for both hypnotic experience and waking fantasies. None of the dissociaters described their waking imagery as entirely realistic, and the earliest memories in this group were all over the age of 3 (mean age - 5). Of the 15 dissociaters, 7 scored below the norm on the Absorption Scale (Mean - 26).

Christianson, S-A (1992). Emotional stress and eyewitness memory: A critical review. Psychological Bulletin, 112, 284-309.

#### NOTES

Although not addressing hypnosis specifically, this is a comprehensive review of literature on memory for negative emotional events relevant to issues of hypnosis and memory. The final conclusion is that emotional events are indeed remembered differently than neutral or ordinary events and are well retained with respect to the event itself and concerning central, critical detail (not peripheral detail). Such

memories seem less susceptible to forgetting. There is evidence for dissociation between memory for emotional information and memory for specific event information. There is also evidence of amnesia or memory impairment effects after high-arousal events, with memory increasing as more time passes after the event. The functional amnesia effects are probably due to an interaction between altered encoding operations and the specific retrieval circumstances aiding consciously and unconsciously controlled reconstructive processes. There is little evidence to support Loftus' contentions that emotional stress is bad for memory.

Claridge, Karen (1992). Reconstructing memories of abuse: A theory-based approach. Psychotherapy, 29, 243-252.

The recovery of traumatic memories is an important part of therapy with survivors of abuse. This article describes a conceptual framework for memory reconstruction based on Horowitz' (1986) theory of stress response syndromes. The client's history of intrusive symptoms provides a way to anticipate the nature of the trauma, even when no memory of it exists. Ongoing intrusive symptoms are used to retrieve memory fragments, and their emotional impact is used to build the client's emotional tolerance. Emphasis is placed on preparing for memories by identifying what the client will need when the memories return, building coping skills, and beginning to restructure cognitions at the "what if" stage of remembering. Case material is used to illustrate.

Dixon, Michael; Laurence, Jean-Roch (1992). Two hundred years of hypnosis research: Questions resolved? Questions unanswered!. In Fromm, Erika; Nash, Michael R. (Ed.), Contemporary hypnosis research (pp. 34-66). New York: Guilford Press.

#### NOTES

These notes summarize only that part of the chapter concerning nonvoluntary behavior (pp 38-39; 58-61).

The concept of 'nonvolition' has been and continues to be an important issue in hypnosis research. The concept pertains to the "subjective report that the hypnotic suggestion is enacted without the subject's conscious and willful participation" (p. 38). When hypnosis was attributed to a magnetic fluid, in the days of Mesmer, the issue did not arise (because of course a person would not have control over something that happened to them physically). However, when hypnosis came to be considered a psychological phenomenon, the issue of how a behavior could be the result of motivated action and yet not perceived as being under conscious influence became important. In 1819 Faria wrote that the nonvolition paradox is due to the hypnotized subject's tendency to misattribute the source or reason for one's behaviors; he noted that successful suggestions depended upon the subject falsely attributing to the hypnotist the power to influence them. From that point forward, circular reasoning was used to state that one is hypnotized if one experiences their behavior as nonvolitional, and nonvolitional behavior signifies that a person is hypnotized.

**"The observation of the seemingly complete automaticity of response in the highly hypnotizable subject led Liebeault in his 1866 book (followed later on by Bernheim and Liegeois) to describe these subjects as 'puppets' in the hands of the hypnotist. This was a quite unfortunate statement, since it would lead to one of the fiercest legal debates surrounding the use of hypnosis in the last 20 years of the 19th century (Laurence & Perry, 1988). ...**

**"The most prominent author (if not the only one) who attempted to tackle this difficult question was Pierre Janet, who would make the investigation of automatism the basis of his theory of hypnosis, rather than suggestion or suggestibility. This theoretical orientation is best exemplified by his concept of desagrégation psychologique seen in some psychopathologies, or the carrying out of a posthypnotic suggestion in the normal individual (Janet, 1889; see also Ellenberger, 1970; Perry & Laurence, 1984; Prevost, 1973). Nonetheless, until the end of the 19th century, and for a good part of the 20th century, these reports of nonvolition were thought to be the end result of some neurological changes happening during hypnosis--an idea that has not been substantiated by contemporary research." (pp 38-39)**

**Reports of nonvolition are explained as due to dissociation by Hilgard, or as the results of misattributing the origins of behaviors and experiences by Spanos and by Lynn. Neodissociationists like Hilgard regard misattribution to be a cognitive alteration, mainly an internal triggering mechanism, while social psychologists like Spanos and Lynn regard the misattribution to be the results of situational demands and therefore an external triggering mechanism.**

**"Regardless of one's preferred metaphor, the issue of nonvolitional reports remains at the core of an integrated view of hypnosis and hypnotizability. The question remains as follows: By which mechanisms does this occur, and how can we predict a priori who will report involuntariness and under what circumstances? Whereas dissociationists have emphasized general cognitive mechanisms and de-emphasized situational factors, social- psychological theorists have emphasized situational variables and de-emphasized individual differences. Given the limitations of both approaches, emphasis will have to be placed not on their continued separation but on their integration, as more and more investigations demonstrate that they clearly interact with each other (see, e.g., Nadon, Laurence, & Perry, 1991)." (p. 60)**

**"At the height of the confrontation between the two French schools, hypnosis found its way into the legal arena. Following a series of criminal cases in which hypnosis had been allegedly involved, the two schools once again found themselves on opposite sides of the fence. For La Salpetriere, only those who had a propensity toward criminality (and hystericals were prime candidates) could be the victims of hypnosis. For the Nancy school, in highly responsive individuals suggestions could lead to criminal behavior. Unfortunately for the Nancy school, it soon became evident that the concept of suggestion was not sufficient in explaining the questions raised by the courts, and Bernheim was forced to recognize that in cases where suggestions had played a role, other dispositional and situational factors were probably more important in the genesis of the reprehensible behaviors. His espousing a too extreme position meant that the baby was thrown out with the bathwater. History may indicate that the same fate is now awaiting contemporary**

theoretical positions that adopt an extreme stance vis-a-vis the phenomenon of hypnosis" (p. 61).

Erdelyi, Matthew, Hugh (1992). Psychodynamics and the unconscious. American Psychologist, 47, 784-787.

The original New Look integrated the constructivist-psychodynamic traditions of Bartlett and Freud. The unconscious (Greenwald's "New Look 3") is a logically different idea, although in practice it is often intertwined with constructivist - psychodynamic approaches. The unconscious is a pretheoretic term with a variety of problems: It has multiple and unsettled meanings; null reports need not signify null awareness; the conscious-unconscious dichotomy implied by the limen may not exist; even "absolute subliminality" (chance-level accessibility) is relative to the time interval of testing, as accessibility can increase to above-chance levels over time (hypermnesia). Yet, the phenomena that the unconscious sloppily subsumes are not simple or dumb. The capacity of subliminal perception should not be confused with the capacity of subliminal (unconscious) memory and cognition.

Frischholz, Edward J. (1992, October). Dissociation. [Paper] Presented at the annual meeting of the Society for Clinical and Experimental Hypnosis, Arlington, VA.

#### NOTES

There are two approaches for studying dissociation 1. phenomenological: describe difference types of dissociative phenomena, e.g., forgetting, multiple personality disorder or MPD 2.theoretical: explain the physiological/ psychological processes by which things become associated/disassociated, e.g., Freud (repression) vs. Janet (dissociation).

Two types of dissociation: 1. dissociation of awareness (amnesia, unconscious cognitions) 2. dissociation of volition (loss of executive control over behavior, psychological automatisms)

Normal Dissociation is characterized as: 1. content is narrow and specific 2. duration is brief 3. awareness of loss of material exists 4. control can be re-established

Abnormal Dissociation is characterized as: 1. content is broad (self-identity) 2. duration is extended 3. no awareness of loss of material exists 4. no re-establishment of control

The most widely used measure is Dissociative Experience Scale (Bernstein & Putnam) which has .84 to .96 test-retest correlation (Bernstein & Putnam, 1986; Frischholz et al.)

Mean Scores for DES MPDs 55. DD NOS 40.8 Students 23.8

He advocates a cutoff score above 40 as indicating abnormal dissociative experiences (that would yield 6% false negatives). Above 65, suspect faking or over-reporting of dissociative experiences.

Factor Analysis of the DES would associate the following items: 1. Absorption Factor: 2, 14, 15, 17, 18, 20 (normal dissociation) 2. Amnesia Factor: 3, 4, 5, 8, 25, 26

(pathological dissociation) 3. Depersonalization/Derealization Factor: 7, 12, 13, 14, 27, 28

Correlations of DES with other tests:

Tellegen Ambiguity Jenkins

Absorption Tolerance Activity DES Total .39 .24 .04 DES Amnesia .24 .22

See Table from AJCH in July 1992, which replicates a study by Nadon Table 2  $r = .12$  with hypnotizability (Nadon reported .18).

One could use both the DES and hypnotizability scores to distinguish between different clinical groups. For example, dissociative patients reverse amnesia while schizophrenics don't.

One could distinguish real MPDs vs Simulators based on Special Hypnotic Phenomena: with Real MPDs half show the hidden observer phenomenon, therefore they hide their MPD; simulators show the hidden observer phenomenon 100% of the time. Another item that discriminates is the Orne Double Person Hallucination item. MPDs 50- 62% show it, but 92-80% [incorrect percentage in these notes?] of simulators do experience the hallucination. Of these 70-75% of the MPDs are able to distinguish the hallucination; only 45-40% of simulators are able to distinguish the hallucination. Real MPDs know, can tell difference between a hallucinated person and the real person whereas simulators maintain they can't tell who is the real person.

It's not true that MPDs are extremely high in hypnotizability. They score in 8-10 range. The MPDs score 1 SD above normals but they are not off the end of the scale. These are good ways of testing whether someone is faking MPD. We have replicated this many times, getting better replication of MPD simulators than high hypnotizable simulators.

Another method for distinguishing true MPDs from simulators involves demonstration of the Einstellung (learning set) effect.

Looking at Water Jar Problems, patients learn to solve the problems the long way. They teach personality A how to solve problem by long solution method (four trials of B - A - 2C); on the fifth trial, 95% of Ss solve the problem by the long method, the Einstellung (learning set) effect. Switch to personality B and give the same test. If there were no transfer, people immediately see A-C, which is a short method for solving the problem. It has been observed that 50-60% of MPDs do not show Einstellung effect; they immediately see the short solution.

Have done this also with retroactive interference word learning model.

Effect of context. Kohlenberg (Behavior Therapy Journal) selectively reinforced one personality of an MPD, which then 'came out' more often; during extinction the frequency of seeing that personality went back to baseline.

I used Greenspan's and Erickson's learning without awareness paradigm. When a low baseline frequency personality emerged, I'd reinforce the person; when a dominant personality came out I'd start yawning, look out the window, etc. During extinction the frequency went back toward normal baseline level, but not all the way. These indicate you can shape the appearance of one personality, but not that it's iatrogenic.

Can also do this with schizophrenics, normal highly hypnotizable subjects.

Frischholz, Edward (1992, October). The dimensionality of hypnotic performance. [Paper] Presented at the annual meeting of the Society for Clinical and Experimental Hypnosis, Arlington, VA.

**NOTES:**

A 1985 article by Balthazar & Woody in Psychological Bulletin is the best I have read on this topic, and on how factor analysis can be used fruitfully.

Many people using the same data sets have arrived at difference conclusions. My results are based on two data sets: Balthazar & Woody's, in which they created a unidimensional scale. (If you factor analyze a simplex matrix you obtain a 3 factor matrix; yet you knew it was unidimensional. They pointed out the 2nd factor correlated with item difficulty, and the 3rd factor had a U-shaped correlation with item difficulty.)

Factor analysis may not be best way to demonstrate unidimensionality.

I decided to use non metric multidimensional analysis to confirm unidimension. By this, Form A appears to be multidimensional. The same holds true for Stanford Form C scale.

Interpretability of the different dimensions? I agree with Dr. Stone: unidimensions are better for interpreting tests. But you should start out by constructing one in the first place.

I argue that Form C is unidimensional, because the items were selected by using item/full score correlations, hence a first component was built into it. But what does the scale measure? The only way to know is to correlate it with external measures, like Woody does. There are no studies using factor analysis showing that different factors on hypnotizability tests have different correlations with external measures (e.g. Factor 1 doesn't correlate differently with Absorption than Factor 3).

We might better start with a theory if we are going to construct new hypnotizability scales. Don't just use item total correlations. It would be better to find items representing different dimensions, scale the items, then correlate them with different external referents.

Then when we do collect data, make sure the items are unidimensional representations.

Third, we should appropriately validate these dimensions.

Frischholz, Edward J.; Lipman, L. S.; Braun, B. G.; Sachs, R. G. (1992). Psychopathology, hypnotizability, and dissociation. American Journal of Psychiatry, 149, 1521-1525.

This study sought to replicate and extend previous findings regarding the hypnotizability of different groups. They compared the hypnotizability of four psychiatric groups--dissociative disorders (N = 17), schizophrenia (N = 13), mood disorders (N = 13), and anxiety disorders (N = 14), as well as a normal college student group (N = 63). Hypnotizability was assessed by four different measures: the eye-roll sign and the induction score of the HIP, the Stanford Hypnotic Susceptibility Scale, Form C, and two self-ratings of hypnotizability. As predicted, dissociative disorder patients had significantly higher hypnotizability scores on al

measures than all other groups. Schizophrenia patients, on the other hand, had significantly lower scores than normal subjects on the eye-roll sign and induction score, but not on the other measures. Some other unpredicted between-group differences were also found. Nevertheless, despite the between-group differences, the intercorrelations between the various hypnotizability measures within the normal group were very similar to those observed in the combined patients groups. Findings suggest that routine hypnotizability assessment may be useful in the differential diagnosis of patients with dissociative disorders.

**Giolas, M. H.; Saners, B. (1992). Pain and suffering as a function of dissociation level and instructional set. Dissociation, 5, 205-209.**

48 female student Ss who scored above 20 on the Dissociative Experiences Scale and 48 subjects scoring below 20 on the DES were compared for response to ischemic pain. Experimental conditions included (1) a group imagining their arm becoming numb and insensitive, (2) a distraction group focusing on their breathing, and (3) a control group with no instructions. Subjects rated pain at one-minute intervals for the sensory experience of pain and for suffering (the emotional experience). The procedure was ended at subject's request or after 20 minutes. Across all conditions, the high dissociative group tolerated pain significantly longer than low dissociatives. Analysis revealed lower suffering ratings for high dissociators in the condition where, like in hypnosis, they imagined their arm numb. This is consistent with beliefs that during abuse in childhood the child learns to use imagination to reduce suffering.

**Hargadon, Robin M.; Bowers, Kenneth S. (1992, October). High hypnotizables and hypnotic analgesia: An examination of underlying mechanisms. [Paper] Presented at the annual meeting of the Society for Clinical and Experimental Hypnosis, Arlington, VA.**

## **NOTES**

**Bowers' dissociated control adaptation of Hilgard's neodissociation theory of hypnosis posits that higher control systems are not used if lower systems are activated.**

**Imagery may be less important for achieving hypnotic effects. It also may contribute differently than previously thought, an uncorrelated factor. If imaginal involvement and imagery is integral to the production of analgesia using hypnosis, one would get results different than if not integral.**

**Research: 65 Ss rated as high on two hypnotizability tests participated.**

**Session 1:**

**Procedure entailed finger pressure pain: baseline, followed by 2 hypnosis treatment trials. Ss were not informed of the second trial before they did the first.**

**Standard suggestions: imagery congruent with the suggestion (hand like block of wood, protected by a glove)**

**Imageless condition: your hand will remain comfortably nonresponsive to the pressure; you will not allow other things to come into your mind.**

## **Outcome Measures**

**Analogue scale for pain 0-10**

**Nonvoluntary experience rated 0-4**

**Session 2:**

**Administered Tellegen Scale, Woody & Oakman Scale, Marks Vividness of Imagery, Bowers' Effortless Experiencing, and Duality of Experience during age regression.**

**RESULTS.** No difference was found between the standard and imageless conditions in amount of pain reduced. So in high hypnotizables, use of imagery or not doesn't matter for controlling pain. Some Ss had a clear preference however, for one or the other method (even counter to their own expectations).

**Feelings of nonvolition did not differ as a function of imagery use.**

**Multiple regression showed effects of hypnotizability and effortless experiencing. Ss who have an effortless experiencing of imagery benefit from using it to reduce pain; those who find it more effortful do better without imagery when attempting to reduce pain.**

**Contrary to last year's results reported by Bowers, high imagery was related to duality of experiencing in age regression.**

**Dissociated control theory is consistent with the results but not necessarily demonstrated. It is important to discriminate between imagery as a mediator rather than as a co-occurrence. This research suggests, as did Zamansky's work on counter suggestions, that imagery is not as critical for hypnotic response as we previously thought.**

**Hilgard, Ernest R. (1992). Dissociation and theories of hypnosis. In Fromm, Erika; Nash, Michael R. (Ed.), Contemporary hypnosis research (pp. 69-101). New York: Guilford Press.**

## **NOTES:**

**[These Notes were made from a prepublication copy and the pagination for quotes added later.]**

**The author reviews the history of dissociation theory, the hidden observer, and the credible-skeptical arguments regarding hypnosis. He briefly summarizes alternative theories about hypnosis, and asserts that we can turn aside from debate by examining the common topic studied, the "domain of hypnosis" or what happens when hypnotist, with consent of subject, attempts to induce hypnosis through conventional procedures: production of hallucinations, contractions, paralyzes, age regression, analgesia, posthypnotic amnesia, etc. Even if one disagrees about the nature of these phenomena or the appropriate explanatory concepts, one can agree on the area to be investigated.**

**The author notes that one never sees these behaviors in the same situation, in any other context. They are distinguishable from other phenomena like meditation, highway hypnosis, responses to a persuasive leader, and even some waking suggestions by several delimiting factors:**

**1. Hypnosis is not simply a response to suggestion, because that kind of response occurs in other situations. Suggestions can be divided into personal and impersonal**

(Hull, 1933); and suggestibility can be divided into primary and secondary (Eysenck & Furneaux, 1945). Primary suggestibility includes responses to waking suggestion (e.g. postural sway) that correlate with hypnotizability; secondary suggestibility involves responses to waking suggestion that do not correlate with primary suggestibility. Hypnotizability does not correlate with social suggestibility (i.e. gullibility or conformity) (Burns & Hammer, 1970; Moore, 1964); nor does it correlate with placebo response (McGlashan, Evans, & Orne, 1979).

2. Test-retest correlations are approximately  $+0.70$  between scores on hypnotizability scales with and without formal inductions. Thus, responses to the type of suggestion on hypnotizability scales--even when in the waking context--belong within the domain of hypnosis. The individual differences in responsivity to items on hypnotizability scales persist over time (Piccione, Hilgard, & Zimbardo, 1989:  $r = .64$  for 10 years test- retest,  $.82$  for 15 years, and  $.71$  for 25 years, on Stanford Form A); and this persistence is observed in twin studies as well (Morgan, 1973; Morgan, Hilgard, & Davert, 1970).

3. Additional evidence of coherence of the domain comes from reports of hypnotized Subjects about their phenomenological experience.

Hilgard's discussion of the executive and monitoring functions within hypnosis place his theory within the area of cognitive psychology. He presents a theory of a central regulating mechanism, with a hierarchy of subsystems that may be activated (and once activated may continue with some autonomy). When autonomous action occurs, the conscious representation of the control system may recede. Furthermore, the hypnotist's suggestions may alter the relationships within the hierarchy of subsystems and may also influence the executive functions. He gives as a common example, when a bilingual person talks in one language, the other language is temporarily inhibited.

There are a number of concepts or positions in the history of psychology that relate to Hilgard's theory of hierarchical control with executive and subsystems:

1. 'Cognitive structure' (Edward Tolman, 1932; 1938; Kurt Lewin, 1935). There may be communication problems between cognitive structures.
2. 'Habit family hierarchy' (Clark Hull, 1934). Habits are organized in a preferential system, so that if one is blocked the next is activated.
3. 'Cell assemblies' (Hebb, 1949; 1975), which are a physiological counterpart of the 'hidden observer' phenomenon.
4. 'Roles' (Sarbin & Coe, 1972) may be considered cognitive substructures.
5. 'Cognitive networks' (Blum, Geiwitz, & Stewart, 1967) serve similar functions.
6. 'Images' and 'plans' (Miller, Galanter, & Pribram, 1960) provide for control of thought and action and have some kind of hierarchy.
7. 'Subordinate ego-structures' (Gill & Brenman, 1959) with a dominant ego; or the ego-apparatuses in a 'conflict-free ego sphere' (Hartmann, 1958).

In hypnosis, central executive functions may be shared between hypnotist and Subject. Hilgard gives extensive examples of varying degrees of split in the executive control system.

"It can be argued that, except for relinquishing control over the subsystems that are specifically dissociated from control by suggestion, and the readiness for relinquishing control, the central executive functions have not been much modified

in hypnosis. In superficial hypnosis, these mild dissociations can occur through waking suggestions, with little alteration of the general state of consciousness. When varied suggestions to a talented hypnotic subject have cumulative effects, as in suggestions of relaxation and detachment from the environment, the more general features of the hypnotic state begin to appear. A more massive dissociation, so far as the executive is concerned, may be the consequence of the summing up of many specific subsystems for which control has been relinquished. Such an interpretation permits hypnosis as a state to be a relative matter, the specific dissociations being identifiable, but the general state being a matter of how many specific dissociations are operative and how pervasive they are. Only when they are sufficiently pervasive is it appropriate to speak of a change of state" (p. 96).

Hilgard also discusses the monitoring function extensively, relating it to trance logic and contrasting it with the waking state. Less of the usual monitor is retained when the hypnotic involvement is greater, as in deep hypnosis, or when the subject becomes more deeply engrossed in an activated system that has been aroused. He also relates the monitoring function to the Hidden Observer phenomenon.

Holroyd, Jean (1992). Hypnosis as a methodology in psychological research. In Contemporary hypnosis research (pp. 201-226). New York: Guilford Press.

#### NOTES:

This chapter deals with how the changes brought about by hypnosis (in cognition, behavior, motivation, etc.) may be used in research in other areas of psychology. "The distinction between experimental effects attributable to a personality trait (i.e. hypnotizability), hypnosis context (i.e. an induction), and interaction between the two is particularly important in using hypnosis as a research strategy.

The author discusses suggestibility, imagery enhancement, and changes in the mind-body relationship (immunology, pain, cognitive neuropsychology, attention, learning and memory, and awareness) as they might be employed in social psychology or psychophysiology research. She reviews problems inherent in using hypnosis as part of the research methodology, while noting that hypnosis nevertheless offers new information when introduced into traditional content areas. "For example, in cognitive psychology it has re-introduced the importance of studying experiential aspects of cognition, i.e. I think, I remember, or self reference (Kihlstrom, 1987)" (p. 223).

She concludes, "Hypnosis as a research method will continue to benefit from contributions of radically different theoretical views of hypnotic phenomena. Social-cognitive psychologists have contributed significantly toward unifying the fields of hypnosis research and general experimental psychology. At the same time, advances in neurophysiology and psychosomatic medicine employing hypnosis indicate that there is a role for hypnosis as a research strategy, solely because of its altered-state characteristics. If theoretical physics can reconcile both wave and particle theories of light, it is conceivable that psychology can accommodate both behavioral and state theories of hypnosis" (p. 224).

**Kihlstrom, John F.; Barnhardt, Terrence M.; Tataryn, Douglas J. (1992). The psychological unconscious. American Psychologist, 47, 788-791.**

**In response to Greenwald's article on contemporary research on unconscious mental processes, the authors address three issues: (a) the independence of much recent research and theory from psychodynamic formulations; (b) the broad sweep of the psychological unconscious, including implicit perception, memory, thought, learning, and emotion; and (c) the possibility that the analytic power of unconscious processing may depend both on the manner in which mental contents are rendered unconscious and the manner in which they are to be processed.**

**Kunzendorf, Robert; Carrabino, Carlene; Capone, Daniel (1992-93). 'Safe' fantasy: The self-conscious boundary between wishing and willing. Imagination, Cognition and Personality, 12, 177-188.**

**This experiment tested the hypothesis that a fantasy will impel people to 'act out' only if they fail to distinguish the fantasy from the anticipated reality. In the experiment, one task obtained a baseline measure of how long subjects could resist eating popcorn, then measured how long subjects could resist popcorn while fantasizing its taste. Another task instructed subjects to merge three circular images with three circular percepts of equal vividness, then presented subjects unexpectedly with only two of the three circular percepts. Some subjects thought that there were three circular percepts during the merger, and for these subjects, the length of resistance to popcorn was significantly shorter during the popcorn fantasy. But for subjects who self-consciously differentiated the two real circles from the three merging images, the normal 'boundary' between wishful fantasy and willful eating was intact.**

#### **NOTES**

**This research investigated whether people can fantasize without acting out. The authors place the study in the context of theories proposed by Freud and William James. Kunzendorf's source monitoring theory of self-consciousness suggests that "self-consciousness \_that one is imaging\_ is the phenomenal consequence of neurally monitoring the central source of one's imaged sensations, and self-consciousness \_that one is perceiving\_ is the subjective quality of neurally monitoring the peripheral source of one's perceived sensations" (p. 178).**

**The ability to carry out source monitoring varies. Those who have difficulty monitoring whether they are imaging or perceiving may also have trouble distinguishing wishful fantasy from anticipatory imagery, and therefore they might act on it.**

**This research "identified subjects with poor source monitoring--nondiscerners of reality--and investigated the effect of fantasy on their impulse control" (p. 179).**

#### **METHODS**

**Subjects sat in front of a computer monitor for all tests; they completed Eysenck's seventh impulsivity questionnaire for measures of impulsivity, venturesomeness, and empathy, Marks' Vividness of Visual Imagery Questionnaire (VVIQ).**

The study used a test in which subjects maintained in mental imagery a red, green, and yellow filled circle that had been on screen, with eyes closed; were instructed to open eyes and merge their 3 imaginary circles with the 3 on the screen (but when they opened eyes only 2 were there), and they were then asked questions about how many circles they saw when they opened their eyes.

Then they were given a taste of popcorn, told to resist eating any more (but could press a key to receive a little if they couldn't resist), and then were told to resist by imagining that they were eating popcorn.

## **RESULTS**

Those who discerned the two real circles while imaging a third circle of equal vividness (the Discerners), could resist eating popcorn for 137 sec in the baseline condition and 132 sec in the fantasy condition. Those who could not discern two real circles while imagining a third (Nondiscerners) could resist eating popcorn for 127 sec in the baseline treatment but only 95 sec in the fantasy treatment.

Discerners could identify the missing circle as the red one, whereas nondiscerners could not do so with any certainty; there was no effect of "image vividness".

"Vivid imagers" whose imagery matched real yellow circles of greater illuminance, exhibited more vivid imagery on the VVIQ as well.

In their Discussion, the authors suggest that "fantasy impels people to 'act out' only if they fail to distinguish fantasized sensations from perceived sensations. ... [the theory] is applicable to sexual fantasy and aggressive fantasy as well. This theory--Kunzendorf's 'source monitoring' theory of self-consciousness--implies that fantasies of the sensory consequences of a behavior should not lead to the behavior, so long as the fantasies are self-consciously known to be imaginal and are not expected to be perceptual... But for people who cannot self-consciously distinguish between wishful images of pure fantasy and anticipatory images of perceptual reality, between wishing and willing, fantasies of gastronomical, sexual, or aggressive sensations are implicitly unsafe.

"Indeed, as Baars notes, 'the issue of voluntary control is at the very core of human psychopathology' [31, p. 254]. But recently, Baars' and others' theories of volition have emphasized the computer-metaphoric distinction between conscious 'willful' behavior and unconscious 'automatic' action [31, 39-40], and have neglected James' distinction between conscious willing and conscious wishing. Decades ago, when pre-computational theorists like Janet used the term 'automatism' to describe psychopathological behavior, they meant that an abnormally behaving patient was \_consciously 'possessed' by a fantasy\_--a wishful image, a hypnotic suggestion, or a fantasized personality [41]. In reemphasizing the phenomena of wishing, willing, and possession by fantasies, the present article redefines the latter phenomenon as possession by 'unmonitored' fantasies, which are distinguishable from anticipatory images impelling action" (pp. 184-185).

**Levitan, Alexander A. (1992). The use of hypnosis with cancer patients. Psychiatric Medicine, 10, 119-131.**

Hypnosis has proven to be extremely valuable in the treatment of cancer patients. Specific applications include: establishing rapport between the patient and members

of the medical health team; control of pain with self-regulation of pain perception through the use of glove anesthesia, time distortion, amnesia, transference of pain to a different body part, or dissociation of the painful part from the rest of the body; controlling symptoms, such as, nausea, anticipatory emesis, learned food aversions, etc.; psychotherapy for anxiety, depression, guilt, anger, hostility, frustration, isolation, and a diminished sense of self-esteem; visualization for health improvement; and, dealing with death anxiety and other related issues. Hypnosis has unique advantages for patients including improvement of self-esteem, involvement in self-care, return of locus of control, lack of unpleasant side effects, and continued efficacy despite continued use.

**Loftus, Elizabeth F.; Klinger, Mark R. (1992). Is the unconscious smart or dumb?. American Psychologist, 47, 761-765.**

How sophisticated is unconscious cognition? This is one of the most fundamental questions about the unconscious that has been posed by research psychologists over the past century. Anthony Greenwald takes a contemporary look at this classical problem and concludes that unconscious cognition is severely limited in its analytic capability. In response, other leading scholars agree that the reality of unconscious processes is no longer questionable. Although there is some disagreement about just how sophisticated these processes are, the consensus is that exciting times are ahead for both research and theory concerning the mental processes involved in unconscious cognition.

**Miller, Scott D.; Triggiano, Patrick J. (1992). The psychophysiological investigation of multiple personality disorder: Review and update. American Journal of Clinical Hypnosis, 35, 47-61.**

#### **NOTES**

A review and methodological critique. Updates Putnam, 1984. Currently, psychophysiological differences reported in the literature include changes in cerebral electrical activity, cerebral blood flow, galvanic skin response, skin temperature, event-related potentials, neuroendocrine profiles, thyroid function, response to medication, perception, visual functioning, visual evoked potentials, and in voice, posture, and motor behavior. Reviews the new research on the psychophysiological investigation of MPD from published, unpublished, and ongoing studies, and attempts to place current findings into a conceptual framework. Authors note results from unpublished and ongoing studies and include a critical analysis of current research methodology as well as suggestions for future research.

**Ofshe, Richard J. (1992). Inadvertent hypnosis during interrogation: False confession due to dissociative state; mis-identified multiple personality and the satanic cult hypothesis. International Journal of Clinical and Experimental Hypnosis, 40, 125-156.**

Induction of a dissociative state followed by suggestion during interrogation caused a suspect to develop pseudo-memories of raping his daughters and of participation in a baby-murdering Satanic cult. The pseudo-memories coupled with influence from authority figures convinced him of his guilt for 6 months. During this time, the suspect, the witnesses, and all the evidence in the case were studied. No evidence supported an inference of guilt and substantial evidence supported the conclusion that no crime had been committed. An experiment demonstrated the suspect's extreme suggestibility. The conclusion reached was that the cult did not exist and the suspect's confessions were coerced- internalized confessions. During the investigation, 2 psychologists diagnosed the suspect as suffering from a dissociative disorder similar to multiple personality. Both psychologists were predisposed to find Satanic cult activity. Each concluded that the disorder was due to "programming" by the non-existent Satanic cult.

Perry, Campbell (1992). Theorizing about hypnosis in either/or terms. International Journal of Clinical and Experimental Hypnosis, 40, 238-252.

The present paper addresses 3 issues raised by Coe (1992). First, it maintains that the "altered state" issue of the 1960s remains buried in current dichotomous classifications of hypnosis theories as involving either "special processes" or the social- psychological position. Given the current diversity of the field, it appears imprudent to classify theorizing in either/or terms; additionally, despite a history of using the term "altered state" in a circular way, it is not an inherently circular formulation. It can be used descriptively simply to point to the observation that some individuals in hypnosis report subjective alterations. A second issue broached concerns the metaphorical status of the term "hypnosis"; it is accepted as a misleading metaphor inherited from 19th century investigators such as Braid, Faria, Puysegur, and Liebeault. Provided that it is recognized that this metaphor refers to a "domain" (E. G. Hilgard, 1973) of characteristically elicited behaviors, no problem ensues in retaining this metaphor derived from nocturnal sleep. A subsequent discussion of current conceptualizations of hypnosis indicates considerable agreement among investigators; there is much consensus that hypnosis is an individual differences phenomenon, in which imagination may, in some individuals, become so intense and so vivid, as to take on "reality value," to the extent that a hypnotized person may have difficulty in distinguishing fantasy from reality. The S abilities of imagery/imagination, absorption, dissociation, and automaticity (which may be proved to be an index of dissociation) are proposed as being the main ingredients of the hypnotic experience. Finally, a synergistic approach is proposed as a means of progressing beyond the current impasse of either/or theorizing.

1991

Bowers, Kenneth S. (1991). Dissociation in hypnosis and multiple personality disorder. International Journal of Clinical and Experimental Hypnosis, 39, 155-176.

The first part of this paper examines the concept of dissociation in the context of hypnosis. In particular, the neodissociative and social psychological models of hypnosis are compared. It is argued that the social psychological model, in describing hypnotic enactments as purposeful, does not adequately distinguish between behavior that is enacted "on purpose" and behavior that serves or achieves a purpose. 2 recent dissertations (Hughes, 1988; Miller, 1986) from the University of Waterloo are summarized, each of which supports the neodissociative view that hypnotic behavior can be purposeful (in the sense that the suggested state of affairs is achieved) and nonvolitional (in the sense that the suggested state of affairs is not achieved by high level executive initiative and ongoing effort). The second part of the paper employs a neodissociative view of hypnosis to help understand the current epidemic of multiple personality disorder (MPD). In particular, it is argued that many symptoms of MPD are implicitly suggested effects--particularly prone to occur in persons who have a lifelong tendency to use dissociative type defenses. The present author believes that this account is easier to sustain conceptually and empirically than the current view, which states that a secondary (tertiary, etc.) personality accounts for the striking phenomenological discontinuities experienced by MPD patients.

#### NOTES

As an example of the fact that behavior that serves a purpose is not always performed on purpose, the author cites not falling out of bed while sleeping, and waking up in response to signals from the bladder to go to the bathroom. Lower levels of control can be dissociated from executive initiative and/or monitoring. "Since the experience of volition is closely tied to executive initiative and effort, suggested behaviors that bypass such initiative and effort are typically experienced as nonvolitional" (p. 157). Dissociated control occurs under waking conditions also, as when one dials a very familiar phone number rather than the one that they intended to dial. In this case, the behavior that is enacted is not what one consciously intended.

Miller's dissertation, also published as Miller & Bowers, 1986, is described on p. 158 ff. Without hypnosis, cold pressor pain (cold water immersion) reduced accuracy of performance on a multiple choice vocabulary test 35%. Both hypnotic analgesia and cognitive pain management strategies were equally effective in reducing pain of cold pressor test (and both interventions were more effective for high than for low hypnotizable Ss). However, the cognitive strategy group showed an additional drop of 30% in vocabulary performance from pre- to posttreatment cold water immersion (despite successfully reducing their pain). In the hypnosis condition, lows showed only a slight additional decrease (8%) while highs showed a slight (10%) increase in their vocabulary performance from pre- to posttreatment immersion. Thus, the effect of hypnosis in pain control "does not depend on S's utilization of high-level cognitive strategies. Rather, hypnotic analgesia seems to involve the dissociated control of pain--that is, control which is relatively free of the need for high- level, executive initiative and effort. ... Because hypnotic analgesia minimizes the degree of executive initiative and ongoing effort required to reduce pain,

however, it seems inappropriate to view such reductions as something achieved on purpose" (p. 161).

Hughes' dissertation is described on p. 162 and ff. Instead of performance decrement on a cognitive task like vocabulary testing, she used increased heart rate as an index of cognitive effort. If heart rate increases when Ss successfully use hypnotic imagery, that would confirm the social psychological view that "suggested effects are achieved by this kind of ongoing allocation of high-level cognitive force or work" (p. 162).

Highs and lows were hypnotized and administered three trials of neutral and three trials of fearful imagery in counterbalanced order. Each imagery trial lasted 1 minute, after which Ss rated vividness of imagery, effort required, and amount of fear experienced.

Average imagery vividness was higher in highs than lows, for both neutral and fear imagery. For lows the correlation between heart rate increases and ratings of cognitive effort were .54 (neutral imagery) and .49 (fear imagery). For highs, the correlations were -.05 (neutral) and -.52 (fear). Thus, "for low but not high hypnotizable Ss, we find the predicted positive relationship between a cardiac indicator of cognitive effort and the ratings of cognitive effort involved in producing neutral imagery" (p. 163).

"First, for low hypnotizables engaged in fear imagery, ratings of effort are correlated .66 with ratings of fear. In other words, the more low hypnotizable Ss work to produce a fearful image, the more frightening the image is. Second, for high hypnotizables engaged in fear imagery, the correlation between ratings of fear and effort is minus .68-- indicating that the less effort highs report in producing fear imagery, the more frightened they become. Finally, for high hypnotizables, the correlation between ratings of fear and heart rate increase is .59, indicating that the more fear high hypnotizable Ss experience when engaged in fear imagery, the more their heart rate increases (the comparable figure for low hypnotizables is .16)" (p. 164).

The authors discuss why the pattern of correlations is different for people high and low in measured hypnotizability, and summarize the implications of both Miller's and Hughes' research. Both investigations indicate that, at least for high hypnotizable people, less initiative and effort are required to effect a response to hypnotic suggestion than one would expect. They show how behavior can be both purposeful and nonvolitional (in the sense of not exhibiting conscious intention and strategic efforts). By noting that the sense of nonvolition that accompanies a response to suggestion is an actual alteration in executive control, they provide a model for dissociative psychopathology such as MPD. For although executive control is dissociated, these experiments do not suggest that there is a second executive system or 'personality' that is responsible for the behavior.

Patients diagnosed with MPD have very high measured hypnotizability (Bliss, 1984). In fact, they seem to engage in self hypnosis, withdrawing into a trance or a dissociated state (Bliss, 1984). The authors quote Wilson & Barber (1983) as indicating that highly hypnotized, fantasy-prone normal individuals may become so absorbed in a character being imagined that they lose awareness of their own identity.

The authors offer a neodissociative account of MPD: "People prone to MPD are very high in hypnotic ability and are, therefore, vulnerable to the suggestive impact of ideas, imaginings, and fantasies; what is more, they are high in hypnotic ability because they have learned to use dissociative defenses as a way of dealing with inescapable threat-- such as physical and sexual abuse (Kluft, 1987). ... Fantasied alternatives to reality (including a fantasied alter ego ... ) can become increasingly complex and differentiated. Gradually, these fantasied alternatives begin to activate subsystems of control more or less directly--that is, with minimal involvement of executive level initiative and control. Such 'dissociated control' of behavior does not necessarily eliminate consciousness of it, though one's actions are apt to be experienced as increasingly ego-alien. If and when the activating fantasies and resulting behaviors become sufficiently threatening, however, they can also be repressed into an unconscious (i.e., amnesic) status, thus further separating high-level executive and monitoring functions from the dissociated, ego-alien aspects of oneself. The fully realized result of this process is an individual who is subject to profound discontinuities in his or her sense of self. ... The experience of behaving in an outwardly uncharacteristic manner requires only that subsystems of control are more or less directly activated by ideas and fantasies in a manner that effectively bypasses executive initiative and control" (pp. 168-169).

923, Bowers, 1992 NOTES: Tart allegedly taught ESP skills based on reinforcement, using a machine that projected display and gave feedback immediately, so the subjects could learn to anticipate the picture better. But the picture presented next was time-linked to the S's response (so S could learn it).

1987 Behavioral and Brain Sciences review, with 2 target articles, makes one doubt strength of findings. ESP research doesn't distinguish between description of an observation and it's proposed cause.

MPD shares with ESP a tendency to predispose toward a certain explanation. Feeling like one has a separate personality leads to finding evidence for one. But an MPD account is wrong-headed because the diagnosis misconstrues a notion of personality, which is a developmental concept (a pattern of thought, feeling, and behavior). Mischel's (1968) account of human functioning competed with trait theory, so "personality" concept became extraneous.

Defining personality in terms of one's experiences or beliefs about oneself has led to further problems, encouraged by the descriptive approach of DSM III (which depends on patient reports). Drew Weston distinguished between the self and self representation. One can't argue that a computer programmed to describe itself is the same as it's descriptions.

Personality can't be reduced to person's beliefs about themselves. A secondary personality cannot be reduced to bizarre experiences a person believes are due to a second personality. Clinicians do not accept as valid the beliefs of a paranoid schizophrenic; or of an anxious neurotic. With multiple personality disorder (MPD) the patient becomes the expert and the clinician the student.

William Smith's 1986 SCEH paper: case study of patient who was convinced her problems were due to unresolved problems from a previous life. He didn't challenge her system but still worked with her successfully, communicating respect without validating her belief.

Advocates of MPDs think the observation that it is associated with high hypnotizability indicates great dissociation; critics think the association indicates great suggestibility. There is a historical parallel: Mesmer probably didn't suggest seizure-like episodes, but implicit suggestions for seizures were probably partially responsible. Mistaken attribution permitted Mesmer to see this as validation of his theory of animal magnetism.

Clinicians are not the only ones to "suggest" MPD syndrome. High profile cases are in the media. We should also remember Orne's 1959 research showing that students who received false information a week earlier in lecture on hypnosis showed the behavior when they were hypnotized.

Janet's disaggregation (dissociation) theory said hysterics and hypnotized people responded to ideas dissociated from the main stream of consciousness. So his contemporaries thought that spontaneous amnesia was a defining feature of hypnosis; yet it is not thought to be so in our era. The idea may have circulated in Janet's time, by popular culture.

MPDs are always highly suggestible so can respond to circulating accounts in the media, and every account that reaches the media can influence these people.

We could abandon the diagnosis of MPD in favor of Spiegel's "disorder of self integration." It is less provocative, does not imply any clinical benefit in the benefits of seeking out more personalities. This might reduce the incidence of this disorder, or likelihood that a suggestible person would develop the disorder iatrogenically.

Brown, Jason W. (1991). Self and process: Brain states and the conscious present. New York: Springer-Verlag.

## NOTES

Author, from the Department of Neurology at New York University Medical School, presents a theory about the genetic unfolding of mental content (mind) through stages, from mental state into consciousness or into behavior. He relates the genesis of mind to brain development but avoids assuming that there is a straightforward correlation between brain development (e.g. myelination) and cognitive development or perception. To some degree, the theory is based on subjective report data and psychological symptoms. The author discusses issues that bear on the phenomena of nonvoluntary responding and dissociation that are reported or described by hypnotized persons.

"The nature of the mental state will determine the relation between self and world, and thus the interpretation given to agency and choice. ... The crossing of the boundary from self to world is a shift from one level in mind to another" (pp. 10-11).

"... if we begin with mind as primary and seek to explain objects from inner states and private experience, the discontinuity between inner and outer evaporates: mind is everywhere, a universe. ... Whereas before we thought to perceive objects, now we understand that we think them" (p. 19).

"The concept of a stratified cognition is central to the notion of a mental state .... This entails an unfolding from depth to surface, not from one surface to the next, a direction crucial to agency and the causal or decisional properties of consciousness"

(p. 52). By unfolding from depth to surface, he means from Core, through Subconscious, then Conscious Private Events, and finally Extra-Personal Space. He goes on to provide a definition of mental states. "A mental state is the minimal state of a mind, an absolute unit from the standpoint of its spatial and temporal structure. ... The state also has to include the prehistory of the organism. ... The concept of a mental state implies a fundamental unit that has gestalt-like properties, in that specific contents-- words, thoughts, percepts--appear in the context of mind as a whole (p. 53).

"The entire multitiered system arborizes like a tree, with levels in each component linked to corresponding levels in other components. For example, an early (e.g., limbic) state in language (e.g., word meaning) is linked to an early stage in action (e.g., drive, proximal motility) and perception (e.g., hallucination, personal memory) ... In sum, a description of the spatial and temporal features of a single unfolding series amounts to a description of the minimal unit of mind, the absolute mental state" (p. 54).

The author's discussion of an individual's physical movement relates to the concept of nonvoluntary movement (or movement without awareness of volition) in hypnosis. "More precisely, levels in the brain state constitute the action structure. As it unfolds, this structure generates the conviction that a self-initiated act has occurred. This structure--the action representation--does not elaborate content in consciousness. ... As with the sensory-perceptual interface, the transition to movement occurs across an abrupt boundary. In some manner, perhaps through a translation of cognitive rhythms in the action to kinetic patterns in the movement, levels in the emerging act discharge into motor (physical) events" (p. 57).

"The self has the nature of a global image or early representation within which objects-to-be are embedded. ... The self is the accumulation of all the momentary cognitions developing in a brain configured by heredity and experience in a particular way (p. 70).

"The deposition of a holistic representation ... creates the deception of a self that stands behind and propagates events. The feeling of the self as an agent is reinforced by the forward thrust of the process and the deeper locus of the self in relation to surface objects. The self appears to be an instigator of acts and images when in fact it is given up in their formation. The self does not cause or initiate, it only anticipates (p. 70).

The foregoing notes cover only the first five chapters, less than half the book. Other chapters relevant to hypnosis would be those titled 'The Nature of Voluntary Action,' 'Psychology of Time Awareness,' 'From Will to Compassion,' and 'Mind and Brain.'

**Brown, Peter (1991). The hypnotic brain: Hypnotherapy and social communication. New Haven, CT: Yale University Press.**

**NOTES: Notes are taken from a review of this book: Diamond, Michael (1993). Book review. Bulletin of the Menninger Clinic, 57 (Winter), 120-121.**

Brown "posits that because the fundamental matrix of the human brain is metaphoric, hypnosis results from skillful matching of metaphorical communication with the brain's biological, rhythmic alterations. The most significant feature of trance experience is thereby located in the hypnotist-subject interaction" (p. 120).

"The middle section [of the book is comprised largely of] literature reviews in support of Rossi's (1986) ultradian rhythm theory of hypnosis and Lakoff and Johnson's (Johnson, 1987; Lakoff & Johnson, 1980) experientialist theory of conceptual thought" (p. 120). The final section includes "research evidence on medical uses of hypnosis, a theory of dissociation and multiple personality disorders, and an uncritical discussion of Milton Erickson's naturalistic hypnotherapeutic approach ... [and also] a brief discussion of the social-cultural functions of possession states among the Mayotte culture" (p. 120).

Cornell, William F.; Olio, Karen A. (1991). Integrating affect in treatment with adult survivors of physical and sexual abuse. American Journal of Orthopsychiatry, 61 (1), 59-69.

Presents a theoretical and technical model for affectively centered treatment of adults abused as children, focusing on the function of denial and dissociation as central defense mechanisms. The concept is introduced of working at an "affective edge." At this experiential point, a client can maintain both cognitive understanding and emotional and bodily awareness without triggering denial and dissociation. This approach fosters careful monitoring of the client's functioning both during and between therapeutic sessions. The proposed therapeutic approach uses noninvasive touch and body-centered techniques. Focus is on integrating affect and on the importance of the therapeutic relationship.

Dixon, Norman F.; Henley, Susan H. (1991). Unconscious perception: Possible implications of data from academic research for clinical practice. Journal of Nervous and Mental Disease, 179 (5), 243-252.

Evidence for the reality of unconscious perception and perceptual defense suggests that the experimental paradigms used to investigate these phenomena might play a role in the understanding and treatment of mental disorders. The literature on applying subliminal stimulation to problems of diagnosis and therapy indicates that data support the view that the meaning of external stimuli of which the recipient is unaware may be responded to and determine emotional responses, lexical decisions, overt behavior, and subjective experience. Data confirm the reality of psychopathology as a substrate of emotionally colored, stored information with a potential for producing somatic symptoms and disorders of thinking, affect, and behavior. To the extent that psychopathology is screened from conscious scrutiny and thus impervious to supraliminal information, it may be accessed and ameliorated by drive-related stimuli of which the S is not aware.

Frankel, Fred H. (1991). Comments on hypnotizability and dissociation. American Journal of Psychiatry, 148 (6), 814-815.

**NOTES:** Responds to comments by D. Spiegel and E. Cardena (see PA, vol 78:29491) concerning F. H. Frankel's (see PA, vol 77:27535) article in which he cautioned against over interpreting the relationship between hypnotizability and dissociation. It is reiterated that the concept of dissociation has been elaborated in recent years to an exaggerated degree.

**Frischholz, Edward J.; Braun, Bennett (1991, August). Diagnosing dissociative disorders: New methods. [Paper] Presented at the annual meeting of the American Psychological Association, San Francisco.**

Five new methods which have proven useful in the differential diagnosis of dissociative disorders from other psychiatric syndromes are identified. The first method involves the use of the Dissociative Experiences Scale, a self-report questionnaire which significantly discriminates dissociative psychopathology from normal dissociative experiences. The second method involves the use of various measures of hypnotizability (e.g., Hypnotic Induction Profile; Stanford Hypnotic Susceptibility Scale, Form C; self-ratings of hypnotizability) in discriminating between various psychiatric groups. The third method involves the use of qualitative responses to individual test items (e.g., instructed posthypnotic amnesia) to discriminate between different psychiatric syndromes. The fourth method involves the use of an implicit memory test to measure the amount of between-personality state amnesia in patients suffering from Multiple Personality Disorder. The fifth method involves the use of special hypnotic phenomena (e.g., the Orne double person hallucination and the Hilgard hidden observer item) to discriminate between dissociative disorder patients and subjects simulating dissociative psychopathology. (ABSTRACT from Bulletin of Division 30, Psychological Hypnosis, Provided by former Editor, James Council.)

#### **NOTES**

Five new methods have proven useful in the differential diagnosis of dissociative disorders. The first method involves the use of the Dissociative Experiences Scale, a self-report questionnaire which significantly discriminates dissociative psychopathology from normal dissociative experiences.

The second method involves the use of various measures of hypnotizability in discriminating between various psychiatric groups.

The third method involves the use of qualitative responses to individual test items (e.g., instructed posthypnotic amnesia) to discriminate between different psychiatric syndromes.

The fourth method involves the use of an implicit memory test to measure the amount of between-personality state amnesia in patients suffering from Multiple Personality Disorder.

The fifth method involves the use of special hypnotic phenomena (e.g., the Orne double person hallucination and the Hilgard hidden observer item) to discriminate between dissociative disorder patients and subjects simulating dissociative psychopathology.

**Barabasz, Marianne (1990). Treatment of bulimia with hypnosis involving awareness and control in clients with high dissociative capacity. International Journal of Psychosomatics, 37, 53-56.**

The details of an easily replicable intervention using hypnosis in the treatment of bulimia are presented. Follow-ups at 1, 3, 6, and 12 months indicated the intervention appeared effective in two out of the three cases presented. Factors affecting treatment outcomes are discussed.

**Bartis, Scott P.; Zamansky, Harold S. (1990). Cognitive strategies in hypnosis: Toward resolving the hypnotic conflict. International Journal of Clinical and Experimental Hypnosis, 38, 168-182.**

Two experiments were carried out to assess the relative contributions of dissociation and absorption as cognitive strategies employed by high and low hypnotizability Ss in responding successfully to hypnotic suggestions. Of special interest was the manner in which Ss deal with conflicting information typically inherent in hypnotic suggestions. In the first experiment, Ss rated their attentional focus and the involuntariness of their experience after responding to a number of hypnotic suggestions administered in the usual manner. In the second experiment, the level of conflict was varied by instructing some Ss to imagine a circumstance that was congruent and other Ss to imagine a circumstance that was incongruent with the suggested behavioral response. The results of the 2 experiments were consistent in suggesting that, depending upon the nature of the hypnotic suggestion, high hypnotizability Ss are able to employ dissociation or absorption in order to respond successfully. Low hypnotizability Ss, on the other hand, seem to be relatively ineffective dissociators. When the structure of the hypnotic suggestion precludes the use of absorption, the performance of low hypnotizables deteriorates.

**Briere, John; Runtz, Marsha (1990). Augmenting Hopkins SCL scales to measure dissociative symptoms: Data from two nonclinical samples. Journal of Personality Assessment, 55, 376-379.**

Describes a 13-item dissociation scale (DS) that uses numerical ratings and presents preliminary data regarding its reliability. The DS was administered to 2 samples of undergraduate women (N=569). Ss also completed the SCL-90 or the Hopkins Symptom Checklist (HSCL). The DS was found to be reliable, and there was a correlation of the DS with self-reported child abuse history. Designed to complement the SCL-90 and the HSCL, the DS may be useful in research on the effects of psychological trauma.

**Counts, R. M. (1990). The concepts of dissociation. Journal of American Academy of Psychoanalysis, 18, 460-479.**

Reviews conceptualizations of dissociation. Dissociation is the underlying mechanism in a number of defensive mechanisms. Repression, intellectualization, splitting, and other defense mechanisms rely upon dissociation to accomplish their specific tasks. Dissociation is thus believed to be the underlying and basic mechanism of many aspects of mental functioning.

**Demitrack, Mark A.; Putnam, Frank W.; Brewerton, Timothy D.; Brandt, Harry A.; et al. (1990). Relation of clinical variables to dissociative phenomena in eating disorders. American Journal of Psychiatry, 147 (9), 1184-1188.**

Compared 30 female patients (aged 16-39 yrs) with eating disorders with 30 age-matched normal female Ss, using the Dissociative Experiences Scale (E. M. Bernstein and F. W. Putnam; see PA, Vol 74:14407) and additional self-report measures such as the Beck Depression Inventory. The patients demonstrated significantly higher levels of dissociative psychopathology compared with controls. Furthermore, the presence of severe dissociative experience appeared to be specifically related to a propensity for self-mutilation and suicidal behavior. Findings are discussed in light of recent data suggesting that neurochemical systems shown to be abnormal in patients with eating disorders may be key pathophysiological substrates for dissociative experience.

**Downs, John M.; Dahmer, Sharon K.; Battle, Allen O. (1990). Multiple personality disorder in India. American Journal of Psychiatry, 147 (9), 1260.**

Comments on the article by Adityanjee et al (see PA, Vol 77:12344) on multiple personality vs possession syndrome in India. The history of the trends of these disorders is presented, and the differences between multiple personality and possession are described. The only fundamental difference between the 2 disorders may be in the voluntary type.

**Fellows, Brian J. (1990). Current theories of hypnosis: A critical overview. British Journal of Experimental and Clinical Hypnosis, 7, 81-92.**

The present state of theory in hypnosis is reviewed and observations are made concerning future prospects. The state- non-state issue continues to dominate theoretical debate, although no satisfactory reply has yet been made to T. X. Barber's criticisms of the 'hypnotic trance' concept. The impact of social-psychological theory has been considerable and the results of Spanos's hypnotic training programme could have significant implications for our understanding of hypnosis. Future theorizing should see a move towards a more integrated sociocognitive approach. Neodissociation theory has generally not fulfilled its early promise and is encumbered with the 'hidden observer' concept. The role of imaginative processes continues to be a dominant theme in hypnosis theory, although the relatively small correlation between imaginative and hypnotic abilities remains a problem. The links between hypnosis, sleep and relaxation deserve further research, although, as theories of hypnosis, their scope seems limited.

Suggestibility and role enactment theories have shown few signs of development in recent years. Theoretical problems over the interpretation of hypnosis need to be more widely recognized and the use of question-begging terminology curtailed. One advantage of the imagination hypothesis is that it provides a bridge, or a point of convergence, between state and non-state approaches (Spanos & Barber, 1974). It also handles certain hypnotic phenomena very well. For example, the known facts of age regression can be readily interpreted, together with the oddities of age progression and past life regression, as imaginative reconstructions (Barber, 1979). However, other phenomena, such as amnesia and analgesia, are less easily explained.

Fischer, Donald G.; Elnitsky, Sherry (1990). A factor analytic study of two scales measuring dissociation. American Journal of Clinical Hypnosis, 32, 201-207.

The present study was designed to investigate the construct validity of dissociation. We administered the PAS and the DES to 507 male (48%) and female (52%) undergraduate students. Factor analysis on each scale separately showed that neither the PAS nor the DES adequately measures the three dimensions hypothesized to underlie dissociative experience. For both scales, a single factor emerged as replicable and reliable. Use of the scales, in their present form, therefore, should be limited to a single dimension representing disturbances in affect-control in the case of the PAS and disturbances in cognition-control if the DES is used at least with normal populations. Analysis of the combined items showed that the scales are measuring conceptually different but statistically correlated dimensions of dissociation. Further development of both scales is desirable, and further research should investigate the effect of different response formats on the internal structure of the scales.

#### NOTES

The stated purpose of this study was to investigate the internal structure of the Perceptual Alterations Scale (PAS) and the Dissociative Experiences Scale (DES) using a large sample from a normal population.

"Sanders (1986) conceived of dissociation as a personality trait that is characterized by modification of connections between affect, cognition, and perception of voluntary control over behavior, as well as modifications in the subjective experience of affect, voluntary control, and perception. She chose items from the MMPI to represent this trait. Bernstein and Putnam (1986), utilizing the DSM-III definition of dissociation, constructed items from information derived from interviews with patients and clinicians to represent a number of different types of dissociative experiences" (0. 202).

"The PAS (Sanders, 1986) is a 27-item scale; subjects respond by checking one of the following categories using a 4-point Likert format: never, sometimes, frequently, almost always. The items related to modifications of regulatory control, changes in self-monitoring, concealment from self and others, and modifications of sensory, perceptual, and affective experiences.

"The DES (Bernstein & Putnam, 1986) contains 28 items. Subjects indicate the percentage of time they experience the feelings or behavior described by the items on a 10- point scale. The items related to the experience of disturbances in identity, memory, awareness and cognition, and feelings of derealization or depersonalization" (pp. 202- 203).

Results were as follows. The one-factor solution for the PAS accounted for 18.5% of the total variance.; 11 of the 28 items did not load significantly on the factor. The one-factor solution for the DES accounted for 26.3% of the total variance; 7 of the 28 items did not load significantly on the factor.

"The 3-factor solution obtained by Sanders (1986) for the PAS was not replicated. An obvious reason for the different is that principal factor extraction was used in the present study, whereas principal components extraction was utilized by Sanders. ... Even when principal components analysis is performed on the present data, however, there are difficulties with the 3-factor solution" (pp. 204-205).

"All of the criteria suggest that a single factor best represents the latent structure of dissociative experience as measured by the PAS and DES. Although the total amount of variance accounted for is low, the one-factor solutions for both scales are interpretable, replicable, and have high internal consistency. The items for the PAS appear to represent primarily the affect and control dimensions, whereas those for the DES represent the cognitive dimension" (pp. 205-206).

"Overall, both scales contain similar items, although the DES has more items relating to disturbances in memory and altered perception of time (i.e., cognition), whereas the PAS has more items reflecting specific disturbances in identity and control. It appears, therefore, that the scales are measuring conceptually separate but statistically correlated dimensions of dissociation" (p. 206).

Frankel, Fred H. (1990). Hypnotizability and dissociation. American Journal of Psychiatry, 147, 823-829.

Describes the multidimensionality of hypnosis and hypnotizability. He also points to the lack of clarity regarding the concept of dissociation and the extent to which its roots lie in the clinical experience of hypnosis. The concept of dissociation increasingly preempts repression and other defense mechanisms in current nosological thinking. The author cautions against equating hypnosis scores with dissociative capacity and advocates a clearer elaboration of the term "dissociation." Meanwhile, restraint in the use of the term "dissociation" is recommended.

Freeman, William B., Jr.; Kessler, Marc; Vigne, Jeffery (1990). Random number generation, absorption, and hypnotizability: A brief communication. International Journal of Clinical and Experimental Hypnosis, 38, 10-16.

Graham and Evans (1977) found that a measure of random number generation (RNG) was related to hypnotizability. In 2 studies, the relationship between hypnotizability and Graham and Evans' RNG (1977) index was examined. In Study 1 Evans' (1981) measures of controlled and automatic absorption were also evaluated. In Study 1 no relationship was found between the measures of absorption

or RNG and hypnotizability. Since Study 1 was carried out primarily to evaluate methods for modifying hypnotizability, Study 2 was designed to evaluate RNG measure directly. Study 2 found no consistent relationship between RNG and hypnotizability, or between RNG and measures of the experience of hypnotic depth and nonvolition.

Frischholz, Edward J.; Braun, B. G.; Sachs, R. G.; Hopkines, L.; Schaeffer, D. M.; Lewis, J.; Leavitt, F.; Pasquotto, J. N.; Schwartz, D. R. (1990). The dissociative experiences scale: Further replication and validation. Dissociation, 3, 151-153.

Interrater reliability for the DES was .96-.99, test-retest reliability was .93-.96, and internal consistency of DES scores was very high .93-.95. Both MPD and dissociative disorder NOS (DDNOS) patients scored significantly higher than students, and MPD patients scored significantly higher than DDNOS patients. A cutoff score of 45 to 55 maximizes the probability of distinguishing students from dissociative disorders (87%) while minimizing false positives (2%-6%) and false negatives (7%-11%). Suggestions for further research are made.

Gravitz, Melvin A. (1990). Adverse behavior associated with the eye-roll test of hypnotizability: Clinical and theoretical considerations. Psychotherapy: Theory, Research and Practice, 27, 267-270.

For 15 years, subjects' response to the eye-roll test has been used to measure susceptibility without adverse effects. A case is described of a hospitalized young man who displayed dissociative behavior when asked to do the eye-roll as part of a diagnostic evaluation. Etiological and theoretical considerations, and implications for therapeutic strategy are discussed.

Halleck, Seymore L. (1990). Dissociative phenomena and the question of responsibility. International Journal of Clinical and Experimental Hypnosis, 38, 298-314.

There are many controversies regarding the prevalence, causation, possible iatrogenicity, and treatment of multiple personality disorder. Those who view the disorder as much more prevalent than has previously been suspected believe it is caused by experiences of severe child abuse and have used rather unorthodox techniques to help the patient relate the experience of abuse to current problems of dissociation. Other clinicians believe the disorder is overdiagnosed and that it may be created or made worse by therapists who unwittingly reinforce symptoms of dissociation. Many of the controversies about these issues can be clarified by considering the manner in which clinicians attribute responsibility for undesirable conduct associated with the disorder. In dealing with multiple personality patients, clinicians regularly must decide whether their therapeutic approach will emphasize the patient's responsibility for undesirable conduct or will minimize it. Practical and theoretical arguments can be made for both approaches. There are important consequences to patients using either approach, and particularly harmful

consequences with inconsistent approaches. Clinical experience and wisdom dictate that until we have more objective data about the results of various forms of treatment, the preferred method of treatment of multiple personality patients should continue to focus upon maximizing their responsibility for any type of undesirable conduct.

Hughes, Dureen J.; Melville, Norbert T. (1990). Changes in brainwave activity during trance channeling: A pilot study. Journal of Transpersonal Psychology, 22, 175-189.

#### NOTES

Authors studied 10 people known trance channels--all had been channeling for more than one year. Used an anthropological field method. Electrode was placed only on left occipital (O1) area, referenced to left ear. Calculated difference between each S's pre- trance and trance EEG beta percentages, for alpha and theta percentages also.

Basically, the pre-trance versus trance sums of differences scores were greater than the post-trance versus trance sums of different scores for each of the three frequency bands--indicating a residual of the trance state. There were large, statistically significant increases in amount and percentage of beta, alpha and theta brainwave activity, and some suggestion of a pattern. The large amount of beta differentiates these Ss from what has been observed with meditators (increases in alpha and theta). Among the Subjects, large amounts of beta activity were recorded continuously throughout the trance period and were coupled with large amounts of high amplitude alpha and theta (relative to the pre- and post-trance states).

The authors compare these results to older hypnosis literature. They conclude that the trance channeling state may be a distinctive state characterized by a particular EEG profile that differs from that found in certain meditative states, hypnotic states, various pathological states, or the waking states of the trance channel Subjects who participated in the study. Authors also liken the differences seen between trance and non-trance states of these Subjects to the differences seen for different alter personalities among people diagnosed with Multiple Personality Disorder.

**DISCUSSION.** The foregoing research suggests that the trance channeling state, as measured in the current study, is characterized by large, statistically significant increases in amount and percentage of beta, alpha and theta brainwave activity. There appear to be definite neurophysiological correlates to the trance channeling state, and furthermore there is some evidence that these correlates may be patterned. This pattern might be provisionally compared to those associated with other altered states of consciousness.

Alvarado, C. S. (1989). Dissociation and state-specific psychophysiology during the nineteenth century. Dissociation, 2, 160-168.

Reviews examples of state-specific psychophysiology in nineteenth century reports of dissociative disorders. These cases occurred in the context of rapid developments both in neurology and in the understanding of phenomena suggesting the possible influence of the mind, emotions, or psychological states on general health and specific bodily functions (e.g., the study of hypnosis and hysteria). It is argued that interest in such cases was part of a general concern with mind/body interactions. The explanations offered to account for these cases reflected different orientations to the mind/body problem prevalent during this era.

Carlson, Eve Bernstein; Putnam, Frank W. (1989). Integrating research on dissociation and hypnotizability: Are there two pathways to hypnotizability?. Dissociation, 2, 32-38.

Attention to the relationship between hypnotizability and dissociation has been limited to date. Reviews recent studies implying a relationship between "dissociativity" and hypnotizability, and places in context of J. Hilgard's theory of two developmental pathways to hypnotizability (imagination/absorption and punishment). This might imply two subsets of hypnotizable persons, as Nadon et al. (1988) postulate--one with a dissociative style and one with an absorption style. Also, high capacity for imaginative involvement may be a necessary condition for a dissociative response to trauma. Branscomb (1988; unpublished) posits a genetic-stressor model for PTSD in which a history of dissociative-proneness and child abuse predispose one to PTSD when a trauma occurs in a non-supportive environment. Relates this theory to hidden observer research and to dissociative patients.

Gabel, Stewart (1989). Dreams as a possible reflection of a dissociated self-monitoring system. Journal of Nervous and Mental Disease, 177 (9), 560-568.

Argues that dreams may be thought of as dissociative phenomena of a particular type that reflect a monitoring of and reaction to internal and external conditions within the dreamer. Under conditions of sleep, memories, emotions, information processing, and judgments about internal and external events may occur independently of the usual waking conscious system's information processing. Experimental and/or clinical work, related to hypnosis, REM phenomena, dreams, and hemispheric specialization are discussed to support this view. Dreams are described within the context of dissociation-based theories of personality organization.

Ganaway, George K. (1989). Historical versus narrative truth: Clarifying the role of exogenous trauma in the etiology of MPD and its variants. Dissociation, 2, 205-220.

The author notes a current trend toward viewing multiple personality disorder (MPD) and its variants as a form of chronic post-traumatic stress disorder based solely on exogenous childhood trauma, and cautions against prematurely reductionistic hypotheses. He focuses on Kluff's Third Etiological Factor, which

includes the various developmental, biological, interpersonal, sociocultural, and psychodynamic shaping influences and substrates that determine the form taken by the dissociative defense. He hypothesizes a credibility continuum of childhood and contemporary memories arising primarily from exogenous trauma at one end, and endogenous trauma (stemming from intrapsychic adaptational needs) at the other. The author offers alternative multidetermined explanations for certain unverified trauma memories that currently are being accepted and validated as factual experiences by many therapists. He describes some potentially deleterious effects of validating unverified trauma memories during psychotherapy, and recommends that the MPD patients' need for unconditional credibility be responded to in the same manner as other transference-generated productions.

Matheson, George; Shu, Karen L.; Bart, Catherine (1989). A validation study of a short-form hypnotic-experience questionnaire and its relationship to hypnotizability. American Journal of Clinical Hypnosis, 32, 17-26.

#### NOTES

Investigated the validity of a 16-item scale inquiring about hypnotic experience, drawn from the Hypnotic Experience Questionnaire developed by Kelly (1985) to measure components of hypnotic experience. We administered the HEQ-S and the Harvard Group Scale of Hypnotic Susceptibility: Form A (HGSHS:A) to 198 students. Factor analysis of the scale produced three stable principal components accounting for 70% of the data variance: Dissociation/Altered State (DAS), Rapport (RAP), and Relaxation (REL). Subscales representing these three factors and a composite measure, "General Depth," were constructed. Subscale correlations with HGSHS:A scores were highest for the DAS subscale (.69) and lowest for REL (.41). Applications of the HEQ-S in clinical and research use are considered.

Using the phenomenological studies and theories of J. R. Hilgard (1979) and Shor (1962), Kelly (1985) constructed the Hypnotic Experience Questionnaire (HEQ), a 47-item scale designed to demonstrate the existence of five factors of the hypnotic experience. These factors included dissociation/altered state, relaxation, rapport, visual imagery, and a negatively correlated factor of cognitive rumination measuring the amount of anxious self-reflective, and interfering thought. A composite scale, General Depth, was also derived to provide a summary measure of the subjective quality of the hypnotic experience. The HEQ was developed as a research instrument.

The HEQ-S was administered immediately after Ss completed the Harvard response record. Items were responded to on a 5-point Likert scale ranging from one (No, none or not at all) to 5 (Yes, a great deal, or almost completely).

#### 1988

Chu, James A. (1988). Some aspects of resistance in the treatment of multiple personality disorder. Dissociation, 1, 34-38.

Therapists who treat patients with MPD commonly experience discomfort and frustration. This paper contends that the most significant cause of therapist

discomfort is the particular resistances encountered in the treatment of MPD. In MPD, etiologic childhood traumatic experiences are defensively repressed and dissociated. In addition, the normal ability to engage in trusting interpersonal relationships is disrupted. Thus, a psychotherapy which requires the retrieval of past traumas in the context of an interpersonal therapeutic relationship is tremendously threatening to the patient with MPD. In the normal course of the psychotherapy of MPD, intense resistances are encountered at every stage. This paper outlines the nature of resistance in the treatment of MPD patients, presents clinical examples, and discusses the importance of understanding and working with resistance as an intrinsic part of the treatment.

**Chu, James A. (1988). Ten traps for therapists in the treatment of trauma survivors. Dissociation, 1, 24-32.**

Patients who have survived trauma, particularly those who have experienced early childhood abuse, stand out in the clinical experience of many therapists as being among the most difficult patients to treat. These patients have particular patterns of relatedness, along with intense neediness and dependency which make them superb testers of the abilities of their therapists. They often push therapists to examine the rationales and limits of their therapeutic abilities, and frequently force therapists to examine their own personal issues and ethical beliefs. A conceptual framework for understanding treatment traps is presented, along with 10 traps which these patients present, consciously and unconsciously, in the course of treatment. Included are traps around trust, distance, boundaries, limits, responsibility, control, denial, projection, idealization, and motivation.

**Gorassini, Donald R.; Hooper, Cynthia L.; Kitching, Kathleen J. (1988). The active participation of highly susceptible hypnotic subjects in generating their hypnotic experiences. Imagination, Cognition and Personality, 7 (3), 215-226.**

Hypnotized individuals have traditionally been considered to be detached from the control of their own suggested behavior. We tested this and the alternative notion that hypnotized subjects attempt to self-generate the experiences (i.e., mainly of involuntariness) as well as produce the behaviors thought to be prototypical of high hypnotic ability. In an experimental investigation, highly susceptible hypnotic subjects were found to engage in the kind of imaginative activity that would be expected of individuals who were attempting deliberately to generate their experiences of involuntariness; they engaged as actively in imagery-generation as did subjects who were specifically instructed to imagine during suggested responding, and they experienced as much involuntariness as subjects in whom suggested movements were produced by an external physical force. The implications of these findings for the neodissociation and social psychological theories of hypnotic responding are discussed.

**Greaves, G. B. (1988). Common errors in the treatment of multiple personality disorder. Dissociation, 1, 61-66.**

Psychotherapists report widely different experiences in their attempts at treating multiple personality disorder (MPD) patients. Some have deepened their interests and developed full-time specialized practices with this clinical population. Others have declined to have any further contact with them at all, referring possible MPD patients to colleagues when they first suspect that this disorder may be present. Still others have decided against treating more than one or two MPD patients. These diverse decisions are examined with a focus upon the effects of therapists' uneven attention to the formal properties of the dyadic psychotherapeutic experiences as a possible influence upon their future work with MPD. Problems concerning the framework of psychotherapy and the countertransference conflicts which often move the therapist unconsciously and irrationally to alter the canons of psychotherapy in mutually detrimental ways appear to be crucial determinants.

Kluft, R. P. (1988). The phenomenology and treatment of extremely complex multiple personality disorder. Dissociation, 1, 47-58.

Contemporary reports indicate that the average number of personalities in recently reported patients with MPD is larger than that reported in the older literature. A minority of these recent patients demonstrate extreme complexity. A group of 26 patients with 26 or more personalities and under observation for a minimum of 3 years was studied. Their presentations, the reasons that appeared to underlie their complexity, and their courses of treatment are reviewed. Findings indicate that this group of patients is diverse, with some proving readily treatable, and others proving quite refractory. Observations that appear constructive for the treatment of such patients are offered. The concept of personality is discussed and an alternative description is explored. The usefulness of the paradigms and metaphors of splitting and division as heuristics for the understanding of MPD is challenged, and a paradigm/metaphor of redoubling and reconfiguration is offered for further study.

Loewenstein, R. J.; Putnam, F. W. (1988). A comparison study of dissociative symptoms in patients with complex partial seizures, MPD, and posttraumatic stress disorder. Dissociation, 1, 17-23.

Depersonalization and dissociative symptoms have been widely reported in chronic seizure disorder patients, especially those with temporal lobe involvement and complex partial seizures (CPS). It has been theorized that development of multiple personality disorder may be related to temporal lobe pathology. We administered the Dissociative Experiences Scale (DES) to 12 male patients with severe chronic epilepsy, primarily of the complex partial type. Patients had epilepsy from 1 to 30 years. Most were being evaluated for intractable seizures occurring several times per week. DES data on the epileptic patients were compared with DES data on 9 male MPD patients and 39 PTSD patients. MPD and PTSD patients were significantly different from CPS patients in median DES scores and all DES subscale scores. MPD and PTSD patients were far more similar on the DES, although MPD patients had a significantly higher score on the

dissociation/psychogenic amnesia subscale of the DES. The authors conclude that there is little data to support a relationship between MPD, dissociation, and epilepsy.

Pettinati, Helen M. (1988). Hypnosis and memory. New York and London: Guilford Press.

#### NOTES

From a review in *British Journal of Experimental and Clinical Hypnosis*, 7, 175-178, by Vernon H. Gregg]:

Book has 5 sections: 1. method, theory 2. mechanisms of memory enhancement 3. hypnotic and other forms of reversible amnesia 4. clinical uses of hypnosis for increasing accessibility of memories and fantasies 5. Summary

The chapter by Martin Orne et al presents a comprehensive review. Perry, Lawrence, d'Eon and Tallant contribute a lively assessment of age regression procedures in the elicitation of inaccessible memories. They provide a description of procedures, a brief historical review, and discuss problems of confabulation and creation of pseudomemories. Their account is illustrated by clinical and forensic examples and gives an interesting account of belief in reincarnation in terms of source amnesia.

Section 3 has Hollander's chapter on hysteria and memory, which illustrates the concept of reversibility of amnesia with two types of hysterical conditions: one of these types, the dissociative disorders, has the potential for amnesia to be reversed but the other, histrionic personality disorders, is characterized by no reversibility.

In the section on clinical studies of memory enhancement Frankel and Kolb both accept that uncovering repressed memories and fantasies is therapeutically beneficial and that the faithfulness of recovered memories is often not important for therapeutic success. Frankel illustrates the usefulness of hypnosis with several case studies. But he thinks that clinical issues are dealt with too briefly in this book. In her summary chapter Pettinati points to the dearth of systematic research into the effectiveness of hypnosis in clinical settings.

Bandura, A.; O'Leary, A.; Taylor, C. B.; Gauthier, J.; Gossard, D. (1987). Perceived self-efficacy and pain control: Opioid and non-opioid mechanisms. *Journal of Personality and Social Psychology*, 53, 563-571.

#### NOTES

Subjects who were trained to use psychological coping strategies (e.g. imagery, distraction, dissociation, sensation transformation) had both better pain tolerance on a cold pressor test and higher self efficacy ratings. Those subjects who were given naloxone (which blocks pain reduction effects of beta endorphins) showed more pain tolerance than subjects not given the cognitive training experiences. They attributed much of the pain tolerance increase associated with cognitive interventions to opiate release, suggesting that cognitive interventions may have physiological mediating effects on pain perception.

**Gorassini, Donald R. (1987). Use of concurrent verbalization to assess the dissociation of conscious controls. Journal of Abnormal Psychology, 96 (3), 218-222.**

The degree of dissociation of conscious controls that occurred when, according to the neodissociation theory (Hilgard, 1977, 1979), conditions were optimal for such an event was assessed. A task that required subjects to locate specified sentences in a textbook was conducted under these optimal conditions, as well as under conditions that were expected to mitigate against the occurrence of dissociation. The sentence-search task necessitated rehearsal for its successful completion. The correspondence between task rehearsal and task performance did not differ between optimal and mitigating conditions, thus suggesting a failure to dissociate. Nevertheless, search behavior was self-rated as substantially more involuntary under the optimal than under the mitigating conditions. The implications of these findings for the neodissociation and social role theories of hypnosis were discussed.

**Hilgard, Ernest R. (1987). Research advances in hypnosis: Issues and methods. International Journal of Clinical and Experimental Hypnosis, 35, 248-264.**

There are substantial areas of agreement upon the classical phenomena of hypnosis, illustrated by what we now have learned about hypnotic talent, amnesia, hallucinations, analgesia, and dissociative processes. While genuine advances in knowledge about hypnosis have been made in recent decades, differing orienting attitudes have kept some controversy alive, particularly in the interpretation of empirical findings. Differences of interpretation of the phenomenal and behavioral facts are to be expected in the present stage of developmental, cognitive, and social psychology.

#### **NOTES**

The author writes of the "domain of hypnosis" as within the larger domain of social psychology (because it is usually interpersonal); cognitive psychology (because of alterations in perception, imagination, memory, and thought); developmental and personality psychology (because of individual differences); and physiological psychology (because of neurophysiological aspects).

In terms of what we know about hypnotic talent, he notes that high hypnotizability is not generally associated with psychopathology; that it may however be associated with a personality measure called absorption; and that there may be some inherited ability (Morgan, 1973). In the author's view, hypnosis is no longer considered simply a response to suggestion, since imagination and/or fantasy are very important.

In reviewing evidence of posthypnotic amnesia the author writes, "Subtleties in language require making careful distinctions among concepts such as compliance, suggestion, compulsivity, belief, self-deception, automaticity, the voluntary, the involuntary, and a happening. If these distinctions are glossed over, the choice of words (e.g., substituting compliance for response to suggestion) may give the impression that a finding departs more widely from conventional views than it does.

We, too, have found that Ss used varied strategies or skills during amnesia, but this need not deny augmentation by suggestion.

"It takes genuinely high Ss to illustrate truly high posthypnotic amnesia... Many of the truly high hypnotizable individuals cannot break amnesia, no matter how hard they try" (p. 253).

Regarding the evidence for hypnotic hallucinations and trance logic, the author suggests that trance logic is not a clear concept because the Subject is capable of good logic while tolerating some inconsistencies. "It is ordinary logic to assume that if your hallucination is your own construction, it is you who can influence it by your own wishes. In the rare cases of transparent or diaphanous hallucinations there is still an 'out there' quality. People who report that they see wispy ghosts also see them as 'out there,' so that they qualify as hallucinations. The distinction appears to be one of perception and perception-like experiences within hypnosis rather than of logic" (p. 256).

In reviewing the evidence for hypnotic analgesia, the author acknowledges that pain relief is available with other kinds of interventions, or by using other kinds of psychological processes, but that does not diminish the contribution of hypnosis (which has a long and impressive clinical history). Following laboratory studies, it is noted that "the amount of alleviation of pain through hypnosis is positively correlated with the hypnotizability of the candidate for pain reduction. This result is not universally accepted, because some clinicians are convinced that those unsuccessful in hypnotic pain reduction are resisting hypnosis" (p. 256-257). In the present paper he acknowledges but does not review physiological literature on hypnoanalgesia.

Regarding the concept of dissociation, the author indicates that he considers it a more useful concept than the concept of trance or hypnotic state "when a person is only slightly or moderately involved in hypnosis ... . The advantage is that dissociations, as compared with altered states, can be described according to limited or more pervasive changes in the cognitive or motor systems that are being activated or distorted through suggestion in the context of hypnosis. Perhaps when all-inclusive enough, such changes can justify the use of the term trance or altered state, but I believe that these terms should be used, if at all, only for those for whom the immersion in the hypnotic experience is demonstrably pervasive" (pp. 258-259).

The author goes on to describe his initial discovery of the 'hidden observer' in an experimental context, and to relate the 'hidden observer' to others' earlier observations of a secondary report of an experience previously concealed from S's consciousness (Binet, 1889-1890/1896; Estabrooks, 1957; James, 1899; Kaplan, 1960). "The issues are still being worked on, but as in the case of trance logic the heart of the problem is not whether to speak of a hidden observer, but to recognize that there may be cognitive distortions in hypnosis even while some more realistic information is being processed in parallel, so that everything is not reportable by S" (p. 260).

Makarec, K.; Persinger, M. A. (1987). Electroencephalographic correlates of temporal lobe signs and imaginings. Perceptual and Motor Skills, 64, 1124-1126.

Significant correlations (0.50) were observed between scores for the Wilson-Barber Inventory of Childhood Memories and Imaginings and the experiences that are indicative of temporal lobe lability. In addition, positive correlations (0.42) occurred between temporal lobe EEG measures (scalp electrodes) and numbers of temporal lobe signs. The numbers of alpha seconds per minute from the occipital lobes were correlated (0.57) with the Wilson-Barber cluster that indicated interests in 'altered states'. Scores on the childhood imaginings section of the Wilson-Barber Inventory were correlated (0.44) with the numbers of spikes per minute over the temporal lobes when the eyes were closed.

## NOTES

Persinger and DeSano (1986) found that people who display temporal lobe signs were also more likely to have more imaginings (as defined by Wilson and Barber's (1983) Inventory of Childhood Memories and Imaginings) and to be more suggestible as indicated by Spiegel's Hypnosis Induction Profile" (p. 1124).

Subjects in this investigation were 12 male and 18 female students, ages 18-39 (M = 25 years) Bipolar measures were taken from just above the ears (approximately T3-T4) and the occipital lobe (01-02). Number of alpha seconds per minute and number of spikes per minute from each lobe was taken for 10 minutes (5 successive pairs of 1 minute eyes- open, 1 minute eyes-closed).

"The total Wilson-Barber score was significantly ( $p < .01$ ) correlated ... with the major (0.46) and minor (0.50) temporal lobe clusters but not with two clusters of control items: normal psychological experiences (0.21) and mundane proprioceptive experiences (0.29). These correlations are similar to those in the Persinger and DeSano study (0.60, 0.50, 0.13, and 0.14, respectively). Like the first study (0.53), the items that were most associated with dissociation (depersonalization) were best correlated with the Wilson- Barber scores (0.60). The Wilson-Barber subcluster: adults' extreme experiences (Items 44 through 52, that indicate physiological changes associated with thinking) was again most strongly correlated with the major (0.55) and minor (0.65) temporal lobe clusters; these values were 0.42 and 0.52 in the first study" (p. 1125).

"The only statistically significant ( $p < .01$ ) correlations between the Wilson-Barber scales and the EEG measures were between the number of alpha seconds from the occipital lobe (with the eyes closed) and the [Wilson-Barber] 'altered state' cluster ( $r = 0.57$ ; Items 33, 41, 42, 43). A weaker correlation (0.36) occurred between the number of alpha seconds per min. (eyes closed condition) and childhood vestibular experiences (items 1, 2, 3, 10, 24)" (p. 1126).

## 1986

Bernstein, Eve; Putnam, Frank W. (1986). Development, reliability, and validity of a dissociation scale. Journal of Nervous and Mental Disease, 174, 727-734.

Dissociation is a lack of the normal integration of thoughts, feelings, and experiences into the stream of consciousness and memory. Dissociation occurs to some degree in normal individuals and is thought to be more prevalent in persons with major mental illnesses. The Dissociative Experiences Scale (DES) has been developed to

offer a means of reliably measuring dissociation in normal and clinical populations. Scale items were developed using clinical data and interviews, scales involving memory loss, and consultations with experts in dissociation. Pilot testing was performed to refine the wording and format of the scale. The scale is a 28-item self-report questionnaire. Subjects were asked to make slashes on 100-mm lines to indicate where they fall on a continuum for each question. In addition, demographic information (age, sex, occupation, and level of education) was collected so that the connection between these variables and scale scores could be examined. The mean of all item scores ranges from 0 to 100 and is called the DES score. The scale was administered to between 10 and 39 subjects in each of the following populations: normal adults, late adolescent college students, and persons suffering from alcoholism, agoraphobia, phobic-anxious disorders, posttraumatic stress disorder, schizophrenia, and multiple personality disorder. Reliability testing of the scale showed that the scale had good test-retest and good split-half reliability. Item-scale score correlations were all significant, indicating good internal consistency and construct validity. A Kruskal-Wallis test and post hoc comparisons of the scores of the eight populations provided evidence of the scale's criterion-referenced validity. The scale was able to distinguish between subjects with a dissociative disorder (multiple personality) and all other subjects.

Davidson, Thomas McCabe (1986, January). Recall organization and volitional/non-volitional experiencing in posthypnotic and intrahypnotic amnesia: Inattention versus dissociation hypotheses (Dissertation, University of Waterloo). Dissertation Abstracts International, 47 (7), 3103-B.

Two studies are reported which seek to evaluate the relative merits of two differing hypotheses concerning the cognitive processes underlying suggested hypnotic amnesia. The inattention hypothesis maintains that amnesia effects are produced when subjects volitionally divert attention from relevant retrieval cues so that recall is inefficient. The dissociation position is that amnesic subjects are prevented from utilizing normally relevant retrieval cues by a dissociative barrier that blocks access to target memories -- a forgetting over which subjects experience no volitional control. The two hypotheses were evaluated by means of a selective amnesia suggestion in the recall organization paradigm. "In the first experiment, high, medium, and low hypnotic susceptible subjects were administered either hypnotic induction or task-motivating instructions. Results indicated that there was no disorganization of amnesia trial recall or forgetting of words not targeted for amnesia, contrary to predictions from the inattention hypothesis. "In the second experiment, high hypnotizable subjects received the selective amnesia suggestion in both posthypnotic and intrahypnotic conditions. Intrahypnotic subjects were also separated into one group that received a ten second interval between the administration of the amnesia suggestion and the amnesia trial, and another group that had a delay between the suggestion and the amnesia trial equivalent to the posthypnotic group. Eight subjects who had testified that they were volitionally amnesic on a pre- screening amnesia test were also included in the posthypnotic condition. Again, the results indicated no recall disorganization or reduction in

recall of words not targeted for amnesia. Subjects also uniformly provided evidence that their amnesia was experienced as non-volitional. There was, however, evidence that some amnesiacs were aware during the amnesia trial of the specific category targeted for amnesia. "The most important finding of both experiments is that subjects may attend to normally relevant retrieval cues and yet continue to evidence amnesia. The evidence is therefore consistent with the dissociation hypothesis, but disconfirms the inattention account of hypnotic amnesia. It appears that the selective amnesia context effectively prevents the successful use of volitional forgetting strategies. (Abstract shortened with permission of author)" (p. 3103).

Holroyd, Jean (1986). Hypnosis applications in psychological research. Imagination, Cognition and Personality, 5, 103-115.

It is proposed that hypnosis leads to altered cognition, affect, or motivation as reflected by changes in 1) reality orientation, 2) attention and awareness, 3) imagery, 4) dissociation, 5) suggestibility, and 6) mind-body interaction. Hypnosis may be used as an experimental method to effect such cognitive, affective and motivational changes in order to pursue research in learning, personality, physiological, and social psychology. Examples of possible applications of hypnosis are provided. The influence of individual differences in hypnotic responsivity on research also is discussed.

#### NOTES

The author concludes, "Contributions of hypnosis to research in psychology may have been diminished by the confusion inherent in searching for main effects while giving insufficient attention to interaction effects between personality variables and experimental manipulations. As psychology becomes more cognitive in orientation, the phenomena of hypnosis may seem less bizarre and more amenable to inclusion in psychological research. However great care must be taken not to confuse the contributions of hypnosis with the contributions of the hypnotically responsive personality" (p. 109).

Laurence, Jean-Roch; Nadon, Robert; Nogrady, Heather; Perry, Campbell (1986). Duality, dissociation, and memory creation in highly hypnotizability subjects. International Journal of Clinical and Experimental Hypnosis, 34, 295-310.

The present paper reports an initial attempt to create a pseudomemory in a group of highly hypnotizable individuals. It was found that for approximately 50% of Ss tested, recall of a specific event was modified when Ss integrated hypnotically suggested material which then posthypnotically was believed to be veridical. This modification in a previously reported memory was linked to a particular cognitive style found in high hypnotizable Ss, namely dual cognitive functioning. Ss reporting duality in hypnotic age regression, and, to a lesser extent, the hidden observer effect, were found to be the most prone to accept a suggested memory as real. These findings suggest the need to emphasize the importance of a cognitive-phenomenological approach to hypnosis and hypnotizability.

Markus, Hazel; Nurius, Paula (1986). Possible selves. American Psychologist, 41 (9), 954-969.

The concept of possible selves is introduced to complement current conceptions of self-knowledge. Possible selves represent individuals' ideas of what they might become, what they would like to become, and what they are afraid of becoming, and thus provide a conceptual link between cognition and motivation. Possible selves are the cognitive components of hopes, fears, goals, and threats, and they give the specific self-relevant form, meaning, organization, and direction to these dynamics. Possible selves are important, first, because they function as incentives for future behavior (i.e., they are selves to be approached or avoided) and second, because they provide an evaluative and interpretive context for the current view of self. A discussion of the nature and function of possible selves is followed by an exploration of their role in addressing several persistent problems, including the stability and malleability of the self, the unity of the self, self-distortion, and the relationship between the self-concept and behavior

Miller, Mary E.; Bowers, Kenneth S. (1986). Hypnotic analgesia and stress inoculation in the reduction of pain. Journal of Abnormal Psychology, 95, 6-14.

Investigated the influence of hypnotic ability on 3 methods of reducing cold-pressor pain. Following a baseline immersion, 30 high- and 30 low-hypnotizable undergraduates were randomly assigned to 1 of 3 treatment groups: stress inoculation training, stress inoculation training defined as hypnosis, or hypnotic analgesia. Analysis of pain reports indicated a significant hypnotic ability x treatment interaction. Among Ss receiving hypnotic analgesia, high-hypnotizables reported significantly less intense pain than lows. There was no differential response for high- and low-hypnotizable Ss receiving stress inoculation training, whether or not it was defined as hypnotic. Moreover, Ss in the stress inoculation condition (whether or not defined as hypnosis) reported using cognitive strategies to reduce pain, whereas this was not the case for Ss in the hypnotic analgesia condition. The present findings seem inconsistent with the social psychological account of hypnosis and are discussed from a dissociation perspective, which views hypnosis as involving changes in the way information is processed.

1985

Bliss, Eugene L.; Larson, Esther M. (1985). Sexual criminality and hypnotizability. Journal of Nervous and Mental Disease, 173, 522-526.

Investigated 33 17-35 yr old sexual offenders, 18 of whom had been convicted of rape, 9 of pedophilia, and 6 of incest. Ss completed a questionnaire containing a list of 15 factors that might have contributed to their crime, a self-report containing 305 items that are symptoms characteristic of 11 major psychiatric syndromes, and the Stanford Hypnotic Susceptibility Scale. Controls for the self-report were 48 individuals taken from a church group, nurses, technicians, and graduate students. Controls for the hypnotizability scale were cigarette smokers who smoked 1 1/2

pack/day and S data taken from the literature. Results show that two-thirds of the Ss had histories of spontaneous self-hypnotic experiences (dissociations); 7 of these were DSM-III multiples and 6 were probable multiples. This group had very high hypnotizability scores. The other one-third without histories of spontaneous self-hypnosis had normal scores. It is concluded that spontaneous self-hypnosis contributed to the perpetration of the crimes in many of these cases, although other factors also directed the antisocial behaviors. (22 ref).

**Gibson (1985). Dreaming and hypnotic susceptibility: A pilot study. Perceptual and Motor Skills, 60, 387-394.**

Previous experimental work has indicated that certain stable personality characteristics are reliably associated with differential susceptibility to hypnosis. It is suggested that people who are more susceptible will be characterized by an awareness of dreaming more frequently, vividly and creatively. This study describes the construction of a Dream Questionnaire and the relations of the scores obtained on it to scores previously obtained on the Harvard Group Scale of Hypnotic Susceptibility. Sex differences were noted in response to the questionnaire. For women, a global score was derived from the questionnaire, and this was positively and significantly associated with hypnotic susceptibility. Men responded rather differently to the questionnaire and as hypnotic susceptibility scores were available for only a more limited number, further analysis was postponed until more data from men may become available. Some suggestions for research are discussed, and the relations between sleep research and hypnosis research are briefly considered.

**NOTES:**

This article provides an example of dissociation-hypnosis contribution to sleep research:

"There has hitherto been little link between research on sleep and on hypnosis. Cartwright's (1978) review of dream research makes no mention of hypnosis, but a little common ground is referred to in Ernest Hilgard's (1975) review of hypnosis research. More recently, Belicki and Belicki (1984) and Perreault and Montplaisir (1984) have renewed the effort to link the two areas. Such research may not begin to pay off in terms of delineating more fully the traits of personality which refer to dissociative ability both in sleep and in wakefulness. It is hoped that the pilot questionnaire provided by the present study will serve to further such research."

[Note that in Nadon, Hoyt, & Kihlstrom, 1987, some questions from Evans' sleep questionnaire were predictive of hypnotizability.]

Kelly, Paul James (1985, November). The relationship between hypnotic ability and hypnotic experience (Dissertation). Dissertation Abstracts International, 46 (5), 1690-B.

"This study investigated the relationship between four types of hypnotic experience and hypnotic ability. The types of experiences were: dissociation, the experience of involuntariness, altered state effects, such as perceptual alterations and diminished reality sense rapport, transference-like involvement with the hypnotist, and

relaxation. A 47-item scale, the Hypnotic Experience Questionnaire was developed to measure types of hypnotic experience. It was given to 484 subjects and then to a subsample of 272 students. When the scale was factored, four stable factors emerged: Nonconscious/Trance, Rapport, Relaxation, and Cognitive Rumination. A Group Profile Scale was also developed to measure students and when it was factor analyzed four factors were extracted: Hallucinations and Fantasies, Amnesias and Post-Hypnotic Compulsions, Motor Inhibition, and Direct Motor Suggestion. "Two statistical approaches were used to investigate the connections between hypnotic ability and hypnotic experience . Canonical analysis was used to identify the main relationships between hypnotic ability and hypnotic experience and factor analysis was used to explore the relationship among measures of hypnotizability and hypnotic experience. Two canonical variates from the canonical analysis were significant. The first variate was characterized by a dissociative-imaginative involvement process, and the second variate tapped a rapport-social compliance process. "When 25 variables, representing components of hypnotic ability and hypnotic experience, were factored, five factors were extracted. Imaginative Involvement, Ideomotor Response, Rapport, Cognitive Inhibition, and Relaxation. The results of the factor analysis suggested that dissociative experience and altered state experience are related to hypnotic ability but rapport and relaxation are not. "The results of study, taken as a whole, suggest that relaxation and rapport may happen in the hypnotic situation, but neither experience is related to the condition of being hypnotized in any essential way. The results suggest that the hypnotic condition is characterized by dissociative experience, altered state experience, and by successful performance on hypnotic ability tasks. From a theoretical point of view, the results strongly supported Hilgard's theory, partially supported Shor's theory, and failed to support Edmonston's theory" (p. 1690).

Morris, Don M.; Nathan, Ronald G.; Goebel, Ronald A.; Blass, Norman H. (1985). Hypnoanesthesia in the morbidly obese. Journal of the American Medical Association, 253 (22), 3292-3294.

The advent of chemical anesthesia relegated hypnosis to an adjunctive role in patients requiring major operations. Anesthesia can be utilized with acceptable risk in the great majority of patients encountered in modern practice. But an occasional patient will present--such as one with morbid obesity--who needs a surgical procedure and who cannot be safely managed by conventional anesthetic techniques. This report describes our experience with such a patient and illustrates some of the advantages and disadvantages of hypnoanesthesia. The greatest disadvantage is that it is unpredictable. Close cooperation between the patient, hypnotist, anesthesiologist, and surgeon is critical. However, the technique may be utilized to remove very large lesions in selected patients. Hypnoanesthesia is an important alternative for some patients who cannot and should not be managed with conventional anesthetic techniques.

#### NOTES

Research on confirmatory bias has uncovered additional cognitive processes that are frequently automatic in function and significant in modifying behavior, affect, and cognition. Snyder and Swann (1976, 1978) provided subjects with set inducing hypotheses about the personalities of certain target individuals. Subjects were then asked to test these hypotheses by interviewing the target individuals. It was found that subjects regularly looked for and found evidence that was consistent with their initial hypotheses rather than for evidence which could show these hypotheses to be incorrect. This biased search strategy of the subjects had more profound effects as well, for it also influenced the behaviors of the target individuals in a manner leading them to produce behaviors that seemed to confirm the original mental set of the subjects. Subjects were unaware that their manner of interviewing was producing a biased sample of behavior from the targets. Here too an automatic cognitive process was affecting perception and thinking without conscious awareness" (p. 280).

#### NOTES:

Provides summary of the history of associationism. Refers to Beddoes' essays (1802-03) which state that (1) emotions play a significant role in strengthening associations, and a study of emotions would be the 'chief secret for unriddling the inconsistencies of dreams,' and (2) variations could occur in associations (from very strong to very weak).

In the 19th century there was an ongoing debate about the role of the reflex in the nervous system, about how high up it could function, and whether it could still take place if it reached areas that subserved consciousness. Dr. William Carpenter postulated three levels: (1) excitomotor reflex (spinal, and maybe lower brain), (2) sensorimotor or consensual (midbrain) which was unconscious, (3) ideomotor (cerebral) - based on evidence from hypnosis in which volition appeared suspended and the subject became 'a mere thinking automaton' whose flow of ideas resulted from external suggestions only. The ideomotor response could be unconscious.

In the 1830's and 40's Thomas Laycock brought Associationism together with the concept of reflex. "By bringing the reflex into 'cerebral processes,' he proposed a model that made fast and automatic responses possible in the realm of ideas. Automatic thinking, speaking, writing, and more complex actions became topics of increasing interest to psychologists later in the century. As early as 1868, Prosper Despine had been speaking of 'psychological automatisms.' Laycock proclaimed most of these responses as being unconscious, that ideas could be charged with

varying amounts of energy, and that ideas could act as causes of human disturbances, both psychological and physiological" (pp. 25- 26).

1860's - 90's saw the rise of hypnotism, with Eugene Azam using it in surgery and psychiatry; Durand de Gros's book on Braid; Liebeault publishing a book; Bernheim launching his career; Charcot shifting interest from organic neurological conditions to functional conditions; and Charcot teaching both Janet and Freud.

The author notes that "in July 1880, a bright and educated young woman of 20 started to nurse her dying father. Like the shamans before her, she had to grapple with the spectre of death and in her own fashion, she developed a creative illness. Her symptoms were myriad, but many had to do with changes in her consciousness (including 'absences,' clear-cut trances) and splits in her memory, including the loss of an entire language. At one point her current personality disappeared and another took its place: in this case it was herself but existing a year before in a state in which she lived without any apparent awareness of what had happened to her in the interim. It is this case of Anna O. and her doctor, Josef Breuer, which became important to the next epoch in our review and who had so much to do in inspiring the studies that followed" pp. 27-28.

Cocores, James A.; Bender, Andrew L.; McBride, Eugene (1984). Multiple personality, seizure disorder, and the electroencephalogram. Journal of Nervous and Mental Disease, 172, 436-438.

Used the EEG to study multiple personality in a 48-yr-old ambidextrous male admitted for alcohol detoxification and individual psychotherapy. Despite conflicting reports in the literature, no changes in the EEG were found that could not be ascribed to the normal changes seen in transitions from various states of alertness. The problems of differentiating multiple personality as a psychiatric entity in itself from those cases arising as a result of chronic partial or partial-complex epilepsy are discussed.

#### NOTES

In 1907 Morton Prince, Editor of *Journal of Abnormal Psychology*, introduced a symposium by listing 6 meanings of subconscious: 1. that portion of our field of consciousness which is outside the focus of attention 2. (Janet's idea) - split off ideas which may be isolated sensations like the lost tactile sensation of anesthesia, or maybe aggregated into groups or systems. The author quotes Janet as stating that "they form a consciousness coexisting with the primary consciousness and thereby a doubling of consciousness results" (p. 87). The primary consciousness is usually dominant, but sometimes is reduced under exceptional conditions (e.g. automatic writing). 3. the subconscious self or hidden self -- a part of every human, not just seen in psychopathology; this is a personalized entity; every mind has a double, with

the unconscious self having powerful effects on feelings, thoughts, and reactions of the conscious self 4. extends #3 to include not only ideas that remain active below surface but also those which are inactive -- forgotten or out of mind 5. Frederic Myers' concept of the 'subliminal self' which had 3 functions:

a) inferior - seen in processes of dissociation

b) superior - seen in works of genius, arising from 'subliminal rush' of information, feelings, and thoughts which lie below consciousness

c) mythopoeic - the unconscious tendency to create fantasies 6. physiological meaning, e.g. William Carpenter's 'unconscious cerebration' in which unconscious phenomena are interpreted in terms of pure neural processes unaccompanied by mental activity.

Prince suggested some redefinitions to clarify unconscious and subconscious. He would replace Janet's subconscious with co-conscious and reserve unconscious for physiological processes that lack the attributes of consciousness. Prince noted that co-conscious ideas have been called unconscious (e.g. by Freud) but said that is confusing and to be avoided.

"Coconscious ideas include states we are not aware of because they are not the focus of our attention, and also pathologically split-off and independently active ideas or systems of ideas, such as occur in hysteria and reach their most striking form in co-conscious personalities and automatic writing.

"Prince prefers the term coconscious to Janet's subconscious for two reasons. First, because it expresses the simultaneous coactivity of a second consciousness. And second, because the coactive ideas or idea systems may not be outside the awareness of the personal consciousness at all. They may be recognized by the personal consciousness as a distinct consciousness existing alongside it.

"Thus, through his redefinition of terms, Prince makes simultaneous activity of two or more systems of consciousness in one individual the key element in dissociation. He thereby moves the issue of amnesia or lack of awareness by one system of another into the background, making it a secondary, nonessential element. Prince was one of the few to provide a theoretical framework for dissociation in which any combination of interawareness among the coconscious systems was possible" (p. 91). Two researchers at the turn of the century came to opposite conclusions about the nature of the Subconscious Self that every human has. Morris Sidis saw it as "a brutelike consciousness with a tendency toward personalization. Frederic Myers held that it included those functions and much more, being the source of all that is human, including the highest intuitive powers" p. 96.

Bernard Hart, in 1910, did an analysis of Janet and Freud. Janet's work is essentially descriptive: "he is always talking about a consciousness which manifests itself in a way we can \_perceive\_, whether by listening to it talk, reading its written communications, or watching its movements" (p. 97). However Janet's spatial model of dissociation cannot explain the presence of the same material (e.g. memories) in two or more dissociated systems. According to Hart, Freud offered the conceptualization that Janet lacked, in his idea of the Unconscious .

Freud's Unconscious is not in competition with Janet's subconscious. "Janet's subconscious is the arena of dissociated phenomena which manifest in observable form as elements coactive with the personal self. Freud's unconscious is a

conceptual, nonobservable construction put forward to explain certain facts of human experience. In this way Hart equates the unconscious with the atomic theory in physics or the theory of heredity in biology" p. 99. But Hart also thought Freud's theory did not do justice to dissociative phenomena. Not only do psychoanalysts show little interest in double personality or multiple personality, they also neglected dissociation on the phenomenal level.

In 1915 Freud denied the existence of a second consciousness and wrote, "there is no choice for us but to assert that mental processes are in themselves unconscious, and to liken the perception of them by means of consciousness to the perception of the external world by means of the sense organs" (p. 101). Janet claimed that Freud had simply taken over his own system and given it a new terminology, and in 1924 Freud wrote an angry rebuttal. For him, "dissociated systems are simply separate groups of mental but unconscious elements. As our consciousness turns now to one group, now to another, as a searchlight shines now on one object and now on another, the dissociated groups manifest in conscious life. ... There exists no doubling of consciousness" p. 102.

Jung's ideas were closer to those of Janet, and like Janet he made dissociation a key concept in his theory. The \_complex\_ is unconscious, has an archetypal core clothed in personal experience, is like a self-contained psyche within the big psyche, sometimes called a fragmentary personality dwelling inside us. Dissociation for him meant being cut off from the Ego, which is the center of an individual's field of consciousness. "Dissociated or autonomous complexes are those which have no direct association with the ego" (p. 103). If complexes are charged with enough energy they will become manifest--as a neurotic symptom, as projected into idea of a god or demon, or perhaps as an alternate personality. Therefore Jungian treatment aims at assimilating dissociated complexes into the ego.

## NOTES

Emphasizes spiritism, hypnotism, and the career of Pierre Janet.

Janet's career paralleled an increased interest in dissociation, because he had contact with scientists studying spiritism, used hypnosis, and insisted on a scientific approach. He coined the words "subconscious" and "dissociation." As his sphere of influence declined, so did scientific interest in dissociation--especially multiple personality disorder.

Scientific study of dissociation began with investigations into religious exorcism and spirit possession. For example, at the behest of Prince Max Joseph of Bavaria, Mesmer duplicated the exorcisms of Father Gassner (causing convulsions) using hypnosis. Following Mesmer, there were reports of multiple personalities (e.g. an "exchanged personality" in Germany, reported in 1791 by Eberhardt Gmelin).

"Partly because of this growth of knowledge of multiple personality, a new model of the mind developed during the early 19th century: the mind was dual; there were conscious and unconscious mental states. Later, it was said that there was a dominant conscious personality with a group of underlying subpersonalities. Eventually it was declared that split fragments of personality could act autonomously" p. 37.

The scientific study of these phenomena continued under the leadership of Frederic Myers of The Cambridge Society for Psychical Research. According to William James, Myers was the first to consider the phenomena of hallucination, hypnotism, automatism, double personality, and mediumship as connected parts of one whole subject. The Cambridge Society was involved in the transition from the use of automatic writing by mediums to its use for clinical purposes and experimental research in the 1880's and 1890's.

Increasing numbers of multiple personalities reported in the literature in late 19th century led to increased interest in hypnosis and to the concept of dissociation. The author details the contributions of Janet, and then explains how interest declined in dissociation and in hypnosis due to the following: 1. Experimental psychologists in Germany (e.g. Wundt) refused to deal with anything that resembled the "unconscious," and neglected the point of view of the experiencing person. 2. Those few psychologists interested in the unconscious found projective tests (Rorschach, TAT) an easier avenue than hypnosis or automatic writing. 3. Many mediums were exposed as frauds, e.g. Flournoy's popular "From India to the Planet Mars". 4. Janet himself was very critical of parapsychology. 5. When Charcot died suddenly, it was discovered that some of his assistants had rehearsed the behavior of hypnotized patients. 6. Hypnotists' extravagant claims (e.g. past life age regression) led to a wave of reaction against them. 7. Questions were raised about the iatrogenic nature of multiple personality. 8. Conscientious hypnotists discovered drawbacks

- not everyone could become good hypnotists (e.g. Freud)
  - not everyone could be hypnotized
  - some patients faked hypnosis
  - extreme sensitivity of hypnotized patients to the hypnotist's wishes led to biased results
  - hypnotist sometimes was conditioned to things in certain way by his first patient
9. Janet didn't have the personality of a leader, and he argued with the psychoanalysts about who should get credit for certain ideas.

Fewtrell, W. E. (1984). Relaxation and depersonalization. British Journal of Psychiatry, 145, 217.

## NOTES

In 40 anxious patients treated with Jacobson's progressive relaxation, 7 reported distress (something like Heide's Relaxation Induced Anxiety). Looking retrospectively at the clinical notes, these seven usually reported symptoms of a depersonalization syndrome prior to treatment. The author administered Dixon's (1963) Self Alienation Questionnaire, which purports to measure depersonalization. The patients who had distress scored significantly higher on Self-Alienation than ten

randomly selected control subjects who had responded to the relaxation procedures without problems (adverse effects patients' mean = 32; controls' mean = 22;  $P = .05$ ). This article presents evidence that the presence of relaxation may distress depersonalized patients, presumably exacerbating feelings of unreality.

Kelly, Paul James (1984, December). The relationship between hypnotic ability and hypnotic experience. Newsletter of Division 30, Psychological Hypnosis, of the American Psychological Association, 5.

This study investigated the relationship between four types of hypnotic experience and hypnotic ability. The types of experience were: dissociation, the experience of involuntariness; altered state effects, such as perceptual alterations and diminished reality sense; rapport, transference-like involvement with the hypnotist; and relaxation. A sample of 230 students was given the HGSHS:A, a group version of the SHSS:C, and the Hypnotic Experience Questionnaire (Kelly, 1984), a 47-item multidimensional scale of hypnotic experience. Items were taken from these tests to form 11 hypnotic ability variables (Positive Hallucinations, Dreams and Regressions, Post-Hypnotic Compulsions, Amnesia (HGSHS:A), Amnesia (SHSS:C), Arm Rigidity, Arm Immobilization, Other Motor Inhibitions, Head Falling, Moving Hands Together, and Hand Lowering). Fourteen hypnotic experience variables were also formed (Generalized Dissociative Effects, Dissociative Inhibition, Trance, Unawareness, Transference-like Involvement, Trust, Friendliness, Physical Relaxation, Mental Relaxation, Imagery Presence, Imagery Vividness, Imagery Detail, Self Consciousness, and Analytic Thoughts). The 25 variables were intercorrelated and factored with principal axis factoring. Five factors with eigenvalues greater than 1 were extracted and rotated to varimax criteria. These factors, which accounted for 54.4 percent of the variance, were called: Imaginative Involvement, Ideomotor Response, Rapport, Cognitive Inhibition, and Relaxation. Hypnotic ability variables loaded significantly on three of the factors (Imaginative Involvement, Ideomotor Response, and Cognitive Inhibition) and these three factors also tapped some aspect of altered state experience and/or dissociative experience. It was concluded therefore that dissociative experience and altered state experience are related to hypnotic ability. The remaining two factors, Rapport and Relaxation, showed significant loadings only for rapport variables and relaxation variables, respectively. Neither of these two factors were related to any of the traditional measures of hypnotic ability or to the experience of dissociative effects or altered state effects. The results of this study suggest that rapport and relaxation may happen in the hypnotic situation but neither experience is related to the condition of being hypnotized in any essential way. The hypnotic condition is characterized by dissociative experience, altered state experience, and by successful performance on hypnotic ability tasks. The results also raise questions about Edmonston's (1981) theory that relaxation is the essence of hypnotic responsiveness. The finding that the experience of relaxation is unrelated to hypnotic ability is more congruent with Hilgard's (1977) view that relaxation is a nonhypnotic process.

Lynn, Steven Jay; Nash, Michael R.; Rhue, Judith W., Frauman, David C.; Sweeney, Carol A. (1984). Nonvolition, expectancies, and hypnotic rapport. Journal of Abnormal Psychology, 93 (3), 295-303.

Prior to hypnosis, subjects were informed either that hypnotizable subjects can resist motoric suggestions or that such control does not characterize good hypnotic subjects. During hypnosis, susceptible and simulating subjects received countering suggestions involving inhibiting suggestion-related movements. Susceptible subjects' responses were found to be sensitive to prehypnotic normative information. There was a corresponding tendency for reports of involuntariness to be sensitive to the expectancy manipulation. Furthermore, subjects were able to feel deeply hypnotized and to rate themselves as good subjects yet concomitantly experience themselves as in control over their actions when normative information supported this attribution. Reports of suggestion-related sensations but not imaginative involvement were associated with movements in response to countersuggestion. Simulators were unable to fake susceptibles' reports of sensations and involuntariness. However, for all subjects, movements paralleled expectancies about appropriate response, supporting the hypothesis that involuntary experiences are sensitive to the broad expectational context and are mediated by active cognitive processes. Also, rapport with the hypnotist was found to be a factor. Susceptible subjects with highly positive rapport resolved hypnotic conflict, in part, by achieving a compromise between meeting normative expectations and complying with the hypnotist's counterdemand.

Nash, Michael R.; Lynn, Steven Jay; Givens, Deborah L. (1984). Adult hypnotic susceptibility, childhood punishment, and child abuse: A brief communication. International Journal of Clinical and Experimental Hypnosis, 32, 6-11.

Earlier empirical and theoretical work has suggested that there is a relationship between higher hypnotic susceptibility and severity of childhood punishment. Experiment 1 surveyed the parents of 14 extremely high and 11 extremely low susceptible Ss concerning punishment. Low susceptible Ss were found to be more frequently punished than highs; no significant differences were found on the severity measure. Experiment 2 assessed the hypnotizability of 16 adult Ss who reported being physically abused before the age of 10 and compared these scores to those of 300 adult Ss who had not reported being abused. The mean hypnotizability of abused Ss was greater than that of controls, and the distribution of their scores appeared bimodal. Limitations of both experiments are discussed and suggestions are made for future investigations.

Nash, Michael R.; Lynn, Steven Jay; Stanley, Scott (1984). The direct hypnotic suggestion of altered mind/body perception. American Journal of Clinical Hypnosis, 27, 95-102.

Attentional and emotional shifts are examined following a hypnotically suggested out-of-body experience (OBE). Two hypotheses were tested: 1) that the OBE is maintained by blocking the perception of body-relevant stimulation at a sensory

level; 2) that a hypnotically produced OBE is an emotionally neutral or even pleasant experience. Fourteen hypnotic subjects and 15 simulating Ss were administered a standardized induction followed by suggestions for an OBE. Geometric figures were then presented to the body but not to the "awareness." Although hypnotic Ss reported that they could not see the information, they still correctly "guess" the identity of the figures beyond chance levels. Thus, body-relevant information was obviously not blocked at a sensory level, but was kept out of awareness by some other mechanism. In addition, a significantly greater number of hypnotized than simulating Ss reported the OBE to be troubling and unpleasant, despite explicit suggestions for a positive experience. The potentially disturbing nature of OBEs and ways to minimize risk of negative affect are discussed.

Perry, Campbell (1984). Dissociative phenomena of hypnosis. Australian Journal of Clinical and Experimental Hypnosis, 12, 71-84.

Janet's concept of dissociation, Freud's notion of the Censor and Hilgard's multiple controls of consciousness are considered in relation to the hidden observer (HO) phenomenon. A review of reports of recent research, including that of the author and co-workers, indicates that the hidden observer effect occurs only in 40-50% of high susceptible subjects. It is speculated that subjects who show Hidden observer have maintained some contact with reality whilst those high susceptibles who do not show hidden observer are more deeply involved in hypnosis.

#### NOTES

Author describes a series of experiments in their laboratory. Ss are double screened to select highly hypnotizable people, and accepted into the research only if they pass the amnesia item of SHSS:C and most of the other 11 items of that scale. Ss are told that hypnosis is a procedure which permits subjects to exercise various skills or abilities such as relaxation, imagination, imagery, absorption and selective attention--that everyone has some of these skills to varying degrees, and that hypnosis is one of many techniques (including yoga, etc.) for bringing out these skills and abilities. All sessions are videotaped for the Experiential Analysis Technique (EAT). The Hidden Observer (HO) procedure was modified so that E touched the S's shoulder lightly at the start of the item, and a second time to terminate the item. Whereas Hilgard used cold pressor pain, they used a mildly unpleasant shock provided by a Take-Me-Along electric stimulator.

Replying to Spanos and Hewitt (1980) in which data was interpreted as implying that the HO is an artifact of demand characteristics, "It struck me then, and still does, that people like Hilgard and ourselves, who believe that the HO is a phenomenon of hypnosis and not just some laboratory artifact, can only get it 40-50% of the time, whereas the investigators like Spanos and Hewitt, who believe it is all laboratory artifact, get the phenomenon almost 100% of the time. Usually it is the other way around, so it seems to me that if the HO is an artifact, it is unique in the history of psychology" (p. 77).

They found that all highs with the HO also reported subjective experiences similar to HO experience when they were not hypnotized. "For instance, one female subject

who has the HO, insists that she is not hypnotized, despite compelling evidence to the contrary, because she feels the same way when she is not hypnotized. By contrast, another subject who is interested in creative writing reports HO type experiences when she is on a creativity binge and also when she is stoned" (p. 79).

They observed several consistent findings in their research: "(1) contrary to the belief that subjects who report HO's are more susceptible than those who do not, our findings are the reverse" (p. 79). The differences are not large enough to be significant, but that may be due to a ceiling effect on the scales since the subjects are already selected to be high hypnotizables. "(2) A second repeated observation is that when all the Ss were administered the HO instructions, they were given a second electric shock to the still analgesic hand, and asked to report the degree of pain they felt on a 1-10 scale where 1 = no pain and 10 = extreme pain. ... the HOs report having the HO experience and their pain reports on the 1-10 scale increase, in the manner described by Hilgard using cold pressor pain. The no HOS report no subjective difference, and their degree of analgesia actually increases" (p. 79).

The author describes further studies in which they obtained results in the opposite direction from what they had expected, based on the supposition that people who do not have the HO appear to set aside critical judgement more and to be more imaginatively involved. "So the finding of greater recall after reversal of amnesia for the no HOs both on number of items and on bits was a surprise" (p. 81). When they extended this research into the area of pseudo-memories, they found that "of the 8 subjects who had the HO, 7 of them believed the pseudo-memory was real. Of the 19 subjects who did not have the HO, only 6 of them accepted the pseudo-memory as real ... The effect was even stronger for duality in age regression. Of 12 subjects reporting duality, 10 reported the hallucinated noises as real; of the 15 with no duality, 3 accepted the reality of the pseudo-memory as actually having happened" (p. 81).

Pettinati, Helen M. (1984, October). Differential hypnotic response in anorexia nervosa and bulimia: An item analysis. [Paper] Presented at the annual meeting of the Society for Clinical and Experimental Hypnosis, San Antonio, TX.

#### NOTES

Because bulimics are thought to be dissociative, congruent with their symptoms, it was predicted that they would score higher on the dissociative items of the hypnotizability scales. Previously published data shows:

N Mean Score College students 203 5.07

Bulimics 21 7.71\*\*

Anorexic Purgers 46 6.13\*

Anorexic Abstainers 19 5.00

\* & \*\* = higher than norms

Hilgard's 3 factors of hypnotizability scales were scored. Bulimics scored higher than norms on the cognitive dissociation factor but not on the motor and motor challenge factors, and purging anorectics also scored higher on this factor. The cognitive dissociation factor consists of neither the easiest nor the most difficult items on Form C, so this doesn't represent item difficulty.

Item analysis: 1. Bulimics score higher on taste hallucination, arm rigidity, dream, age regression, arm immobilization, & hallucinated voice. 2. Purgers score higher on arm rigidity, dream, and arm immobilization 3. Abstainers evidenced no difference from norms.

1983

Myles, (1983, April). Cognition, hypnotic susceptibility, and laboratory induced pain (Dissertation, University of Waterloo). Dissertation Abstracts International, 43 (10), 3360-B.

"Individuals' experiences of pain, and responses to pain treatments vary greatly. This study attempted to relate two areas of research concerned with this variation: (a) cognitions and pain (thoughts, images, etc.), in particular, catastrophizing versus coping; and (b) hypnotic susceptibility and analgesia. "Subjects were preselected for high or low hypnotic susceptibility. Susceptibility assessment was divorced from the laboratory study to minimize the potential bias of expectancies concerning hypnosis. High hypnotic susceptibility was expected to potentiate therapeutic effects of hypnotic-like treatment that did not involve a hypnotic induction. "Ten high and ten low-susceptible subjects were assigned to each of three groups: (a) a cognitive treatment, encouraging subjects to reduce spontaneous catastrophizing and increase self-generated coping cognitions; (b) a dissociative imagery treatment, encouraging subjects to engage in self-generated engrossing images; (c) an attention- placebo manipulation. "Pre and post-treatment assessments involved tolerance and pain-report measures during the cold-pressor task, and interview and questionnaire information concerning cognitions. "No treatment effects were evident on measures of pain. Cognitive data indicated less catastrophizing and more coping during the post-treatment stressor across all groups. Subjects in the dissociative imagery group did report more imagery during the post-treatment assessment than subjects in the other groups, but this increased use of imagery was not associated with a decrease in pain. "Interview and questionnaire data supported prior reports that catastrophizing is related to increased pain. Low catastrophizing was associated with a high sense of control, high use of a variety of coping strategies, and lower pain reports. These relationships were altered following treatment, however, leading to a caution in generalizing about such variables. "High susceptibility did not potentiate therapeutic effects for either experimental treatment. Nor was susceptibility related in any other consistent way to pain, although high susceptibility was associated with more extensive use of post-treatment imagery. "Methodological inconsistencies and problems in laboratory pain research were discussed, and suggestions made for future work in the area" (p. 3360).

Nogrady, Heather; McConkey, Kevin M.; Laurence, Jean-Roch; Perry, Campbell (1983). Dissociation, duality, and demand characteristics in hypnosis. Journal of Abnormal Psychology.

Examined hypnotic dissociation (as indexed by the "hidden-observer" method), duality in age regression, and the potential impact of situational cues on these

phenomena. 12 high- and 9 low-susceptible undergraduates (as determined by the Stanford Hypnotic Susceptibility Scale) were tested in an application of the real-simulating paradigm of hypnosis; 10 high- to medium-susceptible Ss were also employed. Inquiry into Ss' experiences was conducted through the experiential analysis technique, which involves Ss viewing and commenting on a videotape playback of their hypnotic session. Results demonstrate that neither the hidden-observer effect nor duality could be explained solely in terms of the demand characteristics of the test situation. The hidden-observer effect was observed in high-susceptible Ss only; all Ss who displayed the hidden-observer effect also displayed duality in age regression. High-susceptible Ss were distinctive in their reports of multiple levels of awareness during hypnosis. Findings are discussed in terms of the cognitive skills that Ss bring to hypnosis and the degree to which the hypnotic setting encourages the use of dissociative cognitive processes. (43 ref).

1982

Belicki, Kathryn; Bowers, Patricia (1982, October). Dimensions of dissociative processing, absorption and dream change following a presleep instruction. [Paper] Presented at the annual meeting of the Society for Clinical and Experimental Hypnosis, Indianapolis, IN.

#### NOTES

Subjects' tendency to have things pop into their mind when asked to imagine, image them, or to do a divergent thinking task is correlated with behavior change out of awareness (dissociated), change in dream content in response to indirect suggestion - the request to pay attention to a certain element in their dreams. Effortless imagining (as opposed to working at it), a particular type of dissociative phenomenon, is associated with dream change.

Brende, Joel O. (1982). Electrodermal responses in post-traumatic syndromes: A pilot study of cerebral hemisphere functioning in Vietnam veterans. Journal of Nervous and Mental Disease, 170, 352-361.

This paper summarizes the findings of a pilot study which found a relationship between the post-traumatic symptoms of a) psychic numbing, b) intrusive recollections of traumatic events, and c) hypervigilance and lateralization of electrodermal response (EDR) measurements in six victims of psychological trauma. Hypnotically induced imagery of past traumatic events was often associated with left-sided EDR increases, psychic numbing with left-sided EDR decreases or bilateral EDR unresponsiveness, and revivifications of hypervigilant states with right-sided EDR lateralization. In several cases control of the experience of fear was associated with left- sided or bilaterally decreased EDR. These pilot study findings support previously stated hypotheses: a) EDR obtained from an extremity reflects contralateral cerebral hemisphere functioning; b) left hemisphere functioning is associated with hypervigilance; and c) right hemisphere functioning is associated with emotions and imagery. In addition, the pilot study findings suggest additional hypotheses: a) Post- traumatic symptoms are associated with poorly controlled or

integrated cerebral hemisphere functioning; b) psychic numbing and intrusive images, flashbacks, and nightmares are associated with abnormal activation, suppression, or integration of right hemisphere functioning in relationship to the left; c) aggressive behavior, hypervigilance, and character pathology are associated with abnormal activation, suppression, or integration of functioning of the left hemisphere function in relationship to the right; and d) "splitting" as a psychological defense in Vietnam veterans with Borderline Personality Disorders is associated with physiologically impaired interhemispheric integration.

#### NOTES

The authors report that previous research suggests that electrodermal asymmetry may be related to emotional factors. They further suggest that electrodermal responsiveness reflects contralateral cerebral hemispheric functioning, with lower GSR associated with higher activation of the opposite cerebral hemisphere (see Lacroix and Comper, 1979). They indicate that the right hemisphere, which is involved in experience of emotion, also is associated with depression (when there is abnormal inhibitory function of right hemisphere) and affective disorders. The left hemisphere is involved in vigilance (Dimond & Beaumont, 1974). "Based on these findings, the post-traumatic symptoms hypervigilance, anxiety, and behavior disorders appear to be associated with atypical left hemisphere activation, intrusive recollections of traumatic memories and disturbing emotional states with atypical right hemisphere activation, and psychic numbing or emotional unresponsiveness with diminished right hemisphere activation, or overactivation of the left hemisphere" (p. 354).

In this pilot study, the therapist, who used hypnosis in all but one case, interviewed the patient for 30-50 minutes, focusing on helping the S to recall experiences of a traumatic nature. The therapist was supportive when disturbing emotions were evoked, responding flexibly by monitoring S's anxiety and moving back and forth between uncovering and supportive techniques.

#### SUMMARY

There were observably variable changes and bilateral differences in EDR within each of the six subjects in relationship to varying verbal, emotional, and imagery content, postulated to reflect contralateral hemispheric functioning. These observed changes were considered conclusive evidence of such functioning in post-traumatic states" (p. 358). "1. Lateralization of EDR to the left is associated with unpleasant emotions and traumatic imagery. ... "2. Lateralization of EDR to the right is associated with hypervigilance and aggressive outbursts. ... "3. Psychic numbing is associated with inhibition of bilateral EDRs (for example, lack of bilateral EDR activation occurred in every case at times) or with suppression of the left EDR. ... "4. General physiological arousal, a normal response to fear, is associated with increased EDRs bilaterally. ... "5. Relaxation and the subjective experience of safety and well-being, which have been reported to foster interhemispheric integration in normal subjects ... were observed to be associated with bilaterally decreased EDR in case I, an example of a less severe post- traumatic condition, but not observed during attempts at relaxation in Vietnam veterans with more severe post-traumatic

symptoms. "6. Voluntary efforts to cognitively control fear were related to left hemispheric functioning, as observed in case IV when the subject attempted to control intrusive thoughts with cognitive activity and in Case III following the revivification of a frightening event when he made a shift from the hypnotic trance state to waking cognitive activity. In both cases, such cognitive activity was associated with a decreased right-sided EDR" (p. 359).

## DISCUSSION

The results of this pilot study, which demonstrated frequent EDR differences between hands during subjects' recollections of or attempts to suppress recollections of prior traumatic experiences, alters the traditional belief that increased skin conductance is always a predictable physiological measurement when the electrode is placed on only one hand, as Lacroix and Comper (46) have pointed out.

"The finding of EDR lateralization is consistent with the findings of deBonis and Baque (10) who reported that the degree of anxiety determines the presence of lateralization of EDR responses, of Gruzelier and Venables (30, 32) and Myslobodsky and Horesh (53) who reported that the presence or absence of psychopathology determines the direction of the lateralized response, and of Lacroix and Comper (46) that activation of one hemisphere may suppress contralateral EDR" (p. 359).

1981

Chen, Andrew C.; Dworkin, Samuel F.; Bloomquist, Dale S. (1981). Cortical power spectrum analysis of hypnotic pain control in surgery. International Journal of Neuroscience, 13, 127-136.

Cortical power spectrum (CPS) of brain potentials was recorded from the scalp between prefrontal and parietal regions in both right hemisphere (RH) and left hemisphere (LH). A pattern of laterality shift in CPS occurred at different stages during an extensive oral surgery, performed under hypnosis, in a young female patient. Video and audio recordings as well as psychophysiological recordings were obtained through the following 6 stages: Baseline, Hypnosis, Surgery (1 hr, no cortical recording), Immediate Postsurgery Procedure, Hypnotic Re-experience, Hypnotic Rest, and Posthypnotic Baseline. Indications of anxiety and pain scores were reported in writing by the patient through verbal command by the hypnotist. In each stage, 10 min of CPS (10 spectrum/stage, 8 epochs/spectrum, 6 seconds/epoch) were analyzed by a PDP-11 computer. The results of CPS analysis demonstrated significant large total power reduction at different stages. There was significant correlation between both hemispheres at baseline, but dissociation of hemispheric power output occurred during hypnosis stages. LH was more dominant than RH during baseline and presurgery hypnosis, but both were leveled-off immediately following the surgery procedure. However, RH became more dominant during all postsurgery hypnosis stages. Interestingly, this pattern shifted back to the original relationship during the posthypnotic baseline stage. Specific changes of spectral power in theta and alpha of EEG activities in both hemispheres also occurred in conjunction with hypnosis.

## NOTES

Subject was a 25 year old woman, described as only medium in hypnotizability. She scored 3 on the 5-point Stanford Hypnotic Clinical Scale, 7 on the 12-point Stanford Hypnotic Susceptibility Scale, and 3 on up-gaze, between 2 and 3 on eye roll, on the Spiegel eye roll test.

The principal hypnotic approach was a suggestion of dissociation, i.e. that the patient "experience herself swimming freely and powerfully, in a deep cold mountain lake, pre-occupied with the intensity of the blue-black color of the water, the shimmering of light from above, and the possibilities of exploration of rock formations, caves, etc. It was suggested that while she was experiencing the exhilaration and strenuous stimulation of the cold water and the vigorous exercise, an 'observing-self' would remain on the shore, watching and ensuring that no harm would come to the person. The suggestion was reinforced that any stimulation experienced was experienced in the body, not in the person" (p. 129).

The patient was trained in inductions and dissociation first in the therapist's office, then with two sessions in the research laboratory (where tooth pulp stimulation pain thresholds were measured), and then two sessions in the hospital dental operatory.

The results of the computerized CPS were analyzed by hemispheres. "Large reductions in total power occurred at different stages associated with hypnosis and these reductions in power output of the CPS showed significant left-right differences" (p. 130).

"The total energy output of LH [left hemisphere] continued to diminish as hypnosis continued by as much as 80% of baseline value, while RH [right hemisphere] power output tended to be stabilized from the initial hypnosis recording stage until the awake baseline stage" (p. 130).

"Those stages involving hypnosis were characterized by dominant RH energy output in the alpha spectrum. ...

"Alpha output for the LH decreased an average of 65% between awake baseline levels and postsurgery hypnosis stages, while RH alpha only decreased approximately 50% of resting levels. This resulted in a relative shift of alpha output which was approximately equal in both hemispheres prior to surgery, to a 2:1 shift in favor of RH alpha output as hypnosis progressed. This differential shift in laterality of alpha was reversed when the subject awakened from hypnosis.

"Of interest was the observation that total power reductions and laterality shifts associated with hypnosis were not altered by the profound instrumentation of surgery and postoperative pain, nor were observed laterality shifts affected by hypnotic suggestions aimed at recreating the surgical experience (see Stage 5)" (p. 130).

During the experiment when the investigators used hypnotic suggestion to recreate the surgical experience, LH output continued to diminish while RH output did not change, making the LH-RH contrast highly significant. "This suggests that the RH is active during deep stages of hypnosis and can remain so despite hypnotic suggestions which are presumed to be intensely aversive" (p. 131).

In their Discussion, the authors reinforced the conclusion that overall cortical functioning is reduced during hypnosis, and that the left cerebral hemisphere shows

a greater reduction than the right. They discuss the increased theta density in RH and LH during the postsurgery hypnosis stage in terms of reports that theta is associated with altered states of consciousness (Tebecis et al., 1975; Ulett et al., 1972; Anad, China, & Singh, 1961; Banquet, 1973; Kasamatsu & Hirai, 1966; Wallace, 1970) and with cognitive tasks like mental arithmetic (Dolce et al., 1974).

The authors note that their results are congruent with Hilgard's neodissociation theory of hypnosis, and add that since their suggestions were dissociative in nature rather than of local anesthesia, the EEG may reflect the brain physiology of dissociation.

Finally, they comment on the implications for pain neurophysiology. "The total power changes and shifting patterns in laterality of cortical functioning observed more closely tracked the hypnosis experience than the pain experience; this is, in fact, a very puzzling issue. It appears on the face of it that the EEG measurements recorded are not reflective of EEG-related pain phenomenology despite the strenuous and invasive surgical procedures used. The observations that overall power output continued to decrease during the several hypnosis stages after strenuous surgery and then increased as the patient came out of hypnosis makes reasonable the possibility that hypnosis has some functional brain correlates; we cannot conclude from the present cortical power spectrum analysis that any brain correlates of surgical pain were revealed. We are well aware that EEG recordings were not available during actual surgery itself, because of artifacts resulting from head movements, etc. Nevertheless, it can be fairly claimed that recordings obtained immediately after such oral surgery of one hour duration, could reasonably be expected to be associated with a person in pain. But, both by verbal report and available objective data, any surgically induced traumatic pain was of brief duration under hypnosis" (p. 135).

Gross, Meir, M. D. (1981). Hypnosis for dissociation -- diagnostic and therapeutic. Journal of the American Society of Psychosomatic Dentistry and Medicine, 28 (2), 49-56.

## NOTES

Dissociative disorders might be at times very difficult to diagnose and treat, especially since they are very similar to epilepsy in general and to temporal lobe epilepsy in particular. Amnesia, fugue, changing personality and depersonalization are part of both disorders. Patients who suffer from dissociative disorders might be diagnosed and treated for epilepsy with anticonvulsive medications without any beneficial results. These patients are labeled as epileptics and have to face the social stigmata associated with being epileptic. The wrong label could even reinforce the sick role and make it become fixed and chronic.

Hypnosis was used to diagnose the dissociative disorder by using the hand levitation technique for the differential diagnosis. It was found by the author that patients who suffer from dissociative disorders would get into spontaneous hypnotic trance during the hand levitation. Hypnosis was used also for successful therapy of these patients.

Seven cases are presented in which the hand levitation technique was used to diagnose the dissociative disorder. They were also treated by hypnotherapy. Their treatment by hypnosis is discussed. The purpose of this paper is to introduce the hand levitation technique for the differential diagnosis of dissociative disorder and to emphasize the effectiveness of hypnotherapy in the treatment of this disorder. Sorting out the cases of dissociative disorders from the epileptics is very important clinically, since it can save many patients from the anguish of having to take anti-convulsants unnecessarily and having to face the social stigmata of being labeled as epileptic.

McConkey, Kevin M.; Sheehan, Peter W. (1981). The impact of videotape playback of hypnotic events on posthypnotic amnesia. Journal of Abnormal Psychology, 90 (1), 46-54.

Examined the breakdown of amnesia by showing 48 hypnotic and nonhypnotic undergraduates (Harvard Group Scale of Hypnotic Susceptibility) a videotape of the hypnotic events they had experienced. The extent of the amnesia for these events was defined precisely, and simulating procedures were employed to analyze the cues in the overall test situation. Videotape display of the hypnotic events was presented via the Experiential Analysis Technique and served to optimize conditions for breakdown. Some hypnotic Ss' amnesia could not be broken down even though they were exposed via videotape playback to the events to be recalled and when suggestions for the period of amnesia were quite explicit. Simulators showed breaching of amnesia but attributed their recall to the videotape rather than to the hypnotic session. Hypnotic Ss were distinctive in their inability to recall experiential aspects of their performance even though they could recall behavioral aspects. The data are discussed in relation to the hypothesis that dissociative cognitive mechanisms underlie posthypnotic amnesia. (22 ref).

1980

Hilgard, Ernest R. (1980, October). Hypnotic modification of sensitivity and control. [Paper] Presented at the annual meeting of the Society for Clinical and Experimental Hypnosis, Chicago.

#### NOTES

The author presents a factor analysis of several scales in the hypnosis domain: HGSHS:A, Wilson-Barber CIS, Stanford Hypnotic Susceptibility Scale Form C, Questionnaire on Mental Imagery (Sheehan's modification of Betts) and the Tellegen- Atkinson Absorption Scale. Scales were broken down into components first. He didn't report all of the factors, but shows how these tests fall on a graph defined by Factor 1 (Amnesia/Cognitive) and Factor 4 (Absorption/Imagery). "Capacity for fantasy and amnesia are so different that hypnosis probably includes both."

Hilgard concludes that he doesn't like a state theory for hypnosis or the idea of "trance" because it is unidimensional. He prefers "dissociation" because we think of it as a continuum. Even Highs differ one from another in the nature of their responses. Altered- state-of-consciousness theories don't readily explain partial

dissociation (e.g. persistence of a suggestion such as arm rigidity after hypnosis is terminated; or hysterical paralysis).

Prince, Raymond (1980). Variations in psychotherapeutic procedures. In Triandis, Harry C.; Draguns, Juris G. (Ed.), Psychopathology (6, pp. 291-349). Boston: Allyn & Bacon.

#### NOTES

Prince points out that indigenous practitioners often capitalize on the organism's endogenous healing mechanisms which develop spontaneously when the individual is distressed. "healers around the world have learned to manipulate and build upon these endogenous mechanisms in a variety of ways to bring about resolution of life's problems and alleviation of suffering" (p. 292). Prince is referring here to altered states of consciousness such as dreams, trance states, dissociations, and mystical experiences of various sorts which are cultivated and elaborated by indigenous healers for therapeutic purposes. In general, Western type practitioners have denigrated these procedures...." (from *Ann. Rev. of Psychol.*, 1982, pp 243-244).

1977

Anderson, J. W. (1977). Defensive maneuvers in two incidents involving the Chevreul pendulum: A clinical note. International Journal of Clinical and Experimental Hypnosis, 25, 4-6.

#### NOTES

Hypnosis frequently facilitates increased access to the unconscious. In both of these cases, the hypnotized subject gained contact with a thought which otherwise would likely have remained out of awareness. Then the ego quickly resorted to defensive maneuvers in order to deny the thought" (p. 6).

Chertok, Leon; Michaux, D.; Droin, M. C. (1977). Dynamics of hypnotic analgesia: Some new data. Journal of Nervous and Mental Disease, 164, 88-96.

Following two surgical operations under hypnotic anesthesia, it was possible, during subsequent recall under hypnosis, to elicit a representation of the past operative experience. It would seem that under hypnosis there is a persistence of the perception of nociceptive information and of its recognition as such by the subject. From an analysis of these two experiments in recall, it is possible to formulate several hypotheses concerning the psychological processes involved in hypnotic analgesia. In consequence of an affective relationship, in which the hypnotist's word assumes a special importance for the subject, the latter has recourse to two kinds of mechanism: a) internal (assimilation to an analogous sensation, not, however, registered as dangerous-- rationalization); and b) external (total compliance with the interpretations proposed by the hypnotist), which lead to a qualitative transformation of nociceptive information, as also the inhibition of the behavioral manifestations normally associated with a painful stimulus.

Pelletier, K. R.; Peper, E. (1977). Developing a biofeedback model: Alpha EEG feedback as a means for pain control. International Journal of Clinical and Experimental Hypnosis, 25, 361-371.

3 adept meditators voluntarily inserted steel needles into their bodies while physiological measures (EEG, EMG, GSR, EKG, and respiration) were recorded. Although each adept used a different passive attention technique, none reported pain. During the insertion, 2 of the 3 Ss increased their alpha EEG activity. The role of alpha EEG and its relationship to pain control is discussed.

#### NOTES

The three adepts studied were: (1) RCT, a 34 yr old Ecuadorian who had "demonstrated control over pain by placing bicycle spokes through his body, being suspended from hooks inserted under his shoulder blades, and walking through fire -- all without reported pain or observed damage to his skin;" (2) JSL, a 31 yr old Korean karate expert, who "suspended a 25-pound bucket of water from a sharpened spoke placed through a fold of skin on his forearm;" and (3) JS, a 50-yr old Dutch meditator who had "demonstrated pain and bleeding control" (pp. 363-365). "RCT, JSL, and JS each remarked that pain is principally fear of and attention to pain, and they maintained that anyone can learn to control pain through relaxation and passive attention" (p. 367). Both JS and RCT had increased alpha EEG activity during piercing, whereas JSL showed no increase. The authors suggest that "the karate expert practiced a very focused meditation, during which he mentally saw and felt the ki energy as a point, while RCT and JS employed passive attention and did not attend to the body stimuli. Thus, it is possible for physiological measurements to reflect strategies used in dissociation of pain perception, and that the quality of pain perception is altered if S is at either extreme of focused or unfocused conscious attention" (p. 368). "We hypothesize that, for nonadepts, alpha EEG training without alpha blocking to stimuli could become a distraction technique whereby S again could learn self-control and competence as he becomes more successful in controlling his EEG" (p. 369).

Coe, William C.; Basden, B.; Basden, D.; Graham, C. (1976). Posthypnotic amnesia: Suggestions of an active process in dissociative phenomena. Journal of Abnormal Psychology, 85, 455-458.

A retroactive inhibition design was used to examine the process of posthypnotic amnesia. The results supported the notion that "forgotten" material is as available to amnesic subjects at some level as it is to nonamnesic subjects. Further, so-called forgetting appears to be the result of an active process, that is, something the subject does. Implications for understanding dissociative phenomena in general are discussed.

**Erickson, Milton H.; Rossi, Ernest L. (1976). Two level communication and microdynamics of trance and suggestion. American Journal of Clinical Hypnosis, 18, 153-171.**

The authors provide the transcript and commentaries of an hypnotic induction and an effort to achieve automatic writing. An unusual blend of Erickson's approaches to two level communication, dissociation, voice dynamics and indirect suggestion are made explicit in the commentaries. The junior author offers a 'context theory of two level communication' that conceptualizes Erickson's clinical approaches in terms consonant with Jenkins' (1974) recent contextual approach to verbal associations and memory. A summary of the microdynamics of Erickson's approach to trance induction and suggestion is outlined together with a utilization theory of hypnotic suggestion.

**Kampman, R. (1976). Hypnotically induced multiple personality: An experimental study. International Journal of Clinical and Experimental Hypnosis, 24, 215-227.**

The purpose of the study was to clarify the frequency of appearance of a hypnotically induced secondary personality and to compare Ss who were able to create secondary personalities in hypnosis to control Ss who could enter a deep hypnotic trance but were unable to produce secondary personalities.

The sample of 1,200 pupils was made up of the 3 highest grades of the secondary schools in the city of Oulu, Finland. A total of 450 students volunteered to participate in the study. All those who could enter a deep hypnotic state, 78 in all, were selected for closer study. 32 Ss were able and 43 were unable to create multiple personalities in hypnosis.

Ss also underwent a psychiatric interview. In addition, the identity of Ss was measured.

Both the psychiatric interview and identity examination gave parallel results to the effect that Ss capable of producing secondary personalities were clinically healthier and more adaptive than the group without secondary personalities. This finding is at variance with results presented in previous studies.

#### **NOTES**

Procedure for induction of multiple personalities involved re-hypnotizing Ss, suggesting, "You go back to an age preceding your birth, you are somebody else, somewhere else," and repeating the suggestion many times. Other suggestions were given that everything was completely normal, nothing miraculous was happening. A multiple personality was counted if the S then said he was a human being, was able to give his name and where he lived, could describe the social environment and his own personality.

**Hilgard, Ernest R. (1973). A neodissociation interpretation of pain reduction in hypnosis. Psychological Review, 80 (5), 396-411.**

When cold pressor pain is reduced through hypnotically suggested analgesia, the concomitant changes in heart rate and blood pressure remain essentially what they were when the pain of the ice water was normally perceived. Investigation of this somewhat paradoxical finding by way of hypnotically induced automatic writing (or its equivalent in automatic keypressing or automatic talking) reveals that at some cognitive level the subject has experienced the cold and can report its intensity, even though the suffering may be reduced. The theoretical problems posed by the experience are presented according to a possible neodissociation interpretation, compared with interpretations according to psychoanalytic ego theory and role theory. The neodissociation theory is further explicated in relation to the gate theory of pain.

1967

Dittborn, J. M.; O'Connell, D. N. (1967). Behavioral sleep, physiological sleep and hypnotizability. International Journal of Clinical and Experimental Hypnosis, 15, 181-188.

A SLEEP-INDUCTION PROCEDURE REQUIRING MANUAL RESPONSE TO A REPETITIVE AUDITORY SIGNAL WAS ADMINISTERED TO 52 SS WHO HAD CLEAR ALPHA ACTIVITY IN THEIR WAKING EEG AND WHOSE HYPNOTIZABILITY WAS KNOWN. THE OCCURRENCE OF SLEEP WAS DEFINED BY PHYSIOLOGICAL, BEHAVIORAL, AND SUBJECTIVE CRITERIA. NEITHER THE TENDENCY TO DEVELOP EEG SLEEP NOR THE ABILITY OF SOME SS TO RESPOND WHILE IN EEG SLEEP WAS RELATED TO HYPNOTIZABILITY. HYPNOTIZABILITY WAS RELATED TO A TYPE OF DISSOCIATION BETWEEN EEG SLEEP AND BOTH BEHAVIORAL AND SUBJECTIVE SLEEP SHOWN BY 5 SS, ALL HIGHLY HYPNOTIZABLE. 1966

Orne, Martin T. (1966). On the mechanisms of posthypnotic amnesia. International Journal of Clinical and Experimental Hypnosis, 2, 121-134.

Reviews experimental and clinical evidence about posthypnotic amnesia. 2 interpretations are contrasted which seem sharply opposed: (1) posthypnotic amnesia may be seen as essentially like any other hypnotically suggested experience. It can be considered as an explicitly or implicitly administered posthypnotic suggestion. (2) Amnesia can be viewed as a form of dissociation. 1 possible mechanism of such dissociation may be a basic difference of the structure of thought processes involved in hypnosis compared to those of normal waking experience. In this sense amnesia should occur independently of suggestion and be different in kind from most other hypnotic phenomena. The former mechanism may occur more frequently in experimental situations and the latter, in clinical contexts. (Spanish & German summaries) (25 ref.) Field, Peter B. (1965). An inventory scale of hypnotic depth. International Journal of Clinical and Experimental Hypnosis, 13, 238-249. (Abstracted in American Journal of Clinical Hypnosis, 1966, 1, 86)

An inventory of 300 items describing subjective experiences during hypnosis was administered to 102 students after they had wakened from hypnosis. The 38 items that correlated best with a standard measure of hypnotic susceptibility are proposed as an inventory measure of hypnotic depth. Items dealing with absorption and unawareness, automaticity and compulsion, and discontinuity from normal experience correlated best with the criterion, while items dealing with conscious motivation to enter hypnosis, feelings of surface compliance with suggestions, and unusual bodily sensations showed generally weaker relationships to the hypnotizability criterion. Johnson, David L. (1997). Weight loss for women: Studies of smokers and nonsmokers using hypnosis and multicomponent treatments with and without overt aversion. Psychological Reports, 80 (3, Pt 1), 931-933.

Study 1 compared 50 overweight adult female smokers (mean age 37.7 yrs) and 50 nonsmokers (mean age 41.2 yrs) in an hypnosis-based, weight-loss program. Smokers and nonsmokers achieved significant weight losses and decreases in Body Mass Index. Study 2 treated 100 women either in an hypnosis only (n = 50) or an overt aversion and hypnosis (n = 50) program. This multicomponent follow-up study replicated significant weight losses and declines in Body Mass Index. The overt aversion and hypnosis program yielded significantly lower posttreatment weights and a greater average number of pounds lost. (PsycINFO Database Record (c) 2003 APA, all rights reserved)

**1996**

Kirsch, Irving (1996). Hypnosis in psychotherapy: Efficacy and mechanisms. Contemporary Hypnosis, 13 (2), 109-114.

Meta-analyses have established that different psychotherapies have different outcomes. Cognitive-behavioural therapies are significantly more effective than psychodynamic therapies, and their superiority increases when long-term follow-up is assessed. Hypnosis enhances the efficacy of both psychodynamic and cognitive-behavioural psychotherapy, and this effect is especially strong in long-term outcome

of treatment for obesity. The paucity of procedural differences between hypnotic and non-hypnotic treatments in many of the studies demonstrating a substantial advantage for hypnosis suggests that the effect depends on the use of the word 'hypnosis'. Hypnosis can be regarded as an empirically-validated, non-deceptive placebo, the effects of which are mediated by response expectancies.

Kirsch, Irving (1996). Hypnotic enhancement of cognitive-behavioral weight loss treatments--Another meta-reanalysis. Journal of Consulting and Clinical Psychology, 64 (3), 517-519.

In a 3rd meta-analysis of the effect of adding hypnosis to cognitive-behavioral treatments for weight reduction, additional data were obtained from authors of 2 studies, and computational inaccuracies in both previous meta-analyses were corrected. Averaged across posttreatment and follow-up assessment periods, the mean weight loss was 6.00 lbs. (2.72 kg) without hypnosis and 11.83 lbs. (5.37 kg) with hypnosis. The mean effect size of this difference was 0.66 SD. At the last assessment period, the mean weight loss was 6.03 lbs. (2.74 kg) without hypnosis and 14.88 lbs. (6.75 kg) with hypnosis. The effect size for this difference was 0.98 SD. Correlational analyses indicated that the benefits of hypnosis increased substantially over time ( $r=.74$ ).

Wickramasekera, Ian; Price, Daniel C. (1996, November). Morbid obesity, absorption, neuroticism, and the high risk model of threat perception. [Paper] Presented at the annual meeting of the Society for Clinical and Experimental Hypnosis, Tampa, FL.

We studied seventy morbidly obese patients, candidates for gastric exclusion surgery. We found that their mean absorption score was significantly lower and that their mean neuroticism score significantly higher than a matched control group. These results are consistent with predictions from the High Risk Model of Threat Perception (Wickramasekera, 1979, 1988). People high in neuroticism are hypothesized to be hypersensitive to threat at a behavioral and biological level, and therefore, at greater risk for stress related psychobiological disorders. People low in absorption are hypothesized to have poor perception of psychosocial sources of threat have a more restricted range of psychological methods of coping with threat. Therefore, they may be at greater risk during stress of not recognizing psychosocial sources of threat of unconsciously using substances to self-soothe and of perceiving medical surgical solutions to weight gain as more credible than psychosocial therapy programs. We found that low absorption and high neuroticism as predicted by the HRMTP were significantly more prevalent among the morbidly obese seeking surgical therapy than a matched community control group.

Holroyd, Jean (1995). Handbook of clinical hypnosis, by Judith W. Rhue, Steven Jay Lynn, & Irving Kirsch (Eds.) [Review]. International Journal of Clinical and Experimental Hypnosis, 43 (4), 401-403.

## NOTES

"This is a book for the thinking clinician" (p. 401). "The editors are to be congratulated for making this volume much more coherent than most edited books" (p. 402). "My impression is that the book is best suited for an intermediate or advanced course on hypnotherapy, or for people who are already using hypnosis in treatment. Although there is some material on the basics of hypnotic inductions and a few introductory sample scripts for inductions, a beginners' course should probably use a different book, or this book could be accompanied by an inductions manual. ... I recommend it very highly" (p. 403).

Kirsch, Irving; Montgomery, Guy; Sapirstein, Guy (1995). Hypnosis as an adjunct to cognitive behavioral psychotherapy: A meta-analysis. Journal of Consulting and Clinical Psychology, 63 (2), 214-220.

A meta-analysis was performed on 18 studies in which a cognitive- behavioral therapy was compared with the same therapy supplemented by hypnosis. The results indicated that the addition of hypnosis substantially enhanced treatment outcome, so that the average client receiving cognitive-behavioral hypnotherapy showed greater improvement than at least 70% of clients receiving nonhypnotic treatment. Effects seemed particularly pronounced for treatments of obesity, especially at long-term follow-up, indicating that unlike those in nonhypnotic treatment, clients to whom hypnotic inductions had been administered continued to lose weight after treatment ended. These results were particularly striking because of the few procedural differences between the hypnotic and nonhypnotic treatments.

1993

Kraft, Tom (1993). Using hypnosis with cancer patients: Six case studies. Contemporary Hypnosis, 10, 43-48.

Hypnosis can be used in a number of different ways for helping patients suffering from cancer. As well as pain relief, hypnosis may be used to correct insomnia that does not respond to sleeping tablets; for the reduction in skin irritation and dyspnoea when these are due to organic causes, and for treatment-related over-eating. Some patients will use hypnosis in a symbolic way. When this occurs, just as in dream interpretation, it is important to ask the patient for associations, so that these symbols can be understood. Hypnosis can be an extremely useful addition to the medical armamentarium, and should be employed as an adjunct to standard forms of cancer treatment. This paper reports six case studies in which hypnosis was used to help cancer patients.

Saperstein, Guy; Montgomery, Guy; Kirsch, Irving (1993, August). Cognitive-behavioral hypnotherapy: A meta-analysis. [Paper] Presented at the annual meeting of the American Psychological Association, Toronto, Canada.

Meta-analysis was used to compare the effectiveness of cognitive-behavior therapy

(CBT) to that of cognitive-behavior therapy with hypnosis (CBHT). A review of the literature revealed 18 studies in which 20 hypnotic treatments were compared to similar non-hypnotic treatments and in which sufficient data were presented for the calculation of effect sizes. Effect sizes were weighted for sample size and then averaged. This resulted in a mean effect size of 1.37 standard deviation units, indicating that the average client receiving cognitive-behavioral hypnotherapy is better off than 90 percent of clients who receive the same treatment in a nonhypnotic context. Substantial variance in effect sizes was found, indicating the presence of a moderator variable. Further analyses indicated that this variance was limited to treatments in which obesity was the presenting problem. The mean effect size for the addition of hypnosis to treatments of obesity was larger ( $M = 1.98$ ) and more variable (variance = 4.10) than that for the addition of hypnosis to treatments for other presenting problems ( $M = .52$ ; variance = .06). Also, studies of clinical samples yielded larger effects ( $M = 1.72$ ) than analogue studies with college student samples ( $M = .07$ ). The effect of hypnosis was independent of whether relaxation training was included in the nonhypnotic treatment or whether the hypnotic treatment included suggestions that were not included in the nonhypnotic treatment. Consistent with response expectancy theory, these data indicate that the substantial positive effect obtained was due to labeling the treatment 'hypnosis,' rather than to any substantive change in clinical procedure. (ABSTRACT from Bulletin of Division 30, Psychological Hypnosis, Fall 1993, Vol. 2, No. 3.)

1992

Levitt, Eugene E. (1992, August). Hypnosis in the treatment of obesity. [Paper] Presented at the annual meeting of the American Psychological Association, Washington, DC.

The literature dealing with the hypnotherapy of overweight and weight control is comprehensively reviewed. In general, the more recent reports are methodologically more sophisticated than earlier ones. Specific techniques employed include direct and aversive suggestions, imagery, ego-enhancement, self-hypnosis and a variety of behavior modification tactics. Most hypnotherapy is carried out in groups and most subjects/patients have been female. Twenty reports providing group data summarized. All but one report weight reduction at close and at follow-up. Of eight reports using control groups, six found that the group treated by hypnotherapy lost significantly more weight than some or all of the control groups. Hypnosis with behavior modification appears to be the most effective approach. Analysis suggests that hypnosis effectuates behavioral techniques after the close of treatment. Eleven reports presenting correlations between weight loss and hypnotic susceptibility differ sharply depending upon the year of publication. Only one of seven reports published prior to 1982 found a relationship between weight loss and susceptibility. Three of four reports since 1985 found a positive relationship. It is concluded that hypnotherapy for weight control can be effective and that it is probably maximally effective with high susceptibility persons. (ABSTRACT from the Bulletin of Division 30, Psychological Hypnosis, Fall, 1992, Vol. 1, No. 3.)

Rhue, Judith W.; Lynn, Steven Jay; Kvaal, Steven; Mare, Cornelia (1992, October). Hypnosuggestive procedures in the treatment of anorexia nervosa. [Paper] Presented at the annual meeting of the Society for Clinical and Experimental Hypnosis, Arlington, VA.

#### NOTES

Much of this information can be applied to the treatment of bulimic clients. The incidence of eating disorders has increased, and hypnosis has been added to the arsenal of treatments. The literature is sparse, but there is general agreement that hypnosis is useful. See article in *Journal of Contemporary Hypnosis*.

Define one's role as a guide with this population. Define the hypnosis procedure as Self Hypnosis with this population. Use in vivo treatments for countering resistance to treatment.

Do not use hypnosis until weight is stabilized to a minimum acceptable level by a physician (possibly involving hospitalization). Premature use of hypnosis will panic an anorexic patient.

Use graded suggestions. -- Relax, feel happy and content -- Have a daydream or fantasy accompanied by feelings of relaxation and well being (which underscores the importance of fantasy in treatment) --Go to a favorite place where client feels happy (this is more positive on the affective valence; teaches them to use fantasy as a means of withdrawal from difficult feelings) -- Daydream or fantasize about a specific problem or conflict (any arena); can be open- ended and entirely projective; can suggest that you are part of the dream, there to reduce anxiety. Can provide rich material re client's dependency on you. -- Client can imagine in hypnosis that the therapist is providing advice or assistance. -- Consult inner advisor who is emotionally detached yet supportive -- View conflict from multiple perspectives. Some are resistant to viewing themselves from more than one vantage point. -- Imagine possible outcomes of problems or conflicts. Many are paralyzed by decisions. this challenges them to engage in creative problem solving by brain storming. These can be administered in conjunction with the inner advisor suggestions. -- Enact in fantasy an interpersonal problem/conflict that involves an antagonist, to dialogue with her own powerful angry self; this may precipitate cathartic expression. -- Role play interpersonal conflict in the session -- Other techniques like age regression, projecting on a screen -- Indirect suggestions to learn to care for the body and the self.

Treatment lasts 6 mos to 9 years. These suggestions serve as general guidelines.

#### 1991

Oettingen, Gabriele; Wadden, Thomas A. (1991). Expectation, fantasy, and weight loss: Is the impact of positive thinking always positive?. Cognitive Therapy and Research, 15 (2), 167-175.

Investigated the impact of expectation and fantasy on the weight losses of 25 obese women participating in a behavioral weight reduction program. Both expectations of reaching one's goal weight and spontaneous weight-related fantasies were measured at pretreatment before Ss began 1 year of weekly group treatment.

Consistent with the hypothesis that expectation and fantasy are different in quality, these variables predicted weight change in opposite directions. Optimistic expectations but negative fantasies favored weight loss. Ss who displayed pessimistic expectations combined with positive fantasies had the poorest treatment outcome. Expectation but not fantasy predicted program attendance. The effects of fantasy are discussed with regard to their potential impact on weight reduction therapy.

**Demitrack, Mark A.; Putnam, Frank W.; Brewerton, Timothy D.; Brandt, Harry A.; et al. (1990). Relation of clinical variables to dissociative phenomena in eating disorders. American Journal of Psychiatry, 147 (9), 1184-1188.**

Compared 30 female patients (aged 16-39 yrs) with eating disorders with 30 age-matched normal female Ss, using the Dissociative Experiences Scale (E. M. Bernstein and F. W. Putnam; see PA, Vol 74:14407) and additional self-report measures such as the Beck Depression Inventory. The patients demonstrated significantly higher levels of dissociative psychopathology compared with controls. Furthermore, the presence of severe dissociative experience appeared to be specifically related to a propensity for self-mutilation and suicidal behavior. Findings are discussed in light of recent data suggesting that neurochemical systems shown to be abnormal in patients with eating disorders may be key pathophysiologic substrates for dissociative experience.

**Groth-Marnat, Gary; Schumaker, Jack F. (1990). Hypnotizability, attitudes toward eating, and concern with body size in a female college population. American Journal of Clinical Hypnosis, 32 (3), 194-200.**

In this study we investigated the relationship between hypnotizability and attitudes toward food intake. 102 female college students (mean age 21) completed the Eating Attitudes Test and the Goldfarb Fear-of-Fat Scale, and were assessed for hypnotizability on the Harvard. The results indicated that level of hypnotizability was related to attitudes toward food intake and the fear of becoming overweight. Findings support the thesis that hypnotizability may be one of a variety of predisposing factors in the development and maintenance of extreme attitudes toward eating and weight regulation. Implications for changing these attitudes are discussed.

**Vanderlindin, Johan; Vandereycken, Walter (1990). The use of hypnosis in the treatment of bulimia nervosa. International Journal of Clinical and Experimental Hypnosis, 38 (2), 101-111.**

#### **NOTES**

25 people who were highly hypnotizable were treated. Treatment consisted of three phases: introduction to hypnosis, addressing core issues, and ensuring long term results. The induction included focus on breathing, relaxation, and arm levitation. Subject was told to imagine that she is eating a meal, while concentrating and

tasting her food. She is then told to imagine a recent binge and to exaggerate all the negative consequences of bingeing (weight gain, low self-esteem) and all the positive consequences of binge-free life.

To address Subject's core issues of why bingeing started, the Subject is told to separate her ego from her bulimic past, and the therapist then tries to find out why the bulimic past entered the patients' life. The therapist then tries to 'negotiate' with the bulimic past and tries to help the patient find other ways to deal with the problems. Cognitive restructuring and hypnosis techniques are used.

The final phase, which entails a year of followup care, involves helping the patients to become independent from their past. Many bulimic patients are still dependent on their parents, and this may have caused their dependency on food. Therefore, the goal of hypnosis is to allow herself to become emotionally independent and to control her life.

It was estimated that 50% of patients completely recovered and 30% showed great improvement but 20% did not change at all.

1989

Ross, Colin A.; Heber, Sharon; Norton, G. Ron; Anderson, Geri (1989). Differences between multiple personality disorder and other diagnostic groups on structured interview. Journal of Nervous and Mental Disease, 177 (8), 487-491.

The Dissociative Disorders Interview Schedule was administered to 20 Ss with multiple personality disorder, 20 with schizophrenia, 20 with panic disorder, and 20 with eating disorders (mean ages 25.4-38.4 yrs). Findings show that multiple personality could be differentiated from the other groups on variables such as history of physical abuse, sexual abuse, substance abuse, sleepwalking, childhood imaginary playmates, secondary features of multiple personality, and extrasensory and supernatural experiences. Those with multiple personality also differed from the other groups on Diagnostic and Statistical Manual of Mental Disorders (DSM-III) criteria for multiple personality, psychogenic amnesia and psychogenic fugue. The groups did not differ on the number of Ss who had a major depressive episode.

1987

Baker, Elgan L.; Nash, Michael R. (1987). Applications of hypnosis in the treatment of anorexia nervosa. American Journal of Clinical Hypnosis, 29, 185-193.

Historic and current reports in the literature involving applications of hypnosis with anorectic patients are reviewed and integrated to explicate core aspects of hypnotic interventions in treating anorexia nervosa. A comprehensive hypnotherapeutic approach is delineated which emphasizes the use of hypnotic strategies to reduce tension, enhance self-control, support increased and realistic body awareness, alter distorted body image, and foster appropriate autonomy and individuation. Preliminary data are also reviewed which support the clinical efficacy of this approach.

1986

Cochrane, Gordon; Friesen, J. (1986). Hypnotherapy in weight loss treatment. Journal of Consulting and Clinical Psychology, 54, 489-492.

Investigated the effects of hypnosis in weight loss for 60 females, at least 20% overweight and not involved in other treatment. Six client variables (suggestibility, self-concept, quality of family origin, age of obesity onset, education level, and socioeconomic status) and a process variable of representational systems were analyzed in relation to weight loss. Treatment included group hypnosis with metaphors for ego-strengthening, decision making and motivation, ideomotor exploration in individual hypnosis, and group hypnosis with maintenance suggestions. There were two experimental groups (hypnosis with and without audiotapes) and a control group, assessed immediately after treatment and at 6-month follow-up. Hypnotizability, use of audiotapes, and the other five variables were not predictive of weight loss. But, hypnosis was more effective than a control group (17 vs. .5 pounds on follow-up).

Sands, Steven (1986, August). The use of hypnosis in establishing a holding environment to facilitate affect tolerance and integration in impulsive patients. Psychiatry, 49.

This paper is concerned with the use of hypnosis in establishing a facilitating and holding environment in the treatment of impulsive behavior across a range of diagnoses. The reason for this cross-diagnostic viewpoint is to underscore the common sources of such action and the needs to be met in its treatment. Illustrations from work with two patients are presented: One was a hypomanic and bulimic woman who was successful in her profession; the other was an underemployed and sometimes unemployed schizophrenic man. Both were inclined to self-defeating impulsive action---bulimia in the woman, assault in the man.

Andersen, M.S. (1985). Hypnotizability as a factor in the hypnotic treatment of obesity. International Journal of Clinical and Experimental Hypnosis, 33 (2), 150-159.

The study describes a program of time-limited, relatively uncontaminated hypnotherapy for the treatment of obesity, and explores relationships between degree of objectively measured hypnotizability (by the Stanford Hypnotic Susceptibility Scale, Form A of Weitzenhoffer and E. R. Hilgard, 1959) and success at weight reduction via hetero- and self-hypnosis. Of the 43 male and female adult outpatients of the Morton Prince Center for Hypnotherapy in New York City who entered the program, 30 Ss completed the orientation session, 8 weekly individual treatment sessions, and 12 weeks of follow-up, during which self-hypnosis was practiced. These Ss showed an average weight loss of 20.2 pounds. Results indicated a statistically significant positive association between degree of hypnotizability and success at weight reduction. High hypnotizable Ss were significantly more aided by the treatment program than either medium hypnotizable or low hypnotizable Ss.

**Bolocofsky, David N.; Spinler, Dwayne; Coulthard-Morris, Linda (1985). Effectiveness of hypnosis as an adjunct to behavioral weight management. Journal of Clinical Psychology, 41 (1), 35-41.**

**109 17-67 year olds completed a behavioral treatment for weight management either with or without the addition of hypnosis. Results show that, at the end of the 9-week program, both interventions resulted in significant weight reduction. However, at 8-month and 2-year follow-ups, the hypnosis Ss showed significant additional weight loss, while those in the behavioral-treatment-only group exhibited little further change. More Ss who used hypnosis also achieved and maintained their personal weight goals. It is suggested that hypnosis may have been an effective motivator for Ss to continue practicing the more adaptive eating behaviors acquired during treatment. Findings support the utility of employing hypnosis as an adjunct to a behavioral weight management program. (25 ref)**

**Morris, Don M.; Nathan, Ronald G.; Goebel, Ronald A.; Blass, Norman H. (1985). Hypnoanesthesia in the morbidly obese. Journal of the American Medical Association, 253 (22), 3292-3294.**

**The advent of chemical anesthesia relegated hypnosis to an adjunctive role in patients requiring major operations. Anesthesia can be utilized with acceptable risk in the great majority of patients encountered in modern practice. But an occasional patient will present--such as one with morbid obesity--who needs a surgical procedure and who cannot be safely managed by conventional anesthetic techniques. This report describes our experience with such a patient and illustrates some of the advantages and disadvantages of hypnoanesthesia. The greatest disadvantage is that it is unpredictable. Close cooperation between the patient, hypnotist, anesthesiologist, and surgeon is critical. However, the technique may be utilized to remove very large lesions in selected patients. Hypnoanesthesia is an important alternative for some patients who cannot and should not be managed with conventional anesthetic techniques.**

**Pettinati, Helen M.; Horne, Robert L.; Staats, Julia M. (1985). Hypnotizability in patients with anorexia nervosa and bulimia. Archives of General Psychiatry, 42 (10), 1014-1016.**

**Examined the hypnotic capacity at hospital admission of 65 patients with anorexia nervosa and 21 with bulimia, as diagnosed by DSM-III criteria. Anorexics were divided into the subgroups of 19 abstainers and 46 purgers. Ss received 3 standardized hypnosis scales consisting of induction, suggestions, and multiple measures of hypnosis. Analyses showed that hypnotic capacity was significantly higher in bulimic patients than in anorexics or normal, age-matched controls. Anorexic Ss who purged had higher hypnotic capacity than the normal population, although as a group they were not as highly hypnotizable as Ss with bulimia. It is**

suggested that anorexic and bulimic patients with high hypnotic capacity may be able to reduce their distorted body image with the aid of hypnosis. (26 ref).

1984

Bushnell, John A. (1984). Hypnosis and single case experimental design: Some ruminations on a theme. Australian Journal of Clinical Hypnotherapy and Hypnosis, 12 (1), 1-8.

Attempts to study psychotherapeutic interventions have traditionally used a between-groups experimental design which has required large numbers of subjects in order to provide homogeneity of clinical conditions. The practical problems associated with such a method of research are such that rigorous evaluation of hypnosis has most often not been undertaken. Single case design, especially multiple baseline, offers an alternative research strategy which has significant advantages in hypnosis research, enabling proper account to be taken of ethical considerations whilst focussing on clinical rather than statistical significance. Furthermore, single case design enables variability to be interpreted as useful data rather than being lost as error; and it offers a strategy for establishing the existence of treatment effects due to interventions using hypnosis. The application of a multiple baseline research design within routine clinical practice is discussed in the case of a young woman with an unusual eating disorder.

#### NOTES

The patient "complained of regurgitating all food repeatedly after every meal. This occurred about eight times after breakfast, ten times after lunch, and up to 15 times following the evening meal" (p. 3). "The food was rechewed, swallowed and about 5 minutes later the pattern would repeat itself" (p. 3).

Pettinati, Helen M. (1984, October). Differential hypnotic response in anorexia nervosa and bulimia: An item analysis. [Paper] Presented at the annual meeting of the Society for Clinical and Experimental Hypnosis, San Antonio, TX.

#### NOTES

Because bulimics are thought to be dissociative, congruent with their symptoms, it was predicted that they would score higher on the dissociative items of the hypnotizability scales. Previously published data shows:

N Mean Score College students 203 5.07

Bulimics 21 7.71\*\*

Anorexic Purgers 46 6.13\*

Anorexic Abstainers 19 5.00

\* & \*\* = higher than norms

Hilgard's 3 factors of hypnotizability scales were scored. Bulimics scored higher than norms on the cognitive dissociation factor but not on the motor and motor challenge factors, and purging anorectics also scored higher on this factor. The

cognitive dissociation factor consists of neither the easiest nor the most difficult items on Form C, so this doesn't represent item difficulty.

Item analysis: 1. Bulimics score higher on taste hallucination, arm rigidity, dream, age regression, arm immobilization, & hallucinated voice. 2. Purgers score higher on arm rigidity, dream, and arm immobilization 3. Abstainers evidenced no difference from norms.

1983

Spiegel, David (1983). Hypnosis with medical/surgical patients. General Hospital Psychiatry, 5, 265-277.

The role of hypnosis as a tool in the treatment of problems commonly encountered among medical and surgical patients is examined. Hypnosis is defined as a change in state of mind far more akin to intense concentration than sleep. Diagnostic implications of differences in hypnotic responsivity are explored, and scales suitable for use in the clinic are examined. Uses of hypnosis in treating anxiety, pain, childbirth, psychosomatic symptoms, seizure disorders, neuromuscular dysfunction, and habits are described and evaluated. The phenomenon of hypnosis is presented as a means of exploring the mind-body relationship in a controlled fashion, providing information of diagnostic importance while at the same time allowing hypnotizable patients to intensify their concentration and interpersonal receptivity in the service of a therapeutic goal.

1981

Goldstein, Y. (1981). The effect of demonstrating to a subject that she is in a hypnotic trance as a variable in hypnotic interventions with obese women. International Journal of Clinical and Experimental Hypnosis, 29 (1), 15-23.

In order to investigate the question of whether or not Ss experiencing a phenomenon during trance which would be very unlikely to occur outside of trance improves the efficacy of hypnotic treatment for obesity, a S pool of obese women was divided into 3 groups: a non-hypnotic behavior modification group, a hypnosis group without any special phenomenon structured into it, and a hypnosis group with such a phenomenon (hand levitation). Weight-loss data were collected 4 weeks and 6 months after the start of treatment. All treatments resulted in at least moderate weight loss. Statistically significant differences were found between the hypnosis-with-hand-levitation treatment effect and the other treatment effects. Possible reasons for the treatment effects and the differences obtained are discussed.

Wadden, Thomas A.; Flaxman, J. (1981). Hypnosis and weight loss: A preliminary study. International Journal of Clinical and Experimental Hypnosis, 29 (2), 162-173.

The purpose of this study was to determine both the efficacy and the active treatment components of a hypnotherapeutic program for weight loss. 30 Ss at least

10% over their ideal weight were randomly assigned to 1 of 3 conditions: (a) hypnosis, (b) covert modeling, or (c) relaxation-attention control. At the end of 7 weeks all of the groups showed weight losses comparable to those achieved by behaviorally oriented reduction programs, but there were no differential losses among the groups at post-treatment or at 6- and 16-week follow-up assessments. The findings suggest that the efficacy of hypnosis as a weight-reduction strategy is attributable to factors shared in common with a minimum treatment condition, including positive expectancy, weekly participation in a reduction program, relaxation training, and limited dietary counseling. Consistent with previous findings, no relationship was found between hypnotic suggestibility and weight loss. The need to examine both different treatment techniques and overweight populations is discussed.

1980

Bornstein, Philip H.; Devine, David A. (1980). Covert modeling-hypnosis in the treatment of obesity. Psychotherapy: Theory, Research and Practice, 17 (3), 272-276.

Investigated the efficacy of a covert modeling/hypnosis treatment package in the control of obesity. 48 overweight female volunteers (who had been administered the Harvard Group Scale of Hypnotic Susceptibility, Eating Patterns Questionnaire, and Rotter's Internal-External Locus of Control Scale) were randomly assigned to 1 of the following groups: (a) covert modeling/hypnosis, (b) covert modeling, (c) no-model scene control, and (d) minimal treatment (where Ss received a shortened version of the covert modeling/hypnosis procedure following an 8-wk no-treatment period.) Results indicate a significant effect for weight loss from pretreatment to follow-up across all groups combined. Proportion weight loss measures indicated significantly greater weight loss only for the covert modeling/hypnosis group as compared to the no-model controls. Implications for combining behavior therapy and hypnotic techniques are discussed. (30 ref).

Deyoub, P. L.; Wilkie, R. (1980). Suggestion with and without hypnotic induction in a weight reduction program. International Journal of Clinical and Experimental Hypnosis, 28 (4), 333-340.

Identical suggestions for the control of obesity were administered to a group receiving hypnotic induction and a group receiving task-motivational instructions. A no-treatment control group was also included. The only significant finding was greater weight loss by Ss in the task-motivational group than Ss in the control group. Much of the difference was attributed to weight gain of Ss in the control group. Within groups, highly suggestible Ss lost more weight in the hypnotic group, while suggestibility was unrelated to weight loss in the task-motivational group. The possibility that task-motivational and hypnotic Ss approached treatment with different mental sets and expectations was discussed. The role of hypnotizability in the hypnotic treatment of obesity was discussed.

1955

Hershman, Seymour (1955). Hypnosis in the treatment of obesity. Journal of Clinical and Experimental Hypnosis, 3 (3), 136-139.

#### NOTES

Three case histories are presented for patients treated for obesity using hypnotherapy. The procedure in hypnosis involved: (1) visualizing person on a stage who is unhappy, depressed, followed by a person who is happy, content; (2) discussing diet with indirect suggestions that adherence would lead to the happy, contented feelings and vice versa for non-adherence; (3) giving permissive suggestions regarding behavior change (e.g. "Perhaps it is only certain foods that should be distasteful and not the eating of 'allowed' foods" (p. 137). Patients were seen weekly for 4-6 weeks, then bi-weekly or monthly for several months, and then only occasionally. "The easier acceptance of the therapy in the hypnotic state cannot be too strongly emphasized. ... rapport is established more quickly and easily, and the feeling of participation on the part of the patient convinces him that the therapy will be successful" (p. 139).

#### EDUCATION

1998

Oster, M. I. (1998). A graduate school curriculum in clinical hypnosis. American Journal of Clinical Hypnosis, 41 (1), 65-74.

This paper describes a formal, integrated curriculum in clinical hypnosis that is offered through a psychology graduate school. An integrated program offers students and practicing professionals the opportunity to learn hypnosis in an environment that offers ongoing supervision and support of their long term development. Program development and recognition; program philosophy, objectives, and curriculum; and course description and content are described. (PsycINFO Database Record (c) 2003 APA, all rights reserved)

Walling, David P.; Baker, Jeffrey M.; Dott, Sharon G. (1998). Scope of hypnosis education in academia: Results of a national survey. International Journal of Clinical and Experimental Hypnosis, 46 (2), 150-156.

The present article examines the current status of hypnosis training and the attitudes of program chairs toward inclusion of such training in doctoral education. A brief survey on hypnosis training was sent to all psychology doctoral programs accredited by the American Psychological Association (n = 218) as well as 24 nonaccredited doctoral programs. Twenty-six percent of responding programs (n = 44/170) report offering either required or elective coursework in hypnosis. Of those programs offering a course in hypnosis, the mean semester credit hours earned was 3. Although many program directors support opportunities for hypnosis education in doctoral education, other constraints (e.g., available faculty, required coursework) limit its availability.

1996

Cheri (1996). Therapist sexual feelings in hypnotherapy: Managing therapeutic boundaries in hypnotic work. International Journal of Clinical and Experimental Hypnosis, 44 (1), 20-32.

This article elaborates ways that using hypnosis may create special vulnerability for the clinician, not only to experiencing sexual feelings toward patients but also to becoming confused about the meaning of these feelings and their relevance to treatment, as well as about the maintenance of appropriate patient-clinician boundaries. Special qualities of the hypnotic experience and relationship likely to generate erotic feelings and impulses in patients and clinicians alike are addressed. A clinical case example illustrates many possible meanings of therapist sexual feelings and the impulses to avoidance or acting out they may provoke. Clinically appropriate and inappropriate ways of managing boundaries in the presence of sexual arousal and of using sexual feelings to deepen clinical understanding and direct treatment interventions are discussed.

Walling, David P.; Baker, Jeffrey M.; Dott, Sharon G. (1996). A national survey of hypnosis training -- its status in psychiatric residency programs: A brief communication. International Journal of Clinical and Experimental Hypnosis, 44 (3), 184-188.

Hypnosis training in psychiatric residency programs has not previously been well documented in the literature. This article examines the extent of such training in residency programs and the attitudes of residency directors to training and the use of hypnosis. A brief survey requesting information on hypnosis training was sent to all psychiatric residency directors in the United States. Sixty-three percent of responding program directors (n = 154) report offering either required or elective coursework in hypnosis. Of programs offering hypnosis training, the mean number of hours was 8, suggesting that many psychiatrists have only limited exposure to hypnosis during residency. The authors conclude that hypnosis training is widely variable within psychiatric residency programs and is dependent on the faculty and training director interests within individual programs.

Wark, David (1996). Teaching college students better learning skills using self-hypnosis. American Journal of Clinical Hypnosis, 38 (4), 277-287.

Reports the effects of self-hypnosis used by 51 college students enrolled in a 10-wk course on efficient learning skills. All Ss were administered the Creative Imagination Scale (CIS). Subsequently, they learned to enter and deepen alert self-hypnosis. They gave themselves personal suggestions and then studied in hypnosis. They reported their depth of hypnosis and satisfaction with each session. Grades were collected the quarter before, during and after the course. Satisfaction and depth data indicated the Ss were involved throughout the course. Statistical testing

showed that Ss who scored highest on the CIS had the lowest initial GPA, improved most during the course, and significantly increased their GPA in the quarter after.

**1994**

**Brown, Gail W.; Riddell, Rodney; Summers, David; Coffman, Brent (1994, August). Use of hypnosis by practitioners in the school setting. [Paper] Presented at the annual meeting of the American Psychological Association, Los Angeles.**

#### **NOTES**

Hypnosis is a therapeutic procedure that is appropriate for some school-age clients. Through the use of hypnosis that utilizes metaphors and imagery, children can be empowered to find unique solutions to their problems. Children enjoy the feeling of power and mastery that they have when able to perform hypnotic phenomena. They like to play magic and can be told that a finger or other body part will become numb. Because a major goal of hypnotherapy is to teach a child to be an active participant in his or her own behalf, the focus is on creating solutions and mastering the situation rather than enduring the problems. Four case studies demonstrate the utility of hypnosis in the treatment of phantom pain and nausea, sleep terror disorder, school phobia, and spider phobia. In each case, treatment goals were realized. Because the solutions were self-generated, the behavioral changes maintained over time and situation.

**Case #1:** Hypnosis was used to help alleviate phantom limb pain and nausea during chemotherapy following amputation of the right leg at the knee due to cancer in a thirteen-year-old male. The client had indicated that he loved nature and enjoyed the mountains. The metaphor described a young tree that has just begun to grow small silvery leaves. The spring floods tear the limbs and branches from the stump. The deep roots and stump of the tree are all that remain. The tree is not the same as before the flood. Its roots are stronger, its base more sturdy compared to the branches and limbs. The young tree has withstood the catastrophe of the torrent of waters and is even stronger than before. To counter the nausea and vomiting associated with chemotherapy a switch mechanism metaphor was used. The client was adroit with computers and had no difficulty picturing a switch located in his brain which could "turn off" the nausea from chemotherapy. A room contained all the unpleasant feelings that were being experienced. In this room is a light of a particular color that represents all the unpleasant sensations. Press the key on the computer that controls the switch to turn off the colored light in that room. Suggestions for healing were also given. Your body has known for years how to heal. Visualize the battle between good and bad cells and the victory of the good cells.

**Case #2:** Hypnosis was used to alleviate sleep terror disorder in a ten-year-old female. The onset of the subject's parasomnic symptomatology appeared to coincide with her starting kindergarten and her family's relocation shortly before. The initial treatment consisted of progressive relaxation, deep breathing, and the visual image of her "secret safe place." An induction utilizing a variety of images was presented. Hiking barefoot on a cool moss covered mountain trail, sitting in an alpine meadow on a warm summer afternoon, and flying proved most effective in

facilitating trance. The participant was told to "Visualize all your anxiety and tension as hard grey rocks. Pick up these rocks and place them in your pockets. Go to the front porch of your "secret safe place and on the porch is a "magic hefty bag." Place your hard grey rocks that contain all your anxiety and tension in the magic bag. Once in the bag, the rocks will no longer weight you down, you will be free of any feelings of stress or tension. Your bed is magic; it is covered with a special glue which will keep you in a reclining position until you are fully rested and ready to awaken."

Case #3: Hypnosis was used in the treatment of school phobia in a nine-year-old male. The student experienced intense anxiety whenever separation from the primary caretaker occurred. The teacher stated that this boy experienced frequent absences and crying spells that were only relieved by phone calls to his mother or the presence of his mother next to him in class. In preparation for the intervention, the student was asked to draw a picture of how he felt inside during a panic attack. He drew a fire. He also said that only his mother could put that fire out. This information was utilized in creating a metaphor that described a house in a small town. "The mother had left, and a young boy was left alone. While at home, the boy looked out the window and saw several boys trying to burn a neighbor's yard! Acting quickly, he called the fire department, grabbed the fire extinguisher and unraveled the garden hose. He was able to extinguish the fire. The neighbors and friends were very happy and praised the boy's performance. When his mother heard the good news, she quickly returned home and held a celebration in his honor." Following the metaphor, hypnotherapy continued with suggestions about fire extinguishers that the subject could use to put out emotional fires.

Case #4: Hypnosis was used in the treatment of spider phobia. Diagnosis of phobia was made in this eleven-year-old female when the fear or avoidance behavior was distressing. The child's strained facial expressions occurred even at the thought of seeing what she described as "a creepy, crawly creature with 8 legs." Preparatory to her first induction the participant was read the story of Charlotte's Web (White, 1980) to facilitate the imagery for future hypnotic work. In the following session systematic desensitization was accomplished using characters from the story of Charlotte's Web. During the third session the subject was age regressed to the first time she remembered seeing a spider. She recalled playing in the woods outside her family home on an island and seeing a large web stretched between two trees with a very large spider in the center of its web. She was then asked to remain at that place to look closely at that spider as it was most likely Charlotte or one of Charlotte's family. Upon closer investigation she saw not only Charlotte but "teeny-tiny babies." The event was reconstructed as a happy experience. The imagery provided by Charlotte's Web permitted the subject to fantasize her previous frightful experience and reframe spiders as cute little "teeny-tiny" babies with admirable human qualities.

Krippner, Stanley (1994, August). Improvement of academic skills for children and adolescents with hypnosis. [Paper] Presented at the annual meeting of the American Psychological Association, Los Angeles.

## NOTES

Literature and research in this area are sparse, though there is clinical evidence that hypnosis is useful. My definition of hypnosis is a procedure facilitating a variety of structured goals or procedures in which a suggestion or motivation is enhanced by a mechanical device, another person, or oneself.

There are 3 areas of application in academics:

study habits

test taking

strengthening academic motivation

The hypnotist should know the specifics of academic achievement, because specific suggestions (e.g. "Imagine you are at desk focusing well for 20 minutes,") are better. Emphasis on the positive is better than negative. Use the words "imagination," "concentration," or "imagining pictures," rather than "hypnosis." I try to determine what they expect, based in part on what words they use.

In elementary school I focus on attitude and self esteem. I have them imagine reading a story, then how well they feel; that when they notice mistakes they won't be bothered because everyone makes mistakes.

For high school, I help them develop good habits for time motivation (e.g. suggestions to "make an outline to follow while you study"). At college level, I introduce self hypnosis. I make frequent use of mental imagery, at all levels--especially imagery rehearsal, in which the person is engaged in a particular activity. In the NSF report on accelerated learning techniques (a project sponsored by the Army), Lozonov's "suggestopedia" techniques were studied. This review indicated it might enhance training effectiveness and reduce training time.

I have observed the suggestopedia classes in Bulgaria and Hungary. Classes had a relaxed comfortable learning environment. Rather than individual learning, it was group learning. It included preliminary exercises, new material, and a review of what was learned. The first stage used 2/3 of the time. Then suggestions were given by the teacher to promote learning. The presentation phase took one third of the time. The method encourages students to make mental images of the material. In foreign language classes, people take on new roles.

1993

Kokoszka, Andrzej (1993). Occurrence of altered states of consciousness among students: Profoundly and superficially altered states in wakefulness. Imagination, Cognition and Personality, 12, 231-247.

In a questionnaire survey waking altered states of consciousness (ASC) are found to be common among 174 Polish students. The experience of Superficially Altered States of Consciousness (SACS) was reported by 96 percent of subjects and more than half of them had such experiences often. Whereas an experience of Profoundly Altered States of Consciousness (PASC) was confirmed by 75 percent and about one-third of them had them often. The comparison of the experiences accompanying the ASC indicates that SASC are characterized by disturbances in experiencing the reality and oneself combined with positive, pleasant feelings and with quietness. On

the other hand, PASC are accompanied by experiences related to an absolute, universal, eternal, and existential or religious matters. PASC are accompanied by extremely strong positive emotions of happiness, total love, etc. and are experienced as more rational than SASC, and with significantly less feelings of cognitive disturbances than in SASC. The comparison of circumstances of the ASC occurrence indicates that SASC occur in usual and common states and situation of everyday life, whereas PASC mainly in the context of religion and nature. The congruence of these findings with an integrated model of the main states of consciousness suggests a natural tendency for a cyclical occurrence of ASC, or more precisely, the differentiated waking states of consciousness.

LaClave, Linda J.; Kronenberger, William G.; Baker, Elgan L.; Morrow, Catherine (1993). Use of hypnosis following training in a psychiatry residency and psychology internship program: A brief communication. International Journal of Clinical and Experimental Hypnosis, 41 (4), 265-271.

Despite growing numbers of internships and residencies offering training in hypnotherapy, no systematic attempt has been made to assess hypnotherapy beliefs and use among former trainees in these settings. This study investigated posttraining hypnotherapy use and effectiveness beliefs in a sample of 77 former psychiatry residents and psychology interns. Over 50% of the study sample had sought additional hypnotherapy training beyond the standard lectures and seminars, and almost 30% had attended external hypnotherapy workshops or presentations. Beliefs in hypnotherapy effectiveness were high, but use of hypnotherapy in clinical practice was very low. Former residents and interns who had received supervised training with patients, who had attended hypnosis workshops, and who had a colleague using hypnotherapy were more likely to use hypnotherapy following training.

1992

LaClave, Linda J.; Kronenberger, William G.; Baker, Elgan L. (1992, October). Use of hypnosis following training in a psychology internship and psychiatry residency program. [Paper] Presented at the annual meeting of the Society for Clinical and Experimental Hypnosis, Arlington, VA.

## NOTES

Indiana University is embarking on a series of studies of training and characteristics of hypnotherapists.

### Study 1

Purpose: generate hypotheses, from retrospective analysis, to design prospective studies.

In 1962 11%; in 1975 27%; and in 1983 55% of psychology internship sites offered training in hypnosis. Methods of training in these sites included: lectures, supervised peer hypnosis, supervised patient hypnosis, and workshop or program attendance. Standardized curricula have been proposed, but outcome hasn't been evaluated. No study has investigated the long term effectiveness of program components.

This study looks at two outcomes: --Post training use --Post training effectiveness beliefs (how effective they believe hypnotherapy is)

It also looks at how the four training components relate to the two outcomes, and at professional variables (whether psychiatrist or psychologist, etc.).

Authors surveyed an 11 year retrospective. N = 77 respondents. Training is lectures that were strongly encouraged, and could elect the other components.

Number of patients seen in hypnotherapy since end of training 0-5 49 6-10 10 11-20 6 21-25 4 >25 7

**1991**

Daglish, Mark R. C.; Wright, Peter (1991). Opinions about hypnosis among medical and psychology students. Contemporary Hypnosis, 8, 51-55.

A survey was undertaken of opinions about hypnosis among first year medical and psychology students at the University of Edinburgh. Data are presented on the effects of self-estimated hypnotizability and sex, on opinions about hypnosis. The results are compared with those from similar studies conducted in Australia and the USA. Overall, the surveyed population showed a similar level of knowledge about hypnosis to that found among the general public.

**1990**

Evans, Frederick J. (1990). Behavioral responses during sleep. In Bootzin, Richard R.; Kihlstrom, John F.; Schacter, Daniel L. (Ed.), Sleep and Cognition (pp. 77-87). Washington, DC: American Psychological Association.

**NOTES**

Subjects were 19 male student nurses who met a criterion of having EEG alpha density of at least 40% during an eyes closed, waking condition. They slept in the laboratory for two nights in succession, while being monitored by an EEG, and were told only that sleep cycles were being studied. Suggestions were presented while they were sleeping, e.g. "Whenever I say the word itch, your nose will feel itchy until you scratch it" "Whenever I say the word pillow, your pillow will feel uncomfortable until you move it." Then they were tested by Experimenter saying the cue word ("itch" or "pillow") during subsequent REM periods later that night and again on the next night. (The suggestions were not repeated on the second night; but two new suggestions were given on the second night when possible.)

After the Subjects awakened in the morning, they were interviewed to test their memory for the events that had occurred, and also cue words were presented in the context of a word association test to assess memory indirectly by observing behavioral and physiological responses. A more detailed inquiry was made after the second night.

The results were as follows. Ss responded to a mean of 21% of cue words administered. Ss continued to demonstrate REM sleep for at least 30 seconds for 71% of all cues administered, indicating that they were not aroused by the cue. When a suggestion was successfully completed (i.e., without eliciting alpha activity) it was not repeated. However, the cue words were tested in several subsequent REM

periods. Cue word testing occurred immediately (during the same REM period as the suggestion) on the same night, as well as in a later REM period, and during REM on Night 2 (after the suggestion had been given during Night 1).

Correct responses were given for 20% of immediate, 23% of delayed, and 23% of carry-over conditions. Ss did not remember the suggestion, verbal cues, or their responses when they awoke. Since Ss often responded to the cue the next night without repetition of the suggestion itself, the authors inferred amnesia rather than forgetting had occurred. Responses were not elicited by repeating the cue word in the waking state, but appeared to be specific to the sleep condition.

Six Ss returned five months later for a third night of testing. Four had shown carryover response on Night 2 to a Night 1 suggestion. When verbal cues were presented (without re-administering the suggestion) those 4 Ss responded, even though there was no intervening waking memory about the procedure or the suggestions. Some Ss responded even more frequently than during the original two nights; hypnotic depth did not seem to account for the increased responsivity. Experimenters attempted to reverse the amnesia observed during the waking condition by using hypnosis, age regression, and other hypnotic techniques, with some positive effect. The author speculates that perhaps the techniques originally used to probe morning recall were not sufficiently sensitive. He also raises the question of whether this waking state amnesia is related to the amnesia for night dreams when people awaken in the morning.

The relationship between hypnotizability and sleep suggestibility was analyzed. Hypnotizability was measured with the Harvard Group Scale, several weeks later, by Experimenters who were blind to the Ss' rate of responding to suggestions given during sleep. More hypnotizable Ss slept through the verbal stimuli more than low hypnotizable Ss; so they slept longer and more cues could be tested. Ss who responded most frequently to sleep-induced suggestions were more responsive to hypnosis. Analysis of response rate percentage (which controls for higher number of cues administered when Ss slept longer) showed that correlations between sleep suggestibility and hypnotizability were higher for percentage of delayed responses than for percentage of immediate responses.

Analysis by type of item on the hypnotizability scales suggested that the correlation with sleep suggestibility was due to the hallucinatory-reverie and the posthypnotic-dissociative clusters of hypnotic behavior, which are more difficult kinds of items. Correlations were significant for carry-over responses but not for immediate responses. These items represent phenomena experienced by Subjects who can be deeply hypnotized. The author reports that this relationship observed between hypnotizability and response to sleep-induced suggestions was not significant in a later study by Perry et al. (1978).

This author raises a question about why high hypnotizable subjects sleep better than low hypnotizables. The 6 Ss who were least susceptible accounted for 48% of all awakenings that occurred during the 2 experimental nights; the 6 Ss who were most hypnotizable accounted for only 26% of the awakenings ( $p < .01$ ).

Because sleep learning ("hypnopedia") has been extensively practiced in Russia and Eastern Europe, especially for language learning, the author investigated language learning with nine subjects. (Hoskovec, 1966, and Rubin, 1968, have reviewed the

hypnopedic literature, which suggests that only "suggestible" subjects respond; it is not clear whether "suggestible" refers to hypnotizable, or whether expectation of success is cultivated by information given in the waking state.) The nine Ss had responded to the suggestions at least twice while remaining asleep, had no waking recall of the suggestions, but were given pre-sleep instructions (increasing expectancy) that they would learn during sleep.

The verbal association material ("A is for apple; P is for palace;" etc.) was given during EEG sleep stages 2, 4, and REM. (Eight letter-word stimuli pairs were given, two per sleep stage whenever possible.) When they awakened, Ss were asked to check "any familiar word" on a list of 10 words beginning with the letter A, with the letter P, etc. So the probability was .10 for each of the eight lists that they might check one correct word by guessing. They also responded to two dummy lists containing letter-word pairs not used during sleep.

None of the dummy list words were checked, whereas 28% of the administered words were correctly checked; also, Ss selected the correct letter (without identifying the word and with instructions not to "guess") in an additional 17% of all lists. Words were rarely recalled from Stages 2 and 4, but Ss often recognized letters from those stages. False positives (incorrectly recalled words or letters) was almost never observed. Furthermore, no control Subjects (people who had not received a presleep set that they would recall) recalled any words correctly.

It was observed that whenever words presented during REM were later recalled, a transient slower frequency alpha (10.25 Hz vs. 9.64 Hz,  $p < .01$ ) had been evoked within 30 sec after the presentation of the stimuli during sleep.

Total recall of words correlated with the Harvard Group Scale of Hypnotic Susceptibility .69 and the Stanford individually administered scale .42, for the 7 Ss administered hypnotizability tests.

The author concludes that under optimal conditions, sleep learning of relatively easy material can occur with subsequent waking recall.

Harmon, Teresa M.; Hynan, Michael T.; Tyre, Timothy E. (1990). Improved obstetric outcomes using hypnotic analgesia and skill mastery combined with childbirth education. Journal of Consulting and Clinical Psychology, 58, 525-530.

Studied the benefits of hypnotic analgesia as an adjunct to childbirth in 60 nulliparous women. Subjects were divided into high- and low-susceptibility groups before receiving six sessions of childbirth education and skill mastery using an ischemic pain task. Half of the subjects in each group received a hypnotic induction at the beginning of each session; the remaining control subjects received relaxation and breathing exercises typically used in childbirth education. Both hypnotic subjects and highly susceptible subjects reported reduced pain. Hypnotically prepared births had shorter Stage 1 labors, less medication, higher Apgar scores, and more frequent spontaneous deliveries than control subjects' births. Highly susceptible, hypnotically treated women had lower depression scores after birth than women in the other three groups. The authors believe that repeated skill mastery facilitated the effectiveness of hypnosis in the study.

Matheson, G.; Drever, J. M. (1990). Psychological preparation of the patient for breast reconstruction. Annals of Plastic Surgery, 24, 238-247.

#### NOTES

Reviews over 100 women who had undergone rectus abdominis musculocutaneous flap reconstruction, the psychological issues motivating the patient for surgery, and psychological problems to be considered by the surgeon. A method of psychological preparation that was used and a report on the evaluative study of the program is included, and a protocol and verbalization for hypnotic relaxation is included.

1989

Palan, B.M.; Chandwani, S. (1989). Coping with examination stress through hypnosis: An experimental study. American Journal of Clinical Hypnosis, 31, 173-180.

Fifty-six volunteer medical students participated in three groups balanced for number of subjects, performance at last examination, and hypnotizability. The hypnosis and waking groups attended eight group sessions once a week with general ego-strengthening and specific suggestions for study habits, with a ninth session of age progression and mental rehearsal. Subjects in these two groups practiced self-suggestions (in self-hypnosis or waking respectively) daily for the study period of 9 weeks. The control group experienced sessions of passive relaxation induced by light reading for the same period of time. The hypnosis group improved significantly in coping with examination stress, but there was no significant change in performance on examinations by any of the groups.

Spinhoven, Philip; Linssen, A. Corry (1989). Education and self-hypnosis in the management of low back pain: A component analysis. British Journal of Clinical Psychology, 28, 145-153.

Conducted a component analysis of a group program for chronic low back pain patients. 45 patients (aged 31-68 years) participated in the pain control course (PCC), consisting of education about pain and a training in self-hypnosis. A pain diary was used as a measure of pain intensity, up-time, and use of pain medication. Psychoneuroticism and depression were assessed using the Symptom Checklist-90 (SCL-90) scores. No evidence was found for a differential efficacy of education or self-hypnosis on pain diary and SCL-90 scores. Subjects showed significant changes on all measures except reported pain intensity. It is suggested that the PCC is a noninvasive, inexpensive means of treatment that could be used to teach even more severely disabled low back pain patients to cope more adequately with their pain problem.

1988

Pavia, M.; Stanley, R. O. (1988). Effect of defining induction as hypnosis or relaxation. Australian Journal of Clinical and Experimental Hypnosis, 16, 11-21.

Previous studies have shown that the perceived definition of an induction may sometimes affect the subject's responses to the induction. These variations in the effect of induction definition may be due to interactions between a subject's motivations and expectations of the induction technique and the way the induction is defined. These authors explored this interaction with groups of clinical and student subjects. Differing definitions of induction as 'hypnosis' or 'relaxation' did not result in significant differences in response among either group, though subjects in neither group were found to have high expectations of motivation (sic).

1986

Judd, Fiona K.; Burrows, Graham D.; Dennerstein, Lorraine (1986). Clinicians' perceptions of the adverse effects of hypnosis: A preliminary study. Australian Journal of Clinical and Experimental Hypnosis, 14, 49-60.

Questionnaires were sent to all members of the Australian Society of Hypnosis and responses obtained from 202 members and associate members who used hypnosis clinically. Respondents' experience in the use of hypnosis and the frequency of use of hypnosis as a treatment modality varied. Overall 43.5% of respondents reported adverse effects with one or more patients over the preceding year. Most adverse effects attributed to hypnosis were transient and included development of panic or extreme anxiety, development of excessive dependence and difficulty in terminating hypnosis. Exacerbation or precipitation of significant depression was an infrequent but serious adverse effect attributed to hypnosis. Other infrequent adverse effects included symptom substitution, acting out behaviour, fantasied sexual seduction, precipitation or worsening of psychotic illness or difficulties in the management of organic conditions. The difficulties were acknowledged of differentiating between the effects of hypnosis itself and other components of the therapeutic transaction, but the results of this survey suggested both that hypnosis be employed clinically by properly trained professionals and that further sensitive clinical research is needed in the area.

Rogers, Malcolm; Reich, Peter (1986). Psychological intervention with surgical patients: Evaluation outcome. Advances in Psychosomatic Medicine, 15, 23-50.

#### NOTES

The Notes are a direct quotation of the authors' Conclusions. "There is well documented evidence that psychological and behavioral preparation prior to surgery can effect post-operative recovery. In almost all instances, except when patients are characterized by avoidance or denial defenses predominantly, the outcome results have been positive. The effect of interventions have been most consistently positive in reducing length of hospitalization and post-operative pain, but a variety of other improvements in affect and physiologic stability have been shown. As others such as Auerbach have pointed out [76], in all but a handful of

studies different intervention approaches have been combined, making it impossible to sort out the specific effects of information, psychotherapeutic relationship, relaxation training, or suggestion given either with or without hypnosis. Indeed it is not only likely that each has had an effect, but there may also be synergistic effects.

"More recent investigations have begun to include measurements of personality differences between patients so that the nature of the intervention can be more specific and appropriate to the individual's coping style.

"The reduction in length of hospitalization alone (clearly shown to result from pre-operative psychologic preparation) argues forcefully on a cost benefit basis for the inclusions of careful pre-operative preparation. The reduction in pain is also of major importance, and may well reduce future avoidance behavior or post-traumatic disorders, although these latter potential outcomes have not been investigated. It should be kept in mind that there are also a number of studies which have failed to demonstrate the efficacy of psychological intervention on these outcome measures. Moreover, it is extremely difficult in studies of this nature to control adequately for the subtle effects on behavior of experimenter and subject expectation.

"A few points can be made about future strategies in this field. The evidence accumulated to date suggests that all patients undergoing surgery or certain difficult procedures be given the option of pre-operative psychological preparation. The preparation should emphasize what the patient will experience and when, and how to cope with it, i.e., how to move, or breathe, or relax. Rapidly evolving audiovisual capabilities and hospital televisions connected by cable to health education channels will routinely offer such preparation in the future. Patients could choose or not choose to watch (thereby protecting mechanisms of denial).

"Finally, future studies should focus on outcome measures uniquely important to a particular operation and also on longer term rehabilitation outcome measures. An example of the former might be post-operative sexual functioning after prostatectomy. A study by Zokar et al. [77] has shown that the likelihood of this post-operative function is correlated with not only the level of pre-operative anxiety and general 'life satisfaction', but also whether the patient received a pre-operative explanation of what to expect from the surgery" (pp. 45-46).

1985

Fellows, Brian J. (1985). Hypnosis teaching and research in British psychology departments: Current practice attitudes and concerns. British Journal of Experimental and Clinical Hypnosis, 2 (3), 151-156.

#### NOTES

The author mailed a questionnaire to 58 departments of psychology to determine the extent/nature of hypnosis teaching and research, and attitudes toward teaching and research on hypnosis. The author noted a general anxiety about teaching students how to do hypnosis (as contrasted with learning about hypnosis). "Some of the anxieties which departments have about the teaching of hypnosis seem to stem from some rather ancient and invalid conceptions about the nature of hypnosis and what it can do" (p. 153). The author also relates his personal experience teaching

undergraduates "something about the procedures and phenomena which have been traditionally associated with hypnosis" (p. 153). They may use one of the standard hypnotizability scales, study a particular hypnotic phenomenon such as ideomotor action or age regression, or study an empirical issue such as facilitation of recall. He reports not meeting with "any particular difficulties," but also that he has seen two problems: the student who is anxious about doing the procedure, and an occasional subject who reports the experience was unpleasant or disturbing--e.g. during age regression. He reports teaching students to handle these events in a normalizing manner. J. Holroyd

Stager, Gordon L.; Lundy, Richard M. (1985). Hypnosis and the learning and recall of visually presented material. International Journal of Clinical and Experimental Hypnosis, 33, 27-39.

To examine the effect of hypnosis on the learning and recall of visually presented material, high and low hypnotizable Ss were presented, under hypnotized or awake conditions, with a short, entertaining movie followed by questions about the movie. 2 week later Ss, hypnotized or awake, were again asked questions concerning the movie. The principal finding was that high hypnotizable Ss in the hypnotic induction condition increased accurate recall without increasing inaccurate recall. Neither hypnotizability nor hypnotic induction at learning affected recall. The major finding of the present study is that hypnosis during recall of previously learned material is facilitative, but that hypnosis during that previous learning is not.

1984

Channon, L. D. (1984). Some preconceptions about hypnosis among preclinical medical students: A brief communication. International Journal of Clinical and Experimental Hypnosis, 32 (4), 356-361.

372 preclinical medical students from the University of Sydney, Australia were surveyed concerning their beliefs about hypnosis and its medical use. Several "myths" concerning hypnosis emerged (e.g., hypnosis is a passive state, there are sex differences in hypnotizability, posthypnotic amnesia is inevitable, and there is automatic obedience to the hypnotist). Sex differences in expectations of hypnotizability were found. Relatively few physical problems were perceived as being amenable to treatment by hypnosis and the proportion of medical practitioners in the national professional hypnosis society was grossly underestimated.

Wideman, Margaret V.; Singer, Jerome E. (1984). The role of psychological mechanisms in preparation for childbirth. American Psychologist, 39, 1357-1371.

Psychoprophylactic (Lamaze) preparation for childbirth consists of six to eight classes held during the last trimester of pregnancy. These classes include instruction in the anatomy and physiology of gestation and parturition, respiration techniques, controlled neuromuscular relaxation, visual focusing, and the training of a labor

coach. Although the techniques are based upon psychological principles, they have remained largely unstudied by either psychologists or physicians. This article presents a brief history of the development of the training regimen and critically examines the few empirical studies that have been conducted. Because explanations for the efficacy of the preparation, if it exists, are equivocal, literature on the explicit components of the training--that is, information, respiration techniques, conditioned relaxation, cognitive restructuring, and social support--in situations other than child delivery are reviewed and their implications for the Lamaze method discussed. However, because there exist several, more implicit factors that may affect the type of child delivery a prepared woman experiences, the literature concerning social comparison, the effects of commitment and conformity, perceived control, and endorphin secretion are also discussed as they may apply to psychoprophylactic preparation. Problems associated with the study of childbirth preparation are presented, and suggestions for the direction of future research are made.

1983

Rodolfa, E. R.; Kraft, W. A.; Reilley, R. R.; Blackmore, S. H. (1983). The status of research and training in hypnosis at APA accredited clinical/counseling psychology internship sites: A national survey. International Journal of Clinical and Experimental Hypnosis, 31 (4), 284-292.

Although numerous psychologists reported gaining hypnosis skills during their internship experience, few investigations have assessed the characteristics of this training. The present survey of 123 APA accredited clinical/counseling internship sites was conducted in an attempt to describe the training currently available. Other variables investigated were hypnosis research at the sites and training directors' attitudes toward hypnosis. Results indicate that hypnosis training is growing and becoming more formalized; hypnosis research has experienced growth; and attitudes toward hypnosis continue to remain positive.

A procedure for training clinical graduate students in the psychoanalytic theory of the neuroses is presented. The procedure makes use of video tapes of experiments in which hypnotically implanted unconscious conflicts were used to drive a wide variety of psychopathology in the laboratory. In the procedure, the graduate students were asked to predict and rate Ss' psychopathology with foreknowledge of certain personality traits of Ss as well as foreknowledge of the nature of the conflicts. The training appeared to be an effective means of teaching them psychoanalytic theory, as well as helpful in enhancing their assessment skills.

1980

Reilley, R. R.; Parisher, D. W.; Carona, A.; Dobrovolsky, N. W. (1980). Modifying hypnotic susceptibility by practice and instruction. International Journal of Clinical and Experimental Hypnosis, 28 (1), 39-45.

Research was conducted to determine if hypnotic susceptibility could be increased by either having Ss practice hypnosis through repeated induction, or receive instruction about hypnosis. Ss were 37 college students divided into 3 groups. Group one experienced various hypnotic induction techniques, group two was given information about hypnosis through instruction, and group three was the control. The Stanford Hypnotic Susceptibility Scales, Forms A and B (Weitzenhoffer & Hilgard, 1959) were the pre- and posttest measures. Differences were found between both treatment groups and the control group, although no differences were found between the treatments. Repeated hypnotic induction and instruction about hypnosis proved useful techniques for increasing susceptibility. Results were not significantly related to initial level of anxiety.

The present study was undertaken to provide additional information on the effects of hypnosis on academic and test-taking skills. Previous research indicated inconclusive results with inadequate experimental design and statistical methodology. The present study used an experimental research design with appropriate statistical analysis. Ss were 93 college students and treatment was administered by pre-recorded cassette tapes over a 4-week period during regular class time. Tapes consisted of hypnotic and waking suggestions related to course content and general academic skills. Results indicated hypnotic and waking suggestions did not facilitate academic skill learning significantly more than class curriculum alone. Pre-post comparisons did indicate significant improvement by all groups on reading, writing, study skills, and spelling variables.

1978

Porter, J. W. (1978). Suggestions and success imagery for study problems. International Journal of Clinical and Experimental Hypnosis, 26, 63-75.

A procedure is presented for dealing with study problems in cases where patients come with an expectancy of help through hypnosis. Specific suggestions directly related to the study difficulty are given. "Success imagery" is outlined for use under hypnosis and by the student himself in his daily life. Two self-management techniques associated with the relaxation induced by exhalation are given further strength by being made posthypnotic suggestions. A direct posthypnotic suggestion for "concentration and recall" is combined with contingency management to effect more efficient performance when the decision is made to study. Four sessions are shown by clinical experience to be generally adequate to allow a transition from therapy to self-management of the problem aided by the student's own use of self-hypnosis. A general outline of how this is achieved for the first three sessions incorporates both Wolberg's (1965) suggestions to remove barriers preventing progress and Stanton's (1977) Rational-Emotive Therapy suggestions to strengthen the person's belief in himself.

Schumann, John H.; Holroyd, Jean; Campbell, Russell N.; Ward, Frederick A. (1978). Improvement of pronunciation under hypnosis: A preliminary study. Language Learning, 28, 143-148.

This paper reports an experiment which was designed to determine whether foreign language pronunciation could be improved through hypnosis. Twenty subjects were first given the Harvard Group Scale of Hypnotizability to familiarize them with the state of hypnosis. In the second session each subject was individually tested on his/her ability to pronounce Thai words under three conditions: Baseline, Hypnosis, and Post- Hypnosis. For each experimental condition the subjects heard and repeated the stimulus items on one of three lists of 15 Thai words. The subjects' responses were later evaluated by a native Thai linguist. The results indicate that deeply hypnotized subjects (as defined by self-reported depth) performed significantly better than less well hypnotized subjects.

#### NOTES

"Guiora (1972) suggested that pronunciation of a foreign language is more difficult than vocabulary, syntax, and grammar skills because it requires modifying a basic method of self-identification, the way one sounds. He introduced a concept of language ego, analogous to body ego" (p. 143). During hypnosis subjects were evaluated for subjective estimate of hypnotic depth by asking them to "visualize themselves on a stairway in which the top (zero) represented their normal waking state and the bottom (ten) a very very deep relaxed state of hypnosis, and to report the number of the step on which they stood" (p. 146). Thus, "it was not assumed that administration of an induction assured a hypnotized subject, nor was it assumed that subjects rated highly hypnotizable were in a deep trance at the time Thai words were being spoken" (p. 146).

Shipley, R. H.; Butt, J. H.; Horowitz, B.; Farby, J. E. (1978). Preparation for a stressful medical procedure: Effect of amount of stimulus preexposure and coping style. Journal of Consulting and Clinical Psychology, 46, 499-507.

Anxiety during the stressful medical procedure of endoscopy was studied as a function of the number of prior viewings of an explicit preparation videotape and of repression-sensitization coping style. Sixty naive patients viewed a videotaped endoscopy either zero, one, or three times. Dependent measures included heart rate, behavioral ratings, tranquilizer required, and self-report. On each dependent measure, three viewings generally resulted in the least distress; one, more distress; and zero, the most distress. Most comparisons reached statistical significance. These results are interpreted as resulting from extinction and/or habituation of anxiety. The repression-sensitization factor interacted with heart rate change. Sensitizers showed a monotonic decrease in heart rate as a function of number of tape exposures. Repressors showed an inverted-U-shaped function, with one viewing producing the highest heart rate; this is interpreted as resulting from a disruption of repressing defenses by one tape exposure followed by extinction of fear by three exposures.

1976

**Gardner, G. Gail (1976). Attitudes of child health professionals toward hypnosis: Implications for training. International Journal of Clinical and Experimental Hypnosis, 24, 63-73.**

A survey of child health professionals -- pediatricians, pediatric nurses, child psychologists, and child psychiatrists -- revealed that they have generally positive attitudes toward hypnosis but little knowledge of its specific advantages or applications. Recommendations are made for designing training opportunities in hypnosis which might enhance the probability that the professional will actually use hypnosis or refer a child else where for hypnotherapy.

**Illovsky, J.; Fredman, N. (1976). Group suggestion in learning disabilities of primary grade children. International Journal of Clinical and Experimental Hypnosis, 24, 87-97.**

This study reports the effects of tape-recorded hypnotic suggestions given to 48 hyperactive children between the ages of 6 and 8 from 3 public schools. The children had short attention spans, low frustration and tolerance [sic], and poor learning motivation. They were taught by the same method in class and received remedial instruction as in the previous year. In order to participate in this study, the children were brought from their regular classrooms every morning to listen in groups of 9, 10, or 19 -- according to the available accommodation in the school -- to suggestions of relaxation, to ideas of coping with emotional problems, and to suggestions of modifying attitudes towards learning. The corrective reading teachers conducted these 15-minute sessions. After the session was over, the children were returned to their respective classes. At the beginning and at the end of the school year, the classroom teachers evaluated the children's behavior in class and their attitudes toward learning. The addition of the modified hypnotic technique enabled 45 of 48 children to function better in school. The improvement ranged from decreased hyperactivity to better than average performance in class. Significant correlations were found between percent of relaxation with increased attention span ( $r = .40$ ) and number of sessions attended with increased self-confidence ( $r = .46$ ).

Interviewed 101 professionals who were alumni of a course in medical and dental hypnosis. 75% used some hypnotic technique, either formal or informal, in their practice. The predominant technique was direct and indirect hypnotic symptom removal. A wide range of indications was described, the most frequent of which were obesity, anxiety, pain and discomfort, and excessive smoking. Illustrative cases are included. Few doctors encountered either difficulties with colleagues or complications with patients. Of those doctors who did not use hypnosis, the major reasons mentioned were time, patient's unrealistic expectations and feelings of discomfort, lack of skill, and skepticism about hypnosis. The most striking finding was the efficacy of the course in causing enduring changes in the ongoing pattern of practice of a remarkably high percentage of the doctors. Donk, Leonard J.; Vingoe, Frank J.; Hall, Roger A.; Doty, Richard (1970). The comparison of three suggestion techniques for increasing reading efficiency utilizing a counter-balanced research paradigm. International Journal of Clinical and Experimental Hypnosis, 18, 126-133.

Reports an experiment in which both Barber-type and alert-trance procedures significantly increased reading speed while maintaining comprehension when compared to a control group; a traditional hypnotic procedure followed by the specific suggestions failed to obtain these results. 32 volunteer undergraduates were randomly assigned to 4 groups in terms of a counterbalanced design. 2 groups were administered trance inductions (traditional and alert) followed by specific suggestions, a 3rd simply the suggestions, while the 4th served as control. Reading suggestions were to eliminate specific problems, increase speed, and increase or maintain comprehension. (Spanish & German summaries) (PsycINFO Database Record (c) 2003 APA, all rights reserved)

1968

Donk, Leonard J. (1968). Toward an increase in reading efficiency utilizing specific suggestions: A preliminary approach. International Journal of Clinical and Experimental Hypnosis, 16, 101-110.

REPORTS AN EXPERIMENT IN WHICH READING SPEED WAS SIGNIFICANTLY INCREASED AND COMPREHENSION MAINTAINED BY A TRADITIONAL HYPNOTIC INDUCTION FOLLOWED BY SPECIFIC SUGGESTIONS. 24 SS WERE SELECTED FROM AN UNDERGRADUATE CLASS ON THE BASIS OF PERFORMANCE ON A MODIFIED WEITZENHOFFER ABBREVIATED GROUP HYPNOSIS SCALE. SS WERE ASSIGNED TO 2 MAIN GROUPS IN TERMS OF A COUNTERBALANCED DESIGN. SUGGESTIONS TO ELIMINATE SPECIFIC READING PROBLEMS, INCREASE READING SPEED, AND MAINTAIN OR INCREASE COMPREHENSION WERE GIVEN AFTER A TRADITIONAL INDUCTION PROCEDURE. THE USE OF THIS RESEARCH DESIGN IN SUBSEQUENT RESEARCH ON HYPNOSIS AND LEARNING IS DISCUSSED. (SPANISH + GERMAN SUMMARIES) (PsycINFO Database Record (c) 2002 APA, all rights reserved)

1965

Pedersen, Darhl M.; Cooper, Leslie M. (1965). Some personality correlates of hypnotic susceptibility. International Journal of Clinical and Experimental Hypnosis, 13 (3), 193-203.

The present research was directed principally toward determining the relationship of a number of personality variables to hypnotic susceptibility. The personality variables utilized were selected to cover the personality domain as broadly as possible. Hypnotic susceptibility was measured by the Stanford Hypnotic

Susceptibility Scale, Form A. A correlational analysis was completed for 30 Ss. This included (a) the correlations between each of the personality variables and hypnotic susceptibility and (b) the intercorrelations among all of the personality measures. It was found that the following variables correlated with hypnotic susceptibility at the 5% level of confidence: age (-.37), year in college (-.36), and missionary service (.37). Social class rating of father's occupation correlated significantly at the 1% level of confidence (.54). (29 ref.) (PsycINFO Database Record (c) 2002 APA, all rights reserved)

Uhr, Leonard (1958). Learning under hypnosis: What do we know? what should we know?. Journal of Clinical and Experimental Hypnosis, 6 (3), 121-135.

## NOTES

The author reviews the research available on learning under hypnosis, as contrasted with recalling (under hypnosis) material previously learned in the waking state. Very few investigations have taken place, "and the vast majority are inconclusive or of only tangential interest" (p. 131). He gives a number of suggestions for improving the research designs, stressing that different aspects of hypnosis (depth, amnesia, type of suggestion) should be manipulated in order to maximize the possibility of

finding positive outcomes. "'Suggestion' or 'motivation' or 'attention' may well prove to be the crucial variable, the hypnotic state merely the condition that allows the full force of the operating factor to be felt" (p. 132).

McCord, Hallack (1956). Hypnosis as an aid to the teaching of a severely mentally retarded teenage boy. Journal of Clinical and Experimental Hypnosis, 4 (1), 21-23. (Abstracted in Psychological Abstracts 57: 3729)

**NOTES**

A 16 year old boy with I.Q. measured at 55 was hypnotized for 20 minutes daily for one month. During each session he was given material to learn (multiplication tables, spelling words, reading recognition, and general information -- only one presented during each hypnosis session). "At the end of 90 days, the subject was still retaining almost 100 percent of all material presented except for the multiplication tables which showed about 50 percent loss" (p. 22). "As a result of routinely introduced hypnotic suggestions for well-being, happiness, desire to learn, and assurance of acceptance, Ben's motivation to learn in the classroom situation took a sharp surge upward. (It was for this reason that giving him parallel material in the normal state to be used to measure comparative learning rates promptly became scientifically unsound as a control in this study.)" (p. 22). Although he was not given material to study in between sessions, "it was known that he mentally reviewed the material while working and playing in the school program" (p. 23).

Wald, Arthur; Kline, Milton V. (1955). A university training program in dental hypnosis. Journal of Clinical and Experimental Hypnosis, 3 (4), 183-187.

**NOTES**

The training program was a joint project of the American Hypnodontic Society and the Institute for Research of Long Island University.

"The program consists of three full semester courses: Introductory, Advanced, and a Clinical Practicum. Each course meets for a full 14 week semester and consists of 40 hours of instruction. Instructors in the program consist of dentists, psychologists, and physicians experienced with hypnosis and actively working in the psychological and medical fields pertinent to modern dental practice" (p. 184).

The article provides the syllabi for the introductory and advanced courses.

**1954**

Hammer, Emanuel Frederick (1954). Post-hypnotic suggestion and test performance. Journal of Clinical and Experimental Hypnosis, 2, 178-185.

**NOTES**

College students were tested in Normal and Post-hypnotic suggestion conditions, in balanced order (N-P-P-N, or P-N-N-P) but were actually hypnotized before the

Normal as well as the Post-hypnotic trials (i.e. without and with post-hypnotic suggestions, with suggestions for amnesia for the events in the hypnotic state).

"Summary. The purpose of this investigation was to determine whether or not post-hypnotic suggestion can improve some aspects of hypnotizable students' application and efficiency as applied to a number of selected performances connected directly or indirectly to schoolwork. Before the post-hypnotic testing periods, each subject was given post-hypnotic suggestions of ease, confidence, motivation, and increased ability. The study consisted of a comparison of normal and post-hypnotic performances of nine subjects in the areas of motor capacity, attention and perception, association, learning and memory, speed of reading comprehension, and application of abstract ability.

To the extent to which psychomotor speed and endurance, physical fatigue, span and duration of attention, clerical performance, speed of learning (as tested by Meaningful Syllable Lists and Digit Symbol Substitution), speed of association, mental alertness, concentration, mental efficiency, application of abstract number abilities, and speed of reading comprehension are related to schoolwork, the hypothesis is supported that post-hypnotic suggestion can be of aid in hypnotizable college students' schoolwork" (p. 184).

1953

Glasner, Samuel (1953). Research problems in the educational and social psychological applications of hypnosis. Journal of Clinical and Experimental Hypnosis, 1 (2), 42-48.

NOTES

The author reviews literature in which hypnosis is used as an experimental research method in two general areas: hypnosis in learning and recall, and hypnosis in social psychology. "In summary, the application of hypnosis to research in the fields of educational and social psychology is practically virgin territory. Imaginative investigators should be able to develop numerous interesting experiments in these two great areas" (p. 47).

EEG

1995

Barabasz, Arreed F.; Barabasz, Marianne; Jensen, Stacia (1995, November). Effects of hypnosis on cortical event-related potentials during visual and olfactory hypnotic hallucinations. [Paper] Presented at the annual meeting of the Society for Clinical and Experimental Hypnosis, San Antonio, TX.

NOTES

Slotnick and London showed that different wording of suggestions led to very different results, which explains why our study on negative hallucinations and Spiegel's study had opposite results.

This study is still ongoing. Screened for highs who passed visual and olfactory hallucinations and lows who passed only motoric items on hypnotizability tests.

Trained Ss with eyes open induction, and lows had instructions to simulate hypnosis. (Used the eyeroll induction, eyes open.)

Did waking administration of alternating checkerboard pattern on computer screen. Then did eyes open hypnotic induction plus a depth check to make sure they were deep (assign number; then instructed raise a finger when you double it; then again, raise a finger when you double it). Then used checkerboard design again.

Obstructive visual hallucination - "imagine traveling through space, a dark nebula" (better than imagining you are blind. Lows had no difference in waking, obstructive hallucination, and negative hallucination. The highs did--looks like they had to see it before they couldn't see it. "The dark nebula envelopes you completely, and now you can see nothing."

De Pascalis, Vilfredo (1995, November). Psychophysiological correlates of hypnosis and hypnotic susceptibility. [Paper] Presented at the annual meeting of the Society for Clinical and Experimental Hypnosis, San Antonio, TX.

#### NOTES

They recorded 40-Hz EEG temporal density (35-45 Hz band) from the left and right temporo-parietal-occipital scalp regions in four emotional conditions (gladness, happiness, fear, and anger). When measures were made in the waking state, for Highs, during positive emotions they found increase in left and right hemisphere activity compared with resting condition. During fear and anger there was reduction in the left hemisphere and an increase in the right, but for some subjects no left hemisphere change.

Low hypnotizables did not show large or reliable differences across emotions. With the hypnotic state, they found the trend was even greater for Highs.

Pribram, Karl H. (1995). Brain in perception: From Kohler's fields to Gabor's quanta of information. In Proceeding of the 39th Congress of German Society for Psychology (pp. 53-69).

#### NOTES

[The following material was taken from a paper provided by the author as a replacement for a presentation he made on the same topic at the Annual Meeting of the American Psychological Association, 1994, Los Angeles.]

Pribram presents the view that neuroelectric field theory (similar to theories proposed by Kohler and by Lashley earlier in this century) account for complexities observed in the relationship between awareness/perception and sensation. "Nerve impulse generation and transmission in neuronal circuits is but one of the important electrical characteristics of neural tissue. Another characteristic is the production of patterns of pre- and post-synaptic polarizations in axonal and dendritic arborizations. ... [which] are produced everywhere in the brain cortex when nerve impulses arrive at synapses as a result of the fact that the impulses become attenuated due to decreased fiber size resulting from the branching of axons" (p. 53). The polarizations develop a wave front.

Georg von Bekesy performed experiments on tactile perception that demonstrated the complex relationship between sensation and awareness. We often 'perceive' an

object as external to us, even though the immediate specific neural stimulation is of receptors and from there activity is transmitted to the neurons of the brain. Thus we 'see' an object as external to us, even though the light reflected from that object produces an image on our retina. The same kind of externalized projection occurs for hearing. Touch is ordinarily perceived as at the same location as the stimulation (i.e. in the body), except that the von Bekesy experiments demonstrated that touch could also be perceived at a distance, that is, outside the body, if conditions were appropriate.

In the von Bekesy experiments, a pair of vibrators were used to stimulate two fingers, with each vibrator actuated by the same series of clicks and with the delay of time between the clicks varied. "The interesting point in this experiment is that for the condition in which there is no time delay the vibrations are localized between the two fingers where no skin is present" (p. 55). When two vibrators are placed on the thighs, the experimental subject can, by moving the knees apart, experience the vibratory sensation localized in the open space between the knees! Such an externalization of tactile perception is observed in everyday life, as when in using a knife we seem to sense the edge of the knife in order to make the appropriate movements.

Following from von Bekesy's work, it seems that only some neural processes lead to awareness. "In fact, instrumental (often automatized) behavior and awareness are to a large extent opposed; the more efficient a performance, the less aware we become. ... for the neuroscientist, the question becomes: What kinds of neural activity allow awareness to be inversely related to automatized action?"

"Patterns of synaptodendritic polarizations and nerve impulses are two kinds of processes that function reciprocally. A simple hypothesis states that the more or less persistent designs of dendritic field polarization patterns are coordinate with awareness (Pribram, 1971, Chapter 6). This view carries the corollary that circuits of nerve impulses per se and the behavior they generate are unavailable to immediate awareness. Even the production of speech is 'unconscious' at the moment the words are spoken" (pp. 55-56).

Some additional information comes from the experimental work of Ben Libet (1966, 1994), in which direct stimulation of brain tissue in waking subjects yields reports of awareness (of a particular part of the body tingling or being in a certain position). However, the awareness occurs 0.5 to 5 seconds post-stimulus, indicating that "electrical stimulation must set up some state in the brain tissue, and only when that state has been attained does the patient become aware" (p. 56).

The evidence of electrical fields comes from using both high pass filters and low pass filters on the electrical activity generated by the brain and picked up on EEG. There are 'bursts' of spikes, and onset of the field effect precedes the initiation of spikes. "Just as depolarization of axon membranes is a necessary precursor of the generation of action potentials, so also is the local build up of synaptodendritic field potentials a precursor to the recruitment of action potentials in post synaptic neurons" (p. 57).

Maps of the receptive field of an axon can be developed (e.g. using Kuffler's procedure). However, stimulation outside of that receptive field can change that axon's response--a field effect "produced in a more extended field of potentials

occurring in neighboring synaptodendritic fields" (p. 58). In this investigation, the relationship between local field potentials of the rat somatosensory system (whisker stimulation) is studied using the Kuffler procedure. Whiskers were stimulated by rotating cylinders which varied in spacing of grooves and speed of rotation. The resulting variation in density of stimulation yielded a map or manifold of cortical bursts/spikes. Pribram's research fits the experimentally generated data to a theoretical model derived from signal processing theory, using "a rectangular window in the spatiotemporal domain to constrain the two dimensional sinusoidal signal" (p. 62). They noted that the manifolds obtained from somatosensory cortex recordings were similar to receptive field characteristics measured at the primary visual cortex, which "suggests that this process is ubiquitous in the cortical synaptodendritic network" (p. 63).

Referring to the Fourier theorem (that "the original pattern can be reconstituted, reconstructed, by performing the inverse transform" p. 65), the author notes that experimental data are more complex than would be predicted. The author suggests that it would be helpful to employ the Gabor uncertainty principle, in which Gabor (1946) described as a fundamental unit a 'quantum' of information. "Gabor became interested in describing a joint spacetime-spectral domain because he noted that there is a limit on the precision to which simultaneous measurement of spectral components and [space]time can be made. ... the Gabor relation describes the composition of a sensory channel, and the residual uncertainty defines the limits of channel processing span" (p. 65). The Gabor relationships are similar to those described in quantum physics by Heisenberg, so Gabor referred to a quantum of information, which he named a Logon.

The author describes his experimental results as exhibiting Gabor elementary functions, which "are composed in dendritic arborizations, receptive fields of the neurons from which we are recording. ... Each logon, i.e. each such receptive field module, is a channel. According to Gabor, the ensemble of such channels is a measure of the degrees of freedom, the number of distinguishable dimensions or features (e.g., spatial and temporal frequency, degrees of orientations, preferred direction, color). The minimum uncertainty relation expressed by Gabor elementary functions sets the limits on the information processing competence of each of these channels" (pp. 65-66).

In a Coda to this chapter, the author notes that there is a discrepancy between fields (composed of arrival and departure patterns of synapto-dendritic polarizations) and perceptual awareness which "occurs within spacetime coordinates." Discussion of the discrepancy may be found in Pribram and Carlton (1986). Holonomic brain theory in imaging and object perception. *Acta Psychologica*, 63, 175-210; and in Pribram (1991), Lecture 6 of *Brain and Perception*. Basically, there is top-down organization imposed by the cortical system on peripheral sensation/perception. "These various systems not only relate to one another in a hierarchical manner but that the higher order systems operate on lower order systems by interpenetrating. Thus, we ordinarily, immediately perceive named and categorized objects, not just sets of images (though we are capable of 'imaging' by suspending the higher order processes). There is abundant evidence of such top-down penetration in the visual, auditory and somatosensory neural systems" (p. 66).

**Ray, William J. (1995, November). EEG signatures of hypnotic susceptibility and hypnosis: It's what's up front that matters. [Paper] Presented at the annual meeting of the Society for Clinical and Experimental Hypnosis, San Antonio, TX.**

## **NOTES**

**We have done three studies: a psychometric study, one in which we used traditional ways of looking at EEG, and more recent research.**

**Study I found that hypnotizability related to absorption, but not to tests of absent mindedness/cognitive failures, abuse/neglect, attachment, depression and anxiety, NEO Five Factor Test scales (Neuroticism, Extroversion, Openness to Experience, Agreeableness, and Conscientiousness) or the Marlow Crown Social Desirability Scale. Also there was no relationship to Bernstein and Putnam's measure of dissociation, the DES. There is a hint of a relationship to the Openness Scale, actually.**

**Study II included a literature review on 3 questions: 1. Are there differential electrocortical differences between high and low susceptible individuals? 2. Are there electrocortical markers for the hypnotic state itself? 3. Are electrocortical differences found in the trance state mediated by hypnotic procedures?**

**Results of Study II are published in Graffin, Ray, & Lundy, 1995.**

**Study III investigated three questions: 1. Are there initial baseline psychophysiological differences between High and Low susceptible Ss? 2. Are there psychophysiological differences in baseline? 3. Are there behavioral differences on the challenge tasks during the Stanford-C?**

**The Pre-induction baseline followed by post-induction baseline are reported today. (They also administered tasks, not discussed here.)**

**Literature indicates that EEG theta is much higher for highs than lows, especially in frontal and temporal areas. This is a stable finding in a number of studies. There are also posterior differences, but they are not as significant. The differences in theta between highs and lows remains across different tasks (like imaging, spatial rotations, math). Whatever differences in theta exist when high and low hypnotizable subjects walk into the room, continue across tasks. The difference also is observable in alpha.**

**In the whole study we found no alpha differences and no hemisphere differences, but we did find theta differences.**

**We thought there would be less dimensionality as someone enters hypnosis. Dimensionality reflects EEG wave form (e.g. a sine wave is simple; more complex wave is multidimensional) and is analyzed with "chaos measures" [these notes may be poor regarding this issue]. But we didn't find less dimensionality as people entered hypnosis. So if dimensionality reflects brain state maybe people don't change state as they enter hypnosis.**

**Highs do show higher dimensionality vs lows, across all brain areas. What does this mean? It's as if Highs walk into the experiment in a more imagery mode than lows, and they continue that way throughout the whole experiment.**

**The differences found in baseline were all in theta. We compared the Standard Induction vs Self Induction on the EEG Theta variable: highs show more theta**

across the whole brain than lows, and it doesn't matter what type of induction is used.

De Pascalis gets me thinking about the role of attention in hypnosis. Following an induction, on 35-45 Hz band of EEG there is greater frontal activity for Lows whereas for Highs you see more activity posteriorly. The difference is on the rostral-caudal dimension rather than the lateral dimension.

1994

Crawford, Helen J. (1994). Brain dynamics and hypnosis: Attentional and disattentional processes. International Journal of Clinical and Experimental Hypnosis, 42 (3), 204-232.

This article reviews recent research findings, expanding an evolving neuropsychophysiological model of hypnosis (Crawford, 1989; Crawford & Gruzelier, 1992), that support the view that highly hypnotizable persons (highs) possess stronger attentional filtering abilities than do low hypnotizable persons, and that these differences are reflected in underlying brain dynamics. Behavioral, cognitive, and neurophysiological evidence is reviewed that suggests that highs can both better focus and sustain their attention as well as better ignore irrelevant stimuli in the environment. It is proposed that hypnosis is a state of enhanced attention that activates an interplay between cortical and subcortical brain dynamics during hypnotic phenomena, such as hypnotic analgesia. A body of research is reviewed that suggests that both attentional and disattentional processes, among others, are important in the experiencing of hypnosis and hypnotic phenomena. Findings from studies of electrocortical activity, event-related potentials, and regional cerebral blood flow during waking and hypnosis are presented to suggest that these attentional differences are reflected in underlying neurophysiological differences in the far fronto-limbic attentional system.

Crawford, Helen J. (1994). Brain systems involved in attention and disattention (hypnotic analgesia) to pain. In Pribram, Karl H. (Ed.), Origins: Brain and self organization (pp. 661-679). Hillsdale, NJ: Lawrence Erlbaum Associates.

Data are reviewed from regional cerebral blood flow, EEG, and somatosensory event-related potential (SERP; both scalp and intracranial) studies of attention to and disattention (hypnotic analgesia) of painful stimuli to provide further evidence for two neurophysiological systems of pain involving the cortex: (1) the epicritic, sensory system of pain associated with the parietal, posterior region, and (2) the protocritic, distress, comfort-discomfort system of pain associated with the far fronto-limbic region. Studies of neurophysiological changes accompanying suggested hypnotic analgesia support the hypothesis that the executive controller of the far frontal cortex, via the far fronto-limbic attentional system, acts as a gate against the ascent of painful stimuli into conscious awareness by 'directing' downward the inhibition of incoming somatosensory information coming from the thalamic region. In hypnotically responsive individuals who could eliminate the perception of pain, reviewed studies demonstrated increased regional cerebral blood

in the frontal and somatosensory regions, shifts in hemispheric dominance of EEG theta power, differential surface SERP topographical patterns in the anterior and posterior regions of the brain, and reduction of the intracranial SERP P160 waveform in the gyrus cingulus.

#### NOTES

Paradoxically, there may be physiological reactivity to pain stimuli while the hypnotized Subject reports they are not consciously aware of pain. Posner's proposal of two different attentional systems may account for why there is physiological reactivity concurrent with lack of awareness of pain. Posner suggested that the posterior brain is involved with engaging and disengaging attention while the anterior brain is involved in attention for action or effortful attention. "Thus, the posterior region is involved in space and time, the epicritic processes, whereas the anterior region is involved in comfort- discomfort, the protocritic processes (Pribram, 1991)" (p. 665).

In parallel, there appear to be two systems of pain involving the cortex, as revealed in positron emission tomography research. Also relevant is clinical data showing that "removal of the frontal or cingulate cortex in patients with intractable pain leads to the amelioration of distress while not eliminating sensory pain (Bouckoms, 1989)" (p. 665).

The author proposes a neuropsychophysiology of hypnotic analgesia based on Hilgard's (1986) neodissociation theory of hypnosis, together with Pribram and McGuinness' (1975, 1992) attention model. In this view, "Hilgard's executive control system is the far frontal cortex 'directing' the inhibition of incoming painful stimuli" (p. 666) after determining that the somatosensory signal is 'irrelevant.'

"Highly hypnotizable individuals ('highs') have greater attentional and disattentional abilities than low hypnotizable individuals ('lows'). ... Recent neuroimaging techniques (PET, SPECT, CBF) that assess regional brain metabolism have found no differences in waking conditions between low and highly hypnotizable individuals, but have consistently reported that only highs show increased cerebral blood flow during hypnosis, suggestive of enhanced cognitive effort (Crawford, Gur et al., 1993; Halama, 1989; Meyer, Diehl, Ulrich, & Meinig, 1989; Walter, 1992)" (p. 666).

The hippocampus appears to be involved as a gating mechanism in selective attention (Crowne, Konow, Drake & Pribram, 1972; Isaacson, 1982, Isaacson & Pribram, 1986; R. Miller, 1991; Pribram, 1991; Arnolds et al., 1980) This gating function may be promoted "through a cortico-hippocampal relay [that] transmits information by theta wave modulation and Hebbian synaptic modification so that there is selective disattention" (p. 667). The author suggests that hypnotic pain control may involve directing attention away from pain sensory signals.

Highly hypnotizable people generate more EEG theta than low hypnotizables whether they are hypnotized or not, and Crawford (1990) observed marked hemispheric shifts in theta when highs (but not lows) were attempting to control pain with hypnosis.

This paper reports on preliminary results of SERP studies of people given hypnotic analgesia suggestions to reduce electric shock stimulus evoked pain. The results

were analyzed individual by individual, because group data obscured pronounced shifts in SERP patterns (e.g. habituation rates differed among Subjects). For highs, the SERP tended to be reduced, and the lower amplitudes were observed as early as the N100-P200 components. This did not occur for low hypnotizables.

Different kinds of mechanisms may be operative for high hypnotizables, however. "In over half of the high hypnotizable subjects the far frontal region (Fp1, Fp2) showed strong arousal during attention to pain, but during hypnotic analgesia there was a flattening out of the SERPs to the point they are hard to measure. By contrast, the more posterior SERPs (including F3 and F4), while reduced in amplitude, were still evident. The other half of highs showed little SERP activity in the far frontal region in either attend or disattend conditions, but substantial reductions of SERPs at all locations during hypnotic analgesia" (p. 670). Additionally, some of the highs evidenced a contingent negative variation (CNV) or a late 400-500 msec negativity in the far frontal region, which author is inclined to interpret as "a preparation for a response or for an inhibition of a response" (p. 670).

Case studies of two patients with intracranial electrodes and scalp electrodes recording SERPs are presented in support of the experimental data. The two female patients were diagnosed with obsessive compulsive disorder; one was highly hypnotizable and one was not. They received 30 moderately painful stimuli to the left middle finger under sequential conditions: waking attention, hypnosis with analgesia suggestions, and hypnosis with attention instructions. The highly hypnotizable patient reported significantly less pain during suggested analgesia, and that reduction in pain was associated temporally with reduction of SERP at P160 in the gyrus cingulus (and at no other recording sites). The 'unhypnotizable' patient showed no SERP changes. As an aside, the author notes that "Subsequent to the hypnotic analgesia, when the pain was attended to again during waking this patient showed a significant enhancement of the same positivity wave at Fz, as if there was a rebound effect (something we have also observed in some of our SERP subjects at the BRAINS Center)" (p. 674).

Freeman, R.; Barabasz, A.; Barabasz, M. (1994, October). EEG topographic differences between dissociation and distraction during cold pressor pain in high and low hypnotizables. [Paper] Presented at the annual meeting of the Society for Clinical and Experimental Hypnosis, San Francisco.

#### NOTES

Hilgard once said we should study what is going on inside the skull when we study hypnotic behavior. Theta EEG was studied, in 3.5 and 5.5-7.5 band widths, based on Crawford's research (no differences between high and low hypnotizables in low range but significant differences in waking state, eyes closed condition).

Also employed new type of distraction procedure. Previously used as comparison conditions things like imagine a pleasant scene, do whatever you can do to reduce pain, or imagine an instructor giving a lecture. Barabasz theorized that highs, given the opportunity, may spontaneously get involved in imagery; so distraction used in some experiments may actually become hypnosis. Here, distraction involved using a storage box, with plexiglass covering front, and 3 lights--subjects were to recall

sequence of light changes that occurred during 60 sec when arm was in the cold water.

Cold pressor pain. 3 immersions with simultaneous pain reporting and EEG monitoring. --Waking State --Light array distraction --Hypnotic induction and suggested analgesia (Distraction and hypnosis with analgesia were presented in a balanced design)

Pain Ratings ranged from 0 = no pain, 10 = level would very much like to remove arm from water (rating could exceed 10 however). After removing arm, subjects were to report the maximum amount of pain that they had felt. Pain Scores were obtained at 30 seconds and 60 seconds after immersion in the cold water.

Also got qualitative data. During recovery period after each arm immersion, Subjects were asked what if anything they had done to reduce the pain felt.

30 second pain scores: Waking 7.60 vs 7.50 Distraction 8.60 vs 6.80 Hypnotic analgesia 7.80 vs 4.10 (Significantly different).

60 second pain scores: Showed same trend

There was no difference whatsoever for the lows.

Results for the 2 EEG sites: P3 left hemisphere parietal in waking and hypnotic analgesia, high theta, had significantly different activity O1 left hemisphere in waking and hypnotic analgesia, was significantly different between highs and lows (same as above).

Results for two theta ranges: Low theta range, T4 temporal right hemisphere, for lows in waking and [missed words] condition--hard to interpret this finding.

## RESULTS

Highs demonstrated pain reduction in hypnotic analgesia compared to waking and distraction conditions and compared to lows. Lows had no differences in any condition.

Enhanced EEG theta in left parietal area differentiated highs and lows. This suggests that highs generate enhanced disattention that may be controlled by these areas.

P3 area regulates the integration and association of somatic perceptions. The O1 area controls processing of visual imagery. Perhaps high hypnotizables have more ability to alter afferent sensory information through focused attentional processes. Also, the ability to alter the suffering portion of pain experience may involve visual imagery activity.

State and trait differences are apparent.

The low theta range may be more closely related to slower delta range 0-3.5 that is associated with sleep and drowsiness. High theta = low arousal and attention capacity. That's why theta seems associated with wide range of behaviors that appear contradictory

The qualitative data shows highs reported they spontaneously preferred strategies that were more than distraction (associating colors with warmth, thinking of warm water) and the most frequent responses of lows were "nothing" or "told myself it would be over soon."

Highs in analgesia condition used no specific strategy: 8/10 reported the arm simply felt more numb.

## NOTES

In the last 5-6 years we see a beginning of a consistency in this type of research on EEG and hypnosis. Baseline EEG theta for high and low hypnotizable Ss was higher significantly in frontal and temporal areas; less significantly in parietal and occipital areas. It begins to look like a signature of hypnotizability. Our research will be published in the Journal of Abnormal Psychology next year.

In Japan they see theta as sustained attention; some aspects of theta relate to MAO and also to dopamine. Betsy Faith did the same research, replicating almost exactly. There are no differences between Highs and Lows in alpha or beta; but we find differences in theta (especially frontal, and in 40 Hz more posteriorly). It may not be L-R hemisphere difference as previously thought, but more a rostral-caudal dimension.

The signature to hypnotizability is more frontal theta at baseline. This may also relate to a drop in theta after induction, but those results are not so clear. Highs have a larger drop in theta from pre to post induction than is observed in the Lows.

We did a "chaos analysis" of EEG. There are three main measures, including dimensionality. Dimensionality is a measure of complexity. People demonstrate high dimensionality when asked to do tasks, low dimensionality in anesthesia.

High hypnotizable Ss start an induction with higher dimensionality than the Low hypnotizable Ss, and as we go through the induction they remain the same. So this measure shows individual differences but does not give evidence of a state (because it doesn't change).

Chaos dimensions for 2 mental math problems show lower dimensions in frontal compared to posterior areas; but for imagery [labeled on slide as positive and negative emotional tasks] the dimension is the same across areas.

For the dimension measures, lows look like they are doing mental math and highs look like they are doing imagery, in baseline.

**SECOND PART OF RESEARCH--DISSOCIATION.** For 100 years dissociation and hypnosis have been viewed as similar. Two dissociation scales were used - Putnam's DES and Reilly's scale. A factor analysis found four factors: 1. absorption or derealization 2. depersonalization 3. segment amnesia 4. in situ amnesia (Segment amnesia differs from in situ amnesia because you wake up to it at that moment in the in situ vs the segment case.)

We have 20-30 people who score very high on hypnotizability.

Colin Ross finds the same factors as our factors 1 and 2, but he finds only one amnesia factor where we find two.

The correlation between DES and Harvard ranges .05 to .18. Are the high hypnotizables related to high dissociatives, with others not related? A scatter plot did not reveal that.

FFT EEG bands during baseline for high and low dissociation Ss find no differences for high and low dissociative subjects. We conclude that dissociation and hypnosis are two orthogonal processes.

Now we are beginning to look at the pathways that lead one to become highly hypnotizable or dissociative.

#### COMMENTS FROM THE AUDIENCE:

Ian Wickramasekera: Have you introduced threat to high or low DES people?

Answer: High and Low DES people with happy and unhappy imagery tasks do the opposite, with the dimensionality measure. With emotionality you don't see stable baseline differences, you see reactivity differences.

A. Barabasz: I think the DES isn't a good measure of dissociation in hypnosis which is voluntary and not pathological.

D. Spiegel: Sabourin's study found more theta in left frontal during hypnosis, whereas you found less. Answer: That's why I don't know what to do about the state effects.

J. Crawford: Sabourin had Ss doing tasks, so they may have been more active than yours.

#### 1993

Dabic-Jeftic, Mirjana; Barnes, Graham (1993). Event-related potentials (P300) during cognitive processing in hypnotic and non-hypnotic conditions. Psychiatria Danubina, 5 (1-2), 47-61.

In this study authors investigated to find out if there were any specific changes of event related potentials in subjects before hypnosis, entering hypnosis, in deep hypnosis and leaving hypnosis, and to compare mental activities of subjects such as capability of correctly calculating and remembering the exact number of unexpected stimuli delivered by stimulator with their verbal or nonverbal reports during any of the conditions investigated. The methodology was of testing the cognitive evoked potentials elicited by auditory stimuli, using the oddball paradigm. Obtained results show that the most constant values of shortest latency and highest amplitudes of the cognitive waves, especially P300 were found during deep hypnosis. All five subjects in the investigation answered with the exact number of delivered target stimuli only after deep hypnosis. Conversely, in all other conditions their answers were approximate to the correct number of delivered target stimuli. (Author abstract.)

#### NOTES

In this experiment, 5 adult volunteers were told to attend to one of two tones delivered through headphones. The tones were randomly delivered but one occurred 85% of the time (the 'frequent, non-target tone') and the other occurred 15% of the time (the 'rare, target tone'). The subjects were to notice, remember, and count the target tone. Measures were taken during five periods: pre-hypnosis, entering hypnosis, deep hypnosis, leaving hypnosis, and post-hypnosis.

Some subjects had extensive hypnosis experience prior to the experiment; others had little.

The EEG P300 wave was sensitive to condition. Latency of P300 was significantly shorter in deep hypnosis compared with other periods. Higher amplitude of P300 also occurred during deep hypnosis compared with other periods. (Notes taken from secondary reference, Ericksonian Newsletter.)

EEG was recorded monopolarly at frontal (F3, F4), central (C3, C4) and posterior (in the middle of O1-P3-T5 and O2-P4-T6 triangles) derivations during the hypnotic induction of the Stanford Hypnotic Clinical Scale (SHCS) and during performance following suggestions of hypnotic dream and age-regression as expressed in the before-mentioned scale. 10 low-hypnotizable and 9 highly-hypnotizable and right-handed female students participated in one experimental session. Evaluations were Fast-Fourier spectral analyses during the following conditions: waking-rest in eyes-open and eyes-closed condition; early, middle, and late phases of hypnotic induction; rest-hypnosis in eyes closed condition; hypnotic dream and age regression. After spectral analysis of 0 to 44 Hz, the mean spectral amplitude estimates across seven Hz bands (theta 1, 4-6 Hz, theta 2, 6-8 Hz; alpha 1, 8-10 Hz; alpha 2, 10-13 Hz; beta 1, 13-16 Hz; beta 2, 16-20 Hz; beta 3, 20-36 Hz) and the 40-Hz EEG band (36-44 Hz) for each experimental condition were extracted. In eyes-open and -closed conditions in waking and hypnosis highly-hypnotizable subjects produced a greater 40-Hz EEG amplitude than did low hypnotizable subjects at all frontal, central and posterior locations. In the early and middle hypnotic induction highly-hypnotizables displayed a greater amount of beta 3 than did low hypnotizables and this difference was even more pronounced in the left hemisphere. With posterior scalp recordings, during hypnotic dream and age regression, high hypnotizables displayed, as compared with the rest-hypnosis condition, a decrease in alpha 1 and alpha 2 amplitudes. This effect was absent for low hypnotizables. Beta 1, beta 2 and beta 3 amplitudes increased in the left hemisphere during age regression for high hypnotizable; low hypnotizables, in contrast, displayed hemispheric balance across imaginative tasks. High hypnotizables during the hypnotic dream also displayed in the right hemisphere a greater 40-Hz EEG amplitude as compared with the left hemisphere. This difference was even more evident for posterior recording sites. This hemispheric trend was not evidenced for low hypnotizable subjects. Theta power was never a predictor of hypnotic

susceptibility, 40-Hz EEG amplitude displayed a very high main effect ( $p < 0.004$ ) for hypnotizability in hypnotic conditions by displaying a greater 40-Hz EEG amplitude in high hypnotizables with respect to lows.

#### NOTES

In the Discussion section, the authors indicate that they have no idea why they didn't replicate results of other theta studies, including their own, except maybe due to complex interaction among personality, subject selection, situation-specific factors, and hypnotizability.

They observe that the alpha results conform with previous findings (p. 163). Beta bands were sensitive. Highs showed left-hemisphere prevalence in all beta bands during age regression; they also showed hemispheric balance in the hypnotic dream condition. Beta 3 amplitude was also greater among highs than lows. "among high hypnotizables, beta 3 amplitude in the early hypnotic condition was greater in the left hemisphere as compared to the right and as the hypnotic induction proceeded hemisphere balancing, with reduced beta 3 amplitude, was displayed. This result appears in agreement with the predictions of the neurophysiological model proposed by Gruzelier et al. (1984) and Gruzelier (1988) as well as with other studies in which beta rhythm was found to discriminate performances between high and low hypnotizables (e.g., Meszaros et al., 1986, 1989; Sabourin et al., 1990)" (p. 163-164). 40 Hz amplitude was higher in highs and increased in right hemisphere during the hypnotic dream, especially in posterior areas. "This pattern of hemispheric activation may be interpreted as an expression of the greater right-hemisphere activation and of the release of posterior cortical functions during the hypnotic dream and is compatible with the predictions of the Gruzelier model of hypnosis, however, the results obtained in this study for 40-Hz EEG amplitude failed to reveal an inhibition of the left-hemisphere activity with the progress of the hypnotic induction" (p. 164).

(They note that De Pascalis & Penna, 1990, agreed with the Gruzelier 1988 model: highs in early induction had increase of 40-Hz in both hemispheres, but as induction proceeded they had inhibition of left and increase in right hemisphere activity. In this current experiment, only beta 3 showed the hemispheric trend of Gruzelier's model. They cite other details of current study, p. 164, not consonant with Gruzelier.)

"The 40-Hz EEG rhythm, which according to Sheer (1976) is the physiological representation of focused arousal, appeared to discriminate between differential patterns of high and low hypnotizables. Both during hypnotic induction and during hypnotic dream and age regression highly hypnotizables exhibit greater 40-Hz EEG amplitude with respect to the lows. These findings support the validity of the assumption that hypnosis is characterized by a state of focused attention (Hilgard, 1965) and that 40-Hz EEG activity reflects differential attentional patterns among subjects high and low in hypnotizability. On the basis of these findings it would appear that 40-Hz EEG and beta 3 spectral amplitudes may prove to be useful measures of individual hypnotizability" (p. 164).

Gruzelier, John; Warren, Kristen (1993). Neuropsychological evidence of reductions on left frontal tests with hypnosis. Psychological Medicine, 23, 93-101.

Individuals with high and low susceptibility to hypnosis were compared in a baseline condition and after instructions of hypnosis on tests of anterior left and right hemispheric functions of word fluency to letter categories, word fluency to semantic categories, design fluency and bilateral finger tapping dexterity. With hypnosis high susceptibles showed a reduction in word generation to letter categories, no significant change in word generation to semantic categories, an improvement in design fluency, and bilateral reductions in finger tapping dexterity. Low susceptibles showed the opposite changes except for the improvement in design fluency. These results, together with correlational results, were interpreted as evidence of central inhibitory processes, particularly of the left hemisphere, in response to instructions of hypnosis in high susceptibles.

#### NOTES

The authors discussion of their study includes the following statements. "The main result of the study was the differential influence of instructions of hypnosis on high and low susceptibles for word fluency to letter designated categories, as distinct from semantic categories, and design fluency" (p. 98).

"The absence of effects of hypnosis on word generation to semantic categories (left fronto-temporoparietal) versus letter categories (left frontal) has a bearing on evoked potential evidence (Gruzelier et al. 1987). Bilateral comparisons at temporal lobe and central locations showed that high susceptibles were characterized by asymmetric changes in evoked potential amplitude (N116 component) with hypnosis. Activity at the central electrodes was compatible with a left-to-right hemispheric shift of function, but this was not the case at the temporal electrodes. Instead of an inhibition of left temporal activity with hypnosis activation was maintained. Maintenance of activity in the left temporal lobe follows consideration of the fact that hypnosis requires sustained attention to the voice of the hypnotist, which is predominantly a left temporal function" (p. 99).

"The absence of differences in the pre-hypnotic condition between high and low susceptibles indicates that hemisphericity *per se* may not be a factor that characterizes susceptibility. The fact that lateral differences were found in some experiments (e.g. Gruzelier et al. 1984; Gruzelier & Brow, 1985) but not others (e.g. Cikurel & Gruzelier, 1990; McCormack & Gruzelier, 1993) may indicate that such effects, when apparent, were secondary to another factor such as cognitive flexibility as conceptualized by Crawford (1989)" (p. 99).

Jutai, Jeffrey; Gruzelier, John; Golds, John; Thomas, Martin (1993). Bilateral auditory-evoked potentials in conditions of hypnosis and focused attention. International Journal of Psychophysiology, 15, 167-176.

Brain event-related potentials (ERPs) evoked by auditory stimulation were used to study cerebral hemispheric activity during hypnosis. ERPs were recorded from bilateral central (C3 and C4) and temporal (T3 and T4) scalp locations in response to tone pips in 6 medium-high and 6 low-susceptible subjects in three conditions: baseline (tones only), hypnosis (tones plus hypnotic induction), and a focused attention control (tones plus a newspaper story read by the hypnotist). Task

asymmetries were individually adjusted for baseline asymmetries. Responses from central locations did not differentiate hypnosis from focused attention for either group. The same was true of temporal locations for the low-susceptible group. The predominant temporal lobe pattern for both conditions and groups was larger left than right responses. The exception was the hypnosis condition for the medium-high susceptible group where there was an increase in responses in the right temporal lobe.

Brain event-related potentials (ERPs) evoked by auditory stimulation were used to study cerebral hemispheric activity during hypnosis. ERPs were recorded from bilateral central (C3 and C4) and temporal (T3 and T4) scalp locations in response to tone pips in 6 medium-high and 6 low-susceptible subjects in three conditions: baseline (tones only), hypnosis (tones plus hypnotic induction), and a focused attention control (tones plus a newspaper story read by the hypnotist). Task asymmetries were individually adjusted for baseline asymmetries. Responses from central locations did not differentiate hypnosis from focused attention for either group. The same was true of temporal locations for the low-susceptible group. The predominant temporal lobe pattern for both conditions and groups was larger left than right responses. The exception was the hypnosis condition for the medium-high susceptible group where there was an increase in responses in the right temporal lobe.

The influence of an extremely-low-frequency (ELF) magnetic field on the bioelectrical processes of brain and performance was studied by EEG spectral analysis, auditory-evoked potentials (AEP), reaction time (Roletaking) and target-deletion test (TDT). Fourteen volunteers were exposed for 15 min to an intermittent (1 s on/off) 45- Hz magnetic field at 1000 A/m (1.26 mT). Each person received one real and one sham exposure. Statistically significant increases in spectral power through alpha- and beta- bands, as well as in mean frequency of the EEG spectrum were observed after magnetic field exposure. Field-dependent changes of N100 were also revealed. No changes in the amplitudes or latencies of the earlier peaks were observed. No direct effects on Roletaking, nor on TDT performance were seen. However, practice effects on Roletaking (decrease of Roletaking in the course of the test-sessions) seemed to be interrupted by exposure to the magnetic field.

Nishith, Pallavi; Barabasz, Areed F.; Barabasz, Marianne (1993, October). Effects of Alprazolam and hypnosis: EEG spectral decomposition and transient experience. [Paper] Presented at the annual meeting of the Society for Clinical and Experimental Hypnosis, Arlington Heights, IL.

#### NOTES

We wanted to test Hilgard's neodissociation theory and Crawford's and my ideas about theta reflecting processing dissociation where environmental stimuli are ignored.

Hypothesis: highs would show greater EEG theta in hypnosis than lows when exposed to a suggestion to recreate alprazolam (trade name Xanax) effects.

We demonstrated hypnosis to groups, discussed it, administered the Harvard, took highs and lows and then tested them with Stanford C; got 20/group, matched for

age, gender, and handedness. Assigned 10/cell, in drug or placebo (double blind) conditions. Tested females to make sure they weren't pregnant. Ingested the placebo or drug, waited 1 hour; took 5' waking EEG while they were asked to focus on "feelings of relaxation brought on by the drug." Interviewed them (see our chapter in Fromm & Nash book) to determine their transient mood states during the 5' period, plus gave them POMS tension/anxiety questions.

Results of first study: analyzed for hypnotizability x placebo x drug condition. EEG Theta was reduced in hypnosis; hypnotic ability showed no effects. Highs maintained higher beta in alprazolam drug condition (vigilance).

Study 2 counterbalanced conditions: Waking Hypnosis Hypnosis with a suggestion to recreate alprazolam effects.

Used Ss who actually had taken Alprazolam participated in the experiment four days later; induction was a tape recorded version of the Stanford Clinical Scale. Suggestion: imagine taking a dose twice as high as you had before. EEG and transient experience data were collected as before. 2 x 3 Manova's were computed.

1. Theta was higher for highs than lows at  $p < .01$  for both the hypnosis and hypnosis with drug effects suggestion conditions. 2. Alpha - had the same findings as for theta. (and same results as in our Antarctica study). 3. Beta was significantly higher for both high and lows in waking vs hypnosis conditions at all but the T4 site where beta was highest in the two hypnosis conditions only for the highs. 4. POMS analysis: mean tension/anxiety scores were significantly lower for highs in both the alprazolam and hypnotic suggestion conditions.

Both highs and lows showed more theta in hypnotized than in waking conditions. Failure to find differences between groups differing in hypnotizability may be because highs were so good at creating the alprazolam effect that they may have desynchronized theta.

#### NOTES

Cited in Noetic Sciences Review, Autumn, 1992. This geobiologist has discovered that the human brain contains billions of tiny magnets--some 7 billion of them, each so small that their total weight is only one/millionth of an ounce. In magnetite-containing bacteria, the crystals are used as a compass needle which orients the bacteria with respect to the Earth's magnetic field. In birds, bees, and fish, where concentration of the mineral is a few orders of magnitude higher than he found in the human brain, it is used as a navigational aid. He plays down the possible connection to weak electromagnetic fields that supposedly cause cancer (unless fields could induce very weak electrical fields inside the cells, disrupting cellular function). Other possible interpretations: a means for cells to store excess iron, or part of a magnetic sensing system, or a vestigial system left over in evolution from when we were more directly connected with the earth's magnetic field and may have relied on it for navigation or migratory movement.

#### NOTES

A review and methodological critique. Updates Putnam, 1984. Currently, psychophysiologic differences reported in the literature include changes in cerebral electrical activity, cerebral blood flow, galvanic skin response, skin temperature, event-related potentials, neuroendocrine profiles, thyroid function, response to medication, perception, visual functioning, visual evoked potentials, and in voice, posture, and motor behavior. Reviews the new research on the psychophysiological investigation of MPD from published, unpublished, and ongoing studies, and attempts to place current findings into a conceptual framework. Authors note results from unpublished and ongoing studies and include a critical analysis of current research methodology as well as suggestions for future research.

#### 1991

Brown, Peter (1991). Ultradian rhythms of cerebral function and hypnosis. Contemporary Hypnosis, 8, 17-24.

As a consequence of his observations of the clinical work of Milton Erickson, Ernest Rossi has proposed an 'ultradian rhythm theory of hypnosis'. Rossi demonstrated that the spontaneous changes in cognition, affect and behaviour which occur as part of the ultradian cycle (which Erickson referred to as 'the common everyday trance') are similar to the changes which occur during hypnosis. A review of studies of the phasic changes in hemispheric function suggests that ultradian changes do parallel the changes found in hypnosis.

#### NOTES

Falling asleep and waking up are regulated by two separate mechanisms rather than being opposite poles of one mechanism (Winfree, 1980). Kleitman (1961) suggested a 90-min cycle, the basic rest-activity cycle (BRAC). In addition to physiological alterations, there are alterations in cognition, mood and behavior (Rossi & Cheek, 1988); vigilance (Okawa, Matousek & Petersen 1984); peripheral blood flow (Ramano & Gizdulich, 1980); respiratory amplitude (Horne & Whitehead, 1976); visual evoked potentials (Zimmerman, Gortelmeyer & Wiemann, 1983); pupillary diameter, stability and reactivity to light, and saccadic eye movements (Lavie & Kripke, 1981).

These diurnal variations may relate to hypnotic behavior. There is a recurring increase in daydream and fantasy, as well as visual imagery (Kripke & Sonnenschein, 1978). "There is evidence for a parallel recurring cognitive and emotional cycle with increased emotional responsiveness and a more subjective cognitive processing of information (Evans, 1972; Holloway, 1978; Overton, 1978; Thayer, 1987). Subjects appear to repeat the cycle approximately 16 times per day, with a range of 70-120 minutes. Kripke and Sonnenschein (1978) noted that the subjects were personally unaware of any repeating cycle in their mental lives" (p. 19).

The brainstem arousal mechanisms seem to be implicated in periodic changes in the EEG. Ultradian rhythms are "more easily detected under conditions of increased sleep need, reduced external performance demand and lowered motivation to focus externally (Broughton, 1985)" (p. 20). Sterman (1985) observed that the rhythm was most marked in resting state and disappears during complex visuomotor tasks. Relationship of EEG patterns to attentional patterns indicate there may be two different forms of attention, one for focused awareness (often thought to be associated with trance state) and the other a generalized vigilance (which would be reduced in hypnosis). Ultradian changes in consciousness reflected in the EEG may suggest increased internal absorption associated with visual imagery, a feature of the trance state.

"There has recently been a partial direct confirmation of Rossi's hypothesis. Aldrich and Bernstein (1987 [International Journal of Clinical and Experimental Hypnosis]) reported a bimodal distribution of Harvard Group Scale Hypnotic Susceptibility (HGSHS) scores when they are done at different times throughout the day. They note the parallel of the changes in HGSHS scores and the circadian variations in body temperature which suggest changes in hypnotic responsiveness coinciding with the fluctuations of physiological rhythms.

"Other support comes from some highly original work involving breathing rhythms. There are cyclic alterations in relative air flow between the left and right nostrils with an average period of 2-3 hours (Hasegawa & Kern, 1977). This nasal ultradian rhythm is correlated with an increase in contralateral cerebral hemispheric activity (Werntz, Bickford, Bloom & Shannahoff-Khalsa, 1981, 1983; Klein, Pilon, Prosser & Shannahoff-Khalsa, 1986). The alterations in hemispheric function do appear to be related to changes both in the style of cognition, particularly in an increase in vivid visual imagery, and in performance on specific tasks (Klein et al., 1986). Thus these studies support the notion of an ultradian rhythm of cerebral function which is associated with characteristic physical manifestations mediated by the autonomic nervous system. Whether or not these changes are directly related to the findings reported by Aldrich and Bernstein has yet to be established" (p. 21).

The authors conclude that "the most consistent evidence for ultradian rhythms is demonstrated by the mechanisms of the hypothalamic-limbic system and by brainstem mechanisms that regulate arousal and attention processes (Parmeggiani, 1987); neuroendocrine regulatory mechanisms (Follenius, Simon, Brandenberger & Lenzi, 1987) and autonomic nervous system function (Bossom, Natelson, Levin & Stokes, 1983; Gordon & Lavie, 1986). These studies also suggest an ongoing dynamic interaction between cortical and subcortical structures throughout the ultradian cycle (Parmeggiani, 1987), and suggest that these interactions may be of great significance in hypnosis" (p. 21).

Graffin, N. W. (1991, October). EEG concomitants of hypnotic susceptibility and hypnosis (Dissertation, Pennsylvania State University). Dissertation Abstracts International, 52 (4), 2296.

"Many previous studies of EEG and hypnosis were completed prior to development of spectral analysis and typically included data from a limited number of electrode sites. The categorization of subjects as high and low hypnotizables was often done inappropriately, and disparate findings were obtained. In this study, subjects scoring 10 or more and 3 or less on the Stanford Hypnotic Susceptibility Scale, Form C were defined as high and low respectively. EEG was monitored during resting baseline, mental arithmetic, and mental spatial rotation, and before, during, and after hypnotic induction. EEG was recorded monopolarly at frontal (F3,F4), parietal (P3,P4), temporal (T3,T4), and occipital (O1,O2) derivations, and data were fast Fourier analyzed. Mental arithmetic and mental spatial rotation did not produce differential hemispheric activation. High hypnotizables had greater frontal and temporal theta at baseline than lows. All subjects showed increases in parietal and occipital theta during hypnotic induction. During prehypnotic induction baseline, highs had greater parietal and occipital theta than lows, but this difference was smaller after induction. Baseline temporal alpha was greater for highs than lows, but after hypnotic induction, all subjects had less alpha at all sites than before induction. Increases in alpha at all sites for all subjects occurred during hypnotic induction. Beta activity was unrelated to susceptibility but was greater in waking than in hypnotic states for all subjects at all sites. Increases in alpha at all sites for all subjects occurred during hypnotic induction. The theta activity observed suggests that high hypnotizables have a greater capacity for selective attention and imagery and that during hypnosis all subjects experience enhancement of these abilities. The alpha results may suggest an increase in the focusing of subjects on internal processes during hypnosis and greater scanning of the environment after induction" (p. 2296).

Lubar, J. F.; Gordon, D. M.; Harrist, R. S.; Nash, M. R.; Mann, C. A.; Lacy, J. E. (1991). EEG correlates of hypnotic susceptibility based upon fast Fourier power spectral analysis. Biofeedback and Self-regulation, 16, 75-85.

Examined whether there were differences between high and low hypnotic susceptible subjects based upon fast Fourier power spectral analysis of the EEG recorded both before and during hypnotic tasks. Significant differences were obtained based upon EEG recording electrode location, EEG frequency within six different frequency domains, and hypnotic tasks. However, no main effect differences were obtained based upon hypnotic susceptibility. In contrast to some evoked potential studies in which a few differences have been obtained based on hypnotic susceptibility, the lack of any EEG differences in this study even when positive and negative hallucination tasks were employed may have implications for the role of the neocortex in mediating hypnotic phenomena.

#### NOTES

When this study was presented at the annual meeting of the Society for Clinical and Experimental Hypnosis in 1988, in Ashville, the authors remarked that, "Since EEG comes from cortex, the results might be due to subcortical levels. Therefore one should look at cerebral blood flow and metabolism."

#### NOTES

Reviews literature. Conclusion: First, with reinforcement for responding, control of learned behavior can be maintained reliably by stimuli presented during sleep. Second, when stimuli are presented 4 min or more apart, behavioral control results in little or no change in sleep structure, in daytime sleepiness, or in perceptions of sleep quality. Neither perceived wakefulness nor wakefulness as it is scored on the sleep record are necessary for responding, although stimulus/response events typically result in brief EEG or EMG change. Third, within-subject, within-night variance in responsiveness is complexly related to time of night, sleep stage, and REM/NREM cycle.

De Pascalis, Vilfredo; Penna, Pietronilla M. (1990). 40-Hz EEG activity during hypnotic induction and hypnotic testing. International Journal of Clinical and Experimental Hypnosis, 38 (2), 125-138.

The present study evaluates changes in left and right 40-Hz EEG production for 19 high and 20 low hypnotizable female Ss during the hypnotic induction and the administration of the Stanford Hypnotic Susceptibility Scale, Form C (SHSS:C) of the Weitzenhoffer and Hilgard (1962). Scalp recorded 40-Hz EEG density was obtained from the middle of the O1-P3-T5 and O1-P4-T6 triangles. As the hypnotic induction proceeded, high hypnotizable Ss exhibited a shift to greater right-hemisphere activity as compared to a waking-state restcondition. In contrast, low hypnotizable Ss, showed a reduction in left- and right-hemisphere activity. No differences between groups for SHSS:C ideomotor items were observed. A main effect for Hypnotizability among SHSS:C imaginative items was found. A Hypnotizability x Hemisphere x Trial interaction was found for both sensory distortion and imaginative SHSS:C items. A comparison was made between low versus high hypnotizable Ss of 40-Hz EEG activity while they passed the same item. The results of these comparisons indicate that differences in brain activity might be partially related to the differences between experiencing a hypnotic suggestion or failing to do so. Significant relationships between 40-Hz EEG production and hypnotizability and 40-Hz EEG production and level of amnesia were also found.

Edmonston, William E., Jr.; Moscovitz, Harry C. (1990). Hypnosis and lateralized brain functions. International Journal of Clinical and Experimental Hypnosis, 38, 70-84.

Bilateral EEG measures were obtained on 16 high hypnotizable Ss (scores of >8 on the Harvard Group Scale of Hypnotic Susceptibility, Form A, Shor & E. Orne, 1962), while performing hemisphere-specific tasks during hypnosis and a no-

hypnosis control condition. Conditions and tasks were presented in counterbalanced order, and Ss served as their own controls. The data call into question the right hemisphere activation interpretation of lateralized brain function during hypnosis; rather, the data suggest a lack of task appropriate activity during hypnosis. The failure to attend to baseline activity measurements and the use of ratios to evaluate interhemispheric lateralization may contribute to potential misinterpretations of data. It is critical that activity changes of the separate hemispheres be taken into account in the interpretative process.

Hughes, Dureen J.; Melville, Norbert T. (1990). Changes in brainwave activity during trance channeling: A pilot study. Journal of Transpersonal Psychology, 22, 175-189.

## NOTES

Authors studied 10 people known trance channels--all had been channeling for more than one year. Used an anthropological field method. Electrode was placed only on left occipital (O1) area, referenced to left ear. Calculated difference between each S's pre- trance and trance EEG beta percentages, for alpha and theta percentages also.

Basically, the pre-trance versus trance sums of differences scores were greater than the post-trance versus trance sums of different scores for each of the three frequency bands--indicating a residual of the trance state. There were large, statistically significant increases in amount and percentage of beta, alpha and theta brainwave activity, and some suggestion of a pattern. The large amount of beta differentiates these Ss from what has been observed with meditators (increases in alpha and theta). Among the Subjects, large amounts of beta activity were recorded continuously throughout the trance period and were coupled with large amounts of high amplitude alpha and theta (relative to the pre- and post-trance states).

The authors compare these results to older hypnosis literature. They conclude that the trance channeling state may be a distinctive state characterized by a particular EEG profile that differs from that found in certain meditative states, hypnotic states, various pathological states, or the waking states of the trance channel Subjects who participated in the study. Authors also liken the differences seen between trance and non-trance states of these Subjects to the differences seen for different alter personalities among people diagnosed with Multiple Personality Disorder.

## DISCUSSION

The foregoing research suggests that the trance channeling state, as measured in the current study, is characterized by large, statistically significant increases in amount and percentage of beta, alpha and theta brainwave activity. There appear to be definite neurophysiological correlates to the trance channeling state, and furthermore there is some evidence that these correlates may be patterned. This pattern might be provisionally compared to those associated with other altered states of consciousness.

abourin, M. E.; Cutcomb, S. D.; Crawford, H. J.; Pribram, K. (1990). EEG correlates of hypnotic susceptibility and hypnotic trance: Spectral analysis and coherence. International Journal of Psychophysiology, 10, 125-142.

EEG was recorded during waking rest, hypnosis (rest, arm immobilization, mosquito hallucination, hypnotic dream), and waking rest. Twelve very low and 12 very highly hypnotizability subjects participated. Evaluations were fast-Fourier spectral analysis, EEG coherence between selected derivations, and maximum spectral power within EEG bands. In eyes-open and eyes-closed conditions in waking and hypnosis, highly hypnotizability subjects generated substantially more mean theta power than did low-hypnotizable subjects at all occipital, central, and frontal locations in almost all conditions of waking and hypnosis, with a larger difference in frontal locations. Both low and high hypnotizables showed increased mean theta power in hypnosis, suggesting an intensification of attentional processes and imagery enhancement. Mean alpha power was never a predictor of hypnotic susceptibility. Interactions with hypnotic susceptibility showed that highly susceptible subjects had more beta activity in the left than in the right hemisphere, whereas low-susceptible subjects showed only weak asymmetry. No main effects for or interactions between waking/hypnosis and hypnotic level were found for coherence between derivations or maximum spectral power within theta, alpha, and beta EEG bands

1989

Bick, C. H. (1989). An EEG-mapping study of 'laughing': Coherence and brain dominances. International Journal of Neuroscience, 47, 31-40.

Laughter is triggered by pleasurable psychoemotional stimuli and may have healing potential. According to split-brain studies, psychoemotional stimuli are bound up with emotional activity in the right side of the brain. This suggested the idea of studying laughter generated by different sources with regard to electrical brain activity in the right and left hemispheres. This study first used subjects in normal consciousness and with laughter under hypnosis to study the neurophysiological processes connected with laughter.

De Pascalis, Vilfredo; Marucci, Francesco S.; Penna, Pietronilla M. (1989). 40-Hz EEG asymmetry during recall of emotional events in waking and hypnosis: Differences between low and high hypnotizables. International Journal of Psychophysiology, 7, 85-96.

#### NOTES

Sixteen high and thirteen low hypnotizability women, who had participated in our previous study (De Pascalis et al., 1987), were enrolled in a hypnotic session. After the hypnotic induction they were requested to recollect 2 positive and 2 negative personal life experiences. IN our previous study subjects performed similar tasks in a waking-state. Hypnotizability was evaluated the first time with the HGSHS and, a second time, individually, with the Stanford C. The State Trait Anxiety Inventory, Maudsley Personality Inventory, and Tellegen Absorption Scale were administered.

Upper-trapezius electromyogram (EMG) and bilateral electroencephalogram (EEG) activities within the 35-45 Hz band were recorded. Self-report rating scores for vividness of visual imagery and emotional feeling of the material recalled were evaluated. The 40-Hz EEG amplitude and the left and right hemisphere 40-Hz EEG densities were obtained.

The data collected in hypnosis were compared with those in the waking-state. High hypnotizables, while they were in hypnosis, showed an increase of 40-Hz EEG density during emotional recall compared with rest periods. In contrast, low hypnotizables, after hypnotic induction, showed no density during emotional recall compared with rest periods. In contrast, low hypnotizables, after hypnotic induction, showed no density change during tasks compared to the rest conditions. Different hemispheric trends were found between groups. Highs showed an increase of 40-Hz EEG density over both hemispheres during positive emotions and a density increase in the right and a density reduction in the left during negative ones. This hemispheric trend was found in waking and hypnotic conditions although in the hypnotic condition more pronounced hemispheric patterns were observed. The Tellegen Absorption Scale was found positively related to hypnotizability and with the level of 40-Hz density increase on the right hemisphere during emotional tasks. High hypnotizables, with respect to the lows, were able to access affects more readily. They also showed a greater hemispheric specificity in waking and hypnotic conditions.

Spiegel, David; Bierre, Pierre; Rootenberg, John (1989). Hypnotic alteration of somatosensory perception. American Journal of Psychiatry, 146, 749-754.

The effects of hypnotic alterations of perception on amplitude of somatosensory event-related potentials were studied in 10 highly hypnotizable (HH) Subjects and 10 Subjects with low hypnotizability. The HH Subjects showed significant decreases in amplitude of the P100 and P300 waveform components during a hypnotic hallucination that blocked perception of the stimulus. When hypnosis was used to intensify attention to the stimulus, there was an increase in P100 amplitude. Findings are consistent with observations that HH individuals can reduce or eliminate pain by using purely cognitive methods such as hypnosis. Together with data from the visual system, these results suggest a neurophysiological basis for hypnotic sensory alteration.

#### NOTES

Four conditions were presented in random order to each Subject. Normal Attention - subjects were instructed to button-press each time they felt the target stimulus. Passive Attention - subjects were instructed to attend to the stimuli but not button-press. Hypnotic Attention - subjects received a hypnotic induction (eye closure and arm levitation, which provided behavioral confirmation; then instructed to attend carefully to the stimuli, which they were told to experience as 'pleasant and interesting,' and button-press in response to targets. Hypnotic Obstructive Hallucination - hypnotic induction exercise was followed by the hypnotic suggestion of a local anesthetic, such as novocaine, spreading from fingers to hand to forearm

on the stimulated limb; then instructed to make the limb cold, tingling, and numb; then told to button-press if they felt any of the target stimuli.

Experimenter was blind to hypnotizability scores.

Results were that the Highs showed significant decreases in P100 (45%) and P300 (38%) amplitudes during a hypnotic hallucination which blocked perception of the stimulus, but an increase (35%) in P100 amplitude when hypnosis was used to intensify attention to the stimulus. The authors view this as cognitive flexibility akin to the clinical situation in which high hypnotizables reduce or completely eliminate pain. They consider this evidence (along with earlier findings on similar blocking of perception in the visual system) of a neurophysiological basis for hypnotic sensory alteration.

1988

Aravindakshan, K. K.; Jenner, F. A.; Souster, L. P. (1988). A study of the effects of hypnotic regression on the auditory evoked response. International Journal of Clinical and Experimental Hypnosis, 36, 89-95.

Hypnotic regression in 6 hypnotizable Ss experienced in regression was studied by means of the auditory evoked response (AER). AER latency and amplitude is affected by arousal, attention, stimulus strength, and age. Ss aged between 27 and 61 years were regressed to the age of 7-9 years, and AERs were compared among three states of consciousness: normal awareness, hypnotic relaxation, and hypnotic regression. There was no change in AER morphology in the direction of that seen in children. Thus, age regression is not seen as a reversion to an earlier stage of neurological development but perhaps as role playing which is spontaneous and uninhibited, with the benefit of innocent belief in its accuracy.

NOTES

Raikov (1982) regressed 2 experienced Ss, comparing his results with those of actors acting as children and low hypnotizable subjects; he claimed to be able to reproduce neonatal reflexes in the highly hypnotizable Ss but not in the actors and low hypnotizable subjects.

AER's were used "because latency of the major waves and amplitude of the response is affected by level of arousal and attention..., strength of the stimulus, and, more importantly for this study, by age.... Surwillo (1981) noted that peak latencies of AERs were 16-21 msec longer in children aged 9-13 than in adults..." (p. 90)

DISCUSSION

Changes in the intensity of light stimulation can cause significant shifts in the amplitude and latency of the visual evoked response, but neither the amplitude nor the latency have been changed by suggested alterations in stimulus intensity during hypnosis (Andreassi, Balinsky, Gallichio, de Simone, & Mellers, 1976; Beck & Barolin, 1965; Beck, Dustman, & Beier, 1966; Zakrzewski & Szelenberger, 1981). Similarly, significant changes were seldom found in the AER with suggested variations of sound intensity during hypnosis (Amadeo & Yanovski, 1975) and in somatosensory responses to electrical stimuli applied to the fingers with suggested

anesthesia during hypnosis (Halliday & Mason, 1964). Deehan and Robertson (1980) were able to abolish the AER completely during hypnosis, but their stimuli were very different from that used in the present study.

"In all such studies, hypnosis and suggestions were aimed at changing the intensity of the stimulus to S's awareness, while the actual intensity of the stimulus was unaltered. In the present study, the authors attempted to find whether the morphology of the AER in children could be reproduced by age regression, without altering the nature or intensity of the stimulus in its delivery.... Like previous investigators, the present authors noticed that the tracings were cleaner and easier to produce during hypnosis (see Figure 1), although the changes in neurological development observed by Raikov (1982) were not evident" (pp. 93-94).

De Pascalis, Vilfredo; Silveri, Alessandra; Palumbo, Giovanni (1988). EEG asymmetry during covert mental activity and its relationship with hypnotizability. International Journal of Clinical and Experimental Hypnosis, 36, 38-52.

Parietal-occipital EEG was recorded bilaterally while 20 high and 20 low hypnotizable Ss performed, in the eyes-closed condition, 2 covert right-hemisphere tasks (visual long-term memory and fantasy) and 2 covert left-hemisphere tasks (multiplication and verbal long-term memory). Ss were not, however, hypnotized during any aspect of the psychophysiological testing. After each task, Ss rated orally their degree of involvement in the tasks. The integrated amplitude alpha, the alpha density, and the alpha ratio as a measure of hemispheric asymmetry, were evaluated. Finally, the proportion of relatively greater right activation periods during right-hemisphere tasks minus the analogous proportion during left-hemisphere tasks was used as index of hemispheric specificity. The high hypnotizable Ss showed significantly higher alpha amplitude than the low hypnotizables; the alpha amplitude was correlated with hypnotizability, while the alpha density was not. The alpha amplitude of the right hemisphere during right-hemisphere tasks was significantly lower than the same amplitude during left-hemisphere tasks, while no significant differences related to task-type were detected in the left hemisphere. The pattern of task-effect on alpha ratio scores was the same as that on alpha amplitudes. Verbal and multiplication ratings were related to the alpha ratio, imaginative- visual memory ratings were not. No differences in hemispheric specificity between high and low hypnotizable Ss were found to exist, and no relationship between hypnotizability and hemispheric specificity was observed.

#### NOTES

The authors review the literature on differences between the two hemispheres' involvement during hemisphere-specialized tasks. The ratio between left- and right-hemisphere alpha amplitudes has been shown to be a reliable measure of hemisphere lateralization as a function of task demands (Amochaev & Salamy, 1979).

They also review the literature on EEG asymmetry and hypnotizability. Most investigations used tasks with a problem solving component, whereas this study

used "a covert numeric task and other covert self-generated tasks in which the range of cognitive activities resembled natural thinking" (p. 40).

Purposes of this research were "to investigate whether (a) the amount of alpha in EEG is correlated with hypnotizability, (b) high hypnotizable Ss would reveal higher hemispheric specificities during covert mental tasks than low hypnotizable Ss, and (c) verbal-numeric tasks involve more left-hemisphere activation and imaginative-visual tasks more right-hemisphere activation" (p. 40).

The subjects were 40 women (from an original pool of 71), aged 19-23, with no previous experience using hypnosis. To minimize the possible effects of expectation, hypnosis was not mentioned in the invitation to participate in research. All subjects were tested first with the Harvard Group Scale of Hypnotic Susceptibility, then with the Stanford Scale of Hypnotic Susceptibility (SHSS:C). The SHSS:C was used to select 20 high hypnotizables (defined as having a score 1 standard deviation above the group mean of 6.51) and 20 low hypnotizables (with scores 1 standard deviation below the group mean). The mean score for highs was 10.05 (S.D. = .88) and mean score for lows was 2.75 (S.D. = 1.49).

Although subjects were selected on the basis of their measured hypnotizability, hypnosis was not used during the investigation's psychophysiological testing. However, they were required to relax and keep eyes closed during trials on the tasks. After each trial, the subjects rated their involvement in the task.

Tasks used for this research were: 1. Visual long-term memory. Ss were asked to recall from memory pictures, places, faces, or visual scenes that were in a movie, but not scenes with a negative content. 2. Fantasy. Ss were requested to fantasize about something new that they like (nothing from past experience, and nothing sexual). 3. Multiplication. Ss were asked to multiply 2 serially, as,  $2 \times 2 = 4$ ,  $x 2 = 8$ , etc., and to do it verbally without visual representation. 4. Verbal long-term memory. Ss were requested to think of some poem, speech, or other verbal material that they could recall from memory, and to repeat it mentally, to themselves.

Results can be summarized as follows.

Hypnotizability correlated .38 and .35 with right alpha amplitude and left alpha amplitude during baseline (statistically significant).

There was a significant association between alpha density and hypnotizability, when the group was divided at the median on density. (Alpha density = the time periods in which the alpha was present over the 6-second epochs accumulated during each 1-minute period which preceded the tasks). This association may be seen in the Table that follows:

SHSS:C Alpha Density Low High

+ 6 13

- 14 7

Chi Square = 3.61,  $p < .05$

There was a significant interaction between type of task (verbal-numeric, imaginative-visual memory) and hemisphere, which was attributable to changes in alpha amplitudes in right hemisphere, according to tasks. "Alpha amplitude of the right hemisphere during right-hemisphere tasks was significantly lower than during left-hemisphere tasks, while no significant differences were detected in the left

hemisphere as a result of the differences between left- and right-hemisphere tasks" (p. 44)

Alpha ratio = (Right-hemisphere alpha - Left-hemisphere alpha) / (Right-hemisphere alpha + Left-hemisphere alpha) exhibited the same pattern as for alpha amplitudes. The ANOVA 2 (high/low) x 2 (right tasks/left tasks) repeated measures on alpha ratio revealed a significant main effect for tasks, and a significant interaction between right-left tasks and hypnotizability. "During right-hemisphere tasks there were no significant differences ( $p < .5$ ) [sic] in alpha ratio between high and low hypnotizable groups, while during the multiplication task, the low hypnotizable Ss evidenced a higher mean alpha ratio ( $p < .05$ ) than the high hypnotizable group (.08 & .04, respectively); identical ratios were found during verbal tasks" (p. 45).

Task involvement was expected to be positively related with left-hemisphere tasks, but negatively related to right-hemisphere tasks (i.e. greater subjective involvement in the task would be associated with more negative alpha ratios, showing a bias towards right-hemisphere activation. "Verbal ratings were substantially related to alpha ratios ( $\rho = 0.82$ ;  $p < .01$ ), and multiplication ratings moderately related to alpha ratios ( $\rho = 0.31$ ;  $p < .05$ ); visual memory and fantasy ratings were not related to alpha ratios ( $r = -.04$  &  $r = -.18$ , respectively)" (p. 45).

Hemispheric specificity was defined as the proportion of greater relative right-hemisphere activation periods during right-hemisphere tasks minus the analogous proportion during left-hemisphere tasks. The authors did an analysis to "verify whether the task rating moderates the hemispheric specificity (i.e., the level of subjective involvement in a task is related to the level of hemispheric lateralization, while S is carrying it out)" (p. 46). They concluded that hypnotizability (SHSS:C) is not significantly related to Ss' hemispheric specificity.

In the discussion, the authors present a Table summarizing the results of similar investigations. They mention that the alpha-hypnotizability relationship may depend on which alpha variable is taken into account, or whether eyes-open/closed is varied. They conclude that the different methodological procedures render any comparison of results across studies very difficult.

They note that there was a significant correlation between alpha amplitude and hypnotizability even though Ss did not know in advance that hypnosis would be part of the experiment (the hypothesis proposed by Dumas, 1977, to account for this type of correlation). "One possible explanation of these data might lie in a different level of arousal in the high and low hypnotizable Ss: the high hypnotizable Ss might have been simply more relaxed than the lows.

"Nevertheless, his explanation must be taken with caution. The study of Paskewitz and M. T. Orne (1973), in fact, pointed out that in dark-adapted Ss, the relaxation condition does not produce increases of alpha activity. In a further study, contrary to previous reports, M. T. Orne and Paskewitz (1974) also found that a reduction in alpha activity is not a necessary consequence of apprehension or heightened arousal. Thus, it is not yet clear whether a decrease in anxiety tends to cause an increase in alpha density and vice versa" (p. 48).

Lorig, Tyler S.; Schwartz, Gary E. (1988-89). EEG activity during relaxation and focal imagery. Imagination, Cognition and Personality, 8, 201-208.

EEG activity was recorded in nine volunteer subjects while they engaged in eight cognitive tasks. The tasks involved mental arithmetic, relaxation imagery, food imagery and imagery related to "neutral" stimuli (bicycle and automobile). Period analysis of the EEG indicated significant differences in EEG factor activity related to tension and anxiety for the subtraction, relaxation and food imagery trials. Imagery of heaviness and the subject's favorite dessert produced EEG factor activity most characteristic of relaxation. Results of this study are discussed in terms of the relation of odor to food imagery and the ecological validity of the use of food imagery in relaxation training.

#### NOTES

Lorig, in a comparison of spectral and period analysis techniques, found that period analysis had greater sensitivity to task-related EEG effects. More recently, Lorig and Schwartz applied factor analysis to EEG period data and found that the factors identified tended to show greater homogeneity and correspondence to self-report than the traditional EEG bands of alpha, theta and beta. Period analysis reduces data to a histogram of the number of waves of various frequencies which occur during each 10 second data collection epoch for each task.

As is evident from Finding 1, the 8 tasks tend to stratify into two groups which either increase or decrease in Factor 1/theta activity over time. Those tasks which decrease over time seem to be performance or practice-related and include Serial subtraction of threes, of sevens, relaxation imagery of heaviness (HVY) and instructions to concentrate on the word "one" as they inhaled and exhaled (BCON). These tasks may change little in their cognitive demands on the subjects over time. The other tasks (imagery of their first bicycle, imagery of their earliest ride in a car, imagery of their favorite main course, imagery of their favorite dessert) may be more evocative to the Ss since they were asked to recall events from their personal experience. The recall of some of these experiences may kindle the subsequent recall of other events and account for the increases in theta and Factor 1. It is also possible that theta and Factor 1 are attention- related. Thus, as the S participates in a task which changes little over time, attention is diminished. If, however, the task continues to evoke other personally relevant events, attention will be maintained and may even increase over time. If this later hypothesis is correct, the Favorite Dessert task may be of use clinically since it produces EEG patterns associated with less tension and anxiety and also less boredom. This task also produced self-reports of greater happiness ( $p = .0001$ ) and was not different from relaxation imagery of heaviness and instructions to concentrate on the word 'one' as they inhaled and exhaled in self reports of relaxation, tension or calm.

The results of this study indicate that imagery of food, especially one's favorite dessert, has relaxation effects apparent in EEG and self-report. These effects may indicate that food-related odorants exert their relaxation effects by producing imagery of food. Such effects should not be surprising given the early history of

systematic desensitization training in which food was often used as a competing stimulus for anxiety-provoking stimuli.

Spiegel, David; Barabasz, Arreed F. (1988). Effects of hypnotic instructions on P300 event-related-potential amplitudes: Research and clinical applications. American Journal of Clinical Hypnosis, 31, 22-27.

Apparently conflicting findings in two recent studies of the effects of hypnotic hallucination on the P300 component of cortical event-related potentials are examined. In one study, Barabasz and Lonsdale (1983) found an increase in P300 amplitude in response to hypnotic anosmia instructions. However, Spiegel, Cutcomb, Ren, and Pribram (1985) obtained a decrease in P300 amplitude after instructing high hypnotizables that an imaginary cardboard box blocked their view of the stimulus generator. These differences are reconciled on the basis of differences in the hypnotic instructions given. The former study employed language which emphasized negation ("You will not smell anything at all"), while the latter had subjects focus on a competing obstructive hallucination. The anosmia subjects were surprised when they smelled anything at all, leading to an enhanced P300 response, while the subjects in the visual study were so absorbed in the hallucinated obstruction that perception of the stimulus was reduced. Clinical implications of these two studies are examined.

1987

De Pascalis, Vilfredo; Marucci, Francesco; Penna, Pietronilla M.; Pessa, Eliano (1987). Hemispheric activity of 40 Hz EEG during recall of emotional events: Differences between low and high hypnotizables. International Journal of Psychophysiology, 5, 167-180.

This study evaluates individual differences in hypnotizability as reflected in waking-state hemispheric engagement during recollection of 3 positively and 3 negatively valenced personal life events. The State-Trait Anxiety Inventory, Maudsley Personality Inventory, Tellegen Absorption Scale and Harvard Group Scale of Hypnotic Susceptibility (Form A) were administered. Electromyogram (EMG) and bilateral electroencephalogram (EEG) activities within the 40-Hz band were recorded during rest and task conditions in 22 high and 21 low hypnotizable women. Self-report rating scores for vividness of visual imagery and emotional feeling of the material recalled were evaluated. The 40-Hz EMG amplitude and both hemisphere 40-Hz EEG densities were obtained. A 40-Hz EEG ratio, as a measure of hemispheric asymmetry, and a hemispheric specificity index were also computed. High hypnotizables showed significantly lower 40-Hz EEG density than low hypnotizables in all experimental conditions. The relationship between lateralization of 40-Hz EEG and emotional processing was moderated by hypnotizability. High hypnotizables, with respect to rest condition, showed an increase of density over both left and right hemispheres during two of the three positive emotional tasks, while they showed a depressed activity over the left and an increased activity over the right during negative emotional tasks. Low hypnotizables, on the other hand,

did not exhibit differential hemispheric patterns that could be attributed to different emotional valences. The high group showed greater hemispheric specificity in the predicted direction than the low group. High subjects exhibited greater ratings of absorptive ability and emotional feeling than low subjects. Anxiety and EMG levels did not differ between groups. EMG was dependent on the type of emotion which showed greater activity in the negative emotion condition compared with the positive one.

Makarec, K.; Persinger, M. A. (1987). Electroencephalographic correlates of temporal lobe signs and imaginings. Perceptual and Motor Skills, 64, 1124-1126. Significant correlations (0.50) were observed between scores for the Wilson-Barber Inventory of Childhood Memories and Imaginings and the experiences that are indicative of temporal lobe lability. In addition, positive correlations (0.42) occurred between temporal lobe EEG measures (scalp electrodes) and numbers of temporal lobe signs. The numbers of alpha seconds per minute from the occipital lobes were correlated (0.57) with the Wilson-Barber cluster that indicated interests in 'altered states'. Scores on the childhood imaginings section of the Wilson-Barber Inventory were correlated (0.44) with the numbers of spikes per minute over the temporal lobes when the eyes were closed.

#### NOTES

Persinger and DeSano (1986) found that people who display temporal lobe signs were also more likely to have more imaginings (as defined by Wilson and Barber's (1983) Inventory of Childhood Memories and Imaginings) and to be more suggestible as indicated by Spiegel's Hypnosis Induction Profile" (p. 1124).

Subjects in this investigation were 12 male and 18 female students, ages 18-39 (M = 25 years) Bipolar measures were taken from just above the ears (approximately T3-T4) and the occipital lobe (01-02). Number of alpha seconds per minute and number of spikes per minute from each lobe was taken for 10 minutes (5 successive pairs of 1 minute eyes- open, 1 minute eyes-closed).

"The total Wilson-Barber score was significantly ( $p < .01$ ) correlated ... with the major (0.46) and minor (0.50) temporal lobe clusters but not with two clusters of control items: normal psychological experiences (0.21) and mundane proprioceptive experiences (0.29). These correlations are similar to those in the Persinger and DeSano study (0.60, 0.50, 0.13, and 0.14, respectively). Like the first study (0.53), the items that were most associated with dissociation (depersonalization) were best correlated with the Wilson- Barber scores (0.60). The Wilson-Barber subcluster: adults' extreme experiences (Items 44 through 52, that indicate physiological changes associated with thinking) was again most strongly correlated with the major (0.55) and minor (0.65) temporal lobe clusters; these values were 0.42 and 0.52 in the first study" (p. 1125).

"The only statistically significant ( $p < .01$ ) correlations between the Wilson-Barber scales and the EEG measures were between the number of alpha seconds from the occipital lobe (with the eyes closed) and the [Wilson-Barber] 'altered state' cluster ( $r = 0.57$ ; Items 33, 41, 42, 43). A weaker correlation (0.36) occurred between the

number of alpha seconds per min. (eyes closed condition) and childhood vestibular experiences (items 1, 2, 3, 10, 24)" (p. 1126).

1886

De Pascalis, Vilfredo; Palumbo, Giovanni (1986). EEG alpha asymmetry: Task difficulty and hypnotizability. Perceptual and Motor Skills, 62, 139-150.

Parieto-occipital EEG alpha was recorded bilaterally, while 20 high- and 20 low-hypnotizable women performed one left-hemisphere and one right-hemisphere task of low difficulty and two other comparable tasks of high difficulty. Every task was performed twice, once with eyes open and once with eyes closed. All subjects were right-handed. The tasks were originally selected to be of high and low difficulty. The subjective rating of task-difficulty was also evaluated. The integrated amplitude alpha and the alpha ratio ( $R - L / R + L$ ) were the dependent variables. The highly hypnotizable women showed significantly higher alpha amplitude in eyes-closed condition than the low scorers; this difference disappeared during task performance and in the eyes-open condition. The left- tasks showed lower alpha amplitude in both hemispheres than right-tasks and baseline. The right-hemisphere alpha amplitude was lower than left in all experimental conditions. On tasks of high and low difficulty there was different hemispheric behavior on right and left tasks. Performance reflecting the right and left hemispheres in the low-difficulty condition showed no changes between baseline, right- and left-tasks, while under high difficulty there was a decrease in alpha amplitude in the right and even more marked decrease in the left hemisphere during left-tasks. The pattern of task effects for ratio scores was the same as for alpha amplitude, however, despite the analysis of alpha scores, an interaction of hypnotizability x task-difficulty was detected. The highly hypnotizable women showed less negative alpha ratio during a task of low difficulty than during tasks of high difficulty; the reverse was true for the low-hypnotizable women. Finally, the highly hypnotizable subjects showed less subjective difficulty during performance than the low scorers.

DeBenedittis, Giuseppe; Sironi, Vittorio A. (1986). Depth cerebral electrical activity in man during hypnosis: A brief communication. International Journal of Clinical and Experimental Hypnosis, 34, 63-70.

To the authors' knowledge, hypnosis has never been induced in epileptic patients during a depth EEG study. This neurosurgical diagnostic procedure has been routinely used in medically resistant epileptic patients for the preoperative exact delimitation of the epileptogenic lesion. It offers a unique opportunity to obtain fundamental information on the possible neurophysiological mechanisms implicated in hypnosis. Observations were carried out on 1 patient affected by medically resistant partial seizures with complex symptomatology. A chronic deep electrode study explored rhinencephalic structures as well as specific target areas of the cerebral cortex. Background electrical activity during hypnosis showed a significant decrease of slow waves and an increase of alpha and beta rhythms, with constant

increase of amplitude, when compared to activity in the pre- and posthypnosis states. Focal interictal abnormalities were dramatically reduced during hypnosis.

## NOTES

Hypnotizability was assessed with the Barber Suggestibility Scale in order to test for suggestibility without a prior induction of hypnosis. The patient's score was 7 out of 8 possible. Patient was hypnotized with a standard induction procedure (Barber & Calverley, 1963).

**Experimental Protocol:** 15 minutes resting baseline; 15 minute test of mental imagery (waking suggestions with imagination instructions); hypnosis with progressive relaxation; suggestions for dissociation; suggestions for amnesia; arousal from hypnosis (the patient was successful with positive hallucinations, catalepsy, total amnesia, and spontaneous analgesia); and posthypnosis awake and alert (5 minutes eyes open, 5 minutes eyes closed, then 15-minute recording of post-treatment waking baseline).

EEG background activity was scored for the number of sec/minute of delta (0-4), theta (4-7), alpha (8-12), and beta (13-30) rhythms, for each 5-min period. Score = percent as related to the 1-minute epoch. Number, amplitude, and diffusion of interictal spikes also were measured but ictal activity was not recorded during the periods considered. Experimenters also measured heart rate, respiratory rate, and mean blood pressure.

ANOVA for 4 conditions (resting, waking suggestion, hypnosis, and posthypnosis) was computed for background and for focal interictal activities, and the t-test used to evaluate significant differences. ANOVA indicated a significant effect across the four experimental conditions for theta and alpha in the temporal anterior cortex, temporal posterior cortex, and frontal convexity cortex. The effect was attributable only to changes in theta and alpha between baseline and hypnosis (theta decreasing, alpha increasing as the patient went into hypnosis). No other significant difference was found. Following arousal from hypnosis, EEG activity was similar to the EEG activity before the induction.

Interictal focal abnormalities were reduced during hypnosis, compared with before hypnosis. The effect was due to changes in the area of Ammon's horn, the amygdala, the posterior temporal cortex, the mesial temporal cortex, and the inferior temporal cortex.

In their Discussion, the authors note that their data supports earlier work indicating that the limbic system is implicated in hypnosis. They cite the publications of Arnold (1959, *International Journal of Clinical and Experimental Hypnosis*) and Crasilneck, McCranie, and Jenkins (1956). The latter authors observed EEG records taken during brain surgery on one patient. Hypnosis terminated every time the hippocampus was stimulated, leading them to suggest that the hippocampus is part of the neural circuit involved in hypnosis.

"If it is assumed that a convulsion can be considered a result of both pathophysiological and emotional events operating in the individual, emotions being the most common precipitating factor in epilepsy, then any amelioration of one will raise the convulsive threshold or lower the seizure level (Goldie, 1979; MacCabe & Habovick, 1963). Although 'voluntary control of the alpha rhythm' was achieved

over 40 years ago (Jasper & Shagass, 1941), only since 1969 has such control been used for clinical purposes (Kamiya, 1969). One striking characteristic of the EEG pattern of many epileptics is the absence of a 12 to 14 c/s rhythm normally recorded from the anterior portions of the brain (sensorimotor rhythm) and the presence of a 4 to 7 c/s rhythm at the same location (Olton & Noonberg, 1980). Biofeedback may enable the individual to increase the amount of sensorimotor rhythm and to decrease the amount of 4 to 7 c/s activity. As a consequence, clinically significant decreases in seizure activity have been found after biofeedback training (Serman, 1973, 1977).

"The present data demonstrate that in this female patient hypnosis induced a highly significant reduction of the interictal activity, concomitant with an increase of alpha and sensorimotor rhythm and a decrease of slow activity, similar to biofeedback but without prior training.

" In conclusion, a depth EEG study in one epileptic patient comparing EEG activity during hypnosis and pre- and posthypnosis suggests the following conclusions: (a) hypnosis may be associated with significant decrease of slow activity and an increase of alpha and relatively high frequency, beta activity; (b) electrophysiological correlates of hypnotic behavior support the possible role of the limbic system in mediating the trance experience; and (c) hypnosis is effective in reducing focal interictal abnormalities in this patient and so it can be considered a promising technique to prevent and/or reduce emotional precipitating factors and the tendency to develop seizure activity" (p. 69).

## NOTES

Hypnosis is discussed in terms of inhibition/excitation mechanisms in the central nervous system, with both feedback and feedforward controls and lateralizing controls. The author employs a concept of engrams (neural representations of an idea, represented throughout the neocortex) to discuss sensation and perception as well as conscious and unconscious processes. Sensory information is processed serially with encoding of information mostly on the conscious level (but sometimes, less efficiently, on the unconscious level); and it also is processed in parallel. Parallel processing operates almost entirely at the unconscious level and is basic to perception.

Associative phenomena are explained in terms of overlapping engrams, so that two 'related hypercomplex engrams' could be assumed to have at least one simple engram in common. With Premack, he describes three types of engrams: veridical

(primary sensory data perceived), abstract (formalized representations of concepts like line drawings of dog or house; Premack's iconic representations), and symbolic (more complex entities that encompass an entire class of objects, actions, or ideas and may have artificial symbols such as words).

With Neiser he suggests that thinking (verbal and nonverbal) involves logical sequential processing of cognitive engrams of external (environmental), internal (visceral), and intracerebral (ideational) origin. Evoked response investigations shed light on the nature of such engrams, their distribution in brain tissue. John, Bartlett, Slumokochi, & Kleiman (1973) found that an error in choice discrimination learning (cats learning colors) is accompanied by the cortical evoked potential of the stimulus associated with that (erroneous) behavior, not the evoked potential of the true stimulus. In other words, ERPs represented the idea, not the actual visual stimulus provided to the cat.

Emotional/motivational influences are part of every cognition (R. S. Lazarus's position). Interaction of motivational-emotional and cognitive engrams seems to occur primarily in the inferior temporal lobe and the entorhinal cortex. The interaction involves the upper rhinencephalon, the amygdaloid-hippocampal complex, the septal region, the cingulate gyrus, and the inferior and medial aspects of temporal lobe of the cortex. He also explains classical and operant conditioning (on pp. 75-76) in terms of the association of engrams.

The author's position is that consciousness is the subjective equivalent of brain activity in the 'alerting' and 'awareness' systems. Awareness of the environment ('general, vague') appears to involve the limbic area (thalamus and basal ganglia), while more specific awareness of the self entails a system stretching from the basal ganglia through the parietal lobe (posterior aspect).

Normal alert consciousness involves the noradrenergic reticular activating system, as well as associated excitation of the general awareness system in the involved thalamic- basal gangliar nuclei and the self-awareness system in the posterior inferior parietal lobe system. Altered states of consciousness characterized by a relaxed hazy sense of the world involves thalamic activation of the self-awareness system. Dreaming involves activation from cholinergic cells in the pons. "Impaired general awareness occurs with lesions of the thalamic-basal gangliar centers while impaired self-awareness occurs with lesions in the posterior inferior parietal lobes. Finally, in certain physiological states such as sleep, hypnosis, and so on, the entire awareness system--the thalamic-basal gangliar and posterior inferior parietal nuclei--may be activated by different activation systems, such as the cholinergic in the pons or the dopaminergic in the thalamus, to produce different states of consciousness" (p. 82).

Consciousness is described as having seven dimensions: alertness, attention, arousal (heart rate, GSR), activation (EEG, evoked potential), affect, and the two awarenesses. The seven are related, so that changes in any one usually are correlated with changes in others (though dissociation among the seven also can be demonstrated). Motivational-emotional arousal produces electrophysiological activation of the brain, which is translated epiphenomenally into alertness and awareness; awareness is focused through attention onto the cognitively and

motivationally significant events in the internal and external environments to determine the final sequence of drive-oriented behavioral responses.

The EEG is useful for diagnosing different states of consciousness: beta and gamma waves alertness, stemming from locus coeruleus and reticular activating system delta (2-4/sec) waves coma alpha synchronized relaxing influences stemming from thalamus; low level of awareness as in twilight sleep or hypnagogic states theta, delta inactivity due to less stimulus from locus coeruleus reticular activating system influences; associated with increased inhibitory thalamic and septal-hippocampal impulses radiating upward to the cortex.

In some altered states of consciousness there is theta-wave activity, indicating influences from the inhibitory septal-hippocampal circuit.

The reticular activating system (RAS) and thalamus interact in complex ways. The RAS is essential to maintain consciousness, but if destroyed stepwise (in animal research) a low-grade type of consciousness can be maintained by thalamus and basal ganglia. The thalamus has two kinds of influence: it inhibits the cortex, as in sleep; and stimulates the cortex in the form of activating alpha waves. "The median thalamus is also related in a feedforward-feedback circuit with the inhibitory septal-hippocampal complex which generates theta-wave activity, thus accounting for the close association between alpha and theta wave activity in sleep and in other altered states of consciousness" (p. 86).

Thus there are two different activating systems originating in the lower brain stem: the norepinephrine locus coeruleus system that is associated with normal behavior, and the cholinergic FTG neurone system of REM sleep. The relationship of the latter to consciousness, awareness, self awareness, etc. is unknown, since the only time that it is readily observed is during REM sleep. The author reports that altered states of consciousness (e.g. hypnosis, fugue, alpha state) resemble Stage 1 sleep, rather than REM sleep, physiologically, with the central locus of activation in the medial thalamus rather than the RAS and locus coeruleus.

"It appears then that consciousness may be driven by one or another of three different activation centers: the norepinephrine RAS (emanating from the locus coeruleus), the cholinergic FTG cell system in the pons, and the dopaminergic alpha rhythm system radiating upward from the thalamus (Fig. 6-2). Brain activation by each of these centers is associated with a different state of awareness" (p. 91). The relative contribution from each center determines qualitative aspects of awareness.

The author refers to Mesulam and Geschwind (1978) who traced the self-awareness system from amygdala/hippocampus/midbrain to the inferior parietal lobe where they converge with the body's proprioceptive neural tracts. What results is "a sense of self that was not necessarily present in the sense of general awareness stemming from the median thalamic-basal gangliar complex" (p. 97).

The thalamic-basal gangliar complex is both a center for emotional reception and a relay station for somatosensory events. Both somatic sensory reception and somatosensory elements of emotion are also represented in the parietal lobe. "Affective and somatosensory stimuli, which are constant and persistent even

though we are unaware of them most of the time, produce the sense of one's body which is the most basic element in the 'sense of self.'... It is most probable that a major component of the sense of self is produced by the constant barrage of affective and somatosensory stimuli converging from all parts of the body; the majority of these stimuli may not reach consciousness most of the time but they must register a sense of feeling in the thalamus and parietal cortex even though the individual may be unconscious of it" (p. 100).

The author presumes that most of the incoming stimuli that define self are unconscious. "Whether sense-of-self stimuli are unconscious because of constant habituation ... or whether they are unconscious because they are transmitted predominantly to the right hemisphere ..., it appears that the major components of the self- concept are unconscious rather than conscious" (p. 102).

"Even the acutely self-aware component of the self-concept, by definition conscious, varies markedly in different altered states of consciousness. The conscious awareness of oneself in the alert condition is different from (1) that in the twilight state, (2) that in dreams, (3) that in hypnosis, (4) that under the influence of alcohol, (5) that under the influence of other sedatives, (6) that under the influence of stimulants, and (7) that under the influence of hallucinogens. In that sense the acute sense of self is a function of the momentary chemical and physiological state of the brain" (p. 102).

" ... the decision-making apparatus of the brain is lodged largely in a consortium of neocortical centers including the prefrontal lobes (integration), the posterior inferior lobes (motivation and emotion), the anterior and posterior associational areas (cognition), the posterior inferior parietal lobes (self-awareness), the left-hemispheric language centers (language), and the precentral frontal lobe motor area (motor). Within the context of this integrated cortical complex, self-awareness functions are somewhat stronger on the right hemisphere while language and decisional activities are somewhat stronger on the left" (pp. 102-103).

The Chapter titled "Attention as directed consciousness" is relevant for investigations of hypnosis but is not included in these notes.

## 1985

Banyai, Eva I.; Meszaros, Istvan; Csokay, Laszlo (1985). Interaction between hypnotist and subject: A social psychophysiological approach (preliminary report). In Waxman, David; Misra, Prem C.; Gibson, Michael; Basker, M. Anthony (Ed.), Modern trends in hypnosis (pp. 97-108). New York: Plenum Press.

There is a vast amount of literature demonstrating that hypnotic susceptibility is a stable personality trait. In the course of our practice of teaching beginners to hypnotize, however, it occurred to us that hypnotists without sufficient previous training frequently measured a lower level of hypnotic susceptibility than the true score. It has to be emphasized that hypnosis is a special altered state of consciousness which develops as a result of an interaction between a hypnotist and a subject. The failure of beginners to induce hypnosis could be explained by considering an insufficient participation of the hypnotist in this interaction. The purpose of the present study was to analyze the necessary and sufficient subjective,

behavioral and physiological alterations in both participants of the hypnotic interaction. During successful and unsuccessful hypnotic inductions the subjective experiences, behavioral manifestations and physiological indicators including respiration, ECG, EMG, EOG, GSR and bilateral fronto- occipital EEG leads, were recorded simultaneously in the hypnotists and the hypnotized subjects. The results indicate that hypnotic induction is successful if a mutual "tuning" of the other person occurs not only on the subjective and behavioral levels, but first of all on the psychophysiological level.

Spiegel, David; Cutcomb, Steven; Ren, Chuan; Pribram, Karl (1985). Hypnotic hallucination alters evoked potentials. Journal of Abnormal Psychology, 94 (3), 249-255.

Brain electrical potentials evoked by visual stimulation were analyzed to study the neurophysiological mechanism associated with hypnotic hallucination. The visual evoked responses of 6 high- and 6 low-hypnotizable subjects were compared in three hypnotic conditions: stimulus enhancement, stimulus diminution, and stimulus elimination (obstructive hallucination). High-hypnotizable individuals demonstrated significant suppression of the later components of the evoked response (N1 and P3) while experiencing obstructive hallucinations, indicating a change in information processing. This effect was significantly greater in the right, as compared to the left, occipital region.

#### NOTES

In the stimulus enhancement condition, Ss were told that one of two colored stimuli would appear unusually bright and interesting. In the stimulus diminution condition, Ss were told that the alternate color stimulus would appear drab, dull, uninteresting. In the obstructive hallucination condition, Ss were told to visualize a box that blocked their view of the TV monitor, making it impossible to see anything on the TV screen. The stimuli were 8 cm x 8 cm squares (colored gratings) presented 1 meter in front of S: 50% were blue vertical gratings, 50% were pink horizontal gratings.

Ss were told to press a button in response to any stimulus they happened to see; hence all stimuli were potential targets. To control for the effect of motor potentials when they pressed the button, a button-pressing/passive-attention control group was added. Only results significant beyond this control group were attributed to a hypnotic hallucination effect. A second control group of medium level hypnotizable Ss were required to (a) button press after each stimulus presentation and (b) attend passively to the TV monitor screen without button pressing. "Thus, we had three control conditions: (a) for attentional demands, comparing the performance of high hypnotizables in the obstructive hallucination versus the hypnotic stimulus enhancement condition, (b) for hypnotizability, in comparing the high hypnotizables in the obstructive hallucination condition versus the low hypnotizables in the same condition, and (c) for button-pressing behavior, comparing the performance of the high hypnotizables to that of control subjects in press versus no-press conditions" (p. 250).

In their discussion, the authors state, "Our results are consistent with the hypothesis that an hypnotic instruction of obstructive hallucination among high- hypnotizable

subjects is accompanied by a decrease in the amplitude of the P3 component of the evoked response throughout the brain, and of the N2 and P3 components in the occipital region. This dampening of amplitude is particularly notable among high hypnotizables in the right, as compared with the left, occipital area, suggesting greater inhibition of scalp-recorded response to a visual stimulus in the right hemisphere.

"These data show that while experiencing an obstructive hallucination blocking the stimulus, high-hypnotizable subjects demonstrate a change in the information-processing components of the evoked response (Baribeau-Braun, Picton, & Gosselin, 1983), rather than primarily in channel selection, which is reflected more by P1 and N1 (Ford, Roth, Dirk, & Kopell, 1978; Hillyard & Picton, 1979). Although there were differences at P1 and N1 between high and low hypnotizables, they were not significantly greater than those observed in the press/no-press control group. These observations make it possible to address several alternative explanations for the findings, such as the possibility of differences in nonspecific arousal leading to a differential preparation (Naatanen, 1969), which should be reflected primarily in changes in the early components, as would any differences in pupil size. Drowsiness or inattention in this condition should be associated with an increase, rather than a decrease, in response amplitudes (Schacter, 1976). The possibility that high hypnotizables might have defocused their view of the monitor (Schulman-Galambos, & Galambos, 1978) is made less likely by the fact that defocusing is accompanied by increases in P1 latency (Sokol & Moskowitz, 1981), whereas there were no P1 latency differences in the obstructive hallucination condition" (p. 254).

1984

Cocores, James A.; Bender, Andrew L.; McBride, Eugene (1984). Multiple personality, seizure disorder, and the electroencephalogram. Journal of Nervous and Mental Disease, 172, 436-438.

Used the EEG to study multiple personality in a 48-yr-old ambidextrous male admitted for alcohol detoxification and individual psychotherapy. Despite conflicting reports in the literature, no changes in the EEG were found that could not be ascribed to the normal changes seen in transitions from various states of alertness. The problems of differentiating multiple personality as a psychiatric entity in itself from those cases arising as a result of chronic partial or partial-complex epilepsy are discussed.

Gott, Peggy S.; Hughes, Everett C.; Whipple, Katherine (1984). Voluntary control of two lateralized conscious states: Validation by electrical and behavioral studies. Neuropsychologia, 22 (1), 65-72.

A subject is described who can voluntarily select and hold either of two qualitatively different states of consciousness. Evidence is presented which confirmed differential left or right hemisphere dominance in each state. Asymmetries of EEG alpha and task performance scores indicated a state-dependent shift in functional lateralization. Evoked response studies showed directional changes in rate of interhemispheric transmission correlated with state-related hemisphere dominance.

These findings demonstrated the capability for voluntary endogenous control of cerebral dominance under natural conditions.

#### NOTES

A personal communication (letter) from Gott indicates the S switches from one state to the other by visualizing her surroundings and imagining what it would look like in the other state. Immediately she finds herself in that other state. Her drawings demonstrate that her perspective must differ in the two states.

La Briola, Flora; Karlin, Robert; Goldstein, L. (1984, October). Quantitated EEG changes from prehypnotic to hypnotic periods. [Paper] Presented at the annual meeting of the Society for Clinical and Experimental Hypnosis, San Antonio, TX.

#### NOTES

Hemisphere EEG activation was measured before and during hypnosis, while Ss did tasks described as right-hemisphere (nonverbal) and left hemisphere (verbal). Highs shifted to relatively more task specificity as they went from prehypnosis into hypnosis, with a shift to right hemisphere as they went from prehypnosis to hypnosis periods. This is not due to relaxation, as both highs and lows relax. And the shift occurs not only on verbal-nonverbal tasks but on analgesia studies also.

Versions of this paper were presented at the 93rd Annual Meeting of the American Psychological Association, Toronto, Canada, 1984, at the Annual Meeting of the Society for Clinical and Experimental Hypnosis, San Antonio, TX, 1984, and at the 6th International Symposium on Clinical Neurophysiological Aspects of Psychiatric Conditions, Izmir, Turkey, 1985.

#### 1983

Borgeat, Francois; Goulet, Jean (1983). Psychophysiological changes following auditory subliminal suggestions for activation and deactivation. Perceptual and Motor Skills, 56, 759-766.

This study was to measure eventual psychophysiological changes resulting from auditory subliminal activation or deactivation suggestions. 18 subjects were alternately exposed to a control situation and to 25-dB activating and deactivating suggestions masked by a 40-dB white noise. Physiological measures (EMG, heart rate, skin-conductance levels and responses, and skin temperature) were recorded while subjects listened passively to the suggestions, during a stressing task that followed and after that task. Multi-variate analysis of variance showed a significant effect of the activation subliminal suggestions during and following the stressing task. This result is discussed as indicating effects of consciously unrecognized perceptions on psycho- physiological responses.

Nash, John (1983). Negative visual hallucination and concomitant changes in cortical event-related potentials (Dissertation, University of California, Santa Barbara). Dissertation Abstracts International, 45 (2), 716-B. (Order No. DA 8411224)

The purpose of this investigation was to examine the effects of negative visual hallucination (NVH) on cortical event-related potentials (ERPs), and to compare these effects with those of selectively attending to and ignoring stimuli. Five highly hypnotically susceptible subjects, four female and one male, were trained to block from subjective experience, i.e., negatively hallucinate, a ring of strobe-illuminated circles surrounding a central, independently strobe-illuminated circle. This stimulus array was modeled after part of the Titchener-Ebbinghaus circle illusion, since previous research had shown that subjects could attenuate the effects of the optical illusion via NVH of the outer, illusion-producing circles. "Analysis of the ERP data revealed amplitude and latency changes in various ERP components across the three experimental conditions (Attend, Ignore, NVH) for the four female subjects, a negative result which is explained in motivational terms. "The most noteworthy finding was the selection of the P3 amplitude variable at C2 by stepwise discriminant analysis for the four females, and the fact that this amplitude systematically decreased across conditions from largest in Attend to smallest in NVH. A variety of individual patterns were observed in terms of other ERP components which allowed discrimination (successful classification) among the three conditions. The results suggest that both Ignoring and NVH of a stimulus result in a decrease in the subjective certainty of perception of the stimulus. Individual differences in patterns of ERP changes are interpreted in terms of differing strategies for execution of the experimental instructions. The results support the view that NVH instructions produce distinctive ERP effects and that NVH generally can be viewed as an extreme level of ignoring" (p. 716).

1982

Barabasz, Arreed F. (1982). Restricted environmental stimulation and the enhancement of hypnotizability: Pain, EEG alpha, skin conductance and temperature responses. International Journal of Clinical and Experimental Hypnosis, 30, 147-166.

Restricted environmental stimulation procedures were used with 10 Ss. The Stanford Hypnotic Clinical Scale: Adult, modified to include a posthypnotic suggestion for an analgesic reaction, and pain threshold and tolerance tests were administered prior to restricted environmental stimulation technique (REST), immediately after REST, and 10-14 days later. Occipital EEG alpha, skin conductance, and peripheral, core, and chamber temperature data were collected prior to, during, and after REST. A control group of 10 Ss was used to assess the effects of repeated hypnosis upon susceptibility scores and demand characteristics of the experiment. Multivariate analysis of variance results showed SHCS and pain tolerance scores to be significantly enhanced for Ss exposed to REST immediately after and 10-14 days later. Orne's (1959) postexperimental inquiry technique did not reveal experimental demand characteristics which might account for the results. EEG alpha density increased significantly in REST, but the increase was not progressive during the REST period. The maintenance of hypnotizability and pain tolerance at follow-up failed to support Reyher's (1965) theory of brain function and

behavioral regulation. E. R. Hilgard's (1977) neodissociation interpretation combined with J. R. Hilgard's (1974, 1979) imaginative involvement findings is viewed as a possible explanation.

Blum, Gerald S.; Nash, John K. (1982). EEG correlates of posthypnotically controlled degrees of cognitive arousal. Memory and Cognition, 10, 475-478.

Experimental control over five degrees of cognitive (as opposed to organismic) arousal has been developed by hypnotic programming techniques. Previously these posthypnotic manipulations have been applied to the investigation of diverse topics such as visual discrimination, performance on the Stroop test, selective concentration on color versus form of consonants, and cognitive "reverberation." The present study explored EEG correlates of the five degrees of cognitive arousal in a task requiring participants to visualize objects for one-minute periods while lying on a couch with eyes closed. Analysis of data from the occipital area in left and right hemispheres revealed that the highest degree of arousal was accompanied by larger amplitudes of alpha and beta power and smaller amplitudes of theta. This pattern of results was similar in both hemispheres, although more marked in the left. The findings, which provide an independent source of support for validity of the hypnotic programming, are discussed in relation to EEG literature on cognitive activity.

#### NOTES

Hypnosis doesn't enhance imagery. It provides the conditions under which mental alertness may be manipulated, and very clear imagery is associated with the alert condition whereas blurry imagery is associated with the lowest cognitive arousal condition. The other impression comes from clinical work, i.e. that hypnosis enhances imagery. This article is an example of hypnosis used in other research--see last page.

Cutcomb, Steven Donald (1982, May). Studies in the brain correlates of human cognitive function (Dissertation, Stanford University). Dissertation Abstracts International, 42 (11), 4609-4610-B.

Three studies in the electrophysical correlates of human cognitive function are described. In study one, colored gratings were presented tachistoscopically to humans in two selective attention paradigms based upon the design of Hansen and Hillyard (1980), and Hillyard, Hink, Schwent, and Picton (1973). Visual event-related potential (ERP) data from Fz, Cz, Pz, T5, T6, O1, and O2, and behavioral responses were collected, and averaged ERPs were subjected to feature extraction (P1, N1, P2, N2, and P3 amplitudes and latencies) as well as a principle components factor analysis. Both analyses revealed a significantly larger N2 component in the visual ERP, peaking at 310 msec and maximally frontally, during attending to task-relevant (attended-channel) stimuli. The P3 component was significantly larger in response to all attended-channel stimuli. In study two, the task was repeated using a group of six high and six low susceptible subjects during hypnosis. ERPs from Fz, Cz, Pz, O1, and O2, and behavioral responses were recorded during the task, and during a hypnotic suggestion of a negative hallucination (obstructed view of the

stimulus monitor) while the stimuli were presented. The averaged ERP data was subjected to feature extraction followed by analyses of variance. No inter-group differences were found in the ERPs during the selective attention tasks. "During the obstructed view suggestion, the lows showed a normal visual ERP, while the highs had a visual ERP with a significantly diminished P1, P2, N2, and P3 component amplitude at O1 and O2. These results are evidence for an altered brain response during the obstructed view suggestion in high susceptible hypnotized subjects. "In study three, EEG were recorded from twelve high and twelve low susceptible hypnotic subjects (frontal, central, occipital) during baseline and hypnotized conditions. Data were transformed to normalized theta and alpha-band power spectral averages for each group. No significant inter-group alpha differences were found. Highs had significantly more relative theta energy frontally. During hypnotic tasks, the highs showed higher relative theta power at all leads. These results are consistent with the trait conception of hypnotic susceptibility" (pp. 4609-4610).
